Jouret F, Walrand S, Parreira KS, Courtoy PJ, Pauwels S, Devuyst O, Jamar F. Single photon emission-computed tomography (SPECT) for functional investigation of the proximal tubule in conscious mice. Am J Physiol Renal Physiol 298: F454–F460, 2010. First published December 2, 2009; doi:10.1152/ajprenal.00413.2009.—Noninvasive analysis of renal function in conscious mice is necessary to optimize the use of mouse models. In this study, we evaluated whether single photon emission-computed tomography (SPECT) using specific radionuclear tracers can be used to analyze changes in renal proximal tubule functions. The tracers included 99mTc-dimercaptosuccinic acid (99mTc-DMSA), which is used for cortex imaging; 99mTc-mercaptopoietinylglycine (99mTc-MAG3), used for dynamic renography; and 123I-β2-microglobulin, which monitors receptor-mediated endocytosis. 99mTc-DMSA SPECT imaging was shown to delineate the functional renal cortex with a ~1-mm spatial resolution and accumulated in the cortex reaching a plateau 5 h after injection. The cortical uptake of 99mTc-DMSA was abolished in Clcn5 knockout mice, a model of proximal tubule dysfunction. Dynamic renography with 99mTc-MAG3 in conscious mice demonstrated rapid extraction from blood, renal accumulation, and subsequent tubular secretion. Anesthesia induced a significant delay in the 99mTc-MAG3 clearance. The tubular reabsorption of 123I-β2-microglobulin was strongly impaired in the Clcn5 knockout mice, with defective tubular processing and loss of the native tracer in urine, reflecting proximal tubule dysfunction. Longitudinal studies in a model of cisplatin-induced acute tubular injury revealed a correlation between tubular recovery and 123I-β2-microglobulin uptake. These data show that SPECT imaging with well-validated radiotracers allows in vivo investigations of specific proximal tubule functions in conscious mice.

receptor-mediated endocytosis; tubular secretion; CIC-5; Dent’s disease; radionuclear tracers

TRANSGENIC MOUSE STRAINS are widely used to investigate the structure and function of developing and mature kidneys and to model human disorders. Thus far, functional studies into disease mechanisms essentially require animal death and ex vivo investigations that are potentially limited by various factors including low fertility rates, gender effects (e.g., X-linked transmission), or limited life span in some models. These restrictions complicate the design of intervention studies and require the development of large colonies, increasing costs and raising ethical questions. To circumvent some of these limitations, efforts are being made to develop in vivo functional imaging techniques in mice. In particular, the possibility to perform quantitative and/or dynamic molecular imaging studi
by clamping the superior pole of the organ for 30 min under anesthesia. A model of partial or full recovery of acute PT injury was obtained by a single injection of either vehicle (saline) or cisplatin (12 mg/kg BW ip) in C57 mice with follow-up for 2 wk (9). Mice were housed individually in metabolic cages to assess overnight urine flow rate and renal function during the cisplatin protocol. All procedures were performed in accordance with National Institutes of Health guidelines for the care and use of laboratory animals, and with the approval of the Committee for Animal Rights of the Université catholique de Louvain Medical School.

Radiotracers. Human β2-microglobulin (β2M; Sigma, St. Louis, MO) was iodinated with 123I-Na+/H9251 (GE Healthcare, Brussels, Belgium) and Iodobeads (Pierce, Aalst, Belgium) as previously described (7) (purity in excess of 92% trichloroacetic acid-precipitable). Dimercaecoxytriglycine (MAG3) was iodinated with 123I-Na+/H9252 (GE Healthcare, Brussels, Belgium) following the standard procedure. The physical half-life of 123I is 13 h and that of 99mTc is 6 h. Radiopharmaceutical purity was >99%, as confirmed by instant thin-layer chromatography. All radiotracers were diluted in saline (NaCl 0.9%) and injected (lateral caudal vein of the catholique de Louvain Medical School).

Radiotracers. Human β2-microglobulin (β2M; Sigma, St. Louis, MO) was iodinated with 123I-Na+/H9251 (GE Healthcare, Brussels, Belgium) and Iodobeads (Pierce, Aalst, Belgium) as previously described (7) (purity in excess of 92% trichloroacetic acid-precipitable). Dimercaecoxytriglycine (MAG3) was iodinated with 123I-Na+/H9252 (GE Healthcare, Brussels, Belgium) following the standard procedure. The physical half-life of 123I is 13 h and that of 99mTc is 6 h. Radiopharmaceutical purity was >99%, as confirmed by instant thin-layer chromatography. All radiotracers were diluted in saline (NaCl 0.9%) and injected (lateral caudal vein of the tail iv) in a total volume of 150 μl.

SPECT system. The small-animal SPECT device (Linoview Systems, Amsterdam, The Netherlands) is made of four γ-detectors based on pixilated CsI(Na) scintillators (5-mm thickness, 2.44 × 2.44-mm crystal size). Detectors are fitted with a rake collimator equipped with an adjustable slit aperture, made of two iridium square rods (2 × 2 × 60-mm) (Supplemental Fig. 1; all supplementary material for this article is available on the journal web site). The spatial resolution of the system after reconstruction is 0.35 mm (26).

Acquisition procedure. In a preliminary experiment, dynamic 99mTc-MAG3 SPECT imaging was performed before and after anesthesia (ketamine, 100 μg/g, Merial, Brussels, Belgium; xylazine 10 μg/g, Bayer, Antwerp, Belgium) in two pairs of C57 mice. Subsequently, kinetic studies with the three radiotracers were performed on conscious Clcn5 mice placed in a plastic holder to reduce animal motion during imaging (Supplemental Fig. 1). The mice (pairs of Clcn5 WT vs. KO) were studied over a total period of 8 wk, with three sequential injections of DMSA, MAG3, and β2M on the same mice, separated by a minimal interval of 5 days.

Static SPECT was obtained hourly (acquisitions of 5 min each) during 5 h after intravenous (iv) injection of 700 μCi of 99mTc-DMSA (n = 4 pairs). At 6 h postinjection, a 30-min acquisition was performed under anesthesia to obtain high-resolution images. In two pairs of mice, the scanning was repeated 30 min after furosemide injection (10 mg/kg BW ip; final volume: 30 μl). Continuous dynamic SPECT (acquisitions of 15-s each) was achieved over 30 min after iv injection of 600 μCi of 99mTc-MAG3 (n = 3 pairs) or 200 μCi 123I-β2-microglobulin (n = 3 pairs), respectively. The linear motion of the detectors was set in such a way that the four-slit apertures would draw the narrowest rectangle possible around the animal. The distance between the actual contours and the collimator aperture was typically
~3 mm. The linear acquisition generates linograms forming a complete set of tomographic data allowing the reconstruction of the activity map (27).

Data processing. Reconstructions were performed using the maximum-likelihood expectation maximization algorithm with attenuation correction but without scatter correction or spatial resolution recovery (11). Time-activity curves were generated, 99mTc-MAG3 dynamic parameters were calculated using a three-compartment model, by fitting the curves to two exponentials.

The glomerular filtration rate (GFR) of 125I-β2-microglobulin was assessed by fitting all the organ curves (heart, kidney, thyroid, liver, spleen, bladder) by a multicompartmental model (Supplemental Fig. 2). The GFR can be calculated as:

\[ \text{GFR} = \frac{k_i V_p}{i} \]

where \( k_i \) is the glomerular uptake rate of the 125I-β2-microglobulin, and \( V_p \) is the plasma volume. Only the interval from 30 to 180 s postinjection was considered to avoid the effects of dilution after bolus injection, as well as 125I-β2-microglobulin tubular reabsorption and metabolism, respectively. All kinetic parameters of renal uptake were calculated using SigmaPlot 2000 (Systat Software, Erkrath, Germany). The plasma volume of the mice was estimated based on blood volume (8% body wt) (20) and 0.45 as average hematocrit value for the Clcn5 mice.

Autoradiography. For autoradiography, kidneys were exsanguined in situ, removed 7 min after iv injection of 620 ng/g of body weight of 125I-β2-microglobulin, and fixed for 6 h at 4°C in 4% formaldehyde. Ten-micrometer sections were overlaid, treated with emulsion reagent (Ilford Scientific Product, Wilrijk, Belgium), and revealed after 1 mo.

Plasma and urine analyses. Urinary creatinine (modified Jaffé method) and albumin (turbimetric method) and plasma creatinine (enzymatic determination) were measured on a Synchron CX5 analyzer (Beckman Coulter, Brea, CA), following the manufacturer’s protocols (3). The urinary excretion of the LMW Clara cell protein (CC16, 16 kDa) was measured by radioimmunoassay (7).

Statistics. Results are expressed as means ± SD. Comparisons between Clcn5+/+ and Clcn5+/− mice were made by Student’s unpaired t-tests assuming equal variance. The significance level was set at \( P < 0.05 \). Interassay variability was calculated as variation coefficient in 6 kidneys.

RESULTS

Imaging of the kidney cortex based on static 99mTc-DMSA uptake. 99mTc-DMSA is regarded as the ideal tracer for cortical imaging of the kidney. After uptake through the basolateral membrane, 99mTc-DMSA remains firmly bound to PT cells. We first investigated the spatial resolution of 99mTc-DMSA SPECT imaging of the kidney in wild-type (C57) mice. At 5 h postinjection, 99mTc-DMSA SPECT clearly delineated the functional renal cortex, whereas the medulla and the pelvis area (~1 mm) remained silent (Fig. 2A). The tracer uptake was...
abolished over an apical area of experimental infarction, the boundaries of which correlated with the histopathological examination (Fig. 2, A and B).

The kinetics of in vivo $^{99m}$Tc-DMSA uptake in wild-type (Clcn5$^{+/+}$) mice increased progressively to a plateau level of ~10% of the injected dose 5 h after injection (Fig. 2C; Table 1). The interassay variation coefficient (5.6%) demonstrated highly reproducible uptake measurements. Coronal and transverse sections evidenced the accumulation of $^{99m}$Tc-DMSA in the cortex of Clcn5$^{+/+}$ kidneys, insensitive to furosemide (Fig. 2, D and E). In contrast, the cortical uptake of $^{99m}$Tc-DMSA was abolished in Clcn5$^{−/−}$ kidneys (Fig. 2, C and E; Table 1), with minimal activity in the pelvis that was cleared after furosemide injection.

These results demonstrate that $^{99m}$Tc-DMSA SPECT imaging is able to delineate the functional renal cortex in the mouse, with a ~1-mm spatial resolution and a kinetics of uptake similar to the asymptotic curve observed in humans. Defective $^{99m}$Tc-DMSA cortical imaging is observed in cases of defective perfusion (kidney infarction) or generalized dysfunction of PT cells (Clcn5$^{−/−}$ mice).

Dynamic renography with $^{99m}$Tc-MAG3. $^{99m}$Tc-MAG3 is considered as the best tracer for dynamic imaging of the kidney. The tracer is concentrated in PT cells by basolateral uptake, followed by secretion into the urine without intracellular metabolization. The effect of anesthesia on the $^{99m}$Tc-MAG3 uptake by wild-type (C57) mice is shown on Fig. 3. Ketamine-xylazine anesthesia induced a significant delay in $^{99m}$Tc-MAG3 clearance, with a delayed and higher peak of uptake, as well as a higher degree of variability than in conscious mice. The dynamic renography in conscious Clcn5 mice is shown on Fig. 4.

The SPECT imaging of $^{99m}$Tc-MAG3 handling by wild-type Clcn5$^{+/+}$ kidneys is characterized by a rapid extraction from blood ($T_{1/2\text{IN}}$, 0.4 ± 0.1 min), maximal renal accumulation between 90 and 120 s after iv injection (~12% of injected dose/kidney), and subsequent tubular secretion ($T_{1/2\text{OUT}}$, 4.7 ± 0.5 min). Of note, the kinetic parameters of $^{99m}$Tc-MAG3 handling are not significantly affected in Clcn5$^{−/−}$ mice (Fig. 4; Table 1).

Renal handling of $^{123}$I-$\beta_2$-microglobulin in Clcn5 mice. $\beta_2$-microglobulin is a 12-kDa protein that is ultrafiltrated and completely reabsorbed via receptor-mediated endocytosis at the apical pole of PT cells. Monitoring the endocytic uptake of $^{123}$I-$\beta_2$-microglobulin is thus considered as a faithful marker of the activity of PT cells (7). The dynamic SPECT imaging of $^{123}$I-$\beta_2$-microglobulin handling by wild-type Clcn5$^{+/+}$ kidneys showed a rapid glomerular filtration followed by a progressive accumulation in the cortex, with maximal activity (6.4 ± 0.7% of injected dose/kidney) at 7 min postinjection (Fig. 5A; Table 1). The efficient breakdown of $^{123}$I-$\beta_2$-microglobulin in PT cells was reflected by $^{123}$I reflux into the blood. The $^{123}$I

Values are means ± SD. n, No. of kidneys from 4 (3) pairs of Clcn5 mice. SPECT, single photon emission-computed tomography; $^{99m}$Tc-DMSA, $^{99m}$Tc-dimercaptosuccinic acid; %ID, % of injected dose; $^{99m}$Tc-MAG3, $^{99m}$Tc-mercaptoacetyltriglycine; $T_{1/2\text{IN}}$, extraction from blood; $T_{1/2\text{OUT}}$, tubular secretion; $T_{\text{max}}$, maximal renal accumulation; NS, not significant. Unpaired Student’s t-test was used to compare Clcn5$^{+/+}$ and Clcn5$^{−/−}$ mice.
present in \textit{Clcn5}^{Y/+} urine at 60 min postinjection was mostly free iodine (92 $\pm$ 2% of total urine activity, \(n = 3\)). In strong contrast, \textit{Clcn5}^{Y/-} kidneys showed a severe defect in the reabsorption of ultrafiltered \(^{125}\text{I}-\beta_2\)-microglobulin (Fig. 5A; Table 1), with predominant urinary loss of intact \(^{125}\text{I}-\beta_2\)-microglobulin (62 $\pm$ 4% of total urine activity, \(n = 3\)). The autoradiography of kidneys fixed 7 min after injection of \(^{125}\text{I}-\beta_2\)-microglobulin, performed sequentially in the mice used for in vivo SPECT imaging, showed a strong cortical signal in \textit{Clcn5}^{Y/-} kidneys contrasting with the lack of tracer uptake in \textit{Clcn5}^{Y/-} kidneys (Fig. 5B). Importantly, the calculated glomerular filtration rate of \(^{125}\text{I}-\beta_2\)-microglobulin (0.22 $\pm$ 0.02 ml/min), based on the first part of the curve (see Fig. 5A), was similar in both strains of \textit{Clcn5} mice. These data demonstrate that the congenital PT dysfunction caused by the lack of CIC-5 is adequately reflected by SPECT imaging of defective renal handling of \(\beta_2\)-microglobulin.

**Renal uptake of \(^{125}\text{I}-\beta_2\)-microglobulin: recovery after cisplatin injury.** We used a model of reversible tubular toxicity induced by cisplatin, to test the potential of SPECT to provide a longitudinal assessment of acquired PT dysfunction in individual mice. The PT dysfunction, evidenced by the urinary excretion of albumin (and that of CC16, data not shown), peaked at day 5 and showed progressive recovery thereafter (Fig. 6A). A similar profile was observed by sequential SPECT

![Fig. 5](image-url)  
**Fig. 5. Dynamic renal handling of \(\beta_2\)-microglobulin in \textit{Clcn5} mice.** The time-activity curves show the progressive uptake of \(^{125}\text{I}-\beta_2\)-microglobulin following glomerular filtration and apical, receptor-mediated endocytosis by PT cells. The first part of the ascending curve corresponds to the progressive accumulation of the tracer in the urinary lumen (i.e., glomerular filtration), whereas accumulation beyond the first 3 min corresponds to apical endocytosis by PT cells. A: dynamic SPECT analysis \(^{125}\text{I}-\beta_2\)-microglobulin in \textit{Clcn5}^{Y/+} (red circle) and \textit{Clcn5}^{Y/-} (blue square) whole kidneys, and \textit{Clcn5}^{Y/-} cortex (blue square). The curves show the average of 6 kidneys (3 pairs of mice) in each group. In \textit{Clcn5}^{Y/+} mice, \(^{125}\text{I}-\beta_2\)-microglobulin rapidly accumulates in the cortex, with subsequent washout corresponding to breakdown and further release of free \(^{125}\text{I}\) into the blood. In \textit{Clcn5}^{Y/-} mice, \(^{125}\text{I}-\beta_2\)-microglobulin rapidly clears through the kidneys as a pure result of glomerular filtration. B: representative distribution of iodine-labeled \(\beta_2\)-microglobulin in transverse kidney sections at 7 min postinjection in \textit{Clcn5}^{Y/+} and \textit{Clcn5}^{Y/-} mice: in vivo SPECT imaging vs. autoradiography. In \textit{Clcn5}^{Y/+} kidney, \(\beta_2\)-microglobulin is restricted to the cortex by SPECT, correlating with a segmental distribution along radial proximal tubules. In \textit{Clcn5}^{Y/-} mice, SPECT only detects activity in the pelvis without significant uptake in the cortex, as confirmed by the lack of autoradiographic signal. Dotted circles represent the cortical contours in \textit{Clcn5}^{Y/-} kidney. Bars = 5 mm (left) and 1 mm (right).

![Fig. 6](image-url)  
**Fig. 6. Cisplatin-induced acute kidney injury: albuminuria and \(^{125}\text{I}-\beta_2\)-microglobulin handling.** Shown are serial determination of the urinary excretion of albumin (A) and repetitive SPECT imaging of \(^{125}\text{I}-\beta_2\)-microglobulin uptake in mice treated with cisplatin (B). The urinary excretion of albumin (baseline: 0.06 $\pm$ 0.04 $\mu$g/mg creatinine) peaked at day 5 (165 $\pm$ 70 $\mu$g/mg creatinine) and subsequently decreased toward normal values at day 11 (2.5 $\pm$ 1 $\mu$g/mg creatinine) and day 13 (3.8 $\pm$ 3.2 $\mu$g/mg creatinine) (*\(P < 0.05\), at least 4 values/time point). ns, Not significant. Representative sequential SPECT imaging for \(^{125}\text{I}-\beta_2\)-microglobulin handling in control mice (red circle) and a cisplatin-treated mouse reveals defective endocytic uptake at day 5 (blue inverted triangle), with partial recovery at day 12 (blue triangle). Note that the excretion defect (curve >7 min) persists at day 12.
imaging for the renal uptake of $^{123}$I-$\beta_2$-microglobulin in individual mice, with a major defect of uptake at day 5 followed by partial recovery at day 12 (Fig. 6B).

**DISCUSSION**

This report demonstrates the feasibility and validity of both static and dynamic SPECT imaging to investigate specific PT functions in conscious mice. To the best of our knowledge, this is the first report of dynamic SPECT renography in conscious mice demonstrating the feasibility of continuous monitoring of drug handling from the time of iv injection.

Our studies of $^{99m}$Tc-MAG3 showed a delayed tracer clearance and wider intra-assay variability in anesthetized mice, confirming the adverse impact of ketamine/xylazine on baseline renal function (14, 21, 22, 29). To circumvent the need for anesthesia, we used a simple plastic holder, which was sufficient to immobilize the mice without discomfort during SPECT acquisition (Supplemental Fig. 1). The imaging of conscious mice allowed us to sequentially use three radiotracers to assess distinct PT functions in the same mice: 1) uptake of $^{99m}$Tc-DMSA to evaluate the functional cortex with high resolution; 2) dynamic $^{99m}$Tc-MAG3 SPECT to investigate the basolateral capture and apical secretion; and 3) processing of $^{123}$I-$\beta_2$-microglobulin to assess apical receptor-mediated endocytosis. We took advantage of the Clcn5 KO mice (7, 18, 28) to provide a proof of concept for the use of SPECT, which showed a severe defect in both apical receptor-mediated endocytosis and basolateral anionic uptake, without significant alteration of the apical secretion by PT cells.

The renal uptake of $^{99m}$Tc-DMSA showed a progressive accumulation in mouse kidney cortex, matching standard curves reported in humans (16). At the plateau phase, $^{99m}$Tc-DMSA SPECT yields a millimetric delineation of the cortex, sufficient to identify a local area of parenchymal damage, as documented by the experimental infarction model (Fig. 2, A and B). The procedure has a low interassay variability, which supports its usefulness for repetitive and long-term biodistribution studies, as well as longitudinal studies (e.g., evaluation of toxicity following treatment) in the same mice.

The dynamic SPECT quantification of $\beta_2$-microglobulin renal uptake provided the first in vivo time course of PT receptor-mediated endocytosis in conscious mice. The radiolabeled LMW protein is freely filtered by the glomeruli, avidly captured in the renal cortex, and rapidly degraded with subsequent release of the radiotracer and residual peptide/amino acids to peritubular capillaries (2). The compartmental analysis of $^{123}$I-$\beta_2$-microglobulin biodistribution (Supplemental Fig. 2) enabled us to determine a GFR of 0.22 ± 0.02 ml/min, similar to that reported previously by using FITC-inulin clearance (20). The usefulness of SPECT to evaluate PT function is further demonstrated by the Clcn5 KO mice, characterized by defective endocytosis due to the internalization of the multiligand receptors, megalin and cubulin (7, 18). Our data show that the defective PT apical endocytosis previously evidenced by ex vivo counting (7) is confirmed by noninvasive in vivo SPECT of $^{123}$I-$\beta_2$-microglobulin uptake. Despite similar GFR, the tubular reabsorption of $^{123}$I-$\beta_2$-microglobulin is strongly impaired in Clcn5$^{5/7}$−/− mice, with altered metabolism in PT and subsequent loss in the urine, mostly as native $^{123}$I-labeled protein.

Similarly to $\beta_2$-microglobulin, the renal handling of $^{99m}$Tc-DMSA has been regarded as an indicator of PT dysfunction in human and animal models (1, 25). For example, treatment of rats with Na-maleate induces a typical renal Fanconi syndrome, with marked reduction of $^{99m}$Tc-DMSA uptake (19). In our study, SPECT quantification of $^{99m}$Tc-DMSA capture shows that inactivation of Clcn5 is associated with a lack of tracer accumulation in the renal cortex, suggesting a severe deficit in PT basolateral function. It is likely that the residual signal detected in the pelvis of Clcn5$^{5/7}$−/− mice represents a small glomerular filtration of $^{99m}$Tc-DMSA (17). The basolateral uptake of $^{99m}$Tc-DMSA from peritubular capillaries into S3 PT cells is mediated by the Na$^+$/dicarboxylate cotransporter NaDC3 (SLC13A3) (4, 13) (Fig. 1). Of note, the coexpression of nonconductive fragments of CIC-5 with NaDC transporters alters their translation and/or trafficking in Xenopus laevis oocytes, resulting in decreased surface expression (15). The severe deficit in both apical and basolateral SPECT uptake reported here further demonstrates that the functional loss of CIC-5 induces a generalized intracellular trafficking in PT cells (7, 18).

Renal scintigraphy with $^{99m}$Tc-MAG3, a radiolabeled analog of p-aminohippurate, can provide excellent image quality even with severe renal failure (10). For instance, $^{99m}$Tc-MAG3 imaging detected changes in renal function in anesthetized mice as early as 5 h following ischemia-reperfusion injury (22). A model for $^{99m}$Tc-MAG3 secretion by PT cells has recently been proposed, based on in vitro transport experiments in X. laevis oocytes (24) (Fig. 1). $^{99m}$Tc-MAG3 is intracellularly accumulated through the basolateral organic anion transporter OAT1 that is expressed in all PT segments (4). The molecular counterpart of $^{99m}$Tc-MAG3 apical transport could involve the Na$^+$-dependent phosphate transporter NPT1 and/or the multidrug resistance protein MRP2 (5, 24). Our results demonstrate that PT dysfunction caused by the functional loss of CIC-5 is not associated with a defect in $^{99m}$Tc-MAG3 renal handling. The contrast between the complete loss of $^{99m}$Tc-DMSA basolateral uptake and the preserved $^{99m}$Tc-MAG3 secretion in Clcn5 KO kidneys provides further evidence that these two pathways are functionally independent (24) and corroborates immunolocalization studies showing a distinct distribution of NaDC3 and OAT1 in PT segments (4). Additional SPECT studies using mouse models invalidated for distinct organic anion transporters may help establish the metabolic pathways handling these particular radiotracers, as well as other drugs and metabolites.

In conclusion, SPECT analysis represents a new approach to characterize the renal PT function in conscious mice, based on acute and/or repetitive biodistribution studies using distinct radiolabeled tracers. Two limitations cannot be ignored. First, the spatial resolution of SPECT, being limited to the millimetric range, cannot compete with rapidly evolving live-microscopy methods (6). Second, although SPECT offers a temporal resolution of 5–10 s for pharmacokinetic studies, this may not be sufficient to explore faster functions such as organelle activation or intracellular trafficking. Nevertheless, the development of creative approaches dedicated to small-animal imaging will permit further functional investigations of transgenic mouse strains, with relevance for renal physiology or disease mechanisms.
