CHAPITRE 18. Exemple de calcul d’ossature en portique en béton armé.

Example prepared by PHUNG NGOC DUNG, PhD researcher at ULg.

Note 1 !!! In this example, notation « dot . » stands for “comma ,”. Example: 1.2 means 1,2

Note 2 !!! The example is used with $\gamma_c = 1,5$ and $\gamma_s = 1,15$. The values are different in each country France: $\gamma_c = 1,3$ and $\gamma_s = 1,0$; Belgium: $\gamma_c = 1,5$ and $\gamma_s = 1,00$.

I. INTRODUCTION

The design example of a reinforced concrete building which is presented hereafter aims at two main goals:
- To present the partially designing procedures of a reinforced concrete frame under a given seismic excitation according to Eurocode 8 and Eurocode 2
- To check the behaviours of the reinforced concrete frame which is correspondingly designed and detailed to Eurocode 8 under un-given seismic excitations by using Pushover analysis.

In order to get a fully designed and detailed reinforced concrete frame, there are several preliminary designing steps. The final drawings which are used on the sites are the results of series of calculations. To choose the best results, that is, the sectional dimensions, material properties, reinforcement areas, etc, the designing iterations must be carried out. The following presentation of the total design procedures is just some parts of the completely iterative processing.

The issues which are presented in the design example are:
- To describe the building architecture and properties such as materials, loads, …
- To check the chosen cross sectional dimensions in pre-design.
- To analyze the structure under a given seismic excitation.
- To verify the structural elements.
- To check the building under other seismic excitations.

II. GENERAL DESCRIPTION

The building which is chosen to design is an office and flat building. The building has 6 stories. It is a six-story reinforced concrete two-way frame. The floor plan is presented in Figure 1.

Figure 1. BUILDING PLAN
II.1. **Main geometry descriptions:**
There are 3 bays of 5m and 4 bays of 5m. The area of current floor is about 300m²
(20×15 = 300m²).
The structure has in-plane and elevation regularity.
The story height is 3m, except the ground story height is 3.5m.
The cross sectional dimensions for all columns are 400mmx500mm.
The slab thickness is 150mm; the dimensions of all beams are 250x500mm (slab included).

II.2. **Exterior and partitioning walls:**
The perimeter walls are glass and masonry ones. They do not affect the free displacement of
the frame during earthquakes.

II.3. **Loads:**
The characteristic values for the loads are:

II.3.1 **For the intermediate floor:**
- Slab weight → 3.75kN/m²
- Flooring → 1.92 kN/m²
- Live load → 3 kN/m²

II.3.2 **For the roof floor:**
- Slab weight → 3.75kN/m²
- Flooring → 1.92 kN/m²
- Live load → 0.75 kN/m²
- snow load → 0.4 kN/m²

II.4. **Preliminary Considerations:**
- Subsoil Class: C
- Ductility Level: DCM – Medium level.
- Important category of the building is “II” → ordinary building and γ_I = 1.
- The non-structural elements of the building are fixed in a manner as not to interfere with
structural deformations.
- The structure is rigid fixed in non-deformable foundations.
- The relative design ground acceleration for the reference return period is a_{gR} = 0.15g .

II.5. **Materials**
- Concrete class: → C25/30
  \( E = 31 GPa = 31 KN / mm^2 \)
- Longitudinal ribbed reinforcing steel bars → S500 was chosen.
- Transverse ribbed reinforcing steel bars → S500.

II.6. **Design Procedures:**
For the R/C multi-story flexible frame buildings, the inter-story drift control governs the
design. → So, the pre-design procedures of the cross sectional dimensions of the frame members
are the checks of horizontal displacements induced by the earthquakes.

III. **PREDESIGN:**

III.1. **Weights of Masses: - 3.2.4 – EC8**
In accordance to 3.2.4 - EC8 [3], the inertial effects of the design seismic actions shall be
evaluated by taking into account the presence of the masses associated to all gravity loads
appearing in the following combination of actions:

\[
\sum G_{ij} "+" \sum \psi_{E,i} Q_{E,i}
\]

Where:
- \( \psi_{E,i} \): combination coefficients.
- \( \psi_{E,1} \) is determined as following 4.2.4 – EC8 \( \psi_{E,1} = \psi_2 \)
- The value of \( \phi \) is to be from the table 4.2 – 4.2.4 – EC8
\[ \varphi = 1.0 \rightarrow \text{for the top story.} \]
\[ \varphi = 0.8 \rightarrow \text{for the correlated occupancies.} \]
\[ \varphi = 0.5 \rightarrow \text{for the roof story.} \]

(EC8 table 4.2 for categories A-C* - domestic and residential and for stories independently occupied)

\( \psi_{2,i} \): combination coefficients. Determining from the Annex A1:1990:2002, table A.1.1

\[ \psi_{2,i} = 0.3 \rightarrow \text{for the occupancy (category A).} \]
\[ \psi_{2,i} = 0 \rightarrow \text{for the snow and wind loads.} \]

So, the results are:

- For the intermediate stories:
  \[ W_{\text{floor}} = 3.75*300 + 1.92*300 + 0.8*0.3*3*300 = 1917\, \text{KN} \]

- For the roof story:
  \[ W_{\text{roof}} = 3.75*300 + 1.92*300 + 1.0*0.3*0.75*300 + 0.4*0.3*300 = 1768.5\, \text{KN} \]

All weights of masses are calculated from 4.3.1(10P) – EC8 [3]

- Weight of the beams on floors:
  \[ W_b = 0.25*0.5*31 = 339\, \text{KN} \]

- Weight of the columns on floors:
  \[ W_c = (0.4*0.5*3*25 + 0.4*0.5*3.5*25) = 1550\, \text{KN} \]

- Total weights of the building:
  \[ W = \sum W_{\text{floor}} + W_{\text{roof}} + W_b + W_c = 1917 + 1768.5 + 2034.4 + 1550 = 14938\, \text{KN} \]

### III.2. Base shear force: (4.3.3.2.2 – EC8 [3])

- According to 4.3.3.2.2 – EC8 [3], Base shear force induced by an earthquake is determined as the following expression:
  \[ F_b = S_d(T_1) * m * \lambda \] (4.5 – EC8 [3])

Where:
- \( S_d(T_1) \) – the ordinate of the design spectrum at period \( T_1 \)
- \( T_1 \): The fundamental period of vibration of the building for lateral motion in direction considered.
- \( m \): is the total mass of the building. \( m = \frac{W}{g} \)
- \( \lambda \): is correction factor.
  \[ \lambda = 0.85 \text{ if } T_1 \leq 2T_c \text{ and the stories of the buildings } \geq 2 \text{ stories} \]
  \[ \lambda = 1 \text{ if otherwise} \]

- According to 4.3.3.2 (3) – EC8 [3], for the buildings with heights up to 40m, the value of \( T_1(s) \) may be approximated by the following expression:
  \[ T_i = C_i * H^{3/4} \] (4.6 – EC8 [3])

Where:
- \( C_i = 0.75 \) for the concrete frames.
- \( H \): is the height of the building (m); \( H = 3.5*5 + 3 = 18.5\, \text{m} \)

So, we have:
\[ T_i = 0.75 * 18.5^{3/4} = 0.67(\text{s}) \]

- \( S_d(T_1) \) – the ordinate of the design spectrum at period \( T_1 \) is determined from 3.2.2.5 – EC8.

With subsoil class “C”, we have, for the Type 1 spectrum:
1.15 ( ) 0.2 ( ) 0.6 ( ) 2 ( ) 

For $T_b(s)=0.2(s)$ and $T_c(s)=0.6(s)$ and $S_d(T_1)$ is calculated from the expression 3.14 (3.2.2.5 – EC8 [3]),

$$S_d(T_1) = \frac{a_g \times S \times 2.5 \times T_c}{q} \geq \beta \times a_g$$

Where:
- $a_g = \gamma_t \times a_{R} = 1 \times 0.15g – 3.2.1(3)$
- $\beta$ - is the lower bound factor for the horizontal design spectrum, $\beta=0.2$
- $S=1.15$
- $q$ – is the behaviour factor calculated from 5.2.2.2 – EC8. In accordance to 5.2.2.2 – EC8 [3], $q$ is to be calculated from the following expression: $q = q_0 \times k_w \geq 1.5$.
  - $q_0$ is the basic value of the behaviour factor determined from table 5.1 – 5.2.2.2 - EC8. For the concrete frames with the “DCM” ductility class, $q_0$ is calculated by the following expression: $q_0 = 3.0 \times \frac{\alpha_w}{\alpha_i}$, in which the ratio, $\frac{\alpha_w}{\alpha_i} = 1.3$, is calculated from 5.2.2.2 (5a) – EC8. So the value of $q_0$ is $3.0 \times 1.3 = 3.9$
  - $k_w$ is the factor reflecting the prevailing failure mode in structural systems with walls. $k_w$ is calculated from 5.2.2.2 (11). So the value of $k_w$ is 1.00

So, the value of $q$ is determined as below: $q = 3.9 \times 1 = 3.9$

$$\Rightarrow S_d(T_1) = \frac{0.15g \times 1.15 \times 2.5 \times \frac{0.6}{0.67}}{3.9 \times 0.099g} = \frac{0.099g}{0.099g}$$

$$\geq \frac{0.2 \times 0.2g}{0.04g} = 0.04g$$

$$\Rightarrow F_b = S_d(T_1) \times m \times \lambda = \frac{0.099g \times W}{g} \times 0.85 = 0.08415W$$

$$\Rightarrow F_b = 1257 KN$$

### III.3. Torsion Effects

- The torsion effect is taken into account for the transverse current frame in a simplified manner. (4.3.3.2.4 – EC8 [3]).
- According to 4.3.3.2.4 – EC8 [3], if the lateral stiffness and mass are symmetrically distributed in plan and unless the accidental eccentricity of 4.3.2(1)P is taken into account by a more exact method, the accidental torsion effects may be accounted for by multiplying the action effects in the individual load resisting elements resulting from the application of 4.3.3.2.3(4) by a factor $\delta$ given by: $\delta = 1 + 0.6 \times \frac{x}{L_c}$. If the building is distributed symmetrically in plan and elevation, it can be divided into 2 plane models and the factor $\delta$ is determined by $\delta = 1 + 1.2 \times \frac{x}{L_c}$. 

Table 3.2 – Type 1 – 3.2.2.2 – EC8 [3]
According to the building plan, we can determine the values of \( x \) and \( L_e \) as follow: \( x=5 \text{m} \) for frame at line 2, \( x=10 \text{m} \) for frame at line 5; \( L_e=20 \text{m} \).

So, the value of \( \delta \) is calculated by the following expression:

\[
\delta = 1 + 0.6 \times \frac{x}{L_e} = 1 + 0.6 \times \frac{5}{20} = 1.15 \quad \text{and} \quad \delta = 1.3 \text{ for line 5.}
\]

However, we have seen in (Plumier, Construction en zones sismiques,[9]) that in fact a realistic \( \delta \) for such building is rather \( \delta = 1.15 \). In this pre-design step the value of \( \delta = 1.15 \) will be used. It should be checked at the final design state.

III.4. **Seismic force distribution:**

- Seismic forces distributed to all frames of the building depend on both their stiffness and their positions in plan, due to torsion.
- Force distribution along the height of the building using the simplified formula 4.11 or 4.10 – EC8 [3].
- In accordance to 4.3.3.2.3 (1) – EC8 [3], the fundamental mode shapes in the horizontal directions of analysis of the building may be calculated using methods of dynamics or may be approximated by horizontal displacements increasing linearly along the height of the building.
- According to 4.3.3.2.3(2) – EC8 [3], the seismic action effects shall be determined by applying, to the two planar models, horizontal forces, \( F_i \), to all stories.

\[
F_i = F_b \times \sum \frac{s_i \times m_i}{s_j \times m_j}
\]

Where:
- \( F_i \) – is the horizontal force acting on the story \( i \).
- \( F_b \) – is the seismic base shear.
- \( s_i, s_j \) – displacements of masses \( m_i, m_j \) in the fundamental mode shape.
- \( m_i, m_j \) - are the story masses.

According to 4.3.3.2.3(3) – EC8 [3], when the fundamental mode shape is approximated by horizontal displacements increasing linearly along the height, the horizontal forces \( F_i \) are given by:

\[
F_i = F_b \times \sum \frac{z_i \times m_i}{z_j \times m_j}
\]

Where:
- \( F_i \) – is the horizontal force acting on the story \( i \).
- \( F_b \) – is the seismic base shear.
- \( z_i, z_j \) – heights of the masses \( m_i, m_j \) above the level of application of the seismic action..
- \( m_i, m_j \) - are the story masses.

So, the values of \( F_i \) can be calculated as the following table:

<table>
<thead>
<tr>
<th>Story</th>
<th>Height (( z_i )) m</th>
<th>Weight – ( w_i )</th>
<th>( z_i \times w_i )</th>
<th>( \sum z_j \times w_j )</th>
<th>( F_i \text{(KN)} )</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>18.5</td>
<td>2250.375</td>
<td>41631.94</td>
<td>0.267369</td>
<td>321.3376</td>
</tr>
<tr>
<td>5</td>
<td>15.5</td>
<td>2398.875</td>
<td>37182.56</td>
<td>0.238794</td>
<td>286.995</td>
</tr>
<tr>
<td>4</td>
<td>12.5</td>
<td>2398.875</td>
<td>29985.94</td>
<td>0.192576</td>
<td>231.4475</td>
</tr>
<tr>
<td>3</td>
<td>9.5</td>
<td>2398.875</td>
<td>22789.31</td>
<td>0.146358</td>
<td>175.9001</td>
</tr>
<tr>
<td>2</td>
<td>6.5</td>
<td>2398.875</td>
<td>15592.69</td>
<td>0.100139</td>
<td>120.3527</td>
</tr>
<tr>
<td>1</td>
<td>3.5</td>
<td>2436.375</td>
<td>8527.313</td>
<td>0.054764</td>
<td>65.81837</td>
</tr>
</tbody>
</table>

\( F_b = 1257 \text{ [KN]} \).
The above seismic forces, \( F_i \), are total seismic forces acting at each story for the whome building and all frames. According to the stiffness of each frame, we will distribute the seismic forces to each frame linearly including torsion effects.

In the action direction of the earthquake (direction Y or transverse direction), there are 5 portal frames. We will distribute the seismic forces to the transverse frame at line 2 as following:

- \( F_{2-6} = F_6 \times \frac{1}{5} \times \delta = 321.34 \times \frac{1}{5} \times 1.15 = 73.9 \text{KN} \). \( F_{2-5} = F_5 \times \frac{1}{5} \times \delta = 287.0 \times \frac{1}{5} \times 1.15 = 66.0 \text{KN} \).
- \( F_{2-4} = F_4 \times \frac{1}{5} \times \delta = 231.5 \times \frac{1}{5} \times 1.15 = 53.23 \text{KN} \). \( F_{2-3} = F_3 \times \frac{1}{5} \times \delta = 175.9 \times \frac{1}{5} \times 1.15 = 40.5 \text{KN} \).
- \( F_{2-2} = F_2 \times \frac{1}{5} \times \delta = 120.4 \times \frac{1}{5} \times 1.15 = 27.7 \text{KN} \). \( F_{2-1} = F_1 \times \frac{1}{5} \times \delta = 65.8 \times \frac{1}{5} \times 1.15 = 15.14 \text{KN} \).

LATERAL SEISMIC FORCES IN EACH Y-Z OR TRANSVERSAL FRAME

![Figure 2 – Lateral seismic forces](image)

**III.5. The limitation of the inter-story drifts:**

- A plane frame is analysed and the displacements of the frame subjected to the applied forces \( F_{2-1} \) to \( F_{2-6} \), which are computed above, will be determined by using SAP 2000. Version 9.0.3. According to 4.3.1(7) EC8[3], the elastic modulus of Concrete \( E = E/2 = 15.5 \text{KN/mm}^2 \).

- According to 4.4.3.2 – EC8 [3], the following limits shall be observed: For the buildings having non-structural elements of ductile materials attached to the structure:

\[
d_r \times \nu \leq 0.0075 \times h
\]

Where:
- \( h \): is the story height → \( h=3 \text{m} \) and \( h=3.5 \text{m} \)
- \( d_r \): is design inter-story drift as defined in 4.4.2.2 (2) – EC8 [3], evaluated as the difference of the average lateral displacements \( d_i \) at the top and bottom of the story under consideration and calculated according to 4.3.4 → \( d_r = d_{s_i} - d_{s_{i-1}} \).
According to 4.3.4 – EC8 [3], for displacement analysis, if linear analysis is performed the displacements induced by the design seismic action shall be calculated on the elastic deformations of the structural system by means of the following simplified expression:

\[ d_e = q_d \times d_e \]

Where:

+ \( d_e \): is the displacement of a point of the structural system induced by the seismic action.
+ \( d_e \): is the displacement of the same point of the structural system, as determined by a linear analysis based on the design response spectrum according to 3.2.2.5 – EC8.
+ \( q_d \): is the displacement behaviour factor, assumed equal to \( q \) unless otherwise specified. So \( q_d = q = 3.9 \).

\( v \): is the reduction factor to take into account the lower return period of the seismic action associated with the damage limitation requirement. The value of \( v \) also depends on the important class of the building. The important class of the building is “II” so the value of \( v \) is 0.5 (according to 4.4.3.2(2) – EC8 [3]).

- The value of \( d_e \) must be smaller than the value derived from the elastic spectrum.
- When determining \( d_e \), the torsion effects of the seismic actions shall be accounted for.
- Table of drifts:

<table>
<thead>
<tr>
<th>Story</th>
<th>Story elastic displacements. ((d_e - \text{mm}))</th>
<th>Behaviour factor of Displacement (3.9)</th>
<th>(d_s)</th>
<th>(d_e = d_{s_i} - d_{s_{i-1}})</th>
<th>(d_r^*v)</th>
<th>Drift from EC8 ((0.0075h \text{ mm}))</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>46.373</td>
<td></td>
<td>180.8547</td>

</tr>
</tbody>
</table>

So, the condition \( d_r^*v \leq 0.0075*h \) is met.

The section dimensions and material properties which are chosen are satisfied with pre-designed steps according to EC8.

**IV. PRELIMINARY STEPS:** According to EC8 – 4.

**IV.1. Structural regularity.**

**IV.1.1 Regularity in plan:**
According to 4.2.3.2 – EC8 [3], criteria for the regularity in plan are:
- The building structure is symmetrical in plan with respect to two orthogonal directions.
- The plan configuration is compact.
- The in-plane stiffness of the floors is sufficiently large to distribute seismic forces among the vertical structural elements.
- The slenderness \( \lambda = \frac{L_{\text{max}}}{L_{\text{min}}} \) of the building is \( \lambda = \frac{L_{\text{max}}}{L_{\text{min}}} = \frac{20}{15} < 4 \).
- In accordance to 4.2.3.2 (5) – EC8 [3], at each level for each direction of analysis x or y, the structural eccentricity \( e_0 \) and the torsional radius \( r_t \) verify the two conditions below, which are expressed for the direction of analysis y:

\[
\begin{align*}
& e_{0x} \leq 0.3 \times r_x \\
& r_x > I_x
\end{align*}
\]

\((4.1-\text{EC8 [3]})\)
Where:
- $e_{0X}$: is the distance between the centre of stiffness and the centre of mass, measured along x direction, which is normal to the direction of analysis considered.
- $r_X$: is square root of the ratio between torsional effects and lateral stiffness in y direction (torsional radius)
- $l_s$: is the radius of gyration of the floor mass in plan (square root of the ratio of (a) the polar moment of inertia of the floor mass in plan with respect to the centre of mass of the floor to (b) the floor mass).

- There are not setbacks in the plan.

**IV.1.2 Regularity in elevation:**

According to 4.2.3.3 – EC8 [3], criteria for regularity in elevation are:
- All the lateral resisting systems run without interruption from their foundations to the top of the building.
- Both lateral stiffness and the mass remain constant or reduce gradually without abrupt changes, from the base to top.
- There are not setbacks.

**IV.2. Structural Analysis: (4.3 – EC8 [3])**

**IV.2.1 Modelling:**

- Because of the in-plan and in-elevation regularity, in accordance to 4.3.1(5) and to the table 4.1(4.2.3.1) the allowed simplifications are:
  - The analytical model: Planar.
  - The method of analysis: Using simplified method $\rightarrow$ Lateral force method of analysis can be used because all the conditions of 4.3.3.2.1 are met:
    - The building has fundamental period of vibration $T_1$ in the two main directions smaller than the following values:
      $$ T_1 \leq \begin{cases} 4 * T_c \\ 2.0s \end{cases} \iff T_1 = 0.67s \leq \begin{cases} 4 * 0.6 = 2.4s \\ 2.0s \end{cases} $$

- All the criteria for regularity in elevation given in 4.2.3.3 – EC8 are met.
- Behaviour factor: is the reference value.

- The building will be analysed with two planar frames using the lateral force method and comparison with two planar frames using the response spectrum analysis.

**IV.2.2 Natural Periods:**

According to 4.3.3.2 – EC8 [2], the natural period can be determined by Reileight Method or approximated method. The first period $T_1$ defined by approximated formula is equal to the value of 0.67.

**IV.2.3 Local effects of infill**

There is no infill for the current transverse and longitudinal frames.

**IV.3. Verification of structural type:**

**IV.3.1 Torsional Rigidity:**

In accordance to 5.2.2.1 (4)P – EC8 [3], the first four types of systems (i.e. frame, dual and wall systems of both types) shall possess a minimum torsional rigidity that satisfies expression (4.1b) in both horizontal directions.
But in accordance to 5.2.2.1(5), for frame or wall systems with vertical elements that are well distributed in plan, the requirement specified in (4)P above may be considered as being satisfied without analytical verification.

**IV.4. Selection of ductility class**

The chosen ductility class for design is “DCM”. So, designing, dimensioning and detailing must ensure a ductile behaviour of the elements meaning that ductile modes of failure should precede failure modes with sufficient reliability. The plastic hinges which are developed in response to the seismic excitation must be able to dissipate a medium amount of energy in a stable manner.

**IV.5. Material checks**

**IV.5.1 Concrete**

In accordance to 5.4.1.1 – EC8 [3], for ductility class “DCM” the use of concrete class which is lower than C16/20 is not allowed in primary seismic elements. So, we choose the concrete class C25/30.

**IV.5.2 Flexural reinforcement steel**

In accordance to 5.4.1.1 – EC8 [3], only ribbed bars are allowed as reinforcing steel in critical sections of primary seismic elements. The reinforcing steel class S500, the high ductility steel that satisfies the additional requirements in critical regions concerned in table C.1, annex C – EC2 [2], is chosen.

**IV.5.3 Shear reinforcement steel**

In accordance to 5.4.1.1 (2P) – EC8 [3], except for the closed stirrups or cross-ties, only ribbed bars are allowed as reinforcing steel in critical of primary seismic elements. The reinforcing steel class S500 for flexural reinforcement steel was chosen. So, we also choose S500 for shear reinforcement steel.

**IV.6. Second order Effects(P-Δ)**

According to 4.2.2.2 (2) - EC8 [3], the second-order effects (P-Δ effects) need not to be taken into account if the following condition is fulfilled in all stories:

\[
\theta = \frac{P_{tot} \cdot d_{r}}{V_{tot} \cdot h} \leq 0.1(4.28 \text{ – EC8 [3]})
\]

Where:

- \(\theta\) – is the inter-story drift sensitivity coefficient.
- \(P_{tot}\) – is the total gravity load at and above the story considered in the seismic design situation.
- \(d_{r} = d_{s_{1}} - d_{s_{1-1}}\) - is design inter-story drift, evaluated as the difference of the average lateral displacements \(d_{s}\) at the top and the bottom of the story under consideration.
- \(V_{tot}\) – is the total seismic shear at the considered level.

At the ground story:

\[
\theta = \frac{P_{tot} \cdot d_{r}}{V_{tot} \cdot h} = \frac{14282 \cdot 34}{1257 \cdot 3500} = 0.1104 > 0.1
\]

At the intermediate story:

\[
\theta = \frac{P_{tot} \cdot d_{r}}{V_{tot} \cdot h} = \frac{11846 \cdot 40.3}{1191 \cdot 3000} = 0.134 > 0.1
\]

So, the second-order effects cannot be neglected.
V. BEAM DESIGN AND VERIFICATION: According to EC8 [3]– 4 and EC2[2].

V.1. TRANSVERSE CURRENT FRAME OR DIRECTION Y CURRENT FRAME:

V.1.1 Action effects: (According to 5.4.2 – EC8 [3])
- In accordance to 5.4.2 – EC8 [3], for the beams with ductility DCM, the design values for the building moments shall be obtained from the analysis of the structures for the seismic situation according to 6.4.3.4 – EN 1990. Combination of actions for seismic design situations is calculated as following expression: \[ \sum_{j=1}^{\ell} G_{k,j} + \psi + A_{Ed} + \psi \sum_{j=1}^{\ell} \psi Q_{k,j} \]

Where:
- \( G_{k,j} \) – is the permanent or persistent action j.
- \( P \) – is the pre-stressing action.
- \( A_{Ed} \) – is the design value of seismic actions for the reference return period (design spectrum)
- The loads were uniformly distributed along the length of the beam. No redistribution of the bending moments was made.
- The design value of the shear forces shall be determined in accordance with the capacity design rules, EC 8 – 5.4.2.2 – 1(P), considering the equilibrium of the beam under: a) the transverse load acting on it with the seismic design situation and b) end moment \( M_{i,d} \) (with \( i=1,2 \) – denoting the end sections of the beam), corresponding, for each sense of seismic action, to plastic hinge formation at the end of either of the beam or of the vertical elements, which ever takes place first – which are connected to the joint where the beam end and i frame into.
- The analysis is performed using two planar models, one for each main direction.
- The torsion effects were determined separately by these two dimensions according to 4.3.3.2.4(2) – EC8: If the analysis is performed using two planar models, one for each main horizontal direction, torsion effects may be determined by doubling the accidental eccentricity \( e_{ai} \) of the expression \( e_{ai} = \pm 0.05 L_i \) and applying the rules of 4.3.3.2.4 (1) – EC8 with the factor \( \delta, \delta = 1 + 0.6 \frac{x}{L_i} \), replaced by the factor \( \delta, \delta = 1 + 1.2 \frac{x}{L_i} \).
- Because of the symmetry, the actual eccentricity between stiffness centre \( S \) and the nominal mass centre \( M, \, e_0 = 0 \), is equal to 0, and the additional eccentricity, \( e_2 \), taking into account of the dynamic effect of simultaneous transitional and torsional vibration, can not be computed. → So, the only eccentricity taken into account is accidental torsional effect. \( e_i = e_{ai} = \pm 0.05 L_i \) (When using the Response Spectrum Analysis)

Where:
- \( e_{ai} \) – is the accidental eccentricity of the storey mass from its nominal location, applied in the same direction at all floors.
- \( L_i \) – is floor dimension perpendicular to the direction of the seismic action.

V.1.2 Action Summary:

V.1.2.1 Gravity actions:
- DEAD Load: The self-weight load.
- DL slab: The dead loads induced by the floor and coating weight.
- LL slab: The live loads induced by the variable actions
- LL roof slab: The live loads induced by the variable roof actions
- Snow load: The loads induced by the snow.
- Joint load: The loads acting to the joints of the transverse frame induced by perpendicular frames.
- WIND load.
Seismic actions:

- Seismic actions used to analyse in the frames will be determined by two methods of analysis: Lateral Force Analysis and Response Spectrum Analysis.
- The analysis is performed using two planar models, one for each main direction.
- Lateral force Analysis:
  - The torsion effects were determined separately by these two dimensions according to 4.3.3.2.4(2) – EC8: If the analysis is performed using two planar models, one for each main horizontal direction, torsion effects may be determined by doubling the accidental eccentricity $e_{ai}$ of the expression $e_{ai} = ±0.05L_i$ and applying the rules of 4.3.3.2.4 (1) – EC8 with the factor $\delta$, $\delta = 1 + 0.6 \times \frac{x}{L_i}$, replaced by the factor $\delta$, $\delta = 1 + 1.2 \times \frac{x}{L_i}$. So we have $\delta = 1.3$
  - The above seismic forces are total seismic acting in all of the building or all frames. According to the stiffness of each frame, we will distribute the seismic forces to each frame linearly including torsion effects.
  - In the action direction of the earthquake, there are 5 portal frames. When distributing seismic forces to all floors of the frame, the torsion effects will be taken into account by the factor $\delta$ which is calculated from 4.3.3.2.4 (1) – EC8. Factor $\delta$, here, accounts for...
the analysis model with two planar directions. We will distribute the seismic forces to the current transverse frame as following:

\[ F_{2-6} = F_6 \cdot \frac{1}{5} \cdot \delta = 321.34 \cdot \frac{1}{5} \cdot 1.3 = 83.54 \text{KN} . \]

\[ F_{2-3} = F_3 \cdot \frac{1}{5} \cdot \delta = 287.0 \cdot \frac{1}{5} \cdot 1.3 = 74.6 \text{KN} . \]

\[ F_{2-4} = F_4 \cdot \frac{1}{5} \cdot \delta = 231.5 \cdot \frac{1}{5} \cdot 1.3 = 60.2 \text{KN} . \]

\[ F_{2-3} = F_3 \cdot \frac{1}{5} \cdot \delta = 175.9 \cdot \frac{1}{5} \cdot 1.3 = 45.8 \text{KN} . \]

\[ F_{2-2} = F_2 \cdot \frac{1}{5} \cdot \delta = 120.4 \cdot \frac{1}{5} \cdot 1.3 = 31.3 \text{KN} . \]

\[ F_{2-1} = F_1 \cdot \frac{1}{5} \cdot \delta = 65.8 \cdot \frac{1}{5} \cdot 1.3 = 17.11 \text{KN} . \]

- Response Spectrum Analysis:
  - According to 4.3.3.3.1 – EC8 [2], the response of all modes of vibration contributing significantly to the global response shall be taken into account. The requirements may be deemed to be satisfied if either of the following can be demonstrated:
    - the sum of the effective modal masses for the modes taken into account amounts to at least 90% of the total mass of the structure;
    - All modes with effective modal masses greater than 5% of the total mass are taken into account.
  - When using a spatial model, the above conditions should be verified for each relevant direction.
  - According to 4.3.3.3.2 – EC8 [2], whenever all relevant modal responses may be regarded as independent of each other, the maximum value \( E_E \) of a seismic action effect may be taken as:
    \[ E_E = \sqrt{\sum E_E^2} . \]
  - According to 4.3.3.3.3 – EC8 [2], whenever a spatial model is used for the analysis, the accidental torsional effects may be determined as the envelope of the effects resulting from the application of static loadings, consisting of sets of torsional moments
    - \( M_{ai} \) about the vertical axis of each storey \( i \): \( M_{ai} = e_{ai} \cdot F_i \)
    Where:
    - \( M_{ai} \) is the torsional moment applied at storey \( i \) about its vertical axis.
    - \( e_{ai} \) is the accidental eccentricity of storey mass \( i \)
    - \( F_i \) is the horizontal force acting on storey \( i \), as derived in 4.3.3.2.3 for all relevant directions.
  - According to 4.3.3.3.3 (2) - EC8 [2], the effects of the torsional loadings should be taken into account with positive and negative signs (the same sign for all storeys). Whenever two separate planar models are used for the analysis, the torsional effects may be accounted for by applying the rules of 4.3.3.2.4(2) to the action effects computed in accordance with 4.3.3.2. → From all things mentioned above, SAP2000 will be used to analyse the structure with Modal Response Spectrum. The analysis will run accordingly to EC8.

V.1.3 COMBINATIONS:

According to EC8 [3], there are 3 combinations determined from all above actions:

- Combination 1: DEAD Load + DL Slab + Joint Load + Seismic Load + \( \sum \psi_{2,i} \cdot Q_i, i \)
- Combination 2(in opposite direction): DEAD Load + DL Slab + Joint Load - Seismic Load + \( \sum \psi_{2,i} \cdot Q_i, i \)
- Combination3: Envelope of Combination 1 and Combination2.
V.1.4 INTERNAL FORCES:
The internal forces will be determined by SAP2000, version 9.0. The internal forces, which are used to design the section reinforcement of the frames, are determined by Lateral Force Analysis method.

Figure 4 - Transverse or Direction Y Frame Line 2
### V.1.5 DESIGN OF BEAMS OF THE FIRST STORY IN FRAME LINE 2 (members 43-45, 61-63 and 79-81)

#### V.1.5.1 Geometrical Restraints

- **Effective flange width:**
  
  According to 5.4.3.1.1(3) – EC8 [3], the effective flange width \( b_{\text{eff}} \) may be assumed as follows:
  
  - For primary seismic beams framing into exterior columns, the effective flange width, \( b_{\text{eff}} \), is taken to the width \( b_c \) of the column in the absence of the transverse beam, or equal to this width increased by \( 2h_f \) on each side of the beam if there is transverse beam of similar depth.
  
  - For the primary seismic beams framing into interior columns, the above length may be increased by \( 2h_f \) on each side of the beam.

So, the effective flange width of beams framing to the exterior columns is:

\[
\begin{align*}
  b_{\text{eff}} &= b_c + 2h_f = 400 + 2 \times 150 = 1000
\end{align*}
\]

The effective flange width of beams framing to the interior columns is:

\[
\begin{align*}
  b_{\text{eff}} &= b_c + 4h_f = 400 + 4 \times 150 = 1600
\end{align*}
\]

- **Beam – Column centroidal axis distance:**

The beam framing symmetrically into the exterior columns has the eccentricity as following expression: \( e = 0.00 \text{mm} \)

- **Minimum width of the beams:**

  - In accordance to 5.4.1.2.1 – EC8 [3], the effective transfer of cyclic moments from a primary seismic beam to a column shall be achieved, by limiting the eccentricity of the beam axis relative to that of the column into which it frames.

  - A deemed to satisfy rule for 5.4.1.2.1 – EC8 is to limit the distance between the centroidal axes of the two members to less than \( b_c/4 \). 

    \[
    \begin{align*}
    b_w \leq \min \{b_c + h_w; 2b_c\} \\
    b_w \geq 200 \text{mm}
    \end{align*}
    \]

- **Width to height ratio of the web of the beam:**

  In accordance to 4.3.5.7 – EC2 [2], lateral buckling of the slender beams:
- (P1), where the safety of beams against lateral buckling is in doubt, it shall be checked by an appropriate method.
- (P2), the width to height ratio of the beam’s web must be ensure to the following condition: \( h_w < 2.5 * b_w \), so 
  \[
  h_w = \frac{500 \text{mm}}{b_w = 250} \implies 350 < 2.5 * 250 = 625
  \]

- Limitation of the beam width:
  According to 5.4.1.2.1 – EC8 [3], the beam width has to be checked as following condition:
  \[
  b_w \leq \min(b_t + h_w; 2*b_z) \implies b_w = 250 \leq \frac{250 + 500 = 750}{2*250 = 500}
  \]
  This condition is met.

V.1.5.2  
*Flexural reinforcement – Ultimate limit States*

- Bending moment envelope diagram is presented as following:

- The reinforcement of the sections will be calculated by using EC2.
- The actual strength of the materials:
  - Concrete:
    As chosen above, the concrete class is C25/30, according to 3.1.2.4 – EC2 [2], concrete material properties are:
    \[
    f_{ck} = 25 \text{MPa} = 250 \text{N/mm}^2; f_{cm} = 33 \text{MPa} = 330 \text{N/mm}^2; f_{cm} = 2.6 \text{MPa} = 26 \text{N/mm}^2
    \]
    \[
    f_{cd} = \frac{\alpha_c * f_{ck}}{\gamma_c} = 16.67 \text{MPa} = 16.67 \text{N/mm}^2; \alpha_c = 1; \gamma_c = 1.5
    \]
    *(Note: In Belgium \( \gamma_c = 1.5; \) In France \( \gamma_c = 1.3)\)*
  
  - Reinforcing steel:
    As chosen above, the steel class is S500, according to EC2 and EC3, steel material properties are:
    \[
    f_{sk} = 500 \text{MPa} = 5000 \text{N/mm}^2
    \]
    \[
    f_{yd} = \frac{\alpha_s * f_{sk}}{\gamma_s} = \frac{1*500}{1.15} = 434.8 \text{MPa} = 434.8 \text{N/mm}^2
    \]
    *(Note: In Belgium \( \gamma_s = 1.0; \) In France \( \gamma_s = 1.0)\)*
  
  - In accordance to ultimate limit states of bending plus axial force design procedure of 6.1 - EC 2 and 3.1.5 – EC2 [2], we will use a rectangular diagram for compressed concrete block. In this case, the value of \( \eta \) is 1, so \( \eta \) * \( f_{cd} \) = 1 * \( f_{cd} \) = 16.7 MPa.

- Flexural Reinforcing steel of Left – side of first span of the beam (Axis A)
  \[
  M^+ = 92534 Nm
  \]
  \[
  M^- = -186834 Nm
  \]

- For \( M^+ \):
  - Beam’s dimensions: \( b=250 \text{mm}; h=500 \text{mm.} \)
  - Cover:
    \[
    c_{nom} = c_{min} + \Delta c_{dev} \text{ ( Expression 4.1 – EC2 [2])}
    \]
    Where:
\[ c_{\text{min}} = \max[c_{\text{min,b}}, c_{\text{min,dur}}]. (\text{According to Expression 4.2 – EC2}[2]) \]

\[ c_{\text{min,b}} = \text{diameter of bar. Assume 20mm bars and 6 mm hoops - Table 4.2 – EC2}[2]. \]

\[ c_{\text{min,dur}} = \text{minimum cover due to environmental conditions. Assuming that Exposure class is XC1 and Structural Class is S4} \rightarrow c_{\text{min,dur}} = 15\text{mm} \]

\[ \Delta c_{\text{dev}} = 10\text{mm} \]

\[ \rightarrow c_{\text{nom}} = 20 + 10 = 30\text{ mm} \]

- Concrete cover thickness + \( \frac{1}{2} \) reinforcement diameter = 30 + 6 + 7 = 43 mm
- The effective height \( d: d = h - \) concrete cover thickness – stirrup diameter – \( \frac{1}{2} \) reinforcement diameter = 500 – 43 = 457 mm
- The effective width of the beam: \( b_{\text{eff}} = 1450\text{mm} \)
- According to Appendix A1 – Concise EC2 [5], and to How to design concrete using EC2 [6]:

\[ K = \frac{M_{\text{Ed}}}{b_{\text{eff}} \cdot d^2 \cdot f_{ck}} = \frac{92534 \times 10^3}{1600 \times 457^2 \times 25} = 0.01 \]

To restrict the ratio \( x/d < 0.45 \)

\[ \rightarrow \delta = 0.85 \text{ and } K' = 0.168 \]

\[ \rightarrow z = \frac{d}{2} \left[ 1 + \sqrt{1 - 3.53K'} \right] = \frac{457}{2} \left[ 1 + \sqrt{1 - 3.53 \times 0.0122} \right] = 452.03 \leq 0.95 \times d = 434.15 \]

\[ \rightarrow x = 2.5 \times (d-z) = 57.125\text{mm} < 1.25 \times h_t = 1.25 \times 150 = 187.5 \text{mm} \]

- On the other hand we have the relationship: \( M_{\text{Ed}} = A_s \times f_{yd} \times z \), So the area of reinforcement steel can be determined as follows:

\[ A_s \geq \frac{M_{\text{Ed}}}{f_{yd} \times z} = \frac{92534 \times 10^3}{434.8 \times 434.15} = 490.2\text{mm}^2 = 4.9\text{cm}^2 \]

- We choose 4 φ 14 (\( A_s = 6.2\text{ cm}^2 \)) for flexural reinforcements ⇒ The resistance of the section is \( M_{\text{Ed}, b,A} = +119kN\text{m} \) and the over-strength factor is \( \frac{119}{92.5} = 1.29 \).

- The normalised flexural reinforcements are:

\[ \rho = \frac{A_s}{b_{\text{eff}} \times d} = \frac{6.2}{25 \times (50 - 3 - 0.6 - \frac{1.4}{2})} = 0.005 \]

- Checking for spacing of the bars

Clear spacing of the bars: (250 - 2 \times 30 - 2 \times 6 - 4 \times 14)/3 = 40.7mm

According to 8.2(2) – EC2 [2], minimum clear distance between bars:

= max [bar diameter, aggregate +5mm]

= max [14, 20 + 5] = 25mm < 40.7

- For \( M \):

- Beam’s dimensions: \( b=250\text{mm}; h=500\text{mm} \)

- Cover:

\[ c_{\text{nom}} = c_{\text{min}} + \Delta c_{\text{dev}} \] (Expression 4.1 – EC2 [2])

Where:

\[ c_{\text{min}} = \max[c_{\text{min,b}}, c_{\text{min,dur}}]. (\text{According to Expression 4.2 – EC2}[2]) \]

\[ c_{\text{min,b}} = \text{diameter of bar. Assume 20mm bars and 6 mm hoops - Table 4.2 – EC2}[2]. \]

\[ c_{\text{min,dur}} = \text{minimum cover due to environmental conditions. Assuming that Exposure class is XC1 and Structural Class is S4} \rightarrow c_{\text{min,dur}} = 15\text{mm} \]

\[ \Delta c_{\text{dev}} = 10\text{mm} \]

\[ \rightarrow c_{\text{nom}} = 20 + 10 = 30\text{ mm} \]

- Concrete cover thickness + \( \frac{1}{2} \) reinforcement diameter + stirrup diameter = 60mm
- Working height \( d: d = h - \) concrete cover thickness – \( \frac{1}{2} \) reinforcement diameter = 500-60=440mm
The ULS condition:

\[ M_{rd} \geq M_{Ed}; M_{rd} = \mu * b * d^2 * \eta * f_{cd}; M_{Ed} = -186834Nm \]

- The ULS condition:
  \[ \mu \geq \frac{M_{Ed}}{b * d^2 * \eta * f_{cd}} = \frac{186834*10^3}{250*440^3*1*16.7} = 0.231 \]
  \[ \Rightarrow \frac{x}{d} = 0.33 < 0.45; \Rightarrow \frac{z}{d} = 0.85 \Rightarrow z = 0.86 * d = 378.4mm; \]

- On the other hand we have the relationship: \( M_{rd} = A_y * f_{yd} * z \), So the area of reinforcement steel can be determined as follows:
  \[ A_y \geq \frac{M_{Ed}}{f_{yd} * z} = \frac{186834*10^3}{434.8*378.4} = 1134mm^2 = 11.3cm^2 \]

- We choose 3 \( \phi \) 20+2\( \phi \)10 or 4 \( \phi \)20 (\( A_s = 12.6 \text{ cm}^2 \)) for flexural reinforcements \( \Rightarrow \) The resistance of the section is \( M_{rd,b,A} = -218kNm \) and the over-strength factor is \( \frac{218}{186.8} = 1.17 \).

- The normalised flexural reinforcements are:
  \[ \rho = A_y \frac{b_w}{d} = \frac{12.6}{25*(50-2.0-0.6-2.0)} = 0.011 \]

- Checking for spacing of the bars
  Clear spacing of the bars: \( (250-2*30-2*6-4*20)/3 = 32.7mm \)
  According to 8.2(2) – EC2 [2], minimum clear distance between bars:
  \( = \text{max} \) [bar diameter, aggregate +5mm]
  \( = \text{max} \) [14, 20+5] = 25mm < 32.7 \( \Rightarrow \) so this condition is met

- Check for the ratio between negative reinforcement and positive reinforcement: According to 5.4.3.1.2 (4a) – EC8 [3], at the compression zone, reinforcement is not less than half of the reinforcement provided at the tension zone. The compression reinforcement area is 620 mm² and the tension reinforcement area is 1260 mm² \( \Rightarrow \) so this condition is met

- Flexural Reinforcing steel of right – side of first span of beam (Axis B):
  \[ M^+ = 82191Nm \]
  \[ M^- = -176883Nm \]

- For \( M^+ \):
  - Beam’s dimensions: \( b_{eff} = 1600 \text{ mm}; h_w = 500 \text{ mm} \)
  - Concrete cover thickness + \( \frac{1}{2} \) reinforcement diameter = 50mm
  - Working height \( d \): \( d = h - \text{concrete cover thickness} - \frac{1}{2} \text{ reinforcement diameter} = 500-50 = 450mm \)

- The ULS condition:
  \[ M_{rd} \geq M_{Ed}; M_{rd} = \mu * b_{eff} * d^2 * \eta * f_{cd}; M_{Ed} = 82191Nm \]
  \[ \Rightarrow \mu \geq \frac{M_{Ed}}{b_{eff} * d^2 * \eta * f_{cd}} = \frac{82191*10^3}{1600*450^3*1*16.7} = 0.02 \Rightarrow \frac{x}{d} = 0.066 < 0.45 \]
  \[ \Rightarrow x = 29 < h_f = 150; \Rightarrow \frac{z}{d} = 0.977 \Rightarrow z = 0.977 * d = 440mm \]

- Area of reinforcement steel can be determined as follows:
  \[ A_y \geq \frac{M_{Ed}}{f_{yd} * z} = \frac{82191*10^3}{434.8*440} = 429mm^2 = 4.3cm^2 \]

- We choose 4 \( \phi \) 14 (\( A_s = 6.2 \text{ cm}^2 \)) for flexural reinforcements, \( \Rightarrow \) The resistance of the section is \( M_{rd,b,B} = 119kNm \) and the over-strength factor is \( \frac{119}{82} = 1.45 \).
The normalised flexural reinforcements are:

\[
\rho = \frac{A_s}{b_w * d} = \frac{6.2}{25 * (50 - 3.0 - 0.6 - 1.4)} = 0.005
\]

Checking for spacing of the bars

Clear spacing of the bars: \((250 - 2 \times 30 - 2 \times 6 - 4 \times 14) / 3 = 40.7\, \text{mm}\). According to 8.2(2) – EC2 [2], minimum clear distance between bars: \(= \max \{\text{bar diameter, aggregate +5mm}\}

= max [14, 20+5] = 25mm < 40.7 \rightarrow \text{so this condition is met}\)

- For \(M^*\):
  
  Beam’s dimensions: \(b=250\, \text{mm}; \, h=500\, \text{mm}\)
  
  Concrete cover thickness + \(\frac{1}{2}\) reinforcement diameter = 60mm
  
  Working height \(d\): \(d = h – \text{concrete cover thickness} – \frac{1}{2}\) reinforcement diameter = 500-60=440mm
  
  The ULS condition:

  \[
  M_{Rd} \geq M_{sd} \quad ; M_{Rd} = \mu * \frac{b * d^2 * \eta * f_{cd}}{2} \quad \Rightarrow \quad M_{sd} = -176883 \times 10^3 \quad ; \mu \geq \frac{M_{sd}}{250 \times 440^2 \times 16.7} = 0.218
  \]

  \[
  \Rightarrow \frac{z}{d} = 0.312 < 0.45 \Rightarrow \frac{z}{d} = 0.87 \Rightarrow z = 0.87 * d = 382.8\, \text{mm}
  \]

- Area of reinforcement steel can be determined as follows:

  \[
  A_\phi \geq \frac{M_{sd}}{f_{yd} \* z} = \frac{176883 \times 10^3}{434.8 \times 382.8} = 1062.7\, \text{mm}^2 = 11\, \text{cm}^2
  \]

  We choose \(2 \phi 20 + 1 \phi 18 + 2\phi 10\) for flexural reinforcements. \(\Rightarrow\) The resistance of the section is \(M_{Rd, b} = -208\, \text{kNm}\) and the over-strength factor is \(\frac{208}{176} = 1.18\).

- The normalised flexural reinforcements are:

  \[
  \rho = \frac{A_s}{b_w * d} = \frac{11.9}{25(50 - 3.0 - 0.6 - \frac{2.0}{2})} = 0.01
  \]

Checking for spacing of the bars

Clear spacing of the bars: \((250 - 2 \times 30 - 2 \times 6 - 2 \times 18 - 2\times 20) / 3 = 34\, \text{mm}\)

According to 8.2(2) – EC2 [2], minimum clear distance between bars:

\(= \max \{\text{bar diameter, aggregate +5mm}\}\)

\(= \max [14, 20+5] = 25\, \text{mm} < 34\, \text{mm} \rightarrow \text{so this condition is met}\)

- Check for the deflection: According to 15.7 – Concise EC2[5], the SLS state of deflection may be checked by using the span to effective depth approach. To use the span – to effective – depth approach, verify that:

  Allowable \(l/d = N \ast K \ast F_1 \ast F_2 \ast F_3 \geq \text{actual } l/d\)

  Where:

  \(N = \text{Basic } l/d: \text{check whether } \rho > \rho_0 : \rho = \frac{f_{ck}^{0.5}}{1000} = 0.005 \rightarrow \text{use the Exp (7.16a) – Concise EC2 [5]: } N = 11 + 1.5 \ast f_{ck}^{0.5} \rho / \rho_0 + 3.2 \ast f_{ck}^{0.5} \rho / \rho_0 - 1 \right)^{1.5} = 18.5\)

  \(K=1.3 \, \text{(end span)} \) table 15.11 – Concise EC2
F1 = 1; F2 = 1
F3 = 310/σ
Where: σ = (A_{s,pro}/A_{s,req}) = 182/500 ≤ 1.5
l/d = 36.04
Actual l/d = 5000/457 = 10.9. So this condition is met.

V.1.5.3 Specific measures for the flexural reinforcement.
- Min/max reinforcing steel
  - In accordance to 5.4.3.1.2 – EC8 [3], minimum tension reinforcement ratio shall not exceed the value: ρ_{max} = 0.5 * f_{cm} / f_{yk} = 0.5 * 2.6 / 500 = 0.0026 (5.12 - EC8 [3]).

  → The reinforcement content is satisfactory.
  - According to 5.4.3.1.2 – EC8 [3], within the critical regions, the tension reinforcement ratio shall not exceed the value below: ρ_{max} = \rho' + ρ_{max} * \frac{f_{cd}}{f_{yd}}

Where:
  - μ₀ - Curvature ductility, T₁ = 0.67s > T_C = 0.6s → μ₀ = 2 * q₀ - 1 = 6.8.
  - ε_{sy,d} = \frac{f_{yd}}{E_s}

So, ρ_{max} = 0.00532 + \frac{0.018}{6.8} * \frac{16.7}{434.8} = 0.052 > 0.01

→ The reinforcement content is satisfactory.
- Longitudinal bar diameters:
  - According to 5.6.2.2 – EC8 [3], to prevent the bond failure, the diameter of longitudinal bars of the beams is limited as the following conditions:

    - For interior beam – column joints:
      \[ \frac{d_{bl}}{h_c} \leq \frac{7.5 * f_{c,tm} * \left(1 + 0.8 * \gamma_D \right)}{\gamma_{Ed} * f_{yd} * 1.75 * k_D * \rho' \rho_{max}} \leftrightarrow \frac{d_{bl}}{h_c} \leq 4.0 * \frac{f_{c,tm} * (1 + 0.8 * \nu_d)}{f_{yd} \sqrt{h_c}} \] (2.7.2.2.1 – ENV8.)

Where:
  - h_c – is the width of the column parallel to the bars, so h_c = 500mm.
  - f_{c,tm} – is the mean value of the tensile strength of concrete → f_{c,tm} = 2.6N/mm².
  - F_{yd} = 434.8 MPa.
  - ν_d – is the normalised design axial force in column, taken with its minimum value for seismic design situation. ν_d = \frac{N_{Ed}}{f_{cd} * A_c}

N_{Ed} = -1295000N; f_{cd} = 16.67MPa; A_c = 400x500 = 200000mm².

→ ν_d = \frac{N_{Ed}}{f_{cd} * A_c} = \frac{1295000}{16.7 * 200000} = 0.387

  - k_D – is the factor reflecting the ductility class equal to 1 for DCH, to 2/3 for DCM.
  - ρ' – compression steel ratio → ρ' = 0.00532
  - ρ_{max} = 0.052.
  - γ_{Ed} = 1.

So: \[ \frac{d_{bl}}{h_c} \leq \frac{7.5 * 2.6 * (1 + 0.8 * h_c)}{1 * 434.8 * \left(1 + 0.75 * 0.5 \frac{0.00532}{3} \right)} = 0.056 \rightarrow d_{bl} = 500 * 0.056 = 28mm

→ The chosen reinforcement is satisfactory.
- For exterior beam – column joints:

\[ \frac{d_{bl}}{h_c} \leq \frac{7.5 * f_{cm} * 1 + 0.8 \nu_d}{h_c} \leftrightarrow \frac{d_{bl}}{h_c} \leq \frac{4.0 * f_{cm} * (1 + 0.8 * \nu_d)}{f_{yd}} \] (2.7.2.2.1 – ENV8)

Where:
- \( h_c \) – is the width of the column parallel to the bars, so \( h_c = 500 \text{mm} \).
- \( f_{cm} \): is the mean value of the tensile strength of concrete \( \rightarrow f_{cm} = 2.6 \text{N/mm}^2 \).
- \( F_{yd} = 434.8 \text{MPa} \).
- \( \nu_d \) – is the normalised design axial force in column, taken with its minimum value for seismic design situation. \( \nu_d = \frac{N_{Ed}}{f_{cd} * A_c} \)

\[ N_{Ed} = -940000 \text{N}; f_{cd} = 16.67 \text{MPa}; A_c = 400 \times 500 = 200000 \text{mm}^2. \]

\[ \nu_d = \frac{940000}{16.7 \times 200000} = 0.28 \]

- \( k_D \) – is the factor reflecting the ductility class equal to 1 for DCH, to 2/3 for DCM.
- \( \rho' \) – compression steel ratio \( \rightarrow \rho' = 0.00532 \)
- \( \rho_{max} = 0.052. \)
- \( \gamma_{Rd} = 1. \)

So:

\[ \frac{d_{bl}}{h_c} \leq \frac{7.5 * 2.6 * (1 + 0.8 * 0.28)}{1 * 434.8} = 0.055 \rightarrow d_{bl} = 500 * 0.055 = 27.5 \text{mm} \]

\[ \rightarrow \text{The chosen reinforcement is satisfactory.} \]

- Top reinforcement of the beam.
  - In accordance to 2.7.3.4 part 1-3 – ENV8, one fourth of the maximum top reinforcement shall run along the entire beam length.
  - Two \( \phi 20 \) bars will run along the entire span.

**V.1.5.4 Shear resistance**

- Design shear forces computed in accordance to the capacity design criterion:
  - According to 5.4.2.2 – EC8 [3], in the primary seismic beams shear forces shall be calculated in accordance with the capacity design rule, considering the equilibrium of the beam under: a) the transverse load acting on it in seismic design situation and b) end moments \( M_{i,d} \) (with \( i=1,2 \) denoting the end sections of the beam), corresponding for each sense of the seismic action, to plastic hinge formation at the ends either of the beams or of the vertical elements – which are connected to the joint where beam end \( i \) frames into.
  - The calculation of shear forces as following the sketch below:
Determining $M_{+ARd1}$, $M_{-BRd1}$, $M_{+ARd2}$, $M_{-BRd2}$, $V_{A0}$, $V_{B0}$:

- $M_{+ARd1}$ and $M_{+BRd2}$
  
  The bottom reinforcement area of longitudinal bars is $6.2\text{cm}^2$ (4 φ 14), we determine the value of $M_{+ARd1} = M_{+BRd2}$ as following:

  \[
  x = \frac{f_{yd} * A_s}{\eta * f_{cd} * b} = \frac{434.8 * 6.2 * 100}{1 * 16.7 * 250} = 64.6\text{mm}
  \]

  \[
  d = 500 - 30 - 6 - \frac{14}{2} = 455\text{mm}
  \]

  \[
  \frac{x}{d} = 0.139 \rightarrow \frac{z}{d} = 0.95
  \]

  \[
  \rightarrow M_{+ARd1} = z * f_{yd} * A_s = 0.95 * 465 * 434.8 * 620 = 119085198Nmm \rightarrow M_{+ARd1} = 119\text{KNm}
  \]

  $M_{+BRd2} = 119\text{KNm}$.

- $M_{-ARd2}$: The top reinforcement area of longitudinal bars is 4 φ 20 ($A_s = 12.6 \text{cm}^2$), we determine the value of $M_{-ARd2}$ as following:

  \[
  F_{as} = f_{yd} * A_s = 434.8 * 1260 = 547848Nmm
  \]

  \[
  F_c = \eta * f_{cd} * b * (h - z) = 16.7 * 250 * (500 - z)
  \]

  \[
  = 4175 * (500 - z)
  \]

  \[
  F_{as} = F_c \rightarrow 547848 = 4175 * (500 - z)
  \]

  \[
  \rightarrow z = 368.8\text{mm}
  \]

  \[
  M_{-ARd2} = F_{as} * b_{as} + F_c * b_c
  \]

  \[
  b_{as} = z - \text{coating} - \phi\text{stirrup} - \frac{1}{2}\phi\text{bars}
  \]

  \[
  b_{as} = 368.8 - 20 - 6 - 10 = 332.8\text{mm}
  \]

  \[
  b_c = \frac{h - z}{2} = \frac{500 - 368.8}{2} = 65.6\text{mm}
  \]

  \[
  \rightarrow M_{-ARd2} = 547848 * 332.8 + 4175 * (500 - 368.8) * 65.6 = 218256870Nmm \rightarrow M_{-ARd2} = 218\text{KNm}
  \]

- $M_{BRd1}$: The top reinforcement area of longitudinal bars is 2φ20 + 2φ18 ($A_s = 11.9 \text{cm}^2$), we determine the value of $M_{BRd1}$ as following:

  \[
  F_{as} = f_{yd} * A_s = 434.8 * 1190 = 517412Nmm
  \]

  \[
  F_c = \eta * f_{cd} * b * (h - z) = 16.7 * 250 * (500 - z)
  \]

  \[
  = 4175 * (500 - z)
  \]

  \[
  F_{as} = F_c \rightarrow 517412 = 4175 * (500 - z)
  \]

  \[
  \rightarrow z = 376.1\text{mm}
  \]

  \[
  M_{-BRd1} = F_{as} * b_{as} + F_c * b_c
  \]

  \[
  b_{as} = z - \text{coating} - \phi\text{stirrup} - \frac{1}{2}\phi\text{bars}
  \]

  \[
  b_{as} = 376.1 - 20 - 6 - 10 = 340.1\text{mm}
  \]

  \[
  b_c = \frac{h - z}{2} = \frac{500 - 376.1}{2} = 62\text{mm}
  \]

  \[
  \rightarrow M_{-BRd1} = 517412 * 340.1 + 4175 * (500 - 376.1) * 62 = 208043336Nmm \rightarrow M_{-BRd1} = 208\text{KNm}
  \]

- Determining $V_{B0}$ and $V_{A0}$:
\[ V_{B0} = V_{A0} = \frac{3750 \times 5}{2} + \frac{32850 \times 5}{2 \times 2} = 50437.5N = 50.4KN \]

- So we have:

\[ V_{M1} = -\gamma_{rd} \times \frac{(M_{Rd}^{+} + M_{Rd}^{-})}{l} = -1 \times \frac{119 + 208}{5} = -65 \]

\[ V_{M2} = \gamma_{rd} \times \frac{(M_{Rd}^{-} + M_{Rd}^{+})}{l} = 1 \times \frac{218 + 119}{5} = 67; \quad V_{B0} = V_{A0} = 50.4KN \]

And so:
- At support A:
  \[ V_{\text{min}} = V_{M1} + V_{A0} = -65 + 50.4 = -14.6; \quad V_{\text{max}} = V_{M2} + V_{A0} = 67 + 50.4 = 117.4 \]
- At support B:
  \[ V_{\text{min}} = -V_{M2} + V_{B0} = -67 + 50.4 = -16.6; \quad V_{\text{max}} = V_{M1} + V_{B0} = 65 + 50.4 = 115.4 \]

**V_{rd} and V_{Rd} Computations:**
- In the critical sections: \( V_{cd} = 0 \)
- Outside the critical sections: \( V_{cd} = V_{Rd1} \).
- In accordance with EC(2) 4.3.2.3 and neglecting the axial force influence, the value of \( V_{Rd,c} \)

<table>
<thead>
<tr>
<th>EN 1992</th>
</tr>
</thead>
<tbody>
<tr>
<td>[ V_{Rd,c} = \left[ \frac{0.18}{\gamma_{c}} \times k \times (100 \times \rho_{s} \times f_{ck})^{1/3} - 0.15 \times \sigma_{cp} \right] \times b_{w} \times d ]</td>
</tr>
</tbody>
</table>

- \( f_{ck} \) – is compressed strength of the concrete at the age of 28 days. \( \gamma_{c} = 1.5 \)
- \( k = 1 + \sqrt{\frac{200}{d}} \leq 2.0 \) d – mm; \( \rho_{s} = \frac{A_{sl}}{b_{w} \times d} \leq 0.02 \) where:
  - \( A_{sl} \) – is the area of tension reinforcements.
  - \( b_{w} \) – is the minimum width.
  - \( \sigma_{cp} = \frac{N_{sd}}{A_{s}} \); \( N_{sd} \) – is the longitudinal force. MPa
- Replacing with the value of \( f_{ck} \) is 25MPa, reinforcing steel percentage is 820
  \[ \frac{250 \times (500 - 20 - 6 - 7)}{620} = 0.00532 \], so we have:

\[ V_{Rd,ct} = \left[ \frac{0.18}{1.5} \times 1 \times (100 \times 0.00532 \times 25)^{1/3} \right] \times 250 \times 467 = 32942N = 32.9KN \]

**Computations**
- The computations shall run in accordance to 6.2.1(2) – EN1992 and the specific rules shall get along with truss model (EN1998)
- According to 6.2.1(2) – EC2 [2], the shear resistance of a member with shear reinforcement is equal to \( V_{Rd} = V_{Rd,s} + V_{Rd,c} + V_{td} \). \( V_{td} \) is the design value of the shear component of the force in the tensile reinforcement, in the case of an inclined tensile chord, so \( V_{td} = 0 \) and \( V_{cdd} = 0 \).

So:

\[ V_{Rd} = V_{Rd,s} + V_{cdd} \rightarrow V_{Rd,s} = \frac{A_{sw} \times s \times f_{yw} \times \cos \theta}{s} \]

- In critical regions (2*height of the beams) shear force will be carried out only by the stirrups. We choose stirrups with 2 legs, of 6mm in diameter and 80mm spacing. Shear force capacity is:

\[ V_{Rd} = V_{Rd,c} = \frac{57 \times 467 \times 434.8}{80} = 144674.4N = 145KN \gg V_{\text{max}}. \]
- Outside critical regions, shear forces are carried out by stirrups with 2 legs, 6mm in diameter and 120mm spacing. Shear force capacity is:

\[ V_{Rd} = V_{Rd,c} + V_{Rd,s} = 32900 + \frac{57}{120} \times 467 \times 434.8 = 129400 \text{N} = 129.4 \text{KN} \]

- The difference between the shear force values at support A and B is small enough to neglect the possibility of modifying the shear reinforcement. Along the whole beam length, shear force must be less than the value of \( V_{Rd,max} \) which is the design value of the maximum shear force which can be sustained by the member, limited by crushing of the compression struts.

\[ V_{Rd,max} = \alpha_{cw} \times b_w \times h_w \times v_1 \times f_{cd} / (\cot \theta + \tan \theta) \]

Where: \( v_1 \) is a strength reduction factor for concrete cracked in shear, \( \alpha_{cw} \) is a coefficient taking account of the state of the stress in the compression chord. So:

\[ \nu_1 = 0.6 \times \left[ 1 - \frac{f_{ck}}{250} \right] = 0.6 \times 0.9 = 0.54 \text{ and } \alpha_{cw} = 1. \]

\[ \rightarrow V_{Rd,max} = 1 \times 250 \times 467 \times 16.7 / (1+1) = 526000 \text{N} = 526 \text{KN} > V_{max} \]

- The computations shall run in accordance to 6.2.1(2) – EN1992 and the specific rules shall get along with truss model (EN1998)

V.1.5.5 Specific measures

- Detailing:
  - In accordance to 5.4.3.1.2(6P) - EC8 [3], the stirrup minimum diameter within the critical regions is 6mm – this requirement is met.
  - The first hoop is placed not more than 50mm from the end cross section of the beam – this requirement is met.
  - Within the critical regions, the spacing of the hoops is not greater than:
    \[ \frac{h_w}{4} = 125 \text{mm}; 24 \times d_{bw} = 24 \times 6 = 144 \text{mm} \]
    \[ 225 \text{mm}; 8 \times d_{bl} = 8 \times 14 = 112 \text{mm} \]
    So, the condition is satisfactory.

- Casting and Placing for beam: All requirements are met.
**V.1.6 REINFORCEMENT OF OTHER BEAMS**

The reinforcement of other beams of the transverse frame are determined by using the similar ways as the beams on the first floor. They are summarized in the following tables.

<table>
<thead>

V.2. **LONGITUDINAL OR DIRECTION X CURRENT FRAME:**

V.2.1 **Action effects: (According to 5.4.2 – EC8 [3])**

- All the steps are the same as transverse frames.
- The loads were uniformly distributed along the length of the beam. No distribution of the bending moments was made.
- The design value of the shear forces shall be determined in accordance with the capacity design rules, EC 8 – 5.4.2.2 – 1(P).
- The torsion effects were determined separately by these two dimensions according to 4.3.3.2.4(2) – EC8: If the analysis is performed using two planar models, one for each main horizontal direction, torsion effects may be determined by doubling the accidental eccentricity $e_{ai}$ of the expression $e_{ai} = \pm 0.05L_e$ and applying the rules of 4.3.3.2.4 (1) – EC8 with the factor $\delta$, $\delta = 1 + 0.6 \times \frac{x}{L_e}$, replaced by the factor $\delta$, $\delta = 1 + 1.2 \times \frac{x}{L_e}$.

V.2.2 **Action Summary:**

V.2.2.1 **Gravity actions:**

- **DEAD Load:** The self-weight load.
- **DL slab:** The dead loads induced by the floor and coating weight.
- **LL slab:** The live loads induced by the variable actions
- **LL roof slab:** The live loads induced by the variable roof actions
- **Snow load:** The loads induced by the snow.
- **Joint load:** The loads acting to the joints of the longitudinal frame induced by perpendicular frames.
- **WIND load.**

V.2.2.2 **Seismic actions:**

- The analysis is performed using two planar models, one for each main direction.
- The torsion effects were determined separately by these two dimensions according to 4.3.3.2.4(2) – EC8: $\delta = 1 + 1.2 \times \frac{x}{L_e} = 1 + 1.2 \times \frac{2.5}{15} = 1.2$. So we have $\delta = 1.2$.
- The above seismic forces are total seismic acting in all of the building or all frames. According to the stiffness of each frame, we will distribute the seismic forces to each frame linearly including torsion effects.
- In the action direction of the earthquake, there are 4 portal frames. When distributing seismic forces to all floors of the frame, the torsion effects will be taken into account by the factor $\delta$ which is calculated from 4.3.3.2.4 (1) – EC8. Factor $\delta$, here, accounts for the analysis model with two planar directions. We will distribute the seismic forces to the current transverse frame as following:

- $F_{B-6} = F_6 \times \frac{1}{4} \times \delta = 321.34 \times \frac{1}{4} \times 1.2 = 96.4 KN$.
- $F_{B-5} = F_5 \times \frac{1}{4} \times \delta = 287.0 \times \frac{1}{4} \times 1.2 = 86.1 KN$.
- $F_{B-4} = F_4 \times \frac{1}{4} \times \delta = 231.5 \times \frac{1}{4} \times 1.2 = 69.5 KN$.
- $F_{B-3} = F_3 \times \frac{1}{4} \times \delta = 175.9 \times \frac{1}{4} \times 1.2 = 52.8 KN$.
- $F_{B-2} = F_2 \times \frac{1}{4} \times \delta = 120.4 \times \frac{1}{4} \times 1.2 = 36.1 KN$.
- $F_{B-1} = F_1 \times \frac{1}{4} \times \delta = 65.8 \times \frac{1}{4} \times 1.2 = 19.7 KN$. 
• Response Spectrum Analysis: Response Spectrum Analysis will be carried out the same as the transverse frame.

**V.2.3 COMBINATIONS:**
According to EC8 [3], there are 3 combinations determined from all actions above:

- Combination 1: DEAD Load + DL Slab + Joint Load + Seismic Load + \( \sum \psi_{2,i} * Q_{k,i} \)
- Combination 2 (in opposite direction): DEAD Load + DL Slab + Joint Load - Seismic Load + \( \sum \psi_{2,i} * Q_{k,i} \)
- Combination 3: Envelope of Combination 1 and Combination 2.

**V.2.4 INTERNAL FORCES:**
The internal forces will be determined by SAP2000, version 9.0. The internal forces, which are used to design the section reinforcements of the frames, will be determined by Lateral Force Analysis method.

#### V.2.5 DESIGN OF BEAMS OF THE FIRST STORY (members 31-33, 49-51, 67-69 and 133-135)

##### V.2.5.1 Geometrical Restraints

- **Effective flange width:**
  
  According to 5.4.3.1.1(3) – EC8 [3], the effective flange width $b_{eff}$ may be assumed as follows:
  
  - For primary seismic beams framing into exterior columns, the effective flange width, $b_{eff}$, is taken to the width $b_c$ of the column in the absence of the transverse beam, or equal to this width increased by $2h_f$ on each side of the beam if there is transverse beam of similar depth.
  
  - For the primary seismic beams framing into interior columns the above length may be increased by $2h_c$ on each side of the beam.

  So, the effective flange width of beams framing to the exterior columns is:
  
  \[
  b_c = 500 \text{mm} \quad ; \quad h_f = 150 \text{mm} \rightarrow b_{eff} = b_c + 2*2*h_f = 1100 \text{mm}
  \]

  The effective flange width of beams framing to the interior columns is:
  
  \[
  b_c = 500 \text{mm} \quad ; \quad h_f = 150 \text{mm} \rightarrow b_{eff} = b_c + 2*4*h_f = 1700 \text{mm}
  \]

- **Beam – Column centroidal axis distance:**
  
  The beam framing symmetrically into the exterior columns has the eccentricity as following expression: $e = 0.00 \text{mm}$

- **Minimum width of the beams:**
- In accordance to 5.4.1.2.1, the effective transfer of cyclic moments from a primary seismic beam to a column shall be achieved, by limiting the eccentricity of the beam axis relative to that of the column into which it frames.
- A deemed to satisfy rule for 5.4.1.2.1 is to limit the distance between the centroidal axes of the two members to less than \( \frac{b_c}{4} \), \( \Rightarrow b_w \leq \min \left\{ b_c + h_w ; 2b_c \right\} \) \( \Rightarrow b_w \geq 200 \text{mm} \)

- **Width to height ratio of the web of the beam:**
  
  In accordance to 2.7.2.4 – ENV 1998 and 4.3.5.7 – EC2 [2], lateral buckling of the slender beams: (P2)
  - (P1), where the safety of beams against lateral buckling is in doubt, it shall be checked by an appropriate method.
  - (2), the width to height ratio of the beam’s web must be ensure to the following condition:
    \[
    h_w < 2.5 \cdot b_w, \quad \text{so} \quad b_w = \frac{500 \text{mm}}{250} \Rightarrow 350 < 2.5 \cdot 250 = 625
    \]

- **Limitation of the beam width:**
  
  According to 5.4.1.2.1 – EC8 [3], the beam width has to be checked as following condition:
  \[
  b_w \leq \min \left( b_c + h_w ; 2 \cdot b_c \right) \rightarrow b_w = 250 \leq \left\{ \begin{array}{l}
  250 + 500 = 750 \\
  2 \cdot 250 = 500
\end{array} \right. \text{. This condition is met.}
  \]

**V.2.5.2 Flexural reinforcement:**

- In accordance to 2.5.3.3(5) – EC2 and 2.5.3.4.2 (7), a reduction of the design bending moments is made to the column margins.
- The frame is a sway frame, so, according to the principle of 2.5.3.4.2 – EC2 [2], no redistribution of the bending moment is made.
- The actual strength of the materials:
  - Concrete: As chosen above, the concrete class is C25/30, according to 3.1.2.4 – EC2 [2], concrete material properties are:
    \[
    f_{ck} = 25 \text{MPa} = 25 \text{N} / \text{mm}^2; \quad f_{cm} = 33 \text{MPa} = 33 \text{N} / \text{mm}^2; \quad f_{cm} = 2.6 \text{MPa} = 2.6 \text{N} / \text{mm}^2
    \]
    \[
    f_{cd} = \frac{\alpha_* f_{ck}}{\gamma_c} = 16.67 \text{MPa} = 16.67 \text{N} / \text{mm}^2; \alpha_c = 1; \gamma_c = 1.5
    \]
    (Note: In Belgium \( \gamma_c = 1.5; \) In France \( \gamma_c = 1.3 \))
  - Reinforcing steel: As chosen above, the steel class is S500, according to EC2 and EC3, steel material properties are:
    \[
    f_{yk} = 500 \text{MPa} = 500 \text{N} / \text{mm}^2
    \]
    steel material properties are:
    \[
    f_{yd} = \frac{\alpha_* f_{yk}}{\gamma_s} = \frac{1 \cdot 500}{1.15} = 434.8 \text{MPa} = 434.8 \text{N} / \text{mm}^2
    \]
    (Note: In Belgium \( \gamma_s = 1.0; \) In France \( \gamma_s = 1.0 \))
  - In accordance to ultimate limit states of bending plus axial force design procedure of 6.1 – EC 2 and 3.1.5 – EC2 [2], we will use a rectangular diagram for compressed concrete block. In this case \( \eta_* f_{cd} = 1 \cdot f_{cd} = 16.7 \text{ Mpa.} \)
  - **Flexural Reinforcing steel of Left – side of beam (Beam number 31-33):** \( M^+ = 93304 \text{Nm} \)
  \[ M^- = -181173 \text{Nm} \]
  - For M*:
    - Beam’s dimensions : b=250mm ; h=500mm
    - Concrete cover thickness + ½ reinforcement diameter =50mm
    - Working height d: d = h – concrete cover thickness – stirrup diameter – ½ reinforcement diameter = 500 – 50 = 450mm
The ULS condition: 

\[ M_{rd} \geq M_{Ed} \]

\[ M_{rd} = \mu * b * d^2 * \eta * f_{cd} \]

\[ M_{Ed} = 93304Nm \]

- The ULS condition: 
  \[ \mu \geq \frac{M_{Ed}}{1700 * d^2 * \eta * f_{cd}} = \frac{93304*10^3}{1700*450^2*1*16.7} = 0.02 \]
  \[ \Rightarrow \frac{x}{d} = 0.066 < 0.45 \]
  \[ \Rightarrow \frac{z}{d} = 0.977 \Rightarrow z = 0.977 * d = 440mm \]

- On the other hand we have the relationship: \[ M_{rd} = A_s * f_{yd} * z \], So the area of reinforcement steel can be determined as follows:
  \[ A_s \geq \frac{M_{Ed}}{f_{yd} * z} = \frac{93304*10^3}{434.8*440} = 490mm^2 = 4.9cm^2 \]

- We choose \( 2 \phi 14 + 1 \phi 16 \) (\( A_s = 5.1 \text{ cm}^2 \)) for flexural reinforcements. \( \Rightarrow \) The resistance of the section is \( M_{rd,b} = +98kNm \) and the over-strength factor is \( \frac{98}{93.3} = 1.05 \).

- The normalised flexural reinforcements are:
  \[ \rho = \frac{A_s}{b_w * d} = \frac{5.1}{25 * (50 - 3.0 - 0.6 - \frac{1.6}{2})} = 0.004 \]

- For \( M \):
  - Beam’s dimensions: \( b=250mm \); \( h=500mm \)
  - Concrete cover thickness + \( \frac{1}{2} \) reinforcement diameter + stirrup diameter = 60mm
  - Working height \( d \): \( d = h - \text{concrete cover thickness} - \frac{1}{2} \text{reinforcement diameter} = 500 - 60 = 440mm \)
  
  \[ M_{rd} \geq M_{Ed} \]
  
  \[ M_{rd} = \mu * b * d^2 * \eta * f_{cd} \]
  
  \[ M_{Ed} = 181173Nm \]

- The ULS condition: 
  \[ \mu \geq \frac{M_{Ed}}{b * d^2 * \eta * f_{cd}} = \frac{181173*10^3}{250*440^2*1*16.7} = 0.247 \]
  \[ \Rightarrow \frac{x}{d} = 355 < 0.45 \]
  \[ \Rightarrow \frac{z}{d} = 0.85 \Rightarrow z = 0.85 * d = 374mm \]

- Area of reinforcement steel can be determined as follows:
  \[ A_s \geq \frac{M_{Ed}}{f_{yd} * z} = \frac{181173*10^3}{434.8*374} = 1114mm^2 = 11cm^2 \]

- We choose \( 2 \phi 18 + 1 \phi 20 +2\phi10(A_s = 11.9 \text{ cm}^2 \) or \( 2 \phi 20 + 2 \phi 18 \) for flexural reinforcements. \( \Rightarrow \) The resistance of the section is \( M_{rd,b} = -208kNm \) and the over-strength factor is \( \frac{208}{181.2} = 1.14 \).

- The normalised flexural reinforcements are:
\[
\rho = \frac{A_s}{b_w \times d} = \frac{11.9}{25 \times (50 - 3.0 - 0.6 - \frac{2.0}{2})} = 0.01
\]

- Flexural Reinforcing steel of right – side of beam: \(M^+ = 75000Nm\)
  \(M^- = -172000Nm\)

  - For \(M^+\):
    - Beam’s dimensions : \(b=250\text{mm} \; ; \; h=500\text{mm}\)
    - Concrete cover thickness + \(1/2\) reinforcement diameter =50mm
    - Effective height \(d\): \(d = h - \text{concrete cover thickness} - \frac{1}{2}\) reinforcement diameter = \(500-50=450\text{mm}\)

      \[
      M_{rd} \geq M_{Ed}, M_{rd} = \mu \times b \times d^2 \times \eta \times f_{cd} \times M_{Ed} = 75000Nm
      \]

      - The ULS condition: \(\mu \geq \frac{M_{Ed}}{b \times d^2 \times \eta \times f_{cd}} = \frac{75000 \times 10^3}{250 \times 450^2 \times 1 \times 16.7} = 0.088\)

      \[
      \Rightarrow \frac{x}{d} = 0.152 < 0.45; \Rightarrow \frac{z}{d} = 0.94 \Rightarrow z = 0.94 \times d = 423\text{mm}
      \]

      - Area of reinforcement steel can be determined as follows:

      \[
      A_s \geq \frac{M_{Ed}}{f_{yd} \times z} = \frac{75000 \times 10^3}{434.8 \times 423} = 408\text{mm}^2 = 4.1\text{cm}^2
      \]

      - We choose \(3 \phi 14 (A_s = 4.62\text{ cm}^2)\) for flexural reinforcements. \(\Rightarrow\) The resistance of the section is \(M_{rd,b} = +119kNm\) and the over-strength factor is \(\frac{119}{75} = 1.59\).

      - The normalised flexural reinforcements are:

      \[
      \rho = \frac{A_s}{b_w \times d} = \frac{4.62}{25 \times (50 - 2.0 - 0.6 - \frac{1.4}{2})} = 0.004
      \]

  - For \(M^-\):
    - Beam’s dimensions : \(b=250\text{mm} \; ; \; h=500\text{mm}\)
    - Concrete cover thickness + \(1/2\) reinforcement diameter =60mm
    - Working height \(d\): \(d = h - \text{concrete cover thickness} - \frac{1}{2}\) reinforcement diameter = \(500-60=440\text{mm}\)

      \[
      M_{rd} \geq M_{Ed}, M_{rd} = \mu \times b \times d^2 \times \eta \times f_{cd} \times M_{Ed} = -172000Nm
      \]

      - The ULS condition: \(\mu \geq \frac{M_{Ed}}{b \times d^2 \times \eta \times f_{cd}} = \frac{172000 \times 10^3}{250 \times 440^2 \times 1 \times 16.7} = 0.212\)

      \[
      \Rightarrow \frac{x}{d} = 0.30 < 0.45; \Rightarrow \frac{z}{d} = 0.88 \Rightarrow z = 0.88 \times d = 387.2\text{mm};
      \]

      - Area of reinforcement steel can be determined as follows:

      \[
      A_s \geq \frac{M_{Ed}}{f_{yd} \times z} = \frac{172000 \times 10^3}{434.8 \times 387.2} = 1022\text{mm}^2 = 10.2\text{cm}^2
      \]

      - We choose \(3 \phi 18+2\phi 10(A_s = 10.2\text{ cm}^2)\) for flexural reinforcements. \(\Rightarrow\) The resistance of the section is \(M_{rd,b} = -174kNm\) and the over-strength factor is \(\frac{174}{172} = 1.01\).

      - The normalised flexural reinforcements are:

      \[
      \rho = \frac{A_s}{b_w \times d} = \frac{10.2}{25 \times (50 - 2.0 - 0.6 - \frac{1.8}{2})} = 0.01
      \]
V.2.5.3 Specific measures for the flexural reinforcement.

- Min/max reinforcing steel
  - In accordance to 5.4.3.1.2 – EC8 [3], minimum tension reinforcement ratio shall not exceed the value: 
    \[
    \rho_{\text{min}} = 0.5 \times \frac{f_{\text{cm}}}{f_{\text{ctm}}} = 0.5 \times \frac{0.6}{500} = 0.0006 \quad (5.12 – \text{EC8 [3]}).
    \]
  
  → The reinforcement content is satisfactory.
  - According to 5.4.3.1.2 – EC8 [3], Within the critical regions, the tension reinforcement ratio shall not exceed the value below: 
    \[
    \rho_{\text{max}} = \rho + \frac{0.018}{\mu \gamma_{\text{f}} f_{\text{ctm}} \varepsilon_{\text{f}} f_{\text{ctm}}} \leq 0.018 \cdot \frac{16.7}{434.8} = 0.05 > 0.01
    \]
  
  → The reinforcement content is satisfactory.

- Longitudinal bar diameters:
  According to 5.6.2.2 – EC8 [3], to prevent the bond failure, the diameter of longitudinal bars of the beams is limited as the following conditions:
  - For interior beam – column joints:
    \[
    d_{\text{bl}} \leq \frac{7.5 \times f_{\text{cm}}}{\gamma_{\text{f}} f_{\text{ctm}}} \left(1 + 0.8 \nu_d\right) \leq \frac{7.5 \times 2.6}{1 \times 434.8} \left(1 + 0.8 \times 0.385\right) = 0.056 \quad \Rightarrow \quad d_{\text{bl}} = 400 \times 0.056 = 22.4 \text{mm}
    \]
  
  → The chosen reinforcement is satisfactory.
  - For exterior beam – column joints:
    \[
    d_{\text{bl}} \leq \frac{7.5 \times f_{\text{cm}}}{\gamma_{\text{f}} f_{\text{ctm}}} \left(1 + 0.8 \nu_d\right) \leq \frac{7.5 \times 2.6}{1 \times 434.8} \left(1 + 0.8 \times 0.385\right) = 0.056 \quad \Rightarrow \quad d_{\text{bl}} = 400 \times 0.056 = 22.4 \text{mm}
    \]
  
  \[
  \left(1 + 0.8 \nu_d\right) \leq 4.0 \times \frac{f_{\text{cm}}}{f_{\text{ctm}}} \leq \frac{4.0 \times 2.6}{434.8} \left(1 + 0.8 \nu_d\right)
  \]
  
  \[
  \left(1 + 0.8 \nu_d\right) \leq 4.0 \times \frac{f_{\text{cm}}}{f_{\text{ctm}}} \left(1 + 0.8 \nu_d\right)
  \]
  
  → The chosen reinforcement is satisfactory.
\[ \nu_d = \frac{N_{Ed}}{f_{cd} \cdot A_c} \]

\[ N_{Ed} = -896000 \text{N}; f_{cd} = 16.67 \text{MPa}; A_c = 400 \times 500 = 200000 \text{mm}^2. \]

\[ \nu_d = \frac{N_{Ed}}{f_{cd} \cdot A_c} = \frac{896000}{16.7 \times 200000} = 0.268 \]

- \( k_p \) is the factor reflecting the ductility class equal to 1 for DCH, to 2/3 for DCM.
- \( \rho' \) – compression steel ratio \( \rightarrow \rho' = 0.004 \)
- \( \rho_{\text{max}} = 0.05 \).

So: \[ d_{BL} \leq \frac{7.5 \times 2.6 \times (1 + 0.8 \times 0.268)}{1 \times 434.8} = 0.054 \]

\[ \text{Or: } d_{BL} \leq \frac{7.5 \times 2.6 \times \left(1 + 0.8 \times 0.268\right)}{1 \times 434.8} \leq \frac{1 + 0.8 \times 0.268}{1 + 0.75 \times \frac{2}{3} \times 0.0047} = 0.052 \]

\[ \rightarrow d_{BL} = 400 \times 0.054 = 21.6 \text{mm} \rightarrow \text{The chosen reinforcement is satisfactory.} \]

- Top reinforcement of the beam.
  - In accordance to 2.7.3.4 part 1-3 – ENV8, one fourth of the maximum top reinforcement shall run along the entire beam length.
  - Two \( \phi 18 \) bars will run along the entire span.

**V.2.5.4 Shear resistance**

- Design shear forces computed in accordance to the capacity design criterion:
  - According to 5.4.2.2 – EC8 [3], in the primary seismic beams shear forces shall be calculated in accordance with the capacity design rule.
  - The calculation of shear forces as following the sketch below:

![Sketch of beam and shear forces](image)

- **STATIC CASE**
  \[ g - \psi^2 q \]

- **CAPACITY DESIGN SHEAR FORCE**

- Determining \( M^{+}_{\text{Ar1}}, M^{-}_{\text{Br1}}, M^{+}_{\text{Ar2}}, M^{-}_{\text{Br2}}, V_{A0}, V_{B0} \).
  - \( M^{+}_{\text{Ar1}} \): The bottom reinforcement area of longitudinal bars is \( 2\phi 14 + 1\phi 16 \left(5.1 \text{cm}^2\right) \), we determine the value of \( M_{\text{Ar1}} \) following:
    \[ F_{\text{as}} = f_{yd} \cdot A_1 = 434.8 \times 510 = 221748 \text{Nmm} \]
    \[ F_c = \eta \cdot f_{cd} \cdot b \cdot (h - z) = 16.7 \times 250 \times (500 - z) \]
    \[ = 4175 \times (500 - z) \]
    \[ \sum F_{\text{as}} = F_c \rightarrow 221748 = 4175 \times (500 - z) \]
    \[ \rightarrow z = 446.9 \text{mm} \]
    \[ M^{+}_{\text{Ar1}} = \sum F_{\text{as}} \cdot b_{\text{as}} + F_c \cdot b_c \]
\[ b_{ai} = z - \text{coating} - \phi \text{stirrup} - \frac{1}{2} \phi \text{bars} \]

\[ b_{ai1} = b_{ai2} = 446.9 - 20 - 6 - 7 = 413.9 \text{mm} \]

\[ b_c = \frac{h - z}{2} = \frac{500 - 446.9}{2} = 26.6 \text{mm} \]

\[ \rightarrow M^+_{Ard1} = 221748 \times 413.9 + 4175 \times (500 - 446.9) \times 26.6 = 97678517 \text{Nmm} \rightarrow M^+_{Ard1} = 98 \text{KNm} \]

- \( M^+_{Ard2} \): The top reinforcement area of longitudinal bars is \(2\phi 18 + 2\phi 20(A_s = 11.9 \text{ cm}^2)\), we determine the value of \( M^+_{Ard2} \) as following:

\[ \sum F_{ai} = f_{yd} * A_s = 434.8 \times 1190 = 517412 \text{Nmm} \]

\[ F_c = \eta \times f_{yd} \times b \times (h - z) = 16.7 \times 250 \times (500 - z) = 4175 \times (500 - z) \]

\[ \sum F_{ai} = F_c \rightarrow 517412 = 4175 \times (500 - z) \rightarrow z = 376 \text{mm} \]

\[ M^-_{Ard2} = \sum F_{ai} \times b_{ai} + F_c \times b_c \]

\[ b_{ai} = z - \text{coating} - \phi \text{stirrup} - \phi \text{transverse} \frac{1}{2} \phi \text{bars} \]

\[ b_{ai1} = 376 - 20 - 6 - 10 = 340 \text{mm} \]

\[ b_c = \frac{h - z}{2} = \frac{500 - 376}{2} = 62 \text{mm} \]

\[ \rightarrow M^-_{Ard2} = 434.8 \times 1190 \times 340 + 4175 \times (500 - 376) \times 62 = 208017480 \text{Nmm} \rightarrow M^-_{Ard2} = 208 \text{KNm} \]

- \( M^+_{BRd1} \):

The top reinforcement area of longitudinal bars is \(4 \phi 18(A_s = 10.2 \text{ cm}^2)\), we determine the value of \( M^+_{BRd1} \) as following:

\[ \sum F_{ai} = f_{yd} * A_s = 434.8 \times 1020 = 443496 \text{Nmm} \]

\[ F_c = \eta \times f_{yd} \times b \times (h - z) = 16.7 \times 250 \times (500 - z) \]

\[ = 4175 \times (500 - z) \]

\[ \sum F_{ai} = F_c \rightarrow 443496 = 4175 \times (500 - z) \]

\[ \rightarrow z = 394 \text{mm} \]

\[ M^-_{BRd1} = \sum F_{ai} \times b_{ai} + F_c \times b_c \]

\[ b_{ai} = z - \text{coating} - \phi \text{stirrup} - \phi \text{transverse} \frac{1}{2} \phi \text{bars} \]

\[ b_{ai1} = 394 - 20 - 6 - 20 - 9 = 339 \text{mm} \]

\[ b_c = \frac{h - z}{2} = \frac{500 - 394}{2} = 53 \text{mm} \]

\[ \rightarrow M^-_{BRd1} = 434.8 \times 1020 \times 339 + 4175 \times (500 - 394) \times 53 = 173800294 \text{Nmm} \rightarrow M^-_{BRd1} = 174 \text{KN} \]

- \( M^+_{BRd2} \):

The bottom reinforcement area of longitudinal bars is \(3 \phi 14 (4.62 \text{ cm}^2)\), we determine the value of \( M^+_{BRd2} \) as following:

\[ F_{ai} = f_{yd} * A_s = 434.8 \times 462 = 200877.6 \text{Nmm} \]

\[ F_c = \eta \times f_{yd} \times b \times (h - z) = 16.7 \times 250 \times (500 - z) = 4175 \times (500 - z) \]

\[ \sum F_{ai} = F_c \rightarrow 200877.6 = 4175 \times (500 - z) \]

\[ \rightarrow z = 452 \text{mm} \]
\[ M^+ = \sum F_{ai} \cdot b_{ai} + F_c \cdot b_c \]

\[ b_{ai} = z - \text{coating} - \phi \text{stirrup} - \frac{1}{2} \phi \text{bars} \]

\[ b_{ai1} = b_{ai2} = 452 - 20 - 6 - 7 = 419 \text{mm} \]

\[ b_c = \frac{h - z}{2} = \frac{500 - 452}{2} = 24 \text{mm} \]

\[ \rightarrow M^+_{\text{net1}} = 200877.6 \cdot 419 + 4175 \cdot (500 - 452) \cdot 24 = 88977314 \text{Nmm} \rightarrow M^+_{\text{net1}} = 89 \text{KNm} \]

- Determining \( V_{BO} \) and \( V_{A0} \):

\[ V_{BO} = V_{A0} = \frac{3750 \cdot 5}{2} + \frac{32850 \cdot 5}{2} = 50437.5N = 50.4 \text{KN} \]

- So we have:

\[ V_{M1} = -\gamma_{Rd} \cdot \frac{(M_{ABd1} + M_{BBd1})}{l} = -1 \cdot \frac{98 + 174}{5} = -54.4 \]

\[ V_{M2} = \gamma_{Rd} \cdot \frac{(M_{ABd2} + M_{BBd2})}{l} = 1 \cdot \frac{208 + 89}{5} = 59.4 \]

\[ V_{BO} = V_{A0} = 50.4 \text{KN} \]

And so:

- At support A:

\[ V_{\text{min}} = V_{M1} + V_{A0} = -54.4 + 50.4 = -4; V_{\text{max}} = V_{M2} + V_{A0} = 49.4 + 50.4 = 109.8 \]

- At support B:

\[ V_{\text{min}} = -V_{M2} + V_{BO} = -59.4 + 50.4 = -9; V_{\text{max}} = V_{M1} + V_{BO} = 54.4 + 50.4 = 104.8 \]

- \( V_{ced} \) and \( V_{Rd} \) Computations:

- In the critical sections: \( V_{ced} = 0 \)
- Outside the critical sections: \( V_{ced} = V_{Rd,c} \).
- In accordance with EC(2) 4.3.2.3 and neglecting the axial force influence, the value of \( V_{Rd,c} \)

**Table V.5 – Shear resistance of concrete section**

| EN 1992 |
|-----------------|-----------------|
| \( V_{Rd,c} = \left[ \frac{0.18}{\gamma_c} \cdot k \cdot (100 \cdot \rho_j \cdot f_{ck})^{1/3} - 0.15 \cdot \sigma_{cp} \right] \cdot b_w \cdot d \) |
| f_{ck} – is compressed strength of the concrete at the age of 28 days. \( \gamma_c = 1.5 \) |
| k = 1 + \frac{200}{\sqrt{d}} \leq 2.0 \text{ d – mm.} |
| \rho_j = \frac{A_{sl}}{b_w \cdot d} \leq 0.02 \text{ where:} |
| A_{sl} – is the area of tension reinforcements. |
| b_w – is the minimum width. |
| \sigma_{cp} = \frac{N_{sl}}{A} \text{; } N_{sl} – is the longitudinal force. MPa |
| Replacing with the value of f_{ck} is 25MPa, reinforcing steel percentage is 0.01, so we have: |
| \( V_{Rd,c} = \left[ \frac{0.18}{1.5} \cdot 1 \cdot (100 \cdot 0.01 \cdot 25)^{1/3} \right] \cdot 250 \cdot 464 \) |
| = 40703N = 40.7\text{KN} |
Computations
- The computations shall run in accordance to 6.2.1(2) – EN1992 and the specific rules shall get along with truss model (EN1998)
- According to 6.2.1(2) – EN 1992, the shear resistance of a member with shear reinforcement is equal to $V_{Rd} = V_{Rd,s} + V_{ccd} + V_{td}$. $V_{td}$ is the design value of the shear component of the force in the tensile reinforcement, in the case of an inclined tensile chord, so $V_{td} = 0$ and $V_{cc,d} = 0$.

So:
$$V_{Rd} = V_{Rd,s} + V_{ccd}$$

- In critical regions (2*height of the beams) shear force will be carried out only by the stirrups. We choose stirrups with 2 legs, of 6mm in diameter and 80mm spacing. Shear force capacity is:
$$V_{Rd} = \frac{57 \times 450 \times 434.8}{80} = 139408 \text{ KN} = 139.4 \text{ KN} \gg V_{\text{max}}.$$
- Outside critical regions, shear forces are carried out by stirrups with 2 legs, 6mm in diameter and 150mm spacing. Shear force capacity is:
$$V_{Rd} = V_{Rd,c} + V_{Rds} = \frac{57 \times 464 \times 434.8}{120} = 95 \text{ KN}$$

Along the whole beam length, shear force must be less than the value of $V_{Rd,\text{max}}$ which is the design value of the maximum shear force which can be sustained by the member, limited by crushing of the compression struts. 
$$V_{Rd,\text{max}} = \alpha_{cw} * b_w * z * v_1 * f_{cd} / (\cot \theta + \tan \theta)$$
Where:

$$v_1$$ is a strength reduction factor for concrete cracked in shear
$$\alpha_{cw}$$ is a coefficient taking account of the state of the stress in the compression chord.

So: $v_1 = 0.6 \left[ 1 - \frac{f_{ch}}{250} \right] = 0.6 * 0.9 = 0.54$ and $\alpha_{cw} = 1.$

$\rightarrow V_{Rd,\text{max}} = 1 * 250 * 464 * 16.7 / (1+1) = 968 \text{ KN} > V_{\text{max}}$.

V.2.5.5 Specific measures
- Detailing:
  - In accordance to 5.4.3.1.2(6P) - EC8 [3], the stirrup minimum diameter within the critical regions is 6mm – this requirement is met.
  - The first hoop is placed not more than 50mm from the end cross section of the beam – this requirement is met.
  - Within the critical regions, the spacing of the hoops is not greater than:
$$h_w / 4 = 125 mm; 24 * d_{nv} = 24 * 6 = 144 mm; 225 mm$$
$$8 * d_{bl} = 8 * 14 = 112 mm$$
- Casting and Placing for beam: All requirements are met.
V.2.6 REINFORCEMENT OF OTHER BEAMS

The reinforcement of other beams of the transverse frame will be determined by using the similar ways as the beams on the first floor. They are summarized as following tables.

Table V.6: Properties of the section and seismic actions of longitudinal or direction X frame

VI COLUMN DESIGN

VI.1 Ground story column in axis B2 (members 121-122 transverse frame or members 97-98 longitudinal frame)

VI.1.1 Geometrical restraint

- Cross section dimensions: In accordance to 5.5.1.2.2 (1P) – EC8 [3], the minimum cross-sectional dimension of primary seismic columns shall be not less than 250 mm → Because the cross section dimensions for the ground–level columns are 400x500, so this condition is met.
- According to 5.4.1.2.2 (1), unless $\theta \leq 0.1$ (4.4.2.2(2) – EC8 [3]), the cross-sectional dimensions of primary seismic columns should not be smaller than one tenth of the larger distance between the point of contra-flexure and the ends of the column, for bending within a plane parallel to the column dimension considered → Because of $\theta \leq 0.1$, so this condition must not be checked.

VI.1.2 Action effects due to the analysis for the seismic combination

- In order to design the member 121-122, we will determine the actions from two members: 121-122 and 123-124 (see figures 1 and 2)
- According to result from SAP2000 – version 9.0, we have action effects for members 121-122 and 123-124 as following tables:

Table VI.1 Calculated Action effects for members 121-122 and 123-124

VI.1.3 Flexural reinforcement for columns

VI.1.3.1 Design bending moment:

- For columns DCM, the design bending moments are determined in accordance to the capacity design criterion 5.4.2.3 – EC8. So, the sketch of designing column is the following pictures:
Table VI.3: Applied bending moments for column member 121-122 in transverse frame as derived from the analysis of the structure.

<table>

</tbody>
</table>

Calculated action effects of columns

\( M_{CSd1} = 126.1 \text{ KNm} \)
\( M_{DSd1} = 110.1 \text{ KNm} \)
\( M_{CSd2} = 126.6 \text{ KNm} \)
\( M_{DSd2} = 111 \text{ KNm} \)

- According to 4.4.2.3 – EC8, in multi-storey buildings formation of a soft storey plastic mechanism shall be prevented, as such a mechanism might entail excessive local ductility demands in the columns of the soft storey. In frame buildings, with two or more storeys, the following condition should be satisfied at all joints of primary or secondary seismic beams with primary seismic columns: \( \Sigma M_{Rc} \geq 1.3 \Sigma M_{Rb} - 4.29 \)

where

- \( \Sigma M_{Rc} \) is the sum of the design values of the moments of resistance of the columns framing the joint. The minimum value of column moments of resistance within the range of column axial forces produced by the seismic design situation should be used in expression 4.29

- \( \Sigma M_{Rb} \) is the sum of the design values of the moments of resistance of the beams framing the joint. When partial strength connections are used, the moments of resistance of these connections are taken into account in the calculation of \( \Sigma M_{Rb} \).

So, once the beam resistance in bending \( M_{BRd1} \) and \( M_{BRd2} \) have been defined, the required moment resistance in columns are computed as:

\[
M^*_{SD1,CD} = 1.3 \times (M_{BRd1} + M_{BRd2})/\Sigma M_{Rb}\]

(Beam number 31-33): \( M^* = 93304N\text{m} \)

And so, we have: For the top section of column member 121-122 in the transverse frame:

Direction Y 1 →

\[
M_{IR,b} = 1.3 \sum (M_{Rb,l}) = 1.3(208 + 119) = 425
\]

\[
M_{SD1,CD} = \frac{121.4}{121.4 + 144} \times M_{IR,b} = 0.45 \times 425 = 194\text{KNm}
\]

Direction Y 2 ←

\[
M_{IR,b} = 1.3 \sum (M_{Rb,l}) = 1.3(208 + 119) = 425
\]

\[
M_{SD2,CD} = \frac{121.1}{121.1 + 143.1} \times M_{IR,b} = 0.46 \times 425 = 195.5\text{KNm}
\]
For the top section of column member 121-122 in the longitudinal frame:

<table>
<thead>
<tr>
<th>Direction X 1 →</th>
<th>Direction X 2 ←</th>
</tr>
</thead>
<tbody>
<tr>
<td>$M_{ir,b} = 1.3 \sum (M_{Rh,b}) = 1.3(174 + 89) = 342\text{kJNm}$</td>
<td>$M_{ir,b} = 1.3 \sum (M_{Rh,b}) = 1.3(174 + 89) = 342\text{kJNm}$</td>
</tr>
<tr>
<td>$M_{sd1,CD} = \frac{110.1}{110.1+126} \times M_{ir,b} = 0.46 \times 342 = 157\text{kJNm}$</td>
<td>$M_{sd2,CD} = \frac{111}{111+126.6} \times M_{ir,b} = 0.47 \times 342 = 161\text{kJNm}$</td>
</tr>
</tbody>
</table>

For the bottom section of column member 121-122 in the transverse frame:

<table>
<thead>
<tr>
<th>Direction Y 1 →</th>
<th>Direction Y 2 ←</th>
</tr>
</thead>
<tbody>
<tr>
<td>$M_{sd1,CD} = 1.3 \times 1.32 \times 121.4 = 208.3\text{kJNm}$</td>
<td>$M_{sd2,CD} = 1.3 \times 1.32 \times 121.1 = 208\text{kJNm}$</td>
</tr>
<tr>
<td>Safe side:</td>
<td>Safe side:</td>
</tr>
<tr>
<td>$M_{sd1,CD} = 1.3 \times 1.45 \times 121.4 = 229\text{kJNm}$</td>
<td>$M_{sd2,CD} = 1.3 \times 1.45 \times 121.1 = 228.3\text{kJNm}$</td>
</tr>
</tbody>
</table>

For the bottom section of column member 121-122 in the longitudinal frame:

<table>
<thead>
<tr>
<th>Direction X 1 →</th>
<th>Direction X 2 ←</th>
</tr>
</thead>
<tbody>
<tr>
<td>$M_{sd1,CD} = 1.3 \times 1.09 \times 110.1 = 156\text{kJNm}$</td>
<td>$M_{sd2,CD} = 1.3 \times 1.09 \times 111 = 157\text{kJNm}$</td>
</tr>
<tr>
<td>Safe side:</td>
<td>Safe side:</td>
</tr>
<tr>
<td>$M_{sd1,CD} = 1.3 \times 1.17 \times 110.1 = 167\text{kJNm}$</td>
<td>$M_{sd2,CD} = 1.3 \times 1.17 \times 111 = 169\text{kJNm}$</td>
</tr>
</tbody>
</table>

In accordance to 4.3.3.5.1 – EC8 [3], the computations of the flexural reinforcement takes into account the bi-directional character of the seismic action effects. We take into account two seismic action directions:

i. Along X axis

ii. Along Y axis

- According to 4.3.3.5.1 (3) – EC8 [3], the combination of the horizontal components of the seismic action may be computed using two following combinations:

a. $E_{Edx} + 0.30 E_{Edy}$

b. $0.30E_{Edx} + E_{Edy}$

So, we have two combinations of efforts:

a. $M_x = 229\text{kJNm}$, $M_y = 0.3 \times 167 = 50.1 \text{kJNm}$, $N = -1309.3\text{KN}$

b. $M_x = 229 \times 0.3 = 69\text{kJNm}$, $M_y = 167\text{kJNm}$, $N = -1306\text{KN}$

**VI.1.3.2 Column flexural reinforcement:**

The designing follows Concise Eurocode 2 [5] and “How to design reinforced concrete using EC2” [6]:

- Check the slenderness:
- Effective length $l_0$:

$$l_0 = 0.5 \star l \star \left( \sqrt{1 + \frac{k_1}{0.45 + k_1}} \right) \star \left( 1 + \frac{k_2}{0.45 + k_2} \right)$$

(Exp (5.15 – EC2 [2]))

Where: $k_1, k_2$ are the relative flexibilities of rotational restraints at end 1 and 2.

We can compute $l_0$ as following expression:

$$l_0 = 0.85 \star l_{\text{clearance}}.$$

$L_{\text{clearance}} = H - h_w = 3500 - 500 = 3000 \text{mm}$

$\to l_0 = 0.85 \star 3000 = 2550$

- The column slenderness: $\lambda = \frac{l_0}{i}$

Where: $i$ – radius of gyration,

$$i = \sqrt[12]{\frac{I}{F}} \Rightarrow i = \frac{500}{\sqrt{12}} = 144.3 \text{and } i = \frac{400}{\sqrt{12}} = 115.5$$

So, $\lambda = 17.7$ and $\lambda = 22.1$

- The limiting slenderness, $\lambda_{\text{lim}}$

$$\lambda_{\text{lim}} = 20 \star A \star B \star C / \sqrt{n}$$

Where:

- $B = 1.1$
- $A = 0.7$
- $C = 1.7 - r_m = 1.7 - (-M_{01}/M_{01}) = 2.7$
- $\eta = \frac{N_{\text{Ed}}}{A_c \star f_{\text{cd}}} = \frac{1309000}{400 \star 500 \star 16.7} = 0.392$

$$\lambda_{\text{lim}} = 20 \star 0.7 \star 1.1 \star 12.7 / \sqrt{0.392} = 68$$

$\to$ Column is not slender

- Cover:

$c_{\text{nom}} = c_{\text{min}} + \Delta c_{\text{dev}}$ (Exp 4.1 – EC2 [2])

Where:

- $c_{\text{min,b}} =$ diameter of bar. Assume 25mm bars and 8mm hoops
- $c_{\text{min, dur}} =$ minimum cover due to environmental conditions. Assume XC1 $\to c_{\text{min, dur}} = 15 \text{mm}$

$\to c_{\text{nom}} = 25 \text{mm}$

- Design moments:

According to 5.8.8.2(1) – EC2 [2], we calculate the design moments for the flexural reinforcements:

$$M_{\text{Ed}} = \max \left[ M_{02} * M_{\text{Ed}} + M_2 + M_{01} + 0.5 * M_2 \right]$$

Where:

- $M_{02} = M + e_i * N_{\text{Ed}} \geq e_0 * N_{\text{Ed}}$
- $e_i = l_0 / 400$
- $e_{0x} = \max (500/30, 20) = 20 \text{mm}$
- $e_{0y} = \max (400/30, 20) = 20 \text{mm}$

So, we have two cases for design moments:

- CASE 1:

$$M_{02} = 229 + 1309.3 \star \frac{2.55}{400} = 235.4 > 0.02 \star 1309.3$$

and $N = 1309.3$

$$M_{02} = 50.1 + 1309.3 \star \frac{2.55}{400} = 53.8 > 0.02 \star 1309.3$$
CASE 2: $M_{02y} = 167 + 1306 * \frac{2.55}{400} = 160 > 0.02 * 1306$

\[ N = 1306 \]

- According to [4], we use charts to determine flexural reinforcements:

CASE 1:

a. $\beta = \frac{b - 1.5*d_h}{h - 1.5*d_h} = \frac{400 - 1.5*40}{500 - 1.5*40} = 0.8$

b. First estimate of $M_{ax} = M_y + \frac{M_x}{\beta} = 235.4 + \frac{53.8}{0.8} = 302.7 kNm$

c. $\frac{N_{aw}}{N} = 1 + \frac{M_{ax}}{0.4*N*(h - 1.5*d_h)} = 1 + \frac{302.7}{0.4*1309.3*0.5 - 1.5*0.004} = 2.079 \rightarrow \frac{N}{N_{aw}} = 0.48$

d. From table 5.4 [4] \[ a = 1.34 \]

e. \[ \rightarrow \text{Corrected } M_{ax}: M_{ax} = \left[ M_y + \left( \frac{M_x}{\beta} \right)^{\frac{1}{a}} \right] = \left[ 235.4^{1.34} + \left( \frac{53.8}{0.8} \right)^{1.34} \right]^{\frac{1}{1.34}} = 246.3 \]

f. So, $\frac{N}{b*h*f_{ck}} = \frac{1309.3*1000}{400*500*25} = 0.262$

With the ratios $d_h/h$, $\eta = \frac{N}{b*h*f_{ck}}$ and $\frac{M_{ax}}{b*h*f_{ck}}$ is equal to 0.08, 0.262 and 0.116, we use the chart number 5.16 and we have $\frac{A_s*f_{ck}}{b*h*f_{ck}} = 0.24 \rightarrow A_s = 2400mm^2$. We choose $16\phi 16 - A_s = 3216mm^2$.

CASE 2:

a. $\beta = \frac{h - 1.5*d_h}{b - 1.5*d_h} = \frac{500 - 1.5*40}{400 - 1.5*40} = 1.294$

b. First estimate of $M_{ay} = M_y + \frac{M_x}{\beta} = 160 + \frac{76.6}{1.294} = 219.2$

c. $\frac{N_{aw}}{N} = 1 + \frac{M_{ay}}{0.4*N*(b - 1.5*d_h)} = 1 + \frac{219.2}{0.4*1306*(0.4 - 1.5*0.004)} = 2.065 \rightarrow \frac{N}{N_{aw}} = 0.484$

d. From table 5.4 [4] \[ a = 1.34 \]

e. \[ \rightarrow \text{Corrected } M_{ax}: M_{ax} = \left[ M_y + \left( \frac{M_x}{\beta} \right)^{\frac{1}{a}} \right] = \left[ 160^{1.34} + \left( \frac{76.6}{1.294} \right)^{1.34} \right]^{\frac{1}{1.34}} = 190.6 \]

f. So, $\frac{N}{b*h*f_{ck}} = \frac{1306*1000}{400*500*25} = 0.261$
With the ratios $d_b/b$, $\eta = \frac{N}{b * h * f_{ck}}$ and $\frac{M_{ax}}{b * h^2 * f_{ck}}$ is equal to 0.1, 0.261 and 0.119, we use the chart number 5.16 [4] and we have $\frac{A_s * f_{sk}}{b * h * f_{ck}} = 0.24 \rightarrow A_s = 2400\text{mm}^2$. We choose 16φ16 – $A_s = 3216\text{mm}^2$.

**COLUMN REINFORCEMENT SECTION**

**VI.1.3.3 The effective bending moment capacities to uni-axial bending**

- **Along X direction: $M_{x,cap}$**
  - $A_{s,\text{tot}} = 16\phi 16 = 3216\text{mm}^2$; $N = 1295000\text{N}$

- We assume that 12φ16 are in the tensile area, 4φ16 are in the compression area and $z$ is the distance taking from compressed fiber to the neutral axis

  $F_{as} = \sum F_{asi} = \sum A_{ai} * f_{yd} = 12 * 201 * 434.8 = 1048737.6$

  $F_{ai} = \sum F_{ai} = \sum A_{ai} * f_{yd} = 4 * 201 * 434.8 = 349579.2$

  $F_c = f_{cd} * b * (h - z) = 16.7 * 400 * (500 - z) = 6680 * (500 - z)$

  $\rightarrow F_{as} + N = F_{ai} + F_c$

  $\leftrightarrow 1048737.6 + 1295000 = 349579.2 + 6680(500 - z)$

  $\rightarrow 500 - z = 298.5 \rightarrow z = 201.5\text{mm}$

  - The condition of $z$ is that: $(38+16) < 500 - z < (38+16+69.6) \rightarrow 54 < 298.5 < 123$, so the value of $z$ is not correct.

  - We assume that the neutral axis will run through the right – third layer reinforcement; so there are over 6φ16 in compression zone and over 8 φ16 in tension zone.
The condition of $z$ is that $282.8 \leq z \leq 282.8 + 16 = 298.8$, so this condition is met.

- Plastic moment will be calculated as following:

\[
F_{u1} = A_{s1} \cdot f_{yd} = 4 \times 201 \times 434.8 = 349579.2
\]
\[
F_{u2} = F_{u3} = A_{s2} \cdot f_{yd} = 2 \times 201 \times 434.8 = 219789.6
\]
\[
F_{u4} = A_{s4} \cdot f_{yd} \cdot \frac{z - 282.8}{16}
\]
\[
F_{u1} = A_{c1} \cdot f_{yd} = 4 \times 201 \times 434.8 = 349579.2
\]
\[
F_{u2} = A_{c2} \cdot f_{yd} = 2 \times 201 \times 434.8 = 219789.6
\]
\[
F_{u3} = A_{c4} \cdot f_{yd} \cdot (1 - \frac{z - 282.8}{16})
\]
\[
F_c = f_{cd} \cdot b \cdot (h - z) = 16.7 \times 400 \times (500 - z) = 6680 \times (500 - z)
\]
\[
\sum F_{ui} + N = \sum F_{ui} + F_c
\]
\[
\rightarrow z = 287.4 mm
\]

PLASTIC MOMENT CALCULATION

\[
b_{u1} = z - a_{s1} = 287.4 - (38 + 8) = 241.4 mm
\]
\[
b_{u2} = z - a_{s2} = 287.4 - (38 + 16 + 65.6 + 8) = 159.8 mm
\]
\[
b_{u3} = z - a_{s3} = 287.4 - (38 + 16 \times 2 + 65.6 \times 2 + 8) = 78.2 mm
\]
\[
b_{u4} = 287.4 - 282.8 = 4.6 mm
\]
\[
b_{c1} = h - z - a_{c1} = 500 - 287.4 - (38 + 8) = 166.6 mm
\]
\[
b_{c2} = h - z - a_{c2} = 500 - 287.4 - (38 + 16 + 65.6 + 8) = 85 mm
\]
\[
b_{c3} = 16 - b_{u4} = 16 - 4.6 = 11.4 mm; b_c = \frac{500 - z}{2} = 106.3 mm
\]
\[
F_c = 16.7 \times (500 - 287.4) \times 400 = 1420168N
\]
\[
M_{x, cap} = \sum F_{ai} \times b_{ai} + \sum F_{ci} \times b_{ci} + F_c \times b_c =
\]
\[
= 349579.2 \times (241.4 + 166.6) + 219789.6 \times (159.8 + 78.2 + 85) + 219789.6 \times \frac{4.6 \times 4.6}{16}
\]
\[
+ 219789.6 \times \frac{11.4 \times 11.4 + 1420168 \times 106.3}{16} = 366660126 N mm = 367 KN m
\]

- Along Y direction: $M_{y, cap}$
  \[
  A_{s1tot} = 16 \phi 16 = 3216 mm^2; N = 1306000 N
  \]
PLASTIC MOMENT CALCULATION

- We assume that 10\(\phi\)16 are in the tensile area, 6\(\phi\)16 are in the compression area and \(z\) is the distance taking from compressed fiber to the neutral axis.

\[
F_{as} = \sum F_{as} = \sum A_{si} f_{yd} = 10 \times 201 \times 434.8 = 873948.0
\]

\[
F_{at} = \sum F_{at} = \sum A_{ti} f_{yd} = 6 \times 201 \times 434.8 = 524368.8
\]

\[
F_c = f_{cd} b (h - z) = 16.7 \times 500 \times (400 - z) = 8350 \times (400 - z)
\]

\[
\rightarrow F_{as} + N = F_{at} + F_c
\]

\[
\leftrightarrow 873948.0 + 1306000 = 524368.8 + 8350(400 - z)
\]

\[
\rightarrow 400 - z = 198.3 \rightarrow z = 201.7 mm
\]

- The condition of \(z\) is that: \((38+16) < 400 - z < (38+16+86.7) \rightarrow 54 < 198.3 < 140\), so the value of \(z\) is not correct.

- We assume that the neutral axis will run through the first layer reinforcement; so there are less than 8\(\phi\)16 in compression zone and over 8\(\phi\)16 in tension zone.

\[
F_{as1} = A_{s1} f_{yd} = 6 \times 201 \times 434.8 = 524368.8
\]

\[
F_{as2} = A_{s2} f_{yd} = 2 \times 201 \times 434.8 = 174789.6
\]

\[
F_{as3} = A_{s3} f_{yd} \frac{z - 243.4}{16} = 2 \times 201 \times 434.8 \times \frac{z - 243.4}{16} = 174789.6 \times \frac{z - 243.4}{16}
\]

\[
F_{cs1} = 6 \times 201 \times 434.8 = 524368.8 N
\]

\[
F_{cs2} = A_{cs2} f_{yd} (1 - \frac{z - 243.4}{16}) = 174789.6 \times (1 - \frac{z - 243.4}{16})
\]

\[
F_c = f_{cd} b (h - z) = 16.7 \times 500 \times (400 - z) = 8350 \times (400 - z)
\]

\[
\rightarrow \sum F_{si} + N = \sum F_{at} + F_c
\]

\[
\leftrightarrow 174789.6 + 174789.6 \times \frac{z - 243.4}{16} + 1306000 = 174789.6 \times (1 - \frac{z - 243.4}{16}) + 8350(400 - z)
\]

\[
\rightarrow z = 243.5 mm
\]

The condition of \(z\) is that 243.4 < \(z\) < 243.4+16, so this condition is met.

- Plastic moment will be calculated as following:
The effective reinforcing steel percentages:

\[
\rho_x = \frac{A_x}{b*d} = \frac{12*2.01}{40*(50-5.25)} = 0.01684 = 1.684\%; \quad \rho_y = \frac{A_y}{b*d} = \frac{4*2.01}{40*(50-5.25)} = 0.0045 = 0.45\%
\]

So, \( \rho_{tot} = 2.13\% \);

\[
\rho_x = \frac{A_y}{b*d} = \frac{10*2.01 + 6*2.01*356.2-355.9}{50*(40-2.19)} = 0.011 = 1.1\%
\]

\[
\rho_y = \frac{A_x}{b*d} = \frac{6*2.01*\left(1-\frac{356.2-355.9}{16}\right)}{50*(40-2.19)} = 0.00626 = 0.63\%
\]

So, \( \rho_{tot} = 1.73\% \);

VI.1.3.4 Specific measures for the flexural reinforcement

- According to 5.4.3.2.1(3) – EC8 [3], in primary seismic columns the value of the normalised axial force \( \nu_d \) shall not exceed the value of 0.65.

\[
\nu_d = \frac{N_{sd}}{A_e*f_{cd}} = \frac{1309.3*1000}{400*500*16.7} = 0.392 < \nu_{d,max} , \text{so the condition is met}
\]

- According to 5.4.3.2.2(1P) – EC8 [3], The total longitudinal reinforcement ratio \( \rho_l \) shall not be less than 0.01 and not more than 0.04. In symmetrical cross-sections symmetrical reinforcement should be provided (\( \rho = \rho' \)) \( \rightarrow \) The condition is met.

- According to 5.4.3.2.2(2) – EC8 [3], at least one intermediate bar shall be provided between corner bars along each column side, to ensure the integrity of the beam-column joints. \( \rightarrow \) The condition is met.
VI.1.3.5 Shear Resistance

- In accordance to 5.4.2.3 – EC8 [3], the design values for the acting shear forces shall be determined in accordance with the capacity design criterion, as it follows:
  - According to 5.4.2.3(2), end moments $M_{i,d}$ may be determined from the following expression:
    $$M_{i,d} = \gamma_{Rd} \cdot M_{Rc,i} \cdot \min \left(1, \frac{\sum M_R}{\sum M_{Rc}} \right)$$
    and $\gamma_{Rd}$ is equal to 1.1
  
  - $V_{Ed,CD} = \gamma_{Rd} \cdot \frac{M_{DRd} + M_{CRd}}{\ell_f}$

Where:
- $l_{cl} = 3500-500=3000$ mm
- $\gamma_{Rd} = 1.1$
- $M_{DRd} = M_{CRd} = M_{x,cap} = 283$ KNm. So $V_{Ed, CD} = 208$ KN

V. Rd, c Computations:
- In accordance with EC(2) 4.3.2.3 and neglecting the axial force influence, the value of $V_{Rd,c}$ is calculated as below

| EN 1992 |
|-----------------|-----------------|-----------------|
| $V_{Rd,c} = \left[ C_{Rd,c} \cdot k \cdot \left(100 \cdot \frac{\rho_f}{f_{ck}} \right)^{1/3} + \frac{k_1}{C} \cdot \sigma_{cp} \right] \cdot b_w \cdot d $ |

- $C_{Rd,c} = 0.18 / \gamma_c$
- $f_{ck}$ – is the strength of the concrete at the age of 28 days. $\gamma_c = 1.5$
- $k = 1 + \frac{200}{d} = 1 + \frac{200}{378.1} = 1.73 \leq 2.0$
- $\rho_f = \frac{A_{sl}}{b_w \cdot d} \leq 0.02$ where:
  - $A_{sl}$ – is the area of tension reinforcements.
  - $b_w$ – is the minimum width.
- $\sigma_{cp} = \frac{N_{sd}}{A_c}$, $N_{sd}$ – is the longitudinal force. So, $\sigma_{cp} = \frac{1306 \times 1000}{500 \times 400} = 6.53 N/mm^2$
- $k_1 = 0.15$

$$V_{Rd,c} = \left[ 0.18 \times \left(100 \times 0.01 \times 25\right)^{1/3} \right] \times 500 \times 378.1 + 0.15 \times 6.53 \times 500 \times 378.1 = 251508.7 N = 252$ KN

- Computations:
  - The computations shall run in accordance to 6.2.1(2) – EN1992 and the specific rules shall get along with truss model (EN1998)
  - According to 6.2.1(2) – EN1992, the shear resistance of a member with shear reinforcement is equal to $V_{Rd} = V_{Rd,s} + V_{ccd} + V_{td}$. $V_{td}$ is the design value of the shear component of the force in the tensile reinforcement, in the case of an inclined tensile chord, so $V_{td} = 0$. So: $V_{Rd} = V_{Rd,s} + V_{ccd} ; V_{Rd,s} = \frac{A_{sy}}{s} \cdot z \cdot f_{yw} \cdot \cos \theta$
  - Because of $V_{Rd,c} > V_{Ed, CD}$ so the shear resistance of the concrete of the column is enough to carry the shear forces. So we can choose the hoops with 8mm in diameter and 4 legs, the distance is 100mm.

VI.1.3.6 Specific Measures

- In accordance to 5.4.3.2.2 – EC8 [3], in the critical sections of the primary seismic columns the diameter of hoops or cross-tie is at least of 6mm. The diameter of the hoops is of 8mm, so this condition is satisfactory.
- In accordance to 5.4.3.2.2 (11)– EC8 [3], the maximum spacing of the hoops:
  $$s_{max} = \min \left(\frac{b_v}{2}; 175; 8d_{sl}\right) = \min \left(344/2; 175; 8 \times 16\right) = 128$ mm;
  $$s = 100$ mm, so this condition is met.
VI.1.3.7 Local Ductility

- The length of critical regions $l_{cr}$: According to 5.4.3.2.2 (4) – EC8 [3], $l_{cr}$ may be computed as following expression: $l_{cr} = \max\{h_c; l_{cl}/6; 0.45\} = \max\{0.4, 3/6; 0.45\} = 0.5m$

- According to 5.4.3.2.2 (6P and 7P) – EC8 [3], in the critical region at the base of primary seismic columns a value of the curvature ductility factor, $\mu_\phi$, should be provided, and if for the specified value of $\mu_\phi$ a concrete strain larger than $\varepsilon_{cu2} = 0.0035$ is needed anywhere in the cross-section, compensation for the loss of resistance due to spalling of the concrete shall be achieved by means of adequate confinement of the concrete core. These conditions are met if the following conditions are satisfied: $\alpha * \omega_{nd} \geq 30 * \mu_\phi * \nu_d * \varepsilon_{sy,d} * \frac{b}{b_0} - 0.035$

Where:

- $\omega_{nd}$ is the mechanical volumetric ratio of confining hoops within the critical regions.
  So, $\omega_{nd}$ is calculated as follows:
  \[
  \omega_{nd} = \frac{\text{volume of confining hoops}}{\text{volume of concrete core}} = \frac{201*444}{100*444*344} = \frac{434.8}{16.7} = 0.15
  \]

- $\mu_\phi$ is the required value of the curvature ductility factor, $\mu_\phi = 6.8$

- $\nu_d = \frac{N}{b*h*f_{cd}} = \frac{1065.4*10^3}{400*500*16.7} = 0.319$

- $\varepsilon_{sy,d} = \frac{f_{cd}}{E} = \frac{434.8}{200000} = 0.00217$ ; $b_c = 400; b_0 = 344$

- $\alpha$ is the confinement effectiveness factor, equal to $\alpha = \alpha_n * \alpha_s$, with:
  \[
  \alpha_n = 1 - \frac{1}{6} \sum b_i^2 = 1 - \frac{3*148^2}{6*344*444} = 0.93 ; \alpha_s = \frac{1 - \frac{s}{2} \frac{b}{b_0}}{1 - \frac{s}{2} \frac{b}{b_0}} = \frac{100}{100} = 0.96
  \]

\[
\alpha = 0.9 \rightarrow 0.9*0.15 \geq 30*6.8*0.319*0.00217* \frac{400}{344} = 0.129
\]
VI  CHECK FOR RESISTANCE BETWEEN COLUMNS AND BEAMS

• According to 4.4.2.3 (3) – EC8 [3], in multi-storey buildings formation of a soft storey plastic mechanism shall be prevented, as such a mechanism might entail excessive local ductility demands in the columns of the soft storey.

• According to 4.4.2.3(4) – EC8 [3], the following condition should be satisfied at all joints of primary seismic beams and primary seismic columns:

\[
\sum M_{Rc} \geq 1.3* \sum M_{Rb}
\]

Where:
- \( \Sigma M_{Rc} \) – is the sum of the design values of the moment resistance of the columns framing to the joints.
- \( \Sigma M_{Rb} \) – is the sum of the design values of the moment resistance of the beams framing to the joints

• Transverse Frames: It is just necessary to check for the first floor because the reinforcing areas of columns are not changed over their length and the reinforcing areas of the first floor beams are greater than the other beams.
  - \( \Sigma M_{Rc} = 366*2=732 KNm \)
  - \( 1.3* \Sigma M_{Rb} = 1.3* (M_{BRd1} + M_{BRd2}) = 1.3*(208 +119) = 425.1 KNm \)
  - \( \rightarrow \Sigma M_{Rc} > 1.3* \Sigma M_{Rb} \). The condition is met.

• Longitudinal Frames: It is just necessary to check for the first floor because the reinforcing areas of columns are not changed over their length and the reinforcing areas of the first floor beams are greater than the other beams.
  - \( \Sigma M_{Rc} = 283*2=566 KNm \) (from V.1.3.3)
  - \( 1.3* \Sigma M_{Rb} = 1.3* (M_{BRd1} + MB_{Rd2}) = 1.3*(174 +89) = 341.9 KNm \)
  - \( \rightarrow \Sigma M_{Rc} > 1.3* \Sigma M_{Rb} = 341.9 KNm \). The condition is met.

VII  PROVISION CHECK FOR COLUMN-BEAM JOINTS

VII.1  Beam-Column Joint Ductility:

• The Beam-Column joints in the frames play a very important role during an earthquake. Under the horizontal force caused by earthquake the joints are immediately subjected to opposite moments from above and below columns and to similar moments from left and right beams. The internal forces acting on the joints are normally the shear forces. The magnitude of these internal shear forces is usually much greater than those of adjacent elements framing to the joints.

• Normally, the joints should consider as a part of the column and preferably respond within elastic range [4]. They also must have very high ductility to absorb the energy caused by the severe earthquake.

• The chosen ductility of beam-column joints is DCH.

VII.2  Design action effects:

• Action effects will be determined for the interior joint – intersection of column members 122-123 and beam members 63-79 in the transverse frame and intersection of column members 98-99 and beam members 33-49 in the longitudinal frame. It is the interior beam-column joint.

• In accordance to 5.5.2.3 – EC8 [2], the horizontal shear acting on the core of a joint between primary seismic beams and columns shall be determined taking into account the most adverse conditions under seismic actions.

• According to 5.5.2.3 – EC8 [2], simplified expression for the horizontal shear force acting on the concrete core of the joints may be used as follows:

\[
V_{phd} = \gamma_{rd} * (A_{s1} + A_{s2}) * f_{yd} - V_c
\]

Where:
- \( A_{s1} \) – is the area of the beam top reinforcement.
- \( A_{s2} \) – is the area of the beam bottom reinforcement.
- $V_C$ – is the shear force in the column about the joint, from the analysis in seismic design situation
- $\gamma_{Rd}$ – is a factor to account for over-strength due to steel strain hardening $\gamma_{Rd} \geq 1.2$.

For the transverse frame:
- $A_{s1} = 11.9\text{cm}^2$;
- $A_{s2} = 6.2\text{cm}^2$;
- $V_C = 96.6\text{KN}$
- $\gamma_{Rd} = 1.2$
So: $V_{jhd} = 1.2 \times (1190 + 620) \times 434.8 - 96600 = 847785.6N = 848\text{ kN}$

For the longitudinal frame:
- $A_{s1} = 10.2\text{cm}^2$;
- $A_{s2} = 4.62\text{cm}^2$;
- $V_C = 86.365\text{KN}$
- $\gamma_{Rd} = 1.2$
So: $V_{jhd} = 1.2 \times (1020 + 462) \times 434.8 - 86365 = 558008.6N = 558\text{ kN}$

→ The values of shear force taking from the transverse frame will be taken into account for maximum values to design the joints.

**VII.3 Design resistance evaluation and verification**

- Effective joint width: According to 5.5.3.3 – EC8 [3], effective joint width $b_j$ is as follows:
  - If $b_c > b_w$: $b_j = \min\{b_c; (b_w + 0.5h_c)\}$ (5.34a)
  - If $b_c < b_w$: $b_j = \min\{b_w; (b_c + 0.5h_c)\}$ (5.34b)
- In the transverse frame, the value of column width is of $b_c = 400\text{mm}$ and the value of beam width is of $b_w = 250\text{mm}$. So, we have the value of effective joint width is of $b_j = \min\{b_c; (b_w + 0.5h_c)\}$, so: $b_j = \min (400; 250+0.5*500) = 400\text{mm}$.
- In accordance with 5.5.3.3 (1P) – EC8 [3], the diagonal compression induced in the joint by the diagonal strut mechanism shall not exceed the compressive strength of concrete in the presence of transverse tensile strains.
- In accordance with 5.5.3.3 (2) – EC8 [3], if there is no more precise model to compute the requirements of 5.5.3.3 (1P) may be satisfied by means of following rules: At interior beam-column joints the following expression should be satisfied:
  $$V_{jhd} \leq \eta \times f_{cd} \times \sqrt{1 - \frac{V_d}{\eta} \times b_j \times h_{jd}}$$

Where:
- $\eta = 0.6 \times \left(1 - \frac{f_{ck}}{250}\right) \Rightarrow \eta = 0.6 \times \left(1 - \frac{25}{250}\right) = 0.54$
- $h_{jc}$ – is the distance between extreme layers of column reinforcement, so $h_{jc} = 500-40-16=444\text{mm}$.
- $b_j = 400$.
- $\nu_d$ – is the normalised axial force in the column about the joint. So, we have
  $$V_d = \frac{N}{b \times h \times f_{cd}} = \frac{1065.4 \times 10^3}{400 \times 500 \times 16.7} = 0.319$$
  $$f_{ck} = 25\text{MPa}$$
  $$V_{jhd} \leq \eta \times f_{cd} \times \sqrt{1 - \frac{V_d}{\eta} \times b_j \times h_{jd}}$$

- So, $\leftrightarrow 847785 \leq 0.54 \times 16.7 \times \sqrt{1 - \frac{0.319}{0.54} \times 400 \times 444}$ → the condition is met.
  $$\leftrightarrow 847785 \leq 1024595$$
VII.4 Confinement Mechanism

• According to 5.5.3.3 (3) – EC8 [3], adequate confinement (both horizontal and vertical) of the joint should be provided, to limit the maximum diagonal tensile stress of concrete \( \sigma_{ctd} \) to \( f_{ctd} \). In the absence of a more precise model, this requirement may be satisfied by providing horizontal hoops with a diameter of not less than 6 mm within the joint, such that:

\[
\frac{A_{sh} \times f_{ywd}}{b_j \times h_{jw}} \geq \left( \frac{V_{jwd}}{b_j \times h_{jc}} \right)^2 \left( f_{cd} + \nu_d \times f_{cd} \right) - f_{ctd}
\]

Where:
- \( A_{sh} \) is the total area of the horizontal hoops.
- \( A_{sh} = 4 \text{ legs (\( \Phi 8 \text{mm}\))} \times 50.24 \text{mm}^2 \times (500/100) = 1004.8 \text{mm}^2 \).
- \( f_{ywd} = 434.8 \text{MPa}; b_j = 400 \text{mm}, h_{jw} = 500-40-7-10 = 443 \text{mm}; h_{jc} = 444 \text{mm}; \)
- \( f_{ctd} = 2.2 \text{MPa}; \nu_d = 0.319 \)

\[
\rightarrow \frac{1004.8 \times 434.8}{400 \times 443} \geq \left( \frac{847785}{400 \times 444} \right)^2 \left( 2.2 + 0.319 \times 16.7 \right)
\]

\[
2.467 \geq 0.827
\]

• According to 5.5.3.3 (6) – EC8 [3], Adequate vertical reinforcement of the column passing through the joint should be provided, so that:

\[
A_{sv,i} \geq \frac{2}{3} \times A_{sh} \times \frac{h_{jc}}{h_{jw}}
\]

Where:
- \( A_{sv,i} \) denotes the total area of the intermediate bars placed in the relevant column faces between corner bars of the column (including bars contributing to the longitudinal reinforcement of columns). So \( A_{sv,i} = 12 \Phi 16 = 2412 \text{mm}^2 \).
- \( A_{sh} = 1004.8 \text{mm}^2 \).
- \( h_{jc} = 444; h_{jw} = 443 \)

So, we have:

\[
A_{sv,i} \geq \frac{2}{3} \times A_{sh} \times \frac{h_{jc}}{h_{jw}} \leftrightarrow 2412 \geq \frac{2}{3} \times 1004.8 \times \frac{444}{443} = 671 \rightarrow \text{the condition is met.}
\]

Alternatively, Eurocode 8 indicates another design check about the transverse reinforcements in the beam-column node: \( A_{sfywd} \geq \gamma_R d (A_{s1} + A_{s2}) f_{ywd} (1-0.8 \nu_d) \)

\[
A_{sh} = 1004.8 \text{mm}^2 \quad A_{s1} = 1190 \text{mm}^2 \quad A_{s2} = 620 \text{mm}^2 \quad \gamma_R = 1.2 \quad \nu_d = 0.319
\]

1005 x 434 > 1.2 (1190 + 620)434(1-0.8 x 0.319)

436 kN > 702 kN \( \Rightarrow \text{NO} \Rightarrow \text{change diameter of rebars.} \)

Diameter 10 provides 680 \approx 702 kN \quad \text{Diameter 12 provides 979 kN > 702 kN}

VII.5 Specific Measures

In accordance with 5.5.3.3 – EC8 [3], the specific measures for detailing local ductility will be checked as follows:

• The diameter \( d_{bw} \) of the hoops is not less than 6mm. The real diameter of the hoops is minimum 8mm, so this condition is satisfied.

• If framing beams are present on all four faces of the column, the spacing \( s \) of hoops may be increased to: \( s = \min (h_{jw}/2 ; 150 \text{mm}) \). The spacing \( s \) of the hoops is of 100mm, so this condition is met.

• According to 5.4.3.3 (2) – EC8 [3], If beams frame into all four sides of the joint and their width is at least three-quarters of the parallel cross-sectional dimension of the column, the
spacing of the horizontal confinement reinforcement in the joint may be increased to twice, but may not exceed 150 mm. So this condition is satisfactory.

- According to 5.4.3.3 (2) – EC8 [3], at least one intermediate (between column corner bars) vertical bar shall be provided at each side of a joint of primary seismic beams and columns. → All the conditions are met.
PART 2: PUSHER ANALYSIS FOR THE DESIGNED BUILDING.

The behavior of the building under un-given seismic actions in the design example which is presented in the first part can be checked by non linear analysis methods. One is the Nonlinear Static Analysis or Pushover method. Nonlinear static Analysis (Pushover) is presented in 4.3.3.4.2 of EC8[3] Part 1. According to EC8 [3], pushover analysis may be used to assess the structural behavior of existing or of newly designed buildings. Pushover is based on analyzing the structure under constant gravity loads and monotonically increasing horizontal loads. The purposes of Pushover Analysis are:

- To verify or revise the over-strength ratio values $\alpha_u/\alpha_1$;
- To estimate the expected plastic mechanisms and the distribution of damage;
- To assess the structural performance of existing or retrofitted buildings for the purposes of EN 1998-3;
- As an alternative to the design based on linear-elastic analysis which uses the behaviour factor $\eta$.

Under constant gravity loads and monotonically increasing horizontal loads presenting for seismic excitations (the base shear forces at the bottom of the frames), the frames could be considered as working under an un-given earthquake. After obtaining behavior of the frames from the relationship between displacements of the control node which is usually the roof displacement and the base shear forces which are calculated by monotonically increasing horizontal loads, one could estimate the largest magnitude of the earthquake that the designed frames can suffer. The horizontal load patterns used in Pushover are Modal Load Pattern and Uniform Load Pattern. Two types of these patterns are presented in 4.3.3.4.2 of EC8[3] Part 1.

In order to perform Pushover analysis, there are some properties of the frames will be determined such as: Plastic hinge properties of each element in the frames including plastic moments of critical sections taking into account the strain of concrete and reinforcements and rotation capacity of the hinges. To determine such properties, it is necessary to use experimental data (for example the rotation angles of the hinges corresponding to reinforcement ratio and stirrup distance) which are presented in some public documents such as FEMA356… The computer program which is used to perform Pushover Analysis is SAP2000, version 9.0.3. The data needed to carry out Pushover are:

- Plastic moments of critical sections in the frames
- Load Patterns
- Plastic rotation properties of each hinge.

I Plastic moment Determination for User Defined Hinges in SAP 2000

I.1 Transverse Frames

I.1.1 Beams

I.1.1.1 Beams of the first and the second floors (part 1 – III and IV):

- Section at the joint between external columns and beams

  - Negative Moments:

    PLASTIC MOMENT CALCULATION

    $F_{as1} = A_s f_{yd} = 1260 \times 434.8 = 547826.1N$;  
    $F_{cs1} = A_c f_{yd} = 620 \times 434.8 = 269565.2$
\[ F_c = \frac{\alpha_c \cdot f_{ck} \cdot b \cdot (h - z)}{\gamma_c} = 4175 \cdot (500 - z) \]

\[ F_{ax} = F_{cxl} + F_c \leftrightarrow 547826 = 269565.2 + 4175(500 - z) \rightarrow 500 - z = 66.78 \rightarrow z = 433.22m \]

The condition of \( z \) is that: \((36+14) < 500 - z \rightarrow 50 < 105\). So this condition is met.

Plastic moment will be calculated hereafter:

\[ M_{pl} = \sum F_{ax} \cdot b_{ax} + \sum F_{cxl} \cdot b_{cxl} + F_c \cdot b_c = 547826 \cdot 387.22 + 269565 \cdot 23.78 + 4175 \cdot 66.78 \cdot 3.39 = 233010586 Nmm = 233KNm \]

- Positive Moments:

\[ F_{axl} = A_y \cdot f_{yd} = 620 \cdot 434.8 = 269576N ; F_{ax2} = A_y \cdot f_{yd} \cdot \frac{z - 444}{20} = 547848 \cdot \frac{z - 444}{20} \]

**PLASTIC MOMENT CALCULATION**

\[ F_{cxl} = A_y \cdot f_{yd} \cdot \left(1 - \frac{z - 444}{20}\right) = 547848 \cdot (1 - \frac{z - 444}{20}); \]

\[ F_c = \frac{\alpha_c \cdot f_{ck} \cdot b \cdot (h - z)}{\gamma_c} = 4175 \cdot (500 - z) \]

\[ F_{axl} + F_{ax2} = F_{cxl} + F_c \leftrightarrow 269576 + 547848 \cdot \frac{z - 444}{20} = 547848 \cdot \left(1 - \frac{z - 444}{20}\right) + 4175(500 - z) \]

\[ z = 452.7mm \]

The condition of \( z \) is: \(444 < z < 444+20=464 \rightarrow \) This condition is met.

Plastic moment will be calculated hereafter:

\[ b_{axl} = z - a_xl = 452.7 - (30 + 6 + 7) = 409.7mm; b_{ax2} = z - a_{x2} = 452.7 - 444 = 8.7mm \]

\[ b_{cxl} = 20 - b_{ax2} = 11.3mm; b_c = \frac{500 - z}{2} = 23.7mm \]

\[ M_{pl} = \sum F_{axl} \cdot b_{axl} + \sum F_{cxl} \cdot b_{cxl} + F_c \cdot b_c = 269576 \cdot 409.7 + 547848 \cdot \frac{452.7 - 444}{20} \cdot 8.7 + 547848 \cdot \left(1 - \frac{452.7 - 444}{20}\right) \cdot 11.3 + 4175 \cdot 47.4 \cdot 23.7 \]

\[ = 120706465 Nmm = 121KNm \]

- Section at the joint between internal columns and beams: In order to calculate the plastic moment of the sections conveniently, we create the excel sheets or small calculation tables using MathCad program. So, we can obtain plastic moment of the other sections as following:

<table>
<thead>
<tr>
<th>Beams of Floor</th>
<th>Position of column</th>
<th>Sections of the Top reinforcement</th>
<th>Bottom reinforcement</th>
<th>Negative Plastic</th>
<th>Positive Plastic</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floor</td>
<td>of column</td>
<td>Sections</td>
<td>Top reinforcement</td>
<td>Bottom reinforcement</td>
<td>Negative Plastic</td>
</tr>
</tbody>
</table>

| 18-54 |
I.1.1.2 Beams of the other floors (part 1 – III and IV):
Plastic moment at any section of all remaining beams of the frame will be determined similarly as above and they are summarized briefly as following table:

- Negative Plastic Moment of the section at the external joint of the beam on the third and the fourth floors:

| Section at the external joint - Negative Plastic Moment Calculation - Unit Nmm |
|---|---|---|---|---|---|---|---|
| Beam width - \( b_w \) | Beam height-\( h_w \) | Column width - \( b_c \) | Column height-\( h_c \) | \( \phi \) _link - hoop diameter | \( A_{s1} \) | \( A_{s2} \) | \( A_{s3} \) |
| 250 | 500 | 400 | 500 | 6 | 762 | 402 | 620 |
| \( f_{ed} \) | \( f_{yd} \) | \( \phi_{A_{s1}} \) | \( \phi_{A_{s2}} \) | \( \phi_{A_{s3}} \) | \( \phi_{A_{s1}}' \) | \( \phi_{A_{s2}}' \) |
| 16.666667 | 434.7286 | 18 | 16 | 14 |
| \( c_{min,b} \) | \( c_{min,dur} \) | \( c_{min} \) | \( \Delta C_{dev} \) | \( c_{nom} \) | \( a_{s1} \) | \( a_{s2} \) | \( a_{s3} \) | \( a_{s1}' \) | \( a_{s2}' \) |
| 20 | 15 | 20 | 10 | 30 | 45 | 92 | 43 |

I.1.2 Columns
Properties taken from Part 1: \( A_{s,tot} = 16\phi_{16} = 3216 \text{mm}^2; N = 1295000 \text{N} \)
- We assume that 12φ16 are in the tensile area, 4φ16 are in the compression area and z is the distance taking from compressed fiber to the neutral axis.

\[
F_{ai} = \sum A_i * f_{yd} = 12 * 201 * 434.8 = 1048737.6
\]

\[
F_{ai} = \sum A_i * f_{yd} = 4 * 201 * 434.8 = 349579.2
\]

\[
F_c = f_{cd} * b * (h-z) = 16.7 * 400 * (500-z) = 6680 * (500-z)
\]

\[
F_{as} + N = F_{ai} + F_c \iff 1048737.6 + 1295000 = 349579.2 + 6680(500-z)
\]

\[
500-z = 298.5 \implies z = 201.5 \text{mm}
\]

- The condition of z is that: \((38+16)<500-z<(38+16+69.6)\) \(
\iff 54<298.5<123\), so the value of z is not correct.

- We assume that the neutral axis will run through the right – third layer reinforcement; so there are over 6φ16 in compression zone and over 8φ16 in tension zone.

\[
F_{a1} = A_{a1} * f_{yd} = 4 * 201 * 434.8 = 349579.2
\]

\[
F_{a2} = F_{a3} = A_{a2} * f_{yd} = 2 * 201 * 434.8 = 219789.6
\]

\[
F_{a4} = A_{a4} * f_{yd} = \frac{z-282.8}{16}
\]

\[
F_{a1} = A_{c1} * f_{yd} = 4 * 201 * 434.8 = 349579.2
\]

\[
F_{a2} = A_{c2} * f_{yd} = 2 * 201 * 434.8 = 219789.6
\]

\[
F_{a3} = A_{c4} * f_{yd} = \frac{(1-z-282.8)}{16}
\]

\[
F_c = f_{cd} * b * (h-z) = 16.7 * 400 * (500-z) = 6680 * (500-z)
\]

\[
\sum F_{as} + N = \sum F_{ai} + F_c
\]

\[
z = 287.4 \text{mm}
\]

The condition of z is that \(282.8 \leq z \leq 282.8+16=298.8\), so this condition is met.

- Plastic moment will be calculated as following:

\[
b_{a1} = z-a_{a1} = 287.4 - (38 + 8) = 241.4 \text{mm}; b_{a2} = z-a_{a2} = 287.4 - (38+16+65.6+8) = 159.8 \text{mm}
\]

\[
b_{a3} = z-a_{a3} = 287.4 - (38 + 16 * 2 + 65.6 * 2 + 8) = 78.2 \text{mm}; b_{a4} = 287.4 - 282.8 = 4.6 \text{mm}
\]

\[
b_{c1} = h-z-a_{c1} = 500 - 287.4 - (38 + 8) = 166.6 \text{mm}
\]

\[
b_{c2} = h-z-a_{c2} = 500 - 287.4 - (38 + 16 + 65.6 + 8) = 85 \text{mm}; b_{c3} = 16 - b_{a4} = 16 - 4.6 = 11.4 \text{mm}
\]

\[
b_{c4} = \frac{500-z}{2} = 106.3 \text{mm}
\]

\[
F_c = 16.7 * (500-287.4) * 400 = 1420168N
\]
\[ M_{x,\text{sep}} = \sum F_{as1} \cdot b_{as1} + \sum F_{cs1} \cdot b_{cs1} + F_c \cdot b_c = \]
\[ = 349579.2 \cdot (241.4 + 166.6) + 219789.6 \cdot (159.8 + 78.2 + 85) + 219789.6 \cdot \frac{4.6}{16} \cdot 4.6 \]
\[ + 219789.6 \cdot \frac{11.4}{16} \cdot 11.4 + 1420168 \cdot 106.3 = 366660126 \text{Nmm} = 367 \text{KNm} \]

Similarly, we can obtain the plastic moment of other section of the remaining column as following table:

<table>
<thead>
<tr>
<th>Floor</th>
<th>Width of column (mm)</th>
<th>Height of column (mm)</th>
<th>Reinforcement area (mm$^2$)</th>
<th>Negative Plastic Moment (kNm)</th>
<th>Positive Plastic Moment (kNm)</th>
</tr>
</thead>
<tbody>
<tr>
<td>3-4</td>

<td>265</td>
<td>265</td>
</tr>
<tr>
<td>5-6</td>
<td>400</td>
<td>500</td>
<td>16$\phi$14 – 2464</td>
<td>265</td>
<td>265</td>
</tr>
</tbody>
</table>

I.2 **Longitudinal Frames**

I.2.1 **Beams**

I.2.1.1 **Beams of the first and the second floors:**

- Section at the joint between external columns and beams
  - Negative Moments:

  **NEGATIVE PLASTIC MOMENT CALCULATION**

\[ F_{as1} = A_s \cdot f_{yd} = 1190 \cdot 434.8 = 517393.3 \text{N}; \]
\[ F_{cs1} = A_s \cdot f_{yd} = 510 \cdot 434.8 = 221739.1 \text{N} \]
\[ F_c = \frac{\alpha_c \cdot f_{ck} \cdot b \cdot (h - z)}{\gamma_c} = 4175 \cdot (500 - z) \]
\[ \Rightarrow F_{as1} = F_{cs1} + F_c \leftrightarrow 517393.3 = 221739.1 + 4175(500 - z) \]
\[ \Rightarrow z = 429.04 \text{m} \]

The condition of \( z \) is that: \((36+14) < 500-z \rightarrow 50<71\). So this condition is met.

Plastic moment will be calculated hereafter:

\[ M_{pl} = \sum F_{as1} \cdot b_{as1} + \sum F_{cs1} \cdot b_{cs1} + F_c \cdot b_c = 215 \text{KNm} \]

- Positive Moments:

\[ F_{as2} = A_s \cdot f_{yd} = 510 \cdot 434.8 = 221739.1 \text{N} \]
\[ F_{as2} = A_s \cdot f_{yd} \cdot z = 444 \cdot \frac{z - 444}{20} = 517393.3 \cdot \frac{z - 444}{20} \]
\[
F_{csl} = A_{s} * f_{yd} * \left(1 - \frac{z - 444}{20}\right) = 517393.3 * \left(1 - \frac{z - 444}{20}\right)
\]

\[
F_c = \frac{\alpha_c * f_c * b * (h - z)}{\gamma_c} = 4175 * (500 - z)
\]

### PLASTIC MOMENT CALCULATION

\[
\begin{align*}
F_{a1} + F_{a2} &= F_{csl} + F_c \
&= 221739.1 + 517393.3 * \frac{z - 444}{20} = 517393.3 * \left(1 - \frac{z - 444}{20}\right) + 4175(500 - z)
\end{align*}
\]

\[\rightarrow z = 453.5mm\]

The condition of \( z \) is: \( 444 < z < 444+20=464 \) \( \rightarrow \) This condition is met.

Plastic moment will be calculated hereafter:

\[b_{a1} = z - a_{s1} = 453.5 - (30 + 6 + 7) = 410.5mm\]

\[b_{a2} = z - a_{s2} = 453.5 - 444 = 9.5mm\]

\[b_{csl} = 20 - b_{a2} = 10.5mm\]

\[b_c = \frac{500 - z}{2} = 23.25mm\]

\[M_{pl} = \sum F_{asi} * b_{asi} + \sum F_{csi} * b_{csi} + F_c * b_c = \]

\[= 221739.1 * 410.5 + 517393.3 * \frac{9.5}{20} + 547848 * \left(\frac{10.5}{20}\right) * 10.5 + 4175 * 47.4 * 23.25\]

\[= 100716426.2Nmm = 101KNm\]

• Section at the joint between internal columns and beams:

In order to calculate the plastic moment of the sections conveniently, we create the excel sheets or small calculation tables using MathCad program. So, we can obtain plastic moment of the other sections as following:

<table>
<thead>
<tr>
<th>Beams of Floor</th>
<th>Position of column</th>
<th>Sections of beams</th>
<th>Top reinforcement area (mm²)</th>
<th>Bottom reinforcement area (mm²)</th>
<th>Negative Plastic Moment (kNm)</th>
<th>Positive Plastic Moment (kNm)</th>
</tr>
</thead>
<tbody>
<tr>
<td>1-2 Internal</td>
<td>End</td>
<td>1020</td>
<td>462</td>
<td>186.1</td>
<td>91</td>
<td>91</td>
</tr>
<tr>
<td>1-2 Internal</td>
<td>Middle</td>
<td>508</td>
<td>308</td>
<td>95.8</td>
<td>61.4</td>
<td>61.4</td>
</tr>
</tbody>
</table>

### I.2.1.2 Beams of the other floors:

Plastic moment at any section of all remaining beams of the frame will be determined similarly as above and they are summarized briefly as following table:

• Negative Plastic Moment of the section at the external joint of the beam on the third and the fourth floors:
### I.2.2 Columns

- We assume that 10φ16 are in the tensile area, 6φ16 are in the compression area and \( z \) is the distance taking from compressed fiber to the neutral axis

\[
F_{as} = \sum F_{as} = \sum A_s f_{yd} = 10 \times 201 \times 434.8 = 873948.0; F_{ai} = \sum F_{ai} = \sum A_s f_{yd} = 6 \times 201 \times 434.8 = 524368.8
\]

\[
F_c = f_{cd} b (h - z) = 16.7 \times 500 \times (400 - z) = 8350 \times (400 - z);
\]

\[
F_{as} + F_{ai} + F_c \rightarrow 873948.0 + 1306000 = 524368.8 + 8350(400 - z) \rightarrow 400 - z = 198.3 \rightarrow z = 201.7 \text{mm}
\]

- The condition of \( z \) is that: \((38+16)<400-z<(38+16+86.7)\) \( \rightarrow 54<198.3<140 \), so the value of \( z \) is not correct.

---

</tbody>
</table>

---

**PLASTIC MOMENT CACULATION**

The condition of \( z \) is that: \((38+16)<400-z<(38+16+86.7)\) \( \rightarrow 54<198.3<140 \), so the value of \( z \) is not correct.
We assume that the neutral axis will run through the first layer reinforcement; so there are less than 8φ16 in compression zone and over 8φ16 in tension zone.

\[ F_{a1} = A_{a1} \cdot f_{yd} = 6 \cdot 201 \cdot 434.8 = 524368.8 \]

\[ F_{a2} = A_{a2} \cdot f_{yd} = 2 \cdot 201 \cdot 434.8 = 174789.6 \]

\[ F_{a3} = A_{a3} \cdot f_{yd} \cdot \frac{z - 243.4}{16} = 2 \cdot 201 \cdot 434.8 \cdot \frac{z - 243.4}{16} = 174789.6 \cdot \frac{z - 243.4}{16} \]

\[ F_{c1} = 6 \cdot 201 \cdot 434.8 = 524368.8N \]

\[ F_{c2} = A_{a3} \cdot f_{yd} \cdot (1 - \frac{z - 243.4}{16}) = 174789.6 \cdot (1 - \frac{z - 243.4}{16}) \]

\[ F_c = f_{cd} \cdot b \cdot (h - z) = 16.7 \cdot 500 \cdot (400 - z) = 8350 \cdot (400 - z) \]

\[ \sum F_{si} + N = \sum F_{ai} + F_c \]

\[ \Rightarrow 174789.6 + 174789.6 \cdot \frac{z - 243.4}{16} + 1306000 = 174789.6 \cdot (1 - \frac{z - 243.4}{16}) + 8350 \cdot (400 - z) \]

\[ \Rightarrow z = 243.5\text{mm} \]

The condition of \( z \) is that 243.4 <\( z \)<243.4+16, so this condition is met.

- Plastic moment will be calculated as following:

\[ b_{ar1} = z - a_{r1} = 243.5 - (38 + 8) = 197.5\text{mm}; b_{ar2} = z - a_{r2} = 243.5 - (38 + 16 + 86.7 + 8) = 94.8\text{mm} \]

\[ b_{ar3} = z - a_{r3} = 243.5 - 243.4 = 0.1\text{mm}; b_{ai} = h - z - a_{ci} = 400 - 243.5 - (38 + 8) = 110.5\text{mm} \]

\[ b_{ei} = 16 - b_{ei} = 16 - 0.1 = 15.9\text{mm}; b_c = \frac{400 - z}{2} = 78.25\text{mm} \]

\[ F_c = 16.7 \cdot (400 - 243.5) \cdot 500 = 1306775N \]

\[ M_{x,exp} = \sum F_{si} \cdot b_{ai} + \sum F_{ei} \cdot b_{ei} + F_c \cdot b_c = 524368.8 \cdot (197.5 + 110.5) + 174789.6 \cdot 94.8 + 174789.6 \cdot \frac{0.1}{16} \cdot 15.9 + 1306775 \cdot 78.25 = 283092682N\text{mm} = 283\text{KNm} \]

Similarly, we can obtain the plastic moment of other section of the remaining column as following table:

<table>
<thead>
<tr>
<th>Floor</th>
<th>Width of column (mm)</th>
<th>Height of column (mm)</th>
<th>Reinforcement area (mm²)</th>
<th>Negative Plastic Moment (kNm)</th>
<th>Positive Plastic Moment (kNm)</th>

<td>217.2</td>
</tr>
<tr>
<td>5-6</td>
<td>500</td>
<td>400</td>
<td>16φ14 – 2464</td>
<td>217.2</td>
<td>217.2</td>
</tr>
</tbody>
</table>
II Modeling Parameters and Acceptance Criteria for Nonlinear Static Procedures (for User Defined Hinges in SAP 2000)

II.1 Transverse Frames

II.1.1 Beams

The modeling parameters of frame elements used in Nonlinear Static analysis (Pushover) are all properties of the plastic hinges or plastic zones. These parameters can be determined from FEMA 356[7]. According to FEMA 356[7] part 6, the properties of sections which can be transferred to plastic hinges depend on the relationship between Force-Displacement or Moment – Rotation. The general relationship can be defined as follows:

![Diagram of Moment vs. Rotation]

Table 2.1: Properties of the plastic hinge section

III Lateral Loads

Pushover analysis in EC8 [3] follows the N2 method developed by Fajfar (1999). The method consists of applying two lateral distributions to the frame:

- A “modal” pattern, that is a load shape proportional to the mass matrix multiplied by the first elastic mode shape $P^1 = M\phi_1$.
- A “uniform” pattern, that is a mass proportional to the load shape $P^2 = MR$

IV Pushover Curve (Capacity Curve)

By using Non-linear static Analysis in SAP 2000 version 9.0.3[8], the Pushover Curve of two vertical distributions of the lateral forces which correspond to uniform pattern loads and to modal pattern loads will be plotted as following pictures:
Plastic Mechanisms corresponding to two modal load patterns are presented in following pictures.
Figure 2.3: Plastic Mechanism - Uniform Load Pattern
Figure 2.4: Plastic Mechanism Plane YZ - Modal Load Pattern
Figure 2.5: Plastic Mechanism Plane XZ - Modal Load Pattern
To check performance of structure under earthquake excitations, we will determine the target displacements corresponding to given peak ground accelerations. Three values of PGA will be checked ($a_{Rg} = 0.15g; 0.3g$ and $0.6g$). The target displacement of the structure will be determined according to ANNEX B – EC8[3]. The structure which is multi degree of freedom will be transformed to Single Degree of Freedom by using the law of energy equilibrium.

### VI Over-strength Factor and behavior factor

- According to 5.2.2.2 – EC8[3], over strength factor is the ratio between the values of $\alpha_u$, which is the multiplier of the horizontal seismic design action with all other design actions constant, at formation of plastic hinges in a number sections sufficient for the development of overall structural instability and of $\alpha$, which is the multiplier of the horizontal seismic design action at first attainment of member flexural resistance anywhere in the structure. The ratio $\alpha_u/\alpha_t$ taken into account structural behavior at first yielding and plastic mechanism is equal to the ratio between the values of the base force at plastic mechanism and of the base force at first yielding.

All of these values will be displayed as following tables:

**Table 2.30: Over-strength Factor**
According to 3.2.2.5 - EC8 [3], the behaviour factor $q$ is an approximation of the ratio of the seismic forces that the structure would experience if its response was completely elastic with 5% viscous damping, to the seismic forces that may be used in the design, with a conventional elastic analysis model, still ensuring a satisfactory response of the structure. The $q$ – factor will be determined as following table:

<table>
<thead>
<tr>
<th>Frame</th>

<td></td>
</tr>
</tbody>
</table>

VII Check the performance of the structure

The performance of the structure under given earthquake excitation will be obtained by comparing capacity of the structure (capacity curve) and demand of the earthquake excitation. (the target displacements). The state of the structure at target displacement under a given earthquake represented by elastic response acceleration will be summarized as follows:

<table>
<thead>
<tr>
<th>Frame</th>
<th>Modal Load Pattern</th>
<th>Uniform Load Pattern</th>
</tr>
</thead>
<tbody>
<tr>

<td>XZ</td>
<td>433.9 0.25 0.057 4.4 636.9 0.24 0.072 3.3</td>
<td></td>
</tr>
</tbody>
</table>

The behaviors of the structure under PGA 0.15g excitation which are observed at target displacements in two planar frames are similar. There is no soft-story mechanism happening to the structure. The states of all plasticized hinges are in the range of yielding and immediate occupancy (B-IO) that means all of these hinges just begin to yield. The performances of two frames under PGA 0.3g excitation in two load patterns are also similar. Under the PGA 0.5g excitation, the plastic mechanisms are observed in two frames. The desired plastic mechanism in
which the plastic hinges are concentrated at the end of all beams and at the base of column is only attained in Modal Load Pattern for both frames. The collapse of the frames happens when the rotation of plastic hinge at the column’s base section exceeds limit value.

VIII Conclusion

- The reinforced concrete frames in a given seismic region which are correspondingly designed to EC8 [3] are checked by Nonlinear Static Analysis (Pushover). For the acceleration $a_{gR}=0.15g$ equal to the designed acceleration, the behavior of the frames is quite good (the structure can reach to the target displacement with some plastic hinges). There is no soft-story mechanism observed.
- Under greater earthquakes (for $a_{gR}=0.2g$; $a_{gR}=0.3g$), the structure still reach to target displacements with more plastic hinges. There is no soft-story mechanism observed with these accelerations.
- Under the earthquake with $a_{gR}=0.5g$, the structure can not reach to target displacement with because of some local plastic hinge collapses.
The symbols which are used in the design example are:

- $A_{Ed}$: design value of seismic action ($= \gamma _I A_{Ek}$)
- $A_{Ek}$: characteristic value of the seismic action for the reference return period
- $E_d$: design value of action effects
- $Q$: variable action
- $S_e(T)$: elastic horizontal ground acceleration response spectrum also called “elastic response spectrum”. At $T=0$, the spectral acceleration given by this spectrum equals the design ground acceleration on type A ground multiplied by the soil factor $S$.
- $S_{ov}(T)$: elastic vertical ground acceleration response spectrum
- $S_{os}(T)$: elastic displacement response spectrum
- $S_0(T)$: design spectrum (for elastic analysis). At $T=0$, the spectral acceleration given by this spectrum equals the design ground acceleration on type A ground multiplied by the soil factor $S$.
- $S$: soil factor
- $T$: vibration period of a linear single degree of freedom system
- $T_c$: duration of the stationary part of the seismic motion
- $a_{ge}$: reference peak ground acceleration on type A ground
- $a_r$: design ground acceleration on type A ground
- $d_i$: design ground displacement
- $g$: acceleration of gravity
- $q$: behaviour factor
- $\gamma _I$: importance factor
- $\eta$: damping correction factor
- $\xi$: viscous damping ratio (in percent)
- $\phi _{i,z}$: combination coefficient for the quasi-permanent value of a variable action $i$
- $\phi _{i,n}$: combination coefficient for a variable action $i$, to be used when determining the effects of the design seismic action
- $E_{Edx}$, $E_{Edy}$: design values of the action effects due to the horizontal components ($x$ and $y$) of the seismic action
- $E_{Edz}$: design value of the action effects due to the vertical component of the seismic action
- $F_i$: horizontal seismic force at storey $i$
- $F_b$: base shear force
- $H$: building height from the foundation or from the top of a rigid basement
- $L_{max}$, $L_{min}$: larger and smaller in plan dimension of the building measured in orthogonal directions
- $R_d$: design value of resistance
- $S_d$: seismic coefficient for non-structural elements
- $T_1$: fundamental period of vibration of a building
- $d$: displacement
- $d_r$: design interstorey drift
- $e_a$: accidental eccentricity of the mass of one storey from its nominal location
- $h$: interstorey height
- $m_i$: mass of storey $i$
- $n$: number of storeys above the foundation or the top of a rigid basement
- $q_d$: displacement behaviour factor
- $s_i$: displacement of mass $m_i$ in the fundamental mode shape of a building
- $z_i$: height of mass $m_i$ above the level of application of the seismic action
- $\alpha$: ratio of the design ground acceleration to the acceleration of gravity
- $\theta$: interstorey drift sensitivity coefficient
- $A_c$: Area of section of concrete member
- $A_{sh}$: total area of horizontal hoops in a beam-column joint
- $A_{si}$: total area of steel bars in each diagonal direction of a coupling beam
\( A_{st} \): area of one leg of the transverse reinforcement
\( A_{sv} \): total area of the vertical reinforcement in the web of the wall
\( A_{sv,i} \): total area of column vertical bars between corner bars in one direction through a joint
\( \Sigma M_{Rb} \): sum of design values of moments of resistance of the beams framing into a joint in the direction of interest
\( \Sigma M_{Re} \): sum of design values of the moments of resistance of the columns framing into a joint in the direction of interest
\( D_o \): diameter of confined core in a circular column
\( M_{i,d} \): end moment of a beam or column for the calculation of its capacity design shear
\( M_{Rb,i} \): design value of beam moment of resistance at end \( i \)
\( M_{Re,i} \): design value of column moment of resistance at end \( i \)
\( N_{Ed} \): axial force from the analysis for the seismic design situation
\( T_1 \): fundamental period of the building in the horizontal direction of interest
\( T_C \): corner period at the upper limit of the constant acceleration region of the elastic spectrum
\( V_{Ed,\text{max}} \): maximum acting shear force at end section of a beam from capacity design calculation
\( V_{Ed,\text{min}} \): minimum acting shear force at end section of a beam from capacity design calculation
\( V_{Rd,c} \): design value of shear resistance for members without shear reinforcement in accordance with EN1992-1-1:2004
\( V_{Rd,S} \): design value of shear resistance against sliding
\( b \): width of bottom flange of beam
\( b_c \): cross-sectional dimension of column
\( b_e \): effective flange width of beam in tension at the face of a supporting column
\( b_i \): distance between consecutive bars engaged by a corner of a tie or by a cross-tie in a column
\( b_o \): width of confined core in a column or in the boundary element of a wall (to centreline of hoops)
\( b_w \): thickness of confined parts of a wall section, or width of the web of a beam
\( d \): effective depth of section
\( d_b \): longitudinal bar diameter
\( d_{bw} \): diameter of hoop
\( f_{cd} \): design value of concrete compressive strength
\( f_{ctm} \): mean value of tensile strength of concrete
\( f_{yd} \): design value of yield strength of steel
\( f_{yd,h} \): design value of yield strength of the horizontal web reinforcement
\( f_{yd,v} \): design value of yield strength of the vertical web reinforcement
\( f_{yd,m} \): design value of yield strength of the longitudinal reinforcement
\( f_{ywd} \): design value of yield strength of transverse reinforcement
\( h \): cross-sectional depth
\( h_c \): cross-sectional depth of column in the direction of interest
\( h_{fl} \): flange depth
\( h_{je} \): distance between extreme layers of column reinforcement in a beam-column joint
\( h_{jw} \): distance between beam top and bottom reinforcement
\( h_o \): depth of confined core in a column (to centreline of hoops)
\( h_s \): clear storey height
\( h_w \): height of wall or cross-sectional depth of beam
\( k_D \): factor reflecting the ductility class in the calculation of the required column depth for anchorage of beam bars in a joint, equal to 1 for DCH and to 2/3 for DCM
\( k_w \): factor reflecting the prevailing failure mode in structural systems with walls
\( l_{et} \): clear length of a beam or a column
\( l_{cr} \): length of critical region
\( n \): total number of longitudinal bars laterally engaged by hoops or cross ties on perimeter of column section
\( q_o \): basic value of the behaviour factor
s: spacing of transverse reinforcement  
\(x_0\): neutral axis depth  
z: internal lever arm  
\(\alpha\): confinement effectiveness factor, angle between diagonal bars and axis of a coupling beam  
\(\alpha_0\): prevailing aspect ratio of walls of the structural system  
\(\alpha_1\): multiplier of horizontal design seismic action at formation of first plastic hinge in the system  
\(\alpha_u\): multiplier of horizontal seismic design action at formation of global plastic mechanism  
\(\gamma_c\): partial factor for concrete  
\(\gamma_{Rd}\): model uncertainty factor on design value of resistances in the estimation of capacity design action effects, accounting for various sources of overstrength  
\(\gamma_s\): partial factor for steel  
\(\varepsilon_{cu2}\): ultimate strain of unconfined concrete  
\(\varepsilon_{cu2,c}\): ultimate strain of confined concrete  
\(\varepsilon_{u,k}\): characteristic value of ultimate elongation of reinforcing steel  
\(\varepsilon_{sy,d}\): design value of steel strain at yield  
\(\eta\): reduction factor on concrete compressive strength due to tensile strains in transverse direction  
\(\zeta\): ratio, \(V_{Ed,min}/V_{Ed,max}\), between the minimum and maximum acting shear forces at the end section of a beam  
\(\mu_\phi\): curvature ductility factor  
\(\mu_\delta\): displacement ductility factor  
\(\nu\): axial force due in the seismic design situation, normalised to \(A_c f_{ed}\)  
\(\xi\): normalised neutral axis depth  
\(\rho\): tension reinforcement ratio  
\(\rho'\): compression steel ratio in beams  
\(\sigma_{cm}\): mean value of concrete normal stress  
\(\rho_{max}\): maximum allowed tension steel ratio in the critical region of primary seismic beams  
\(\rho_w\): shear reinforcement ratio  
\(\omega_\nu\): mechanical ratio of vertical web reinforcement  
\(\omega_{wd}\): mechanical volumetric ratio of confining reinforcement  
\(\Gamma\): transform factor  
\(m^*\): the mass of the equivalent SDOF system  
\(F^*\): The force \(F^*\) and displacement \(d^*\) of the equivalent SDOF system  
\(d^*\): the displacement \(d^*\) of the equivalent SDOF system  
\(d_y^*\): the yield displacement of the idealised SDOF system  
\(E_m^*\): the actual deformation energy up to the formation of the plastic mechanism.  
\(d_n^*\): the displacement of the idealised SDOF system at plastic mechanism of MDOF system.  
\(T^*\): the idealized equivalent SDOF system  
\(F_y^*\): the yield force of the idealised SDOF system  
\(d_{t*}\): The target displacement of the structure with period \(T^*\) and unlimited elastic behaviour  
\(S_e(T^*)\): the elastic acceleration response spectrum at the period \(T^*\).  
\(d_t^*\): target displacement of the idealised SDOF system  
\(d_t\): The target displacement of the MDOF system
