It is affirmed that Paeonia suffruticosa Andrews only includes the cultivars of tree peony and should be strictly separated from any wild species, e.g., Paeonia rockii (S G. Haw et Lauener) T. Hong et J. J. Li in Bull. Bot. Res (Harbin) 12: 223, 1992 [*Paeonia suffruticosa* Andrews subsp. *rockii* S G. Haw et Lauener in Edinb. J. Bot. 47(3): 279-1990]. The so-called “Paeonia suffruticoa Complex” is an artificially “mixed bag” including cultivars and some wild species of tree peony.

P1415. Revision of the Genus *Knautia* L. (Dipsacaceae) in the Italian Alps

J. Magos Brehm[1,2], C. Bonomi[3], A. Bonazza[3], F. Prosser[4], N. Maxted[1];
[1]University of Birmingham, Birmingham, United Kingdom, [2]Museu Nacional de História Natural, Jardim Botânico, Lisbon, Portugal, [3]Museo Tridentino di Scienze Naturali, Trento, Italy, [4]Museo Civico di Rovereto, Rovereto, Italy.

Knautia L., a Central European and Mediterranean genus shows high intrinsic taxonomic complexity and a centre of diversity in the Alps. The species are polymorphic and closely related, making identification difficult. The genus is subjected to taxonomic erosion with three species occurring in this region that are listed as threatened under the IUCN Red List categories. As the genus has had limited previous taxonomic study, urgent revision is required to facilitate conservation actions.

Knautia specimens representing *K. arvensis*, *K. longifolia*, *K. baldensis*, *K. illyrica*, *K. purpurea, K. persicina*, *K. velutina* species with their provenance in the Trentino region (SE Italian Alps) were loaned from ROV, K, BM and RGN. They were scored for 103 morphological characters for over 100 specimens. The morphometric analysis of the data includes a cluster and a principal coordinates analysis, presenting a revised classification of *Knautia* species found in the Trentino region and thus providing easily usable identification aids for field workers. This will facilitate the evaluation of the species threatened status and the development of regional conservation actions.

P1416. Chloroplast DNA variation in Indonesian Dipterocarpaceae

S. Indrioko, R. Finkeldey, **O. Gailing**;
Institute of Forest Genetics and Forest Tree Breeding, Göttingen, Germany.

Dipterocarpaceae (subfamily Dipterocarpoideae) dominate tropical rainforests in Southeast Asia. In order to construct a molecular phylogeny of Indonesian dipterocarps we performed PCR-RFLP of the chloroplast regions *rbcL*, *petB*, *psbA*, *psaA*, and *trnLF* with 7 restriction enzymes including 58 species from 9 genera. A total of 104 restriction site polymorphisms and 12 length polymorphisms were detected. In the strict consensus tree with *Monotes kerstingii* as outgroup Indonesian Dipterocarpaceae were divided into two major clades. One clade consisted of *Upuna*, *Cotylelobium*, *Anisoptera*, *Vatica*, *Dipterocarpus* (tribe Dipterocarpeae) and *Dryobalanops* in a basal position (tribe Shoreae). Tribe Dipterocarpeae is monophyletic, tribe Shoreae is polyphyletic since *Dryobalanops* is a sister group to tribe Dipterocarpeae. In the neighbor-joining tree the position of *Dryobalanops* is not resolved. Wihin genus *Shorea* phylogenetic relationships are poorly resolved and partly in constrast to the classification in botanical sections according to morphological characters. Analysis of additional nuclear genes may help to resove the relationships within *Shorea*.

P1417. Geographic differentiation within *Shorea leprosula* and *Shorea parvifolia* (Dipterocarpaceae) as revealed by amplified fragment length polymorphism (AFLP) markers

C. Cao, R. Finkeldey, O. Gailing;
Institute of Forest Genetics and Forest Tree Breeding, Göttingen, Germany.

Shorea leprosula and *Shorea parvifolia* are widely distributed in Indonesia and constitute economically and ecologically important species. We analysed 6 populations of *Shorea parvifolia* and 7 populations of *Shorea leprosula* from a total of 6 locations in Sumatra and Borneo and one plantation at 56 well scorable AFLP markers. Cluster Analysis (NTSYS pc2) revealed a clear differentiation between species. A high differentiation between geographic origins could be observed for *Shorea parvifolia* (G_{st} = 0.31) and *Shorea leprosula* (G_{st} = 024). For both species, AFLP markers with very strong differentiation between geographic regions could be found. For *Shorea leprosula*, we detected one "diagnostic" marker that differentiated between origins from Sumatra and Borneo with a frequency difference of 96%. For two additional populations of both species, specific "private" AFLP markers could be detected. We want to characterize these markers more closely for wood certification purposes.

P1418. Heterospermy in some Ericaceae

G. M. Anisimova;
Komarov Botanical Institute, St-Petersburg, Russian Federation.

Heterospermy is widely presented in plant world and is inherent both for wild and cultured forms. It manifests firstly in seed size, herewith the sizes of embryo cotyledons and hypocotyl, endosperm, seed mass could change. In the fruits of studied representatives of the Ericaceae (*Andromeda polifolia*, *Calluna vulgaris*, *Ledum palustris*, *Chamaedaphne calyculata*, *Oxycoccus quadripetalus*, *Vaccinium myrtillus*, *V. uliginosum*, *V. vitis-idaea*), collected during dissemination, the seeds varied in sizes, morphology and anatomical structure. Large seeds had, as a rule, normally developed embryo, endosperm and seed coat; the seeds of intermediate sizes usually failed to contain the embryo, and the endosperm either was poor or lacked; small seeds were presented mainly by exotesta, sometimes by the remnants of middle integument layers. Sometimes seeds, except small ones, contained underdeveloped embryos. The ratio of the large, middle and small seeds in the fruit for Leningradskaya region strongly varies. The most high quantity of large seeds has *O. quadripetalus* (about 60%), while in *V. myrtillus*, *V. uliginosum*, *V. vitis-idaea* their amount composes only 30%.

P1419. Molecules and morphology: phylogeny and species delimitation in the genus Escallonia (Escalloniaceae)

F. Zapata[1], P. F. Stevens[2];
[1]University of Missouri-St. Louis, St. Louis, MO, United States,
[2]Missouri Botanical Garden, St. Louis, MO, United States.

Escallonia (Escalloniaceae, Euasterid II-unplaced) includes about 39 species; these are herbs (as *Valdivia*) to trees found in the Andes from Tierra del Fuego to the mountains of Costa Rica, the south Atlantic Forest in Brazil, Juan Fernández Island and, remarkably, Réunion in the Indian Ocean (as *Forgesia*). This genus presents a complex pattern of morphological variation that has led to disagreement over the number of species and uncertainty over its phylogeny. This study will re-evaluate species limits in *Escallonia* using a combination of molecular systematics, morphometrics and natural history. Gene genealogies allow recognizing species as individual segments of population lineages connected by common history. While independent regions with high levels of DNA sequence variation will generate hypotheses of relationship, morphometric analyses will indicate the potential correlation of phenotypic variation at different eco-geographic scales. The results of the different analyses will be compared and, if appropriate, combined to illuminate species limits. The phylogeny will also be used to clarify the perplexing biogeography of this genus.

P1420. “Escallonian Alliance” - an attempt to undo a taxonomic knot with the help of comparative carpology

E. Y. Yembaturova, O. A. Korovkin;
Moscow Agricultural Academy, Moscow, Russian Federation.

Most genera of a compound group usually referred to as “Escallonian Alliance” were originally placed in the subfamily *Escallonioideae* (*Saxifragaceae*), then in the *Escalloniaceae*, but the taxon showed high polymorphism and needed a thorough revision. Currently these genera are distributed between more than 10 families (often monotypic) within *Hydrangeales, Saxifragales*, *Celastrales* or even *Cornales*.

Our investigation revealed numerous carpological distinctions between the representatives of this group. The main traits that carpological classifications are based upon (ovary position, number of seeds and carpels, pericarp consistence, dehiscence type) appeared to vary significantly within the group; anatomical differences were even greater. Only a few genera showed resemblance in fruit anatomy (*Carpodetus* and *Abrophyllum* with baccate fruits, *Quintinia* and *Itea* with capsules). Therefore, placing most of the genera into monotypic families seems to be the best solution for “Escallonian Alliance”, and the position of some of them (*Corokiaceae, Brexiaceae*) is still to be determined.

P1421. Histological studies on cyathia of some *Euphorbia* species

N. Papp, L. Szabó;
University of Pécs, Pécs, Hungary.

Euphorbia species have a special inflorescence namely cyathia: it contains a central female flower surrounded by 5 male flowers, 4-5 nectaries and bractea. We studied the histology of the cyathia, with special emphasis on the nectaries in some *Euphorbia* species. Nectaries have cuticle, epiderm, glandular tissue and parenchyma in all species. The xylem vessels have spiral secondary cell wall thickenings. The nectary cuticle of *E. amygdaloides* and *E. palustris* is thin, that of *E. cyparissias*, *E. esula*, *E. myrisnites* and *E. virgata* living at xeroterm area is thicker. Nectary of *E. palustris* has the highest epidermal cells and the largest number of cell rows of glandular tissue (6-7) which varied from 1 to 4 in the other plants. Cells of glandular tissue are isodiametric in all species except of *E. cyparissias*. Biggest cells of glandular tissue were detected in the nectary of *E. virgata*. The histological structure of the nectary was specific for the studied plant species.

P1422. Histological studies on cyathia of some *Euphorbia* species

N. Papp, **L. G. Szabó**;
University of Pécs, Pécs, Hungary.

Euphorbia species have a special inflorescence namely cyathia: it contains a central female flower surrounded by 5 male flowers, 4-5 nectaries and bractea. We studied the histology of the cyathia, with special emphasis on the nectaries in some *Euphorbia* species. Nectaries have cuticle, epiderm, glandular tissue and parenchyma in all species. The xylem vessels have spiral secondary cell wall thickenings. The nectary cuticle of *E. amygdaloides* and *E. palustris* is thin, that of *E. cyparissias*, *E. esula*, *E. myrisnites* and *E. virgata* living at xeroterm area is thicker. Nectary of *E. palustris* has the highest epidermal cells and the largest number of cell rows of glandular tissue (6-7) which varied from 1 to 4 in the other plants. P1423. The Brazilian Caatinga: phytogeographical patterns inferred from distribution data of the Leguminosae

L. P. de Queiroz;
UEFS, Feira de Santana, Bahia, Brazil.

The Caatinga represents the largest and most isolated of the South American dry forests, occupying an area of almost 900,000 km^2 in the semiarid region of north-eastern Brazil. Leguminosae is the best represented family in the Caatinga, with 292 species in 77 genera, and comprises almost one third of the total plant diversity there. The geographical distribution patterns of its taxa define seven major centres of endemism. Similarity analysis combined with these patterns reveal two major floristic groups with distinct composition and phenological traits. One group occupies c. 70 % of a mostly continuous surface of soils primarily derived from crystalline basement rocks. The other group occurs on disjunct and sandy sedimentary surfaces. The data supports a scenario wherein the sedimentary areas became dissected during a huge process of pediplanation during the Tertiary period, which promoted both the vicariance of its flora and opened the way to the expansion of the flora related to the seasonally dry tropical forests.

P1424. Research of different of Nitrogen and Phosphorous on the yield of Sainfoin in dry land conditions

H. Iran Nejad, N. Schahbazian;
University of Teheran, Abouraihan Campus, Department of Agronomy and Plant Breeding, Teheran, Islamic Republic of Iran.

Sainfoin (Onobrychis sativa) is a soft forage plant with high protein content. This plant has some characteristics such assistance to unsuitable environmental conditions like low fertility of soil and intensive cold of winter, resistance to drought in dry land farming with acceptable yield, resistance to overgrazing in rang lands and direct grazing capability without causing the blowing.

To study the effect of various levels of Nitrogen and Phosphorous fertilizer on the forage yield of Sainfoin of experimental design was carried out as the randomized complete block design with four replication and two factors. Nitrogen fertilizer in three levels and the other phosphorous fertilizer in four levels.The main purpose of

this experiment was to introduce scientific strategies to sure of the daneerlees use of chemical fertilizers to produce acceptable yield with sustainable environment conservation purpose.
In this study, dry matter yields ,wet weight yield ,and shoot height were measured and compared.
In spite of shoot height above mentioned characteristics was significantly affected by various Levels of Nitrogen and Phosphorous fertilizers.

P1425. Lower Miocene Leguminosae flowers from the amber of Simojovel, Chiapas, México

L. Calvillo-Canadell[1], S. R. S. Cevallos-Ferriz[2];
[1]Posgrado en Ciencias Biológicas, UNAM, Del. Coyoacan, México D.F., Mexico, [2]Instituto de Geología, UNAM, Del. Coyoacan, México D.F., Mexico.

Leguminosae abundance/diversity in Mexican extant vegetation resembles that of the Tertiary flora of the region. They are collected in most Eocene-Recent localities bearing flowering plants. New amber samples contain flowers comparable with those of legume plants. An inflorescence with 8 pentamerous, actinomorphic, perfect flowers, each with ca. 10 floral bracts, gamosepalous calyx with 5 small pubescent and striated lobes, 5 lobed thin gamopetalous corolla, abundant free stamens (ca. 50) with pedicelated glands on dorsifixed anthers, and ovary with thick large apical style, resembles those of *Acacia* (Acacieae) or *Albizia* (Inegeae). A second flower resembles that of *Hymenaea mexicana* (Detarieae) in being actinomorphic and perfect, pubescent in pedicel and receptacle, having 3 elliptic free sepals, free stamens with dorsifixed anther, and ovary inserted on a disc with seeds in axilar position. These flowers confirm that Leguminosae were established some 23.5 mybp in southern Mexico.

P1426. *Astragalus* sect. *Incani* (Fabaceae) in Iran

M. Ranjbar[1], M. Rahiminejad[2];
[1]Bu-Ali-Sina University, Hamadan, Islamic Republic of Iran, [2]Isfahan University, Isfahan, Islamic Republic of Iran.

sect**.** *Incani* **(**subgen. *Cercidothrix***)** belongs to bifurcate haired group *Astragali*. Iran is the center of diversity of the section, with cf 50 species of which about 35 are endemic. New findings are given for the *Astragalus* sect. *Incani*, which occurs within the area of flora of Iran. The seed surface sculpturing of *Astragalus* have been studied. The basic pattern of the seed testa in Iranian *Astragalus* particularly between sections is remarkably heterogeneous. Variation arises from differences in both size and shape of the seed. The shape of the seed is oblong, square or reniform. Its color is light or dull brown. The surface of the seed is usually rough (observable with SEM). Results showed micromorphological diversity and taxonomic value of this feature.
Five seed coat patterns were found: A) bilayer-reticulate, B) monolyer-reticulate C) reticulate-verucate, D) rugulate and E) foveo-rugulate. The evolution trends of testa micromorphology show phylogenetic relationships. As fine reticulate pattern existed commonly, the pattern is regarded as the most primitive type. Other types are derivatives from the basic reticulate pattern.

P1427. Biosystematical study on the genus *Lathyrus* (Fabaceae) in Iran

R. Karamian[1], M. Ranjbar[1], V. Niknam[2], M. Hedyelu[1];
[1]Bu-Ali-Sina, Hamadan, Islamic Republic of Iran, [2]University of Tehran, Tehran, Islamic Republic of Iran.

Morphological study were performed on 23 species of Iranian *Lathyrus* using 38 characters. Also micromorphological study on seed surface were done by SEM. Seed storage proteins of seeds were studied by SDS-PAGE gel electrophoresis. Flavonoid compounds in glycosyle ester forms were extracted from leaves and separated by TLC method. Obtained dendrogram from morphological studies by NTSYS software shows that there are 5 sections in the genus that confirm its current classification in flora of Iran. Results from the micromorphological and flavonoid compound studies confirm above results and show that *L. cicera* and *L. sativus* are closely related. Also *L. pratenis* and *L. Laxiflorus* are placed in the uniqe section and *L. Boissieri, L. cyaneus* and *L. brachypterns* are placed in another section. Results from electrophoretic study do not confirm above results compeletly and are not suitable for classification of the genus.

P1428. Taxonomic significance of anatomical characters and pollen morphology in *Astragalus* sect. *Onobrychoidei* in Iran

R. Karamian[1], M. Ranjbar[1], A. Movahedian[1], M. Rahiminejad[2];
[1]Bu-Ali-Sina, Hamadan, Islamic Republic of Iran, [2]Isfahan University, Isfahan, Islamic Republic of Iran.

Astragalus L. with more than 840 species, is the largest genus in the flora of Iran. It is the most problematic group in legume systematic. *Astragalus*. sect**.** *Onobrychoidei* belongs to the bifurcate haired group *Astragali*. Iran with more than 25 species is one of the main centers of diversity of the section. The pollen surface sculpturing of the species of the section has been studied. Two basic types of the pollen surface were observed in these Iranian *Onobrychoidei*. Also in order to evaluate the internal structure in the classification of the section, 31 anatomical characters were studied. The results showed that the stem and peduncle have different shapes (e.g. stellate, orbicular and sometimes trapezoid) in different taxa. Furthermore, epidermal features, type of collenchyma cells, type of vascular bundles and the habit of the stem have important value in distinguishing the species.

P1429. Species Richness and Distribution Patterns of the Colombian Species of *Inga* (Leguminosae: Mimosoideae: Ingeae)

C. Romero, E. Forero;
Instituto de Ciencias Naturales, Bogotá, Colombia.

Inga is one of the largest neotropical genera of Leguminosae (c. 300 species). In the process of preparation of a taxonomic revision of *Inga* for Colombia, 95 species were found, including 29 new records for the country. The 95 species represent 11 of the 14 sections recognized by Pennington (1997). The genus is widely distributed in the country and has 3 centers of species diversity: the Amazon, the Andes and the Pacific region (62, 58 and 48 species respectively). In Colombia, the species of *Inga* grow in a wide range of habitats such as gallery forests, wet/very wet tropical forest, pluvial tropical forests, forests on periodically flooded lands, grass pastures and forest on terra firme in the Amazon region. The genus also exhibits wide altitudinal distribution, ranging from sea level to 2900 m. Most species are widely distributed altitudinally, while only a few show restricted altitudinal distribution patterns.

P1430. A contribution to the systematics of annual species of *Astragalus* (Fabaceae) in the Old World

F. Taeb[1], **S. Zarre**[1], D. Podlech[2], H. J. Tillich[2], S. Kazempour Osaloo[3], A. A. Maassoumi[4];
[1]Department of Biology, University of Tehran, Tehran, Islamic Republic of Iran, [2]Institut für Systematische Botanik der LMU, Munich, Germany, [3]Department of Plant Biology, Faculty of Basic Sciences, Tarbiat Modares University, Tehran, Islamic Republic of Iran, [4]Department of Botany, Research Institute of Forests and Rangelands, Tehran, Islamic Republic of Iran.

Sixty annual species of *Astragalus* were analyzed for hair micromorphology using SEM and floral morphology. Characters from hair micromorphology, flower morphology and some vegetative characteristics of the plants have been used in a cladistic analysis of annual *Astragalus*. The analysis resulted in 12 trees. The strict consensus tree using morphological characters is in several aspects similar to the cladogram presented recently based on ITS sequences. In both cladograms most of the species attributed to sects. *Hispiduli*, *Platyglottis* and *Sesamei* represent the most derived group and form a monophyletic clade. The monotypic sections *Ophiocarpus*, *Dipelta* and *Mirae* cluster within the same clade. The most important disagreement between the cladograms is regarding sections *Bucerates*, *Oxyglottis* and a part of sect. *Annulares*. Morphological characters correlating the species attributed to these groups are plesiomorphic and can only characterize paraphyletic groups. Based on available data from molecular systematics and cladistic analysis of morphological characters, circumscription of several sections in *Astragalus* should be changed.

P1431. Spine anatomy and its systematic application in *Astragalus* sect. *Rhacophorus* s. l. (Fabaceae) in Iran

A. Pirani[1], S. Zarre[1,2], V. Niknam[1], H. J. Tillich[2], D. Podlech[2];
[1]Central Herbarium of Tehran University, Tehran, Islamic Republic of Iran, [2]Institut für Systematische Botanik der LMU, Munich, Germany.

Cross sections of petioles in 35 species mainly belonging to *Astragalus* sect. *Rhacophorus* were studied for insights into circumscription of natural groups within the section and reliable characters in delimiting polymorphic species. The following characters were determined to be informative: number of parenchymatous cell layers in pith, diameter of median sclerenchymatous vascular bundle sheath and diameter of the cross-section as whole. *Astragalus amblolepis*, *A. andalanicus*, *A. floccosus*, *A. meyeri*, *A. paralipomenus*, *A. pycnocephalus* and *A. stenolepis* are characterized by large pith and relatively large sclerenchymatous bundles. Most of these species belong to sect. *Rhacophorus* s. str., comprising large-flowered species as circumscribed by some taxonomists, but few species of sects. *Stenonychium* and *Platonychium* also show these features. Our results show that spine anatomy is not useful for circumscribing sections in spiny *Astragalus*, but applicable in delimiting small natural groups and circumscribing species.

P1432. Testa topography & Seed Coat Anatomy of the Genus *Alysicarpus* Desv.

D. S. Pokle, A. S. Dhabe;
Vivekanand College, Aurangabad, India.

Since last 10 years revision of genus *Alysicarpus* for India was undertaken. It was felt that more exomorphic studies are insufficient for taxa delimitations. Hence other parameters were exploited. One of these parameters is seed testa topography and seed coat anatomy.

Seeds of 17 taxa were examined by SEM. Two note worthy features were noted. First, duplex testa topography was found in 9 taxa. Secondly, 15 taxa show multirugulate and faveolate pattern. According to Larsten, these features are prevalent in tribe *Hydesareae*. This feature is of evolutionary significance.

Seed coat anatomical studies of 24 taxa were undertaken. Macrosclereids, Osteosclereids, Parenchyma and Endosperm are unique in each taxon at even variety & form level. These anatomical features are taxon specific. This feature is most reliable for taxa delimitation.

P1433. Phytochemical Studies on the Genus Alysicarpus Desv.

A. S. Dhabe, D. S. Pokle, M. Daniel;
Dr.B.A.M.University, Aurangabad, India.

Alysicarpus Desv. is a tiny herbageous genus of fabaceae-Desmodeae. During the course of investigations, phytochemical studies were undertaken on Alkaloids, Irridoids, Tannins, Saponins & phenolics, which are taxonomically significant. In all these alkaloids are of not much importance taxonomically. Overall results of phytochemical analysis of 24 taxa (13 species, 7 varieties & 4 forms) are presented in the paper. On the basis of phytochemical analysis, it was revealed that a dimorphic form of A.monilifer, erect & trifoliolate forms of *A.scariosus* should be raised into new species (sp.novo). *A.vaginalis* var.*nummularifolius* be raised to species level & *A.hamosus* trifaliolate form be raised to variety level. In general *A.bubleurifolius* var.*gracilis* is most primitive and *A.luteo-vexillatus* & *A.monilifer* (dimorphic form) are most advanced among the genus.

The analysis for fodder nutrient proved that the almost all species are nutritionally compitible to *Medicago sativa* even in wild state.

P1434. Evolution of the series *Microphyllae* (Subgen. *Acanthadesmia*, *Adesmia,* Fabaceae) in the Andean ranges: A biogeographic perspective

M. A. K. Mihoc[1,2], J. J. Morrone[3], L. A. Cavieres[1,2], M. A. Negritto[1];
[1]Departamento de Botánica, Facultad de Ciencias Naturales y Oceanográficas, Universidad de Concepción, Concepción, Chile, [2]ECOBIOSIS, Concepción, Chile, [3]Departamento de Biología Evolutiva, Facultad de Ciencias, UNAM, México D.F., Mexico.

This study explores a preliminary hypothesis about the evolution of the series *Microphyllae* (Subgen. *Acanthadesmia*, genus *Adesmia*, Fabaceae), comprising about 33 species. *Microphyllae* is distributed exclusively in the Andean region of South America, from Peru (13°W) to Argentina (40°W) representing the total distribution of the subgenus *Acanthadesmia*. The biogeographic history of this series is unclear, and current knowledge does not enable a clear understanding of the evolutionary history of the genus.

We carried out a track analysis based on the distributional patterns of 22 species of this series. Five generalized tracks were found and two nodes were identified. Parsimony analysis of endemicity of the individual track split the total area in two (northern and southern) sub-areas. Our result suggest a recent differentiation resulting from isolation of populations along the Andean cordillera, i.e. vicariance events fragmented the distribution and caused subsequently differentiation.

Acknowledgments: CONICYT AT-4040202, Proyecto MECESUP UCO 0214.

P1435. Study of the Flora of Cicer (Papilionaceae) in Iran

N. Jalilian[1], M. Assadi[2];
[1]Reserch center of Agriculture and Natural Resources, Kermanshah, Islamic Republic of Iran, [2]Research Institute of Forests and Rangelands, Tehran, Islamic Republic of Iran.

The genus Cicer which belongs to the tribe Vicieae of Papilionaceae is very well known by the globally important cultivated species *Cicer arietinum* L. other than the cultivated species. It also comprises forty two (42) species in the world (among two subgenera) from which ten (10) species grow in Iran. The aim of this study is providing the flora of Cicer including description of taxa, the keys for determination and the geographical distribution of Iranian species. For this purpose a classical systematic study was performed based on morphological (vegetative as well as reproductive) characters. According to these studies the taxonomic status of *Cicer kermanense* was changed from species to subspecies and *Cicer bijugum* was introduced as a new record for the flora of Iran.

P1436. Study of the Flora of Cicer (Papilionaceae) in Iran.

M. Assidi, **N. Jalilian**;
Reserch center of Agriculture and Natural Resources, Kermanshah, Islamic Republic of Iran.

The genus Cicer which belongs to the tribe Vicieae of Papilionaceae is best known by the globaly important cultivated species C. arietinum L. other than the cultivated species. It also comprises 43 species, from which 10 species grow in Iran. The aim of this study is providing the flora of Cicer including description of taxa, keys for determination and geographical distribution of Iran species. For this purpose classical systematic study was performed based on morphological (vegetative and reproductive) characters.The numerical taxonomy was done by cluster analysis. As a result, Leaflet numbers and peduncle lengh have maximum variance and leaflet form (leaf or spine form) has minimum amount of variance. According to these studies the taxonomic status of C. kermanense was changed from species to subspecies and C. bijugum was introduced as a new record for the flora of Iran.

Keywords: Cicer species, Papilionaceae, Cicer arietinum, classical systematic.

P1437. Fagaceous fossils from the Eocene Buchanan Lake Formation, Axel Heiberg Island, Canadian High Arctic

Y. Liu[1], J. F. Basinger[2];
[1]University of Wisconsin-Stevens Point, Stevens Point, WI, United States, [2]University of Saskatchewan, Saskatoon, SK, Canada.

Fagaceous fossils represented by pollen, leaves, and cupule/nuts were recovered from middle Eocene Buchanan Lake Formation, Axel Heiberg Island, Canadian High Arctic. They are assigned to three extant genera, viz. *Castanea, Fagus,* and *Quercus*, and one unassignable taxon (Fagoideae gen. et sp. indet.). The first two genera are only represented by pollen, among which one pollen type of *Castanea* and three pollen types of *Fagus* were recognized, while the occurrence of *Quercus* was supported by both pollen and leaves. On the basis of leaf and pollen morphology, the oak fossils are assigned to two sections of subgenus *Quercus*, viz. sect. *Lobatae* and sect. *Quercus*. The unassignable taxon represents the cupule and nuts, displaying characters not in any extant fagaceous taxon, thus probably representing an extinct member of early Fagaceae lineage. All the fossils might be deciduous in nature, which is consistent with paleoclimate and paleofloristics, reconstructed from other evidence. The study shows that the *Fagus* pollen are probably one of the earliest record and the red and white oaks would be differentiated as early as in the middle Eocene.

P1438. Wood anatomy and chemical identification of oak (Quercus)

R. B. Miller, M. C. Wiemann;
USDA Forest Service, Forest Products Laboratory, Madison, WI, United States.

The wood anatomy of *Quercus* is rather homogeneous, but typically 3 groups of species are recognized: ring porous white oaks, ring porous red oaks and live oaks, which are diffuse porous. In addition to porosity, features used to distinguish the groups are ray height and latewood vessel arrangement. In temperate regions white and red oaks generally follow taxonomic classifications, but subtropical and tropical regions only have live oaks. The phytochemistry of oaks generally revolves around tannin chemistry. Although tannins are present in all oaks, there is a distinct difference in the tannins or precursors between white and red oaks. A 10 % solution of sodium nitrite applied to the transverse surface of oak heartwood clearly distinguishes red and white oaks. White oaks show a positive reaction turning a dark blue or black and the red oaks are negative showing an orange color. This test was performed on all the specimens in our collections and few exceptions were noted.

P1439. Genetic variability of *Quercus faginea* and *Q. broteroi* in Iberian populations

R. Morales[1], J. A. Vicente[1], N. Henriques-Gil[2], A. Galán[1];
[1]Universidad San Pablo CEU, Departamento de Ciencias Ambientales y Recursos Naturales., Boadilla del Monte, Madrid, Spain, [2]Universidad San Pablo CEU, Laboratorio de Genética., Boadilla del Monte, Madrid, Spain.

The genus *Quercus* L. has several taxonomic problems due to its frequent hybridisations and introgressions in the Iberian Peninsula. *Quercus faginea* Lam. was considered as a species divided in two subspecies: *Q. faginea* subsp. *faginea* and *Q. faginea* subsp. *broteroi* (Coutinho) A. Camus. However some authors distinguish them as two species: *Q. faginea* and *Q. broteroi* (Coutinho). Furthermore, these authors indicate two subspecies for *Q. faginea*: *Q. faginea* subsp. *faginea* and *Q. faginea* subsp. *alpestris* (Boiss.) Maire.

After reviewing the morphology of both species, the aim of this work is to find out its biogeographic and genetic variation. Populations of *Q. faginea* and *Q. broteroi* across the Iberian Peninsula were used for this study. Also, other species of genus *Quercus* were included as outgroup. The molecular biology techniques carried out were RFLP and SSR markers.For the first study two pairs of primers from cpDNA were used: trnC-D and trnD-T. The amplified products were digested with Taq I revealing low polymorphism. For this reason, one microsatellite maker from cpDNA (ccmp3) and four from nrDNA (ZAG ½, 15, 36 and 110) were used showing more variability.

P1440. Geometric morphometrics leaf variation in oaks (Quercus) of Central-Southern Italy.

V. Viscosi, P. Fortini;
Dip. S.T.A.T. Università degli Studi del Molise, Isernia, Italy.

Genus Quercus has a problematic taxonomy because of widespread hybrization between the infragenetic taxa. Q. pubescens, Q. virgiliana and Q. dalechampii, dominant trees of mediterranean and temperate forest in Central-Southern Italy, are studied. The patter of morphological leaf variation was evaluated for evidence of hybridization. Since previus studies suggest that oak leaf morphology is a good indicator of putative hybridization. Geometric morphometrics methods were applied to two data set of leaf charcaters from six populations. Landmarks and entire outlines were compared to describe variation in leaf morphology. Similar results were found when differences in shape were analysed by discriminant analyses of shape coordinates (landmarks) and Fourier coefficients (outlines). It appears that there is hybridization involving three taxa studied and the hybridization between Q. pubescens and Q. virgiliana is greater, in the populations sampled.

P1441. Spatial distribution model of cork oak (*Quercus suber*) in south-western Spain

J. Marín[1], P. J. Hidalgo[1], M. Patiño[2], M. A. Heras[1], J. Quijada[2], J. M. Moreira[2];
[1]Biología Ambiental y Salud Pública, Huelva, Spain, [2]Consejería de Medio Ambiente, Sevilla, Spain.

A spatial distribution model of cork oak (*Quercus suber*) has been developed for the province of Huelva (south-western Spain). This model has been carried out by means of the available digital cartographic information of cork oak distribution. The topographic data (altitude, slope and orientation) have been obtained from the Digital Terrain Model (20 m). Rainfall, temperature and PET models have been based on data collected from the network weather stations (NIM). Litologic data have been obtained from litologic map of Huelva (1:100.000). The final scale of work is a mesh of points of 100 m of resolution. Each point of this mesh contains the corresponding values of bioclimatic, topographic and litologic variables in a georeferencied data matrix. Applying binary logistic regression analysis to the data matrix, those variables responsible of cork oak distribution have been pointed out. The spatial distribution model has been produced by applying the equation obtained in the regression to spatial analyst software. This model is proposed as a basis of future reforestation plans, especially in more affected areas by forest fires.

P1442. Where does the Italian cork oak (*Quercus suber* L.) come from? A phylogeographic study using chloroplast markers.

S. Fineschi[1], M. C. Simeone[2], R. Bellarosa[2], D. Magri[3], B. Schirone[2], F. Sevastiani[4], G. G. Vendramin[5];
[1]Istituto per la Protezione delle Piante, Sesto Fiorentino - Firenze, Italy, [2]Dipartimento di Tecnologie, Ingegneria e Scienze dell'Ambiente e delle Foreste, Universita' della Tuscia, Viterbo, Italy, [3]Dipartimento Biologia Vegetale, Università di Roma "La Sapienza", Roma, Italy, [4]Dipartimento di Biotecnologie Agrarie, Università degli Studi di Firenze, Sesto Fiorentino - Firenze, Italy, [5]Istituto di Genetica Vegetale, Sesto Fiorentino - Firenze, Italy.

Cork oak is distributed in Western Europe. It is still debating whether the centre of origin and diversification has to be found only in the Iberian Peninsula. In this study we analysed by chloroplast DNA markers over 40 cork oak populations collected within the Italian distribution range, and compared them with populations sampled in the rest of the natural range. The goals were: i) to describe the phylogeographic structure and to investigate the possible origin of the Italian populations; ii) to infer the potential human impact in shaping the chloroplast diversity. Results showed a strong genetic differentiation among populations. Three groups of haplotypes were detected in Italy, suggesting different origins: 1) Northern-central Italy, 2) the Southern-central regions, including Sicily, and 3) Sardinia. Italian populations do not share haplotypes with the other European and African populations, with the exception of Sardinia (and Corsica) which have the same haplotype of Tunisia and Algeria. We speculate about the possible role that ancient Mediterranean civilisations might have played in determining the present day distribution of cork oak.

P1443. On the ecology and distribution of Quercus macranthera Fisch. et May.

M. C. Simeone[1], A. Papini[2], A. Di Filippo[1];
[1]Dipartimento di tecnologia, ingegneria e scienze dell'Ambiente e delle Foreste (D.A.F.), Universita', Viterbo, Italy, [2]Dipartimento di Biologia Vegetale, Università degli Studi di Firenze, via La Pira 4, 50121 Firenze, Italy.

Quercus comprises 350-500 species distributed throughout the Northern Hemisphere, as conspicuous members of both temperate deciduous and evergreen forests of North America, Europe and Asia. Oak taxonomy is often complicated, as some taxa are not clearly differentiated and distinguishable or may present large clinal transitions in their intermediate positions.

The purpose of the present study was to assess the ecological and distributional features of *Quercus macranthera* Fisch. et May, an oak species endemic to Caucasus and Asia Minor whose geographic range is not yet well defined, mostly due to scarce data and uncertainties on the ranking value of some populations. We present a comprehensive distributional map of the species, including all (eventual) intra-specific entities. Altitudinal, climatic and vegetation components of the interested areas are reported so that the main ecological requirements of the species are delineated. Collected data allow to support the hypothesis of the Euxinian forests (along the southern shores of the Black Sea) as a glacial refugium, with the Caucasus Mountains probably acting as a significant biological barrier.

P1444. Post-glacial evolutionary trends within the genus *Quercus* in Eurasia and America: Divergence versus genome sharing

R. S. Dodd[1], Z. Afzal-Rafii[2];
[1]University of California, Berkeley, CA, United States, [2]CNRS, Universite d'Aix-Marseille III, France.

Climatic cycles during the Quaternary had far-reaching influences on distributions, population sizes, genetic diversity and differentiation in *Quercus*. Divergence associated with displacement to multiple glacial refugia has been documented for European and western North American species. Rates of re-colonization of vacant habitat following the last glacial retreat have been remarkably rapid for *Quercus* considering seed weight and morphology, so that long-distance dispersal events must have been an important mode of migration. Recently, pollen dispersal followed by introgression has been invoked to explain observed patterns of chloroplast sharing in European and western North American species and this may have contributed to long distance dispersal. The high frequency of hybrids within all sections of the genus *Quercus* from North America and Eurasia has been the source of much taxonomic confusion, but may have major evolutionary consequences. Has pollen dispersal been a general mode of colonization since the last glacial maximum in a genus renowned for hybridization and are hybrids merely a dead end, or are they contributing to evolution in this genus?

P1445. Current status of the genus *Quercus* in the Iberian Peninsula

F. Llamas, C. Acedo, A. Molina;
University of León, Leon, Spain.

In *Flora Iberica* there are twelve species reported. Then two more species have been described, *Q. pauciradiata* and *Q. orocantabrica,* and we consider some taxa at different taxonomic level *Q. rotundifolia*, *Q. broteroi* and *Q. subpyrenaica*. We have noticed that hybrids are very frequent when the parents live together, although the hybridization occurs only in some spots of the sympatric area. The leaf trichomes are very specific, and most species can be identified by means of their leaf trichomes. The hybrids always have the trichome types of both parents. *Q. pauciradiata* is considered critically endangered. For other species, there are populations in the edge of its distribution area as *Q. lusitanica* in Galicia, which is considered threatened by hybridization with other species. As many species are forming forests, and there are several laws at regional level protecting some forest types, the species of *Quercus* are protected by these means. Finally, we offer distribution maps as accurate as possible in order to establish the distribution area for the taxa in which this information was not available, and an identification key.

P1446. Taxonomical , anatomical and palynological study on Muscari Mill. species in Iran.

A. Jafari[1], A. Maassoumi[2];
[1]khorassan, Mashad, Islamic Republic of Iran, [2]Tehran, Tehran, Islamic Republic of Iran.

Muscari Mill.is belong to Scillea tribe and Liliaceae. It has 10 species,4 species from subgen.*Leopoldia ,*4 species from *Botryanthus* and 2 species from *Pseudomuscari* in Iran .In this research a record is introduced(*M.microstemum)* from subgen.*Botryanthus*..In anatomical study leaves,stems,roots were cut by microtome (12 micron) and stained by saffranin and fast green. Root had spiral vessel and stem had tracheid.Leaf upper and lower mesopyll is pallisadic in subgen.*Leopoldia* and circular-elliptical in subgen.*Botryanthus* and circular in subgen.*Pseudomuscari In* stem is posed epidermis,2 layers parenchyma,several layers sclerenchyma and parenchyma. For palynological research ,pollens were elliptic,monosulcate,assymetric,distal polar,semitectate and reticulate.In subgen.*Leopoldia* and *Pseudomuscari*,furrow is shallow and narrow and in the subgenus this is deep and large. The result is: anatomy and palynology can show differences between subgenus

P1447. Morphometric analysis of Croatian and Slovenian populations of *Iris sibirica* sensu lato (Iridaceae)

P. Cigic, B. Mitic, T. Nikolic;
Department of Botany, Faculty of Science, University of Zagreb, Zagreb, Croatia.

Species *Iris sibirica* L. s. l. in Croatia and Slovenia include populations from lowlands and mountains. The taxonomical status of mountain populations is not clear, although some authors recognize them as a different taxon (*Iris erirrhiza* Pospichal). As populations variability was detected, but until now not researched, we started with morphometric analyses of populations to detect their possible differentiations. A total of 108 specimens from eleven populations in Croatia and Slovenia were collected. Features for morphometry included: stem length, number of leaves, greatest width of the largest and smallest leaf, length of the largest and smallest leaf, length of the spathe, number of flowers, pedicel length, widths and lengths of falls and standards, length of anthers and filaments, ovary length and length of styles.
Relationships between populations and individual plants were analysed by methods of univariate and multivariate statistics. On the basis of investigated features there was no separation of mountain from lowlands populations. The results are in favour of the opinion that both types of population belong to the same species.

P1448. The ecological importance of a chemotype polymorhism in *Thymus vulgaris*.

B. K. Ehlers[1], J. Amiot[2], P. Gauthier[2], C. Collin[2], Y. B. Linhart[3], J. D. Thompson[2];
[1]Department of Ecology and Genetics, 8000- Århus C, Denmark, [2]Centre d'Ecologie Fonctionelle et Evolutive, CNRS, Montpellier, France, [3]Department of Environmetal Population and Organismic Biology, Boulder, CO, United States.

Thymus vulgaris provides a fascinating example of genetic polymorphism in secondary compound production. In southern France six distinct chemical types (chemotypes) are found. Local populations are mainly dominated by one or two chemotypes creating a striking spatial pattern of chemotype distribution on a very local scale. Our research focus on whether chemotypes show local adaptation to their abiotic and biotic environments and if associated species also show performance variation indicating adaptation to the different chemotypes. Reciprocal transplants of seedlings and adult plants among sites dominated by phenolic and non-phenolic chemotypes were followed over four years. Difference in performance among chemotypes show that phenolic outperfom non-phenolic chemotypes in their phenolic populations providing strong evidence for local adaptation. The performance of an associated grass species from sites dominated by either phenolic or non-phenolic chemotypes provides evidence of adaptation to the environmental modifications associated with the local thyme chemotype. Adaptave variation of thyme and its associated plant species are discussed

P1449. Epidermal leaf structures of the species of genus Micromeria, section Pseudomelissa (Lamiaceae)

V. N. Slavkovska, R. B. Jancic, D. L. Stojanovic, B. S. Lakusic;
Faculty of Pharmacy, Belgrade, Serbia and Montenegro.

The genus Micromeria Bentham includes about 120 species widespread in the Mediterranean region (Doroszenko, 1986). In the flora of Serbia and Montenegro this genus is represented by 10 species, seven of which are endemic (Silic 1979). On the basis of their morphological characteristics the species of the Micromeria genus are grouped in three sections (Boissier 1879): Cymularia, Eumicromeria and Pseudomelissa. In this work we are going to describe surface leaf structures of the following species of section Pseudomelissa: M. thymifolia (Scop.) Fritsch, M. dalmatica Bentham, M. pulegium (Rochel) Bentham and M. albanica (Griseb. ex K. Maly) Silic. Features such as: thickness and ornamentation of the cuticle, epidermal cell walls characteristics, number, distribution and type of stomata, and indumentum density (number and size of the nonglandular and glandular peltate and capitate trichomes) represent structural adaptations to a complex of factors present in the habitats populated by the investigated species. These features can be used as additional characters when defining the species of section Pseudomelissa genus Micromeria.

P1450. Molecular phylogeny of Conradina and other scrub mints (Lamiaceae) from the southeastern USA using nuclear and plastid markers: evidence for hybridization in Pleistocene refugia?

C. E. Edwards[1,2], D. E. Soltis[1], P. S. Soltis[2];
[1]Department of Botany, University of Florida, Gainesville, FL, United States, [2]The Florida Museum of Natural History, Gainesville, FL, United States.

Conradina (Lamiaceae) consists of six allopatric species endemic to the southeastern United States, four of which are federally endangered or threatened. The limits and status of several taxa have been contested based on morphological grounds, and clarification of these limits is necessary for the design and implementation of effective and fiscally responsible protection and management plans. The objectives of this study were to investigate the monophyly of *Conradina* and its relationship to other related mints which are endemic to the southeastern United States, to understand the patterns of diversification in *Conradina*, and to clarify species relationships. A molecular phylogeny was inferred by sequencing regions from the nuclear and plastid genomes from multiple accessions of each species of *Conradina* and multiple individuals from species of *Clinopodium, Dicerandra, Piloblephis, Stachydeoma*, *Monarda, Pycnanthemum,* and *Mentha.* The nuclear and plastid phylogenies conflict, which may be due to shared ancestral polymorphism and lineage sorting, or more likely, introgression that occurred very recently or during the Pleistocene.

P1451. A molecular perspective for tribal concepts and generic boundaries in subfamily Nepetoideae (Lamiaceae)

C. Bräuchler[1], H. Meimberg[1,2], T. Abele[1], G. Heubl[1];
[1]Department Biology I, Section: Biodiversity Research, Systematic Botany, LMU, Munich, Germany, [2]UC Davis, Department of Plant Sciences and Center of Population Biology, Davis, CA, United States.

Among the subfamilies of Lamiaceae Nepetoideae seems to be a well defined monophyletic lineage with three tribes recognised (Elsholtzieae, Ocimeae and Mentheae). Tribal subdivision and generic concepts remain speculative and unclear. We performed comparative sequencing of the *trn*K intron and *trn*L-F region to test relationships within Nepetoideae. Tribes Elsholtzieae and Ocimeae are indicated as subsequent sisters to tribe Mentheae. Subtribe Salviinae is well defined followed by some genera of more or less uncertain affinities. Subtribe Nepetinae is well supported sister to subtribe Menthinae, the members of which are arranged in a four clade polytomy. One clade represents *Satureja* s.str., a second includes genera *Thymus*, *Origanum* and their close relatives. Two sections of *Micromeria* form a third lineage, while one is embedded within a clade chiefly containing *Clinopodium* species. This group colonised the New World probably once starting from Africa. We could confirm tribal but only partially subtribal or generic concepts. *Micromeria* appears polyphyletic and *Clinopodium* as currently circumscribed is paraphyletic to a vast number of genera.

P1452. Biosystematics of tribe Scilleae (Liliaceae) in India: Northern Western Ghats: a likely centre for diversification of tribe Scilleae (Liliaceae) in India

S. R. Yadav[1], U. S. Yadav[2];
[1]University of Delhi, Delhi, India, [2]Willingdon College, Sangli, India.

Tribe Scilleae of the family Liliaceae is represented by three genera viz. *Dipcadi, Drimia, Scilla* and about 16 species in India. Northern Western Ghats of India (hotspot of plant diversity) harbour 12 species of which 10 are endemic and restricted to the region. Genus *Scilla* is represented by 3 species of which two occur in northern Western Ghats. Scilla hyacinthiana is represented by cytotypes with peculiar distribution pattern, morphological variations and blotching patterns of leaf. Out of the 5 Indian species of the genus *Drimia*, 4 are endemic to northern Western Ghats. Both diploids and tetraploids of *D. congesta, D. indica* occur in the region with definite pattern of distribution of cytotypes. *Drimia indica* is found almost throughout India but triploid are restricted to coastal regions of India. Genus *Dipcadi* is represented by 8 species in India of which 6 are found in northern Western Ghats. The study suggests northern Western Ghats to be the likely centre for diversification of the tribe Scilleae in India.

P1453. A Comparative Pharmacognostic Investigation of the Leaves of *Aloe schweinfurthii* and *Aloe vera*

O. M. Odeleye, A. A. Elujoba;
Obafemi Awolowo University, Ile-Ife, Nigeria.

The *Aloe* plant (family: Liliaceae)has been used all over the world for many years for various medicinal and health purposes. Studies on the macro- and micro-morphology of *Aloe schweinfurthii* Baker with reference to those of *Aloe vera* (Linn.) Burm. f., a world acknowledged *Aloes* species, were carried out on the leaf for their comparative identification, authentification, chemo-microscopy, quantitative microscopy and phytochemical profiles that could be used as part of their monographs in the proposed Nigerian Herbal Pharmacopoeia (NHP). The results showed that both *Aloe* species possess many similarities in morphological characters, with some distinct diagnostic differences in their physical characteristics. For example, the stomata number and stomata indices on the lower and upper surfaces for both species show some similarities and differences. Comparative phytochemical screening of the methanolic extracts of both *Aloe* species revealed the presence of free and combined anthraquinones, starch, flavonoids, steroidal and phenolic compounds.

P1454. Systematic Position of *Lilium akkusianum* R.Gämperle (Liliaceae) Based on Morphological and nrDNA ITS Sequence Data

N. Ikinci[1], A. Güner[2], C. Oberprieler[3];
[1]Department of Biology, Abant Izzet Baysal University, Bolu, Turkey, [2]Nezahat Gökyiĵ it Botanical Garden, Istanbul, Turkey, [3]Universität Regensburg, Naturwissenschaftliche Fakultät III-Biologie und Vorklinische Medizin, Regensburg, Germany.

Lilium akkusianum R.Gämperle is an endemic species to North-Eastern Turkey. It has a very narrow distribution area composed of only a few populations. It is closely related to another Turkish endemic *L. ciliatum* P.H.Davis, but can be distinguished from it by larger, less recurved flowers and smaller bulbs. These two endemic species differ from the other yellow-flowering Turkish lilies by long-ciliate hairs on their leaf margins and glabrous leaf veins. Distribution of *L. akkusianum* does not overlap with distributions of other Turkish *Lilium* L. species. Phylogenetic analyses based on majority rule of the sequences of the nuclear ribosomal DNA internal transcribed spacer region (ITS) confirmed the close relationship between *L. akkusianum* and *L. ciliatum*. The results of the molecular studies also revealed that there is sufficient molecular divergence between these two species to support their status as separate species.

P1455. Karyological studies of Liliaceae s. l. taxa in Transcarpathian Region (Ukraine)

R. Kish;
Laboratory for Environment Protection, Botany Department, Uzhgorod National University, Uzhgorod, Ukraine.

In the Transcarpathian Region 35 to 38 wild species (39 to 41 including subspecies) of Liliaceae s. l. (sensu Krause) grow in nature. Cytotaxonomic studies and comparative karyological analysis of about 150 natural populations of these taxa were carried on. It was found that along with stability in some species there is intraindividual and interpopulational variability of the karyotypes according to the level of ploidy, morphology of individual chromosomes, nucleolar-organiser regions of the satellite chromosomes and B-chromosomes. In particular, a considerable B-chromosome polymorphism was observed in Lilium martagon L. populations, taxa of genus Ornithogalum L., the latter showing the inhibiting influence of B-chromosomes accumulation on the development of individuals.

Cytotypes relationship of Transcarpathian and Balkan populations was stated, as well as their difference from the Central European cytotypes, which indicates the Balkan paths of invasion of these species in Transcarpathia. On the other hand, a number of taxa in their karyotype structure are similar to the cytotypes of Central European populations and differ from the Balkan ones.

P1456. A contribution to the systematic relationships among some European taxa of genus Lilium

I. Resetnik, D. Greguras, T. Nikolic;
Department of Botany, Faculty of Science, University of Zagreb, Zagreb, Croatia.

In this paper systematic relationships among several European taxa of genus *Lilium* are discussed, with special observations about the morphologically similar taxa belonging to the *L. carniolicum* group (*L. pyrenaicum, L. carniolicum, L. bosniacum* and *L. jankae*) that have historically been a cause of doubt or confusion. Another objective was to analyse the relationships between *L. martagon* and its close relative, a Dalmatian endemic taxa with an unclear taxonomic status, *L. cattaniae*.

Combined analysis of the restriction-site variation of PCR-amplified cpDNA fragments (trnT-trnL, trnL-trnF and atpB-rbcL), mtDNA fragment (nad4 intron) and nrDNA ITS data was conducted as a first step towards a better differentiation of dubious taxa and to provide the basis for phylogenetic comparisons.

The obtained restriction patterns effectively separated clear taxa, but provided no resolution of closely related taxa. The most systematically valuable was the ITS region which provided separation of clear taxa with all used restriction enzymes.

P1457. Taxonomic revision of the genus *Sticta* (Lobariaceae, Peltigerales) in East Asia

K. Takahashi[1], H. Tsubota[1], L. Wang[2], H. Deguchi[1];
[1]Department of Biological Science, Graduate School of Science, Hiroshima University, Higashi-hiroshima-shi, Japan, [2]Kunming Institute of Botany, Chinese Academy of Science, Kunming, Yunnan, China.

The macrolichen genus *Sticta* are distributed throughout the world but centered in Southern Hemisphere. East Asian species of *Sticta* were taxomically revised. Eleven species were recognized to occur, among which a photosymbiodeme was observed only in *S. wrightii* Tuck. Molecular phylogenetic approach was first applied for the photosymbiodeme of *S. wrightii* based on the specimens collected from Yunnan, China. It suggested that the morphologically different photomorphs of this species share a single mycobiont. The characters recognized to be of taxonomic importance include; (1) the cortex structure including the thickness of epicortex and luster, (2) the shape of isidia (cylindrical to coralloid or phyllidiate), (3) the margins of cyphella (thickened or not thickened), (4) the basal anatomy of apothecia (apothecia with a constricted base or a non-constricted base), and (5) the spore shape (acicular to linear or fusiform).

P1458. Five species of Magnoliaceae New to the flora of Thailand

P. Chalermglin;
Thailand Institute of Scientific and Technological Research, Khlong Luang, Thailand.

The revision of Magnoliaceae in Thailand was reported by King in 1975 with 17 species in 7 Genera ; Aromadendron 1, Kmeria 1, Magnolia 3, Manglietia 1, Michelia 6, Paramichelia 1 and Talauma 4. There are 14 native species and 3 introduced species. After the field and herbarium work on plant conservation project under the initiation of H.R.H. Princess Maha Chakri Sirindhorn since 1996 and reported in 2002 with 23 species in 3 Genera ; Magnolia 20, Manglietia 2 and Pachylarnax 1 due to the new name from proceedings of the international symposium on the family Magnoliaceae in Beijing in 2000. There are 19 native species and 4 introduced species. Five species of native Magnoliaceae are reported as new to the flora of Thailand. They are identified as *Magnolia compressa* Maxim, *Magnolia gustavii* King, *Magnolia mediocris* (Dandy) Figlar, *Manglietia insignis* (Wall.) Blume and *Manglietia utilis* Dandy. Where as *Magnolia gustavii* King and *Manglietia utilis* Dandy were reported as rare and endangered species.

P1459. The Phylogeny and Taxonomy of Magnoliaceae

D. Fu;
Nontimber Forestry Research and Development Center, Zhengzhou, China.

The family Magnoliaceae is one of the most primitive groups of angiosperms and has played an important role in the research of the origin, evolution and systematics of flower plants. In this paper author has reviewed the history and new progress of taxonomic and phylogenetic research, especially the controversial views and insufficiencies of current systems such as Y. H. Law's (1998) and R. B. Figlar & H. P. Nooteboom's (2004). Some important species with special taxonomic meanings are discussed and some new taxa are described. Moreover the new phylogenic viewpoints, new cladogram and new system of the family are put forward. The system includes 3 subfamilies: Michelioideae (Law) D. L. Fu, subfam. comb. nov., *Magnolioideae* and Liriodendroideae (Bark.) Law, 5 tribes: Michelieae Law, Yulanieae D. L. Fu, trib. nov., Alcimandrieae (Law) D. L. Fu, trib. comb. nov., Magnolieae and Kmerieae D. L. Fu, trib. nov., 10 genera: *Michelia* L., *Paramichelia* Hu, *Yulania* Spach, *Alcimandra* Dandy, *Gynopodium* (Dandy) D. L. Fu, gen. comb. nov., *Magnolia* L., *Talauma* Juss., *Pachylarnax* Dandy, *Kmeria* (Pierre) Dandy and *Liriodendron* L..

P1460. The ancient flora fossil of México

D. Hernández Láscares[1], E. Galvan Mendoza[2], V. Salazar Vazquez[3];
[1]Universidad Autónoma Metropolitana, México, D.F., Mexico, [2]Facultad de Estudios Superiores, Zaragoza. UNAM, México, D.F., Mexico, [3]Secretaría del Medio Ambiente y Recursos Naturales, México, D.F., Mexico.

The ancient flora fossil of Mexico aged from the Superior Carboniferous, 320 million years, it is known as flora “Matzitzi” and its location is in the state of Puebla on the central south part of Mexico. What characterizes this group is the Carboniferous worlds variety and rich typical flora to determine the age, it was based on the data of sub-overjacent rocks, on measures of stratigraphical sections, on geological mapping, on petrographical and paleobotanical studies. The flora, it is mainly made up of the: *Sigillaria sp., Spenophylum sp., Anularia sp., Calamites sp., Lepidodendron sp., Holcospermum sp.* genders, and of a significant group of *Marattiales,* as well as, of a similar branch of Gyngophytas. Currently the collection consists of more than one thousand specimen that were found within three hundred square kilometers. The similarity of its flora in regard to other latitudes (northeast of usa, southeast of Canada, France, Spain Germany, England, Poland, Checoslovakia, and South Asia), permits to propose that the mexican flora is more related to the northern hemisphere (Laurasia) than to the southern hemisphere (Gondwana).

P1461. Taxonomical revision of Behuria Cham. (Melastomataceae), a endemic genus from Brazil.

J. F. A. Baumgratz[1], R. A. M. Tavares[2];
[1]Instituto de Pesquisas Jardim Botânico do Rio de Janeiro; Bolsista CNPq, Rio de Janeiro, Brazil, [2]Instituto de Pesquisas Jardim Botânico do Rio de Janeiro, Rio de Janeiro, Brazil.

Its presents a taxonomic revision of the neotropical genus Behuria. The morphological study has been analysed the external morphology. Some anatomical characters of the leaves have also analysed to typify the trichomes and vascularization patterns. In the taxonomic treatment, 14 spp. are recognized, in which one taxon is described for the first time. It is provided a key to identify the species, morphological descriptions, illustrations, distribution maps, taxonomic comments, phenology and geographic distributional data of the taxa. For the first time, the occurrence of interpeciolar stipules is signed to Behuria, besides verticillate leaves. The center of genetic diversity of the genus is the Atlantic Forest vegetation in Rio de Janeiro state, where 10 spp. are found and 9 spp. are endemic. New synonyms are proposed: Benevidesia under Behuria and Behuria mouraei var. rotundifolia under Bisglaziovia. All species had their typus material characterized and some lectotypes were designated. Comments with close related genus, mainly Bisglaziovia and Huberia, are also presented.

P1462. Phylogenetic relationships of the Urticaceae, Cecropiaceae and Moraceae based of its comparative carpology

T. I. Kravtsova, A. A. Oskolski;
Komarov Botanical Institute, St.Petersburg, Russian Federation.

Comparative morphological and anatomical study and cladistic analysis of the fruit diversity in the members of the most Urticaceae, Cecropiaceae and in several Moraceae genera is carried out. The results obtained by traditional methods support the distinction between three families studied. The “intermediate” family Cecropiaceae (Berg, 1978) is more closely related to Urticaceae, than Moraceae, which is in accordance with the opinion of Corner (1962) and recent molecular data (Systma et al, 2002, Datwyler & Weiblen, 2004). The Cecropiaceae is found to be heterogeneous taxon probably isolated early in the evolution of the Urticales. Contrarily, the cladistic analysis based on carpological data shows the derivied position of the Cecropiaceae: the genera Musanga, Cecropia, Coussapoa belong to distinct Afro-American clade within the Urticaceae, whereas the position of the Australasian genus Poikilospermum remains unclear.

P1463. Cytoplasmic genotyping of *Musa* diploid and triploid accessions revealing hybrid origins and their geographical distribution.

R. Boonruangrod, D. Desai, K. Burg;
Austrian Research Centre Seibersdorf, A2444 Seibersdorf, Austria, Seibersdorf, Austria.

The *Musa* genome is constantly expanding with its high rate of somaclonal variations. The current classification based on morphological characters and predicted genomic constitution after crossing over makes this system unreliable for sterile, heterozygous and polyploid *Musa* accessions. There is an urgent need of molecular markers system for screening of *Musa* accessions. Due to its uniparental inheritance cp and mtDNA provides an interesting and comprehensive tool for parental analysis of plants. In this study we have used cpDNA and mtDNA PCR-RFLP marker system revealing hybrid origins and geographic distribution of 48 *Musa* accessions using universal primers. So far we have detected 31 and 35 cytotypes with mtDNA and cpDNA markers respectively. Phylogenetic analysis provided the clear distinction between A and B cytoplasm and relationships between their polyploid progenies. The organellar genome analysis of *Musa* showed that the use of conserved gene markers for cp and mtDNA analysis is not only useful in determining inter and intraspecific variation but also for confirming hybrid origins and geographic distribution of *Musa* accessions.

P1464. Lineages in Banana Cultivars as Revealed by DNA Sequence Polymorphisms

S. Swangpol[1,2], H. A. Volkaert[3,4], T. Seelanan[1];
[1]Chulalongkorn University, Bangkok, Thailand, [2]Mahidol University, Bangkok, Thailand, [3]Kasetsart University, Nakorn Pathom, Thailand, [4]NSTDA – BIOTEC, Pathum Thani, Thailand.

We have explored the use of polymorphisms at chloroplast (cp) and nuclear (nu) gene loci to determine the genealogy of cultivated bananas. Four cp marker loci; *rpl*16 and *ndh*A introns, *psa*A-*ycf*3 and *pet*A-*psb*J-*psb*L-*psb*F intergenic spacers, and one nu marker corresponding to part of *Gbss* gene have been developed. *Musa acuminata* (A) and *M. balbisiana* (B)-genome derived alleles could be easily distinguished at each of the loci. Five maternal lineages were identified. Diversity within triploid hybrids was found and particular B-genome-rich triploids (ABBs) were given new genome designation as BBAs to indicate their maternal genealogy. Two *Gbss* loci were found in the investigation of the nu genome. Relationships of these bananas were inferred using neighbor joining and maximum parsimony methods. Our DNA sequence investigation opens the opportunities to easily trace lineages of contributing genomes within the banana cultivars, which subject has been puzzled crop scientists for decades.

P1465. New species in Myrtaceae and Leguminosae from Brazil.

L. H. Soares-Silva[1], V. F. Mansano[2], M. Sobral[3];
[1]Universidade de Brasília, Brasília, Brazil, [2]Jardim Botânico do Rio de Janeiro, Rio de Janeiro, Brazil, [3]Universidade Federal de Minas Gerais, Belo Horizonte, Brazil.

Two new species from Paraná State, Brazil are described: *Eugenia myrciariifolia* Soares-Silva & Sobral (Myrtaceae) and *Exostyles godoyensis* Soares-Silva & Mansano (Leguminosae). The first species is a small tree from seasonal forest of central and western Paraná, up 5 m high, with spathulate to linear cataphylls in base of younger twigs. The specific epitet is allusive to the resemblance of this species with some of the genus *Myrciaria,* especially *Myrciaria tenella* O. Berg, with which it can be easily confused when sterile due to its small leaves and dense foliation. The other one is the fourth species described in the small genus *Exostyles.* This species, from submontane semideciduous forest of the state of Paraná, is geographically disjunct from all the other species in the genus. It´s a tree up 20 m high known only from type locality, required classification as critically endangered (CR) according to the IUCN (2001) categorization. The both species are illustrated.

P1466. Microsporogenesis and Gametogenesis in *Oncidium flexuosum* Sims and *Calanthe lyroglossa* Reichb. f. (Orchidaceae)

M. H. Chuang, C. S. Kuoh;
Department of Life Sciences, National Cheng-Kung University, Tainan, Taiwan Republic of China.

Microsporogenesis and gametogenesis in two orchids, *Oncidium flexuosum* and *Calanthe lyroglossa* were studied with both Light and Electronic Microscopy, and the tissue processor, PELCO BioWave®, was choose for fixation, dehydration, resin infiltration and staining the sample of *C. lyroglossa*.
The results show that the differentiation and development of pollen grains in pollinia are position related. In microsporogenesis, the tetrahedral and decussate tetrads make up the bulk of the pollinia, and the linear tetrads can only be found at the outside of the pollinia. In gametogensis, the inner pollen grains with only intine are major for pollen germination, and the outer pollen grains with tectum are major for protection. The pollen grains are differentiated into two types both in structure and function.
Meanwhile, we recommend to use microwave equipment that can keep pace with the ever-quickening need for rapid specimen turnaround while maintaining quality as high as ever.

P1467. Molecular phylogeny of *Phalaenopsis* Blume (Orchidaceae) based on the internal transcribed spacer of the nuclear ribosomal DNA

C. H. Chou[1,2], C. C. Tsai[3,2], S. C. Huang[4];
[1]National Pingtung University of Science and Technology, Pingtung, Taiwan Republic of China, [2]National Sun Yat-sen University, Kaohsiung, Taiwan Republic of China, [3]Kaohsiung District Agricultural Improvement Station, Pingtung, Taiwan Republic of China, [4]Floricultural Research Center, Taiwan Agricultural Research Institute, Taichung, Taiwan Republic of China.

The internal transcribed spacer of ribosomal DNA was sequenced from 53 species of genus *Phalaenopsis*. A phylogeny was developed for the genus based on the neighbor-joining and maximum parsimony analyses of molecular data. This result concurred that the genera *Doritis* and *Kingidium* should be treated as being parts of the genus *Phalaenopsis* suggested by Christenson (2001). Within the genus *Phalaenopsis*, both subgenera *Aphyllae* and *Parishianae* were not monophyletic and highly clustered with the subgenus *Proboscidioides* plus sections *Esmeralda* and *Deliciosae* of the subgenus *Phalaenopsis*. Those species also have the same characters of morphology of four pollinia and similar biogeography. Furthermore, both subgenera *Phalaenopsis* and *Polychilos* were also not monophyletic. Within the subgenus *Phalaenopsis*, only section *Phalaenopsis* was highly supported to be monophyletic. As to the subgenus *Polychilos*, only section *Polychilos* was moderately supported to be monophyletic. In conclusion, the present molecular data obtained from the ITS sequence of nrDNA of the genus *Phalaenopsis* provided valuable information for elucidating the phylogeny of this genus.

P1468. Detecting bias in host and fungal associates of three epiphytic *Aeridinae* orchids of Australia

K. M. Gowland[1,2], M. A. Clements[2], A. B. Nicotra[1];
[1]School of Botany and Zoology, Canberra, Australia, [2]Center for Plant Biodiversity Research, CSIRO, Canberra, Australia.

An epiphyte is an organism that utilizes another organism as a substrate upon which to live. Epiphytes derive no direct benefit from, nor do they confer any direct benefit to their host, thus most epiphytes are not host specific. Despite this, research on three epiphytic *Aeridinae* orchids of eastern Australia uncovered non-random distribution patterns within four disparate field sites. Two of the orchids, *Sarcochilus olivaceous* and *Plectorrhiza tridentata*, exhibited distinct host species preferences. All orchids depend upon a mycorrhizal fungus to germinate, thus it is intuitive that the host bias reflects a non-random fungal distribution. To test this hypothesis *Rhizoctonia*-like fungi were isolated from orchid roots from two field sites, pure cultures were obtained and the nuclear ribosomal ITS sequences of these isolates determined. The results suggest that these fungi are neither restricted to particular species of woody plants, nor to the different sites. They also demonstrate that these orchids associate with distinct clades of *Ceratobasidium* fungi and that their fungal associates correlate strongly with their ecological preferences.

P1469. Phylogenetic and geographical analyses of the orchid genus *Bulbophyllum* on Madagascar and the Mascarenes: can main speciation bursts be correlated with climatological, geological or ecological changes?

G. Fischer[1], B. Gravendeel[2], P. Cribb[3], T. Pailler[4], M. Kiehn[1], P. Heiselmayer[5];
[1]Institute of Botany, Vienna, Austria, [2]Nationaal Herbarium Nederland, Leiden, The Netherlands, [3]Royal Botanic Gardens Kew, London, United Kingdom, [4]Faculte des Science et Technologies Reunion, Saint-Denis, France, [5]Department of Organismic Biology -Study Group Ecology and Diversity of Plants, Salzburg, Austria.

The project proposed primarily aims a phylogenetic and biogeographic analysis of the Madagascan and Mascarenes species of Bulbophyllum (Orchidaceae), taking current and historical data into account.
The project proposes to apply three different techniques to determine whether main speciation bursts correlate with climatological, geological or ecological events. First, main clades

of closely related species will be identified and dated using phylogenetic analyses of DNA sequences and calibrations by vicariance. Secondly, analyses of distribution patterns using GIS will be performed to identify species-rich areas. Finally, possible correlations between main speciation events and climate, geology and ecological parameters will be investigated using phylogenetic-contrast analyses. The results will constitute an important evaluation of a major species-rich group of plants and provide a basis for designing areas deserving nature protection on Madagascar.

P1470. Intra- and inter-specific relationships in *Epidendrum* section *Amphiglottium* (Orchidaceae) inferred from AFLP markers

F. Barros[1], F. Pinheiro[2], A. Salatino[2], M. L. F. Salatino[2];
[1]Institute of Botany, São Paulo, Brazil, [2]University of São Paulo, São Paulo, Brazil.

The section *Amphiglottium* is an example of the variability that can be found in the genus *Epidendrum* L., with their polymorphic species, such as those in the *Epidendrum secundum* complex. The goal of this study was to clarify the relationships among the species of *Epidendrum* section *Amphiglottium*, and between them and the subsections *Carinata* and *Tuberculata*, by means of the AFLP (Amplified Fragment-Length Polymorphism) procedure. Three combinations of pairs of primers were employed (AC/CTA, TG/CTC, and AG/CTT) in 70 accessions. The data was processed by Cluster Analysis using UPGMA, with Jaccard's coefficient. The accessions of subsection *Carinata* were split into two groups: the first covers species from the Amazon Plateau, Andes, and the Brazilian Central Plateau, and the second contains species from the Atlantic seashore, and Southeastern Brazil. Subsection *Tuberculata* emerges as a different group, that were also split into two sub-groups: the first encompassing plants with lilac, orange, red or white flowers, that may be a single species - *E. secundum*; the second containing only plants with yellow flowers, which may also be a single species - *E. xanthinum*.

P1471. Circumscription and Interspecific Relationships of *Masdevallia* Subgenus *Pygmaeia* (Orchidaceae - Epidendroideae - Pleurothallidinae)

A. D. Abele, J. G. Rohwer, B. Rudolph;
Biocenter Klein Flottbek, University of Hamburg, Germany.

Pygmaeia is the most taxonomically complex as well as confused subgenus in the genus *Masdevallia*. It includes 34 species grouped in four sections previously recognized as groups within the subgenera *Masdevallia* and *Amanda*. To examine the circumscription and resolve interspecific relationships of subgenus *Pygmaeia* 20 taxa were investigated using DNA sequence data from the nuclear internal transcribed spacers (ITS) as well as morphological data. Parsimony analyses of both individual and combined data sets indicated that subgenus *Pygmaeia* is polyphyletic. Its species are resolved as members of two well - supported clades: the first clade includes species of sections *Zahlbrucknerae* and *Amaluzae,* the second clade includes species of sections *Amaluzae, Aphanes* and a representative of section *Pygmaeae*, viz. *M. hoeijeri*, recently transferred to a new genus, *Diodonopsis.* The second analyzed member of section *Pygmaeae*, *M. erinacea,* for which the genus *Diodonopsis* was erected, does indeed fall out of *Masdevallia* as previously published.

P1472. The "fly orchid" *Telipogon nervosus*: Morphology and anatomy of a bizarre regular flower in a bilateral neighborhood

N. Pabón Mora, F. González, G. Romero de Pérez;
National University of Colombia, Bogota, Colombia.

The Neotropical genus *Telipogon* (Orchidaceae-Epidendriodeae-Maxillarieae) consists of ca. 100 spp., some of which have regular perianth. The genus was included (as a synthetic terminal taxon) by Freudenstein & Rasmussen (1999) but most floral characters remain missing or obscure. We studied the floral development, anatomy and morphology of *T. nervosus*, a high-Andean species, which exhibits regular perianth. The vasculature of the labellum is more complex than that of the lateral inner tepals, which are located below the labellum. Two different types of unicellular trichomes in the column are associated to the pseudocopulation syndrome of these orchids with Tachnid flies; the short trichomes are located mostly towards the base of the labellum, whereas the long ones are mostly around the single 2-celled anther. There are 4 pollinia attached to a tegula. The ontogeny of the inner tepals (associated to the regular symmetry), the anther, and the gynoecium is discussed. Resupination is also discussed along with the inflorescence morphology. Finally, the structure of the ovary, including the massive, commissural structures along the carpels, is also discussed.

P1473. Rooting the Orchids: Testing root anatomy in the *Dryadella-Masdevallia-Porroglossum-Trisetella-Pleurothallis-Scaphosepalum- Platystele* clade (Orchidaceae: Pleurothallidinae)

E. C. Buitrago Delgado;
Instituto de Ciencias Naturales, Universidad Nacional de Colombia, Bogota, Colombia.

Colombia is one of the most diverse countries worldwide in the orchid family, with ca. 205 genera and 3 200 species. The subtribe Pleurothallidinae, with c 32 genera and 4000 species in the New World, is particularly rich in Colombia. Phylogenetic analyses in the Pleurothallidinae subtribe have been increased recently. Unfortunately the sampling is still limited in studies based upon both molecular (e.g. Pridgeon *et al.* 2001) and morphological (e.g. Neyland *et al.* 1995) data. Furthermore, these analyses have arrived at conflicting phylogenetic relationships of genera such as the New World *Porroglossum*. This genus is recognized as all their species have a remarkable tactile mechanism on their labellum. In a more inclusive level, Neyland *et al*. (1995) proposed some anatomical characters of the velamen as potential sinapomorphies of the clade formed by the genera *Dryadella - Masdevallia - Porroglossum - Trisetella - Pleurothallis - Scaphosepalum - Platystele,* all of them present in Colombia. In this work, we are testing in a phylogenetic context the anatomical characters related to the roots in a broader sampling of these genera, primarily from Colombian species.

P1474. The influence of habitat conditions on individuals characteristics of *Dactylorhiza fuchsii* (Druce) Soó in the Snieznik Massif (Poland)

J. Pokorny;
The Agrucultural University of Wroclaw, Department of Botany and Plant Ecology, Wroclaw, Poland.

The reserch was carried in the Snieznik Massif (Sudeten Mts.) out in 1999-2005. The subject of the research was study of populatios of *Dactylorhiza fuchsii.* This species grow in the meadows and pastures of class *Molinio-Arrhenatheretea,* water-logged spruce trees and broad-leawed forest of class *Querco-Fagetea.* This species characterizes great differentiation of individuals characteristics. This study plants divided in the 4 of groups. (I group)The plants that are growing in the alkaline and sunny habitat, have short and gnarly inflorecence (4-6 cm), leafs (6-8cm), often the colour of light green without spots. (II group) The plants are growing in the acid habitat, water-logged and shaded have long (8-12 cm) and narrow (1,7-2,5 cm) leafes the colour of dark-green for spots and loose inflorescence. (III group) This plants are growing in the alkaline and forest habitat, often water-logged have long and oval leaf, for dark spots.(IV group) This plants are growing acid and sunny habitat, length plants 30-45 cm.The study has been covered by the research study No.3P04 G 01224 in the years 2003-2006 funded by the Ministry of Research and Information Technology.

P1475. Taxonomical, Morphological, and Anatomical Investigations on Some Species of *Orchis* L. in Central Anatolia

E. Ataκlar;
Science & Art Faculty, Eskķ ehķ, Turkey.

Ebru ATASLAR, Meltem ERTEN, Ilham POYRAZ
Osmangazi University, Eskisehir, TURKEY

In this study, the morphological, taxonomical and anatomical properties of three taxa of *Orchis* namely *Orchis mascula* (L.) L. subsp. *pinetorum* (Boiss. & Kotschy) G.Camus, *O. tridentata* Scop. and *O. coriophora* L., collected from center Anatolia, have been studied. It is determined that they mostly variable in size, shape of labellum, lenght of sepal hood, sepal shape and coloration of floral parts. The findings were compared with those in Flora of Turkey.

In Turkey, for many centuries, various kinds of *Orchis* have been extracted from the tubers and exported under the name of *Sahlep*, hot drink during the winter. *Orchis mascula* and *O. coriophora* have the tubers entire and usually used for making the *Sahlep* and ice-cream. They have widely distribution in Turkey but due to of excessive gathering by indigenious people, their natural population have been decreasing in the course of time.

The studies on cross-sections of the root, stem, leaves and surface sections of leaves of these three *Orchis* members are also presented with their anatomical similarities and differences.

P1476. Contribution of Biomechanics to the analysis of anatomically-preserved fossil plants - a late Devonian example: the genus *Pietzschia* Gothan (Cladoxylopsida)

A. Soria[1], N. P. Rowe[2], T. Speck[1];
[1]Plant Biomechanics Group, Freiburg, Germany, [2]AMAP CIRAD, Montpellier, France.

The biomechanical approach developed by Speck and Rowe, aimed at determining growth forms characterizing terrestrial vascular plants, is applied to the study of the late Devonian anatomically-preserved genus *Pietzschia*(Cladoxylopsida). This genus includes three species on which we performed an architectural and developmental analysis. The latter resulted in plant reconstructions for two species, *P. schulleri* and *P. levis*. The third one, *P. polyupsilon*, provided a number of structural informations. On this basis, the biomechanical properties of the three species were explored. Our work shows the essential role of Biomechanics in the study of anatomically-preserved fossil taxa, validating the preliminary reconstructions. A mixed biomechanical signal is identified in *P. levis*, originally reconstructed as an erect plant not exceeding 2 m high. A semi-self-supporting growth form is assigned to the large-sized species *P. schulleri*. Our analyses revealed that the typically-cladoxylopsid dissected vasculature does not play a significant role in the stability of stems. The biomechanical approach also highlighted a number of ecological aspects.

P1477. *Condrusia* : a novel Famennian pre-ovulate structure.

C. Prestianni;
Paléobotanique, Paléopalynologie et Micropaléontologie, Sart-Tilman, Belgium.

The genus *Condrusia* has briefly been described by Stockmans in 1948 as a putative seed. New specimens from six late Famennian (Upper Devonian) localities from Southern Belgium allow us to demonstrate that Condrusia possesses the traits that characterises pre-ovules.

The cupule of *Condrusia* is composed of two flat bilaterally symmetrical wings appressed against each other. The cupule is thought to have played a major role in the dispersion of the pre-ovule. Sections have allowed us to understand the structure of the pre-ovule body (integument, nucellus and megaspore) which is radiospermic. The sections further suggest that the integument is not dissected into lobes and show a complex organisation with three layers, the middle one consisting of large sclerified cells. The nucellus appears to be fused with the integument. Its apex is modified into a very long salpinx protruding above both the integument and the cupule.

Condrusia, with its bilaterally symmetrical cupule, its complete complex integument, and its very long salpinx, illustrates a novel and highly distinctive architectural type amongst the Upper Devonian pre-ovules.

P1478. Growth of the earliest land plants is promoted by epiphytic bacteria

U. Kutschera;
Institut für Biologie, Universität Kassel, Kassel, Germany.

Liverworts, the most basal lineage of extant land plants, have been used as model systems in the reconstruction of adaptations to life on land. In this study we used gemmae (specialized propagules) that were isolated from mature gemma cups of two distantly related species of liverworts, *Marchantia polymorpha* L. and *Lunularia cruciata* L. (order Marchantiales). We show that methylobacteria (genus *Methylobacterium*), microbes that inhabit the surfaces of land plants where they secrete certain phytohormones, promote the growth of isolated gemmae cultivated on agar plates. As a control, two species of higher plants, maize (*Zea mays* L.) and sunflower (*Helianthus annuus* L.) were raised aseptically from sterile seeds (i. e., caryopses, achenes). Inoculation of these propagules with methylobacteria was without effect on growth in the above-ground phytosphere (expansion of stems and leaves). We conclude that normal development of the "living fossil" - plants *Marchantia* and *Lunularia* is dependent on (and possibly regulated by) epiphytic methylobacteria, whereas higher plants grow at optimal rates in the absence of these prokaryotic epiphytes.

P1479. Adaptive Strategies of Aquatic Basal Angiosperms and Monocots

J. L. Seago, L. C. Marsh;
State University of New York at Oswego, Oswego, NY, United States.

We explore the adaptive strategies of representative families of aquatic plants from the Basal Angiosperms through Monocots in order to explain the basis for the prevalence of aquatic Monocots, especially rooted floating and emergent macrophytes, and their dominance of certain wetlands. In the existing habitats of these plants, clonal reproduction is common whereas seed production leading to seedling establishment occurs more often in new habitats. The plants dominate their habitats by clonal reproduction and appear to use seed reproduction most successfully in extending their habitats. Successful adaptive strategies involve overcoming anoxic conditions imposed upon their roots, transport of oxygen from aerial environments to anoxic root conditions, and evolution of root/shoot aerenchymatous systems. The occurrence of cortex modifications of aerenchyma and barrier layers, endodermis and hypodermis (exodermis), is characteristic not only of roots, but also of shoots in the substrate or water for many plants. It also appears that many exhibit phenotypic plasticity, especially in some of their anatomical and morphological characters.

P1480. Application of petiole anatomy in taxonomic problems and relationships of some *Peucedaneae* and *Smyrnieae* (Apiaceae) in Iran

Y. O. U. Ajani;
Department of Biology, Faculty of Science, Tehran University, Tehran, Islamic Republic of Iran.

Opopanax hispidus and *Smyrniopsis aucheri* (*Smyrnieae*) have been placed in two different tribes (senso Drude), but the recent classification based on cpDNA sequences has shown that they constitute a monophyletic group. This study also showed that they shared in some significant character.

Opopanax with *Laser* and *Leutea* with *Dorema* based on serotaxonomical researches considered as a close genera. This study also showed that they have a similar characters.

The monotypic genus *Azilia eryngioides* has also some common character with *Leutea.*

Another monotypic genus *Haussknechtia elymaitica* that was supposed synonym or very close to *Dorema,* this study clearly showed that they are very far from each other.

Members of *Peucedanum* complex based on recently cpDNA sequences constitute a polyphyletic group, but all members in Iran have a common character. However, in comparison with other species of the other part they don’t show a similarity.

P1481. Study of effects plant density on quality characterizes in wheat (Triticum aestivum.L)

O. -. Masoudifar;
-, Tehran, Islamic Republic of Iran.

In order to evaluating of row spacing and seed value on quality characterizes in Kohdasht wheat (*Triticum aestivum.L.*)and study about new cultivar an experiments was conducted under dry land farming in experimental farm of Agricultural Research Center of Gonbad (Golestan province- Iran)in 2003-2004(farming year).The experiments was arranged as randomized complete blocks design (statiscal methode)with three replication (1200 m2).The treatments resulted from the factorial combination of three row spacing (12.5 , 17and 25 cm) and four seed value (250, 300, 350 and 400 seed per m^2). After expriment , in chemical labrotary for plants and with SAS program ,Zeleny index was significantly affected by different seed value .And water adsorption percentage was significantly by interaction effect. Study of results showed the best row spacing is 17 cm and seed value is 300-350 seed per m^2

P1482. Winter wheat yield increase through wheat, alfalfa, fallow, soybean rotation and application of manure in Varamin province in Iran

I. Alahdadi, N. Schahbazian, H. Iran-Nejad, G. Abbas Akbari;
University of Teheran, Abouraihan Campus, Department of Agronomy and Plant Breeding, Teheran, Islamic Republic of Iran.

A two year (2001-2002) experiment was conducted to study the effect of winter wheat rotation with legume crops and the effect of fallow and different amounts of manure on success of winter wheat crop in the region of Varamin. The experiment was initiated on a land laid fallow for the two precedent years, and was arranged in a split plot design with winter wheat, annual alfalfa, soybean and fallow as main plot and manure levels (0 and 5 t/ha) as subplots.In 2001 a single wheat crop was cultivated and a two factorial experiment in four replications was carried out. The manure and rotation effects were positively significant on winter wheat yield and its components. In rotation of wheat, fallow, soybean, alfalfa, 1860, 2579, 4080 and 4830 kg/ha of grain yield in manure treated plots and 1490, 2090, 3130 and 4100 kg/ha of grain yield in no manure plots were obtained respectively. The results of this study showed that using winter wheat yield in rotation with annual alfalfa and soybean with manure application brought considerable increase in yield.

P1483. Geographical pattern in genome size of *Festuca pallens*: phylogeographical interpretation of distribution range of polyploid complex.

P. Šmarda, P. Bureš;
Masaryk University in Brno, Brno, Czech Republic.

Considerable genome size variability in both ploidy levels and at various spatial scales was detected in *Festuca pallens* Host using DAPI stained flow-cytometry. Witnin- and among related sites, DNA content was relatively homogenous. However, mean differences up to 5.9 % between nearby localities or up to 11.6 % within the populations were rarely detected. Within the whole distribution area, maximum differences 15.9 % (in diploids) and 14.0 % (in tetraploids) were observed. In both ploidy levels, genome size was correlated with geographical coordinates, with the largest genomes situated in the southeastern parts. Mutual geographic relation between DNA content of diploids and tetraploids was confirmed. Tetraploids have in general lower DNA content than expected by doubling of their diploid progenitors. The main differences in DNA content of tetraploids were attributed with affiliation to 3 different, taxonomically unevaluated types. Affinity of larger genomes to different types of glacial vegetation (steppes rather than periglacial tundra, together with relation to relict habitats in diploids, give reasons for phylogeographic interpretations.

P1484. C3 photosynthesis in Aristida longifolia: Implication for diversification of photosynthesis in Aristidoideae (Gramineae)

R. Cerros--Tlatilpa[1,2], J. Travis Columbus[2];
[1]Universidad Autonoma del Estado de Morelos, Cuernavaca, Morelos, Mexico, [2]Rancho Santa Ana Botanic Garden, Claremont, CA, United States.

Aristida (ca. 300 species) is one of three genera in Aristidoideae (Gramineae) along with Sartidia (4) and Stipagrostis (50). The genus is distributed in the tropics and subtropics, growing on grassy plains, arid lands, and open ground. Studies of this taxonomically difficult genus have relied primarily on morphology and anatomy. Aristida and Stipagrostis carry out C4 photosynthesis (NADP-ME and NAD-ME, respectively), whereas Sartidia undergoes C3 photosynthesis. A survey of the leaf blade anatomy of Aristidoideae and carbon isotope ratio tests has revealed the presence of non-Kranz anatomy and C3 photosynthesis in Aristida longifolia Trin. This species is distributed from Central to South America and grows in partial shade along margins of gallery forests. This discovery represents the second report of non-Kranz anatomy and C3 photosynthesis in Aristidoideae. The first report involves species of Aristida now treated in the segregate genus Sartidia. Molecular phylogenetics of Aristidoideae indicate that A. longifolia does not form a clade with Sartidia but is sister to the remaining Aristida, and that C3 photosynthesis is likely pleisiomorphic.

P1485. Phylogenetic relations of the South American species of *Rytidosperma* Steud. (Danthonioideae, Poaceae) based on morphoanatomical characters

M. A. Ortúzar[1], M. A. Negritto[2], E. Ruiz[2], C. M. Baeza[2], W. Cruz[3];
[1]Instituto de Botánica, Universidad Austral de Chile, Valdivia, Chile, [2]Departamento de Botánica, Universidad de Concepción, Concepción, Chile, [3]Lab Bioquimica y Biologia Molecular, Univ Nac. Federico Villarreal, Lima, Peru.

The phylogenetic relations among 36 species of *Rytidosperma* Steud. (Poaceae) were inferred from 21 morphological and anatomical characters. The matrix was elaborated from direct measurements and observations of the six South American species *R. lechleri* Steud, *R. pictum* (Nees et Meyen) Nicora, *R. quirihuense* C.Baeza, *R. sorianoi* Nicora, *R. violaceum* (Desv.) Nicora, *R. virescens* (Desv.) Nicora besides Easter Island's *R. paschale* (Pilg.) C. Baeza. They were after put together in the matrix with the rest of the *Rytidosperma* species used by Linder and Verboom (1996). Parsimony Analysis were applied through the Ratchet Method utilising Winclada ver. 1.00.08. *Danthonia unispicata*, *Danthonia malacantha* (Poaceae), *Tribolium pusilla* (Poaceae) and *Schismus inermis* (Poaceae) were considered as outgroups, rooting the cladogram from the former species. The results support the hypothesis that the South American species conform a monophyletic clade.

Grant Mecesup UCO0214

P1486. Revision of Monnina (Polygalaceae)

A. Freire-Fierro;
Missouri Botanical Garden, St. Louis, MO, United States.

Monnina (Polygalaceae) is a genus of herbs and shrubs distributed from southwestern United States to southern South America. It occurs from sea level to 4100 m in both open and forested areas. It has three subgenera, about 150 species and almost 400 names. Although there are floristic treatments for species from North and Central America, Brazil, Colombia, Ecuador, Peru, Venezuela, and a century old taxonomic treatment, there is no comprehensive monograph of *Monnina.*

At least for identification purposes, these morphological characters seem to be the most informative: extra-floral nectaries, habit, stems and leaves vestiture, external sepals, fruits, and filaments. In addition, most of the species with similar flower morphology seem to have two character suits: 1) herbaceous plants, lax inflorescences, dry fruits and lowland distribution; and 2) woody plants, dense inflorescences, fleshy fruits and highlands distribution. A third group of species also has herbaceous plants with lax inflorescences and lowland distribution, but it has fleshy or dry fruits and different flower morphology.

P1487. Molecular phylogeny of the Polygonaceae based on chloroplast *matK* Sequences

M. Kim, H. Won, C. Park;
Seoul National University, Seoul, Republic of Korea.

Polygonaceae comprises approximately 1000 species in about 40 genera. Most species within the family show very complicated patterns of morphological variation, and many different infrafamilial classification schemes have been proposed. We have analyzed chloroplast *matK* sequences from 75 species representing 30 genera using maximum parsimony to infer phylogenetic relationships among the taxa within the family. The strict consensus tree obtained strongly suggests that Polygonaceae and subfam. Eriogonoideae are monophyletic. However, subfam. Polygonoideae appears to be paraphyletic. Of the five tribes recognized within subfam. Polygonoideae, only Persicarieae, Rumiceae, and Triplareae are monophyletic; *Muehlenbeckia* and *Fallopia*, traditionally placed in tribe Coccolobeae, are nested within Polygoneae. At the generic level, *Polygonum* s. str., *Fallopia*, and *Chorizanthe* appear to be nonmonophyletic.

P1488. The evolution of reproductive systems and sex-determining mechanisms within *Rumex* (Polygonaceae) inferred from nuclear and chloroplastidial sequence data

R. Navajas-Pérez[1], R. De la Herrán[1], G. López González[2], M. Jamilena[3], R. Lozano[3], C. Ruiz Rejón[1], M. Ruiz Rejón[1], **M. A. Garrido-Ramos**[1];
[1]Universidad de Granada, Granada, Spain, [2]Real Jardin Botánico Madrid, Madrid, Spain, [3]Universidad de Almeria, Almeria, Spain.

We compare nuclear ITS and chloroplast intergenic sequences of 31 species of *Rumex*. Our phylogenetic analysis supports a systematic classification of the genus, which differs from that currently accepted. This new phylogeny suggests a common origin for all Eurasian and American dioecious species of *Rumex,* with gynodioecy as an intermediate state on the way to dioecy. Our results support the contention that sex determination based on the balance between the number of X chromosomes and the number of autosomes (X/A balance) has evolved secondarily from male-determining Y mechanisms and that multiple sex chromosome systems, XX/XY_1Y_2, were derived twice from an XX/XY system. The resulting phylogeny is consistent with a classification of *Rumex* species according to their basic chromosome number, implying that the evolution of *Rumex* species might have followed a process of chromosomal reduction from x=10 toward x=7 through intermediate stages (x=9 and x=8).

P1489. The shoot architecture in Portulacaceae

T. A. Feodorova, A. C. Timonin;
Lomonosov Moscow State University, Moscow, Russian Federation.

The Portulacaceae includes about 20 genera and more 500 species. The structure of inflorescences and shoot has not been investigated good yet. We report here the data of shoot system organisation of Talinum paniculatum, T. triangulare, Calandrinia grandiflora, C. compressa, Portulaca oleracea, P. cryptopetala, Claytonia sibirica, C. acutifolia, Montia fontana. The shoot architecture of some Portulacaceae does not unequivocally fit the Troll's model of the inflorescence. Then, modules of the shoot systems have been recognised which are different in various representatives. In all Portulacaceae except for Claytonia, module are terminated by the flower and sympodially disposed. Claytonia strikingly differs in monopodial rosette shoot bearing axial monochasia. Claytonia is a separate genera from Montia. The two genera might be placed into separate subtribes or tribes. The project is carried out under financial support of RFBR, grant N 04-04-49010.

P1490. Preonanthus: An Independent Genus Formed by Alpine Ranunculacea Taxa

J. L. Szentpéteri;
Institute of Biology, Pécs, Hungary.

Pulsatilla, genus of Ranunculaceae family, contains more than 170 taxa, but the objective correlations between these categories are still unclear. The morphologically variable species make the correct classification really difficult. However, there are some taxa (P. alpina and its subspecies, variants), which show significant morphological difference from other Pulsatilla species. We tried to support this difference with phylogenetic studies.

Molecular phylogeny was constructed using nucleotide sequences of internal transcribed spacer (ITS) regions of nr DNA. A phylogenetic tree was constructed from the nucleotide sequence alignment using PAUP* 4.0. ITS regions seem to be valuable source in identifying different species, while significant polymorphism manifested in most of the studied taxa at species level. 2 samples showed significant polymorphism at generic level.

While these species are exactly the same, which differ in numerous morphological characters from all the other Pulsatilla taxa and were classified as Preonanthus species, we think these taxa should be considered generically different and Preonanthus genus should be recalled.

P1491. Phylogeny and evolution of Ranunculus s.l. (Ranunculaceae)

O. Paun[1], J. T. Johansson[2], C. Lehnebach[3], T. Armstrong[4], **L. Chen**[5], P. Lockhart[3], E. Hörandl[1];
[1]Department of Systematic and Evolutionary Botany,, Vienna, Austria,
[2]Botaniska Institutionen, Stockholms Universitet, Stockholm, Sweden,
[3]Allan Wilson Centre, Institute of Molecular BioSciences, Palmerston North, New Zealand, [4]Landcare Research, Auckland, New Zealand,
[5]School of Pharmacy, Yan Tai University, Yan Tai, China.

Ranunculus belongs to the 40 largest plant genera of angiosperms, comprising c. 600 species (plus c. 600 agamospecies) and occuring worldwide in a broad range of habitats. Phylogenetic reconstruction using DNA sequences (nrITS, *matK-trnL*) is incongruent with previous classifications due to homoplasy of morphological characters. Combined molecular data suggest a generic delimitation excluding *Ficaria*, *Ceratocephala*, *Myosurus*, *Beckwithia*, *Halerpestes*, *Peltocalathos*, *Callianthemoides*, and *Arcteranthis*. On infrageneric level, clades correspond to widespread ecological or regional geographical groups, and to basic chromosome numbers. Age calibrations suggest an age of *Ranunculus* s.s. of c. 24 Myr, a diversification into main ecological/geographical clades in the late Miocene and into present species during the Pliocene and Pleistocene. Split decomposition analyses suggest reticulate evolution within several groups. The evolutionary success of the genus is probably caused by adaptation due to high morphological plasticity and a broad range of reproductive strategies, plus hybridization and polyploidy as important factors for speciation.

P1492. Rose: a model system to study abnormal somatic embryogenesis

P. Kumar Pati;
Department of Botanical and Environmental Sciences, Guru Nanak Dev University, Amritsar, India.

Study on developmental and structural aspects of somatic embryogenesis has received great attention in recent years. Information on developmental regulation of somatic embryogenesis at molecular level has started to flow. However, little progress has been achieved toward understanding the switching over cell programming from normal process of somatic embryo development to abnormal somatic embryogenesis. Moreover, in certain cases abnormality were induced to study the alteration in cell programming.

In the present investigation, Rose, a woody ornamental plant was taken up to study somatic embryogenesis. The zygotic embryos harvested at different developmental stages were subjected to various concentrations of 2,4-D and physical conditions. During this process a wide range of abnormal embryos were observed. The origin of this abnormal somatic embryogenesis was elucidated by electron microscopy. The stage of shift of their developmental parttern was also identified by comparing it to the normal somatic embryo development in angiosperm. In the present study, the diverse kinds of abnormal embryos as well as the ease in obtaining them strongly advocates the use of **Rose plant as a model system** to study abnormal somatic embryogenesis and to address various unanswered questions on plant morphogenesis.

P1493. The endocarp of European Rubus-species

K. Pagitz;
Botany, Innsbruck, Austria.

In Europe 4 subgenera of the genus *Rubus* (subgen. *Chamaerubus*, *Cylactis*, *Idaeobatus* and *Rubus*) and several hundred species occure.

Usually morpholigical features are used to characterize the taxa. Not taken into further consideration is the endocarp (seeds). It consists of two layers strongly sclerenchymatous cells, one right-angled, the other parallel to the longitudinal axis. Diagnostic relevant features are surface (mostly reticulate), shape and size.

The herbaceous species of the subgen. *Chamaerubus* and *Cylactis* are characterised by a smooth surface (*Rubus chamaemorus*, *R. arcticus*) and (exept *R. arcticus*) big seeds. Similar to in size and shape, but significant smaller is *Rubus caesius* (subgen *Rubus*, sect. *Caesii*). The reticulum is less prominent than in *Rubus* subgen. *Idaeobatus* and *Rubus* sections *Rubus* and *Corylifolii*.

Rubus idaeus (Subgen. *Idaeobatus*) shows rather small to medium sized seeds, whereas the endocarp of the brambles (subgen. *Rubus*, sect. *Rubus*) is much moore variable. A further differentiation of species of the sections *Rubus* and *Corylifolii* is possible when all features are taken into consideration.

P1494. Evolution of *Nertera* (Rubiaceae) with focus on the Tristan da Cunha archipelago

G. Jakubowsky, M. Kiehn, R. Samuel, T. F. Stuessy;
Department of Systematic and Evolutionary Botany, University of Vienna, Vienna, Austria.

The genus *Nertera* is distributed from SE-Asia to South America and the isolated Tristan da Cunha archipelago. ITS and trnL-F sequences and AFLPs were analysed to answer questions from species to population level. Results suggest that the genus originated in New Zealand and subsequently spread into the Pacific area. *Nertera depressa*, the only widespread species, is genetically diverse and can be divided into three geographical groups: (1) Southeastern Asian Group, (2) Northern South American Group, (3) Southern South American Group. From the latter it dispersed to Tristan da Cunha were the two endemic species *N. assurgens* and *N. holmboei* evolved. Morphology and taxonomy were found to be incongruent with the genetic relationships. *Nertera depressa* from Tristan da Cunha is genetically more closely related to the two endemic species than to *N. depressa* from Chile and the Falkland Islands, and within the archipelago *N. depressa* from Inaccessible is genetically closer to the endemics than to *N. depressa* from Gough and Tristan. Both endemic species seemingly evolved on Inaccessible when Tristan, the largest island in the group, was not yet in existence.

P1495. The chromosome study of *Argostemma spp.* (Rubiaceae) from Thailand.

S. Appinyanand, L. Eksomtrames, **K. Sridith**;
Prince of Songkla University, Hat Yai, Thailand.

Abstract: The new information on the chromosomes of selected species in the genus *Argostemma* Wall. (Rubiaceae) from Thailand had been achieved. Concerning the fact that there are two major groups of *Argostemma* due to the morphological characters i.e. the group with bell-shaped flowers and the other with star-shaped flowers. The former had centre of origin in peninsular Malasia while the later had distribution ranges mostly in Thailand and neighbouring areas. It is to be doubted whether the genus should be separated into two subgenera due to this distinct characteristics or not. Chromosomes of selected species of *Argostemma* from Thailand, mostly from the peninsula, had been investigated. Most species have the same number as 2n=22. The relationships between species in the genus due to the chromosome number and karyological characters had been discussed. It is suggested here that *Argostemma* Wall. might remain a “good genus”. However, more information on chromosome numbers together with the karyotype patterns of some selected species would be needed in order to support the relationships between various taxa in the genus.

P1496. Is the Origin of *Veronica* L. Genus Turkey?

A. Ozturk;
Canakkale Eighteen March University, Fen-Edebiyat Fakultesi, Biyoloji Bolumu,, Canakkale, Turkey.

In this article, we tried to explain the distrubution of *Veronica* genus throughout the world that distrubuted from Turkey. This subject has been considered in this article firstly as original and scientific. Over 80 out of 200 species of *Veronica* genus are found in Turkey which is small region comparing to world land and endemism rate is very high. This suggest that *Veronica* species on the World may originate from Turkey. The richness of this species may be affected by different factors those are different kind of geomorphologic structure and climate and microclimate in the region, specific sediments belong to geologic period and positioned in the moderate zone as a geographic situation and even paleomorphologic, paleogeographic and paleoclimatologic changes. Also, historical, ethnographical and some other natural factors have contribution to this distribution. Since a small region of Turkey comparing world area contains high number of *Veronica* taxa. Turkey is situated in the geometrical center of the disribution of *Veronica* in the earth. It can be concluded that Turkey is the original centre of *Veronica* Genus, gene pool according to scientific and theoritic data.

P1497. Notes on the genus *Orobanche* in Italy, 1. Taxa described by Bertoloni

G. Domina, **P. Mazzola**;
Dipartimento di Scienze Botaniche, Palermo, Italy.

In order to prepare the revision of the genus *Orobanche* in Italy, the 11 species as new described by Antonio Bertoloni, in 1810 and 1846, are considered. Five of them were described on material collected by Bertoloni himself; the other, on specimens received from Vaucher, Moris and the younger Savi. Subsequently, all names proposed by Bertoloni were relegated to synonymy. The revision of the original material housed in BOLO results as follows: *O. bicolor* Bertol. (non Meyer) belongs to *O. cernua* L., *O. cruenta* Bertol. to *O. gracilis* Sm., *O. stricta* Moris ex Bertol. to *O. schultzii* Mutel, *O thyrsoidea* Moris ex Bertol to *O. rapum-genistae* subsp. *rigens* (Loisel) P. Fourn, *O. critmi* Bertol. to *O. minor* Sm., *O. vitalbae* Bertol. to *O. picridis* F. W. Schultz, *O. fragrantissima* Bertol. to *O. lutea* Baumg, *O. laurina* Bertol. to *O. hederae* Duby, *O. yuccae* Savi f. ex Bertol. to *O. hederae* Duby [not to *O. minor* Sm. as had been suggested], *O. centaurina* Bertol. to *O. litorea* Guss. [and not to *O. picridis* F. W. Schultz]. However, *O. australis* Moris ex Bertol., referred by Beck to *O. canescens* C. Presl, appears to be a good species so far known only from Sardinia.

P1498. Variation trends in the genus Melampyrum (ex-Scrophulariaceae)

M. Štech;
Faculty of Biological Sciences, University of South Bohemia, Ļeské BudŊjovice, Czech Republic.

The genus *Melampyrum* belongs to the most variable plant genera in Europe. The indistinct species limits in some groups are a source of taxonomic uncertainties at the interspecific level. Most conspicuous at the intraspecific level is so-called “seasonal variation”, which is traditionally evaluated as the most important taxonomic character at this level. The ecological plasticity and relationships with host-plants are another source of the intraspecific variation.

A detailed morphometric study of model species belonging to groups with different patterns of inter- and intraspecific variation was performed. Some morphologically intermediate types in groups of *M. nemorosum* and *M. sylvaticum* indicated a possibility of hybridisation, which may result in morphologically intermediate types in some groups. This hypothesis was supported by hybridisation experiments.

Analyses of intraspecific variation in *M. nemorosum* and *M. pratense* show different patterns of seasonal variation in these species. The structure of seasonal variation tends to have reticulate pattern in some species but constitutes distinct clusters of similar types in other species.

P1499. Eco-geographic distribution of ploidy levels in wild and cultivated potatoes (*Solanum* section *Petota*)

D. M. Spooner[1,2], T. Gavrilenko[3], S. Stephenson[1], J. Bamberg[4,2], A. Salas[5], R. J. Hijmans[6];
[1]USDA, Agricultural Research Service, Madison, WI, United States, [2]University of Wisconsin, Madison, WI, United States, [3]N.I. Vavilov Institute of Plant Industry, St. Petersburg, Russian Federation, [4]USDA, Agricultural Research Service, Sturgeon Bay, WI, United States, [5]International Potato Center, Lima, Peru, [6]University of California, Berkeley, CA, United States.

Wild potatoes (*Solanum* sect. *Petota*; 187 species) occur from the SW USA to Chile. There are diploids, triploids, tetraploids, pentaploids and hexaploids; cultivated potato (*Solanum tuberosum*) has all these levels except hexaploid. We compiled 8697 ploidy reports, including 912 new determinations, and analyzed the frequency and the eco-geographic distribution of species with different ploidy levels and of cytotypes within a species. Thirty-six percent of the wild species are entirely or partly polyploid. Multiple cytotypes exist in 22 species. There are more diploid species, and they occupy a larger area than the polyploids but tetraploid species have, on average, similar range sizes as diploid species. Polyploid species frequency is much higher from Mexico to Ecuador than further south. Compared to diploids, triploids tend to occur in warmer and drier areas, while higher level polyploids tend to occur in colder areas. There are no diploids from Costa Rica to Colombia, the wettest part of the group’s range. Tetraploid cytotypes of *S. tuberosum* occur much more frequently than the diploids; the triploids and pentaploids are restricted to colder and drier areas.

P1500. Sinopsis of *Solanum* subgenus *Leptostemonum* in Brazil

M. F. Agra;
Laboratório de Tecnologia Farmacêutica, João Pessoa, Paraíba, Brazil.

Solanum subgenus *Leptostemonum* is the second largest of the *Solanum*, with approximately 450 species and cosmopolitan distribution having its primary center of diversity in South America and secondary centers in Australia and Africa. Morphological characters used to distinguish it from other subgenera include: stellate indument, prickly herbage, and attenuate anthers. In Brazil approximately 251 specific names have been applied to the species, of which, 131 are recognized as synonyms. *Solanum* subg. *Leptostemonum* is represented in Brazil by about 120 species, of these, 45 are endemic, including the undescribed taxa. They are assigned to the following sections: *Acanthophora, Crinitum*, *Melongena, Erythrotrichum, Herposolanum, Lasiocarpa, Micracantha, Persicariae*, *Polytrichum* and *Torva*. They are encountered in many kinds of vegetation and display marked adaptations to humid, dry, hot and seasonal habitats. The principal center of diversity and endemism in Brazil is found in Southeastern coastal region, which has 67 species, representing 61% of the total, of which, twenty two are endemic to the area.

P1501. Anatomy of foliar epidermis in species of Solanum Section Geminata (Solanaceae)

C. E. Benitez;
Universidad Central de Venezuela. Facultad de Agronomía., Maracay, Venezuela.

Solanum falconense, S. tanysepalum and S. lucens of the S. arboreum group; S. imberbe and S. sieberi of S. deflexiflorum group were studied in the context of an ongoing anatomical research in the Geminata section. Material was treated using conventional anatomical procedures. Location, type and distribution of the stomata and trichomas, shape and wall thickness of the normal epidermal cells were evaluated. The species were amphistomatic with anisocytic and staurocytic stomata, being the late less frequent. Trichomes were located on the abaxial and adaxial surface. Glandular trichomes were present in S. imberbe, S. sieberi, S. lucens and S. tanysepalum. Only S. falconense had mixed trichomes in both surfaces. Epidermal cells differed depending of their location on adaxial or abaxial surface, being sinuous in the abaxial surface in all studied species. The species S. falconense, S. sieberi and S. imberbe exhibited polygonal anticlinal cell walls on the adaxial surface, while S. lucens and S. tanysepalum presented undulate anticlinal cells walls.This results may represents a contribution to the understanding of species in the section Geminata.

P1502. *Verbenaceae* from Guerrero, Mexico, morphology and polen.

S. Peralta Gómez[1], **N. Diego Pérez**[2];
[1]Laboratorio de Etnobotánica Facultad de Ciencias, UNAM, México, Mexico, [2]Laboratorio de Plantas Vasculares Facultad de Ciencias, UNAM, México, Mexico.

The taxonomic knowledge above the Verbenaceae family in Mexico it's so far to be complete, actually there is just a fragmented and incomplete record of this vascular plant group. There are a few known studies about the taxa delimitation and their relationships, and those are supported on morphological characters judgments for taxa delimitation. In this project 15 genera and 48 species in Guerrero state distributed were studied and mean all of them interesting taxonomic cases and approaches for the Mexican flora knowledge, as the *Lantana* genus and its so many specific and infraespecific taxa. For this reason we decided to employ the palinological morphology as the aim to carry on findings more analysis elements in addition to morphology. The obtained results show that the genera studied does present particular morphological characteristics and some of them can be supported with the palinological morphology, however the great number of the specific taxa doesn't have sharp and precise palinological characters.

P1503. La familia Verbenaceae en Guerrero, México: morfología y polen.

S. Peralta Gómez[1], N. Diego-Pérez[2];
[1]Facultad de Ciencias, México, Mexico, [2]Facultad de Ciencias, U. N. A. M. Mexico, Mexico.

The taxonomic knowledge about the Verbenaceae family in Mexico it's so far to be complete, actually there is just a fragmented and incomplete record of this vascular plant group. There are a few known studies about the taxa delimitation and their relationships, and those are supported on morphological characters judgments for taxa delimitation. In this project 15 genera and 48 species in Guerrero state distributed were studied and mean all of them interesting taxonomic cases and approaches for the Mexican flora knowledge, as the *Lantana* genus and its so many specific and infraespecific taxa. For this reason we decided to employ the palinological morphology as the aim to carry on findings more analysis elements in addition to morphology. The obtained results show that the genera studied does present particular morphological characteristics and some of them can be supported with the palinological morphology, however the great number of the specific taxa doesn't have sharp and precise palinological characters.

P1504. New insights in high altitude environments evolution inferred through a phylogenetic hypothesis of *Lippia* spp. (Verbenaceae).

F. R. G. Salimena[1], K. S. C. Yotoko[1], M. A. Machado[2], M. F. Martins[2], L. F. Viccini[1], A. L. S. Azevedo[1], A. L. Campos[2], P. H. P. Peixoto[1];
[1]Universidade Federal de Juiz de Fora, Juiz de Fora, Brazil, [2]EMBRAPA /CNPGL, Juiz de Fora, Brazil.

We built a phylogenetic hypothesis for 12 species of *Lippia* which occur in the Espinhaço Chain of Minas Gerais, a high endemism area. In our tree, most of the basal branches were very short while the terminals were long, indicating that most variation is not shared by different species. It can be explained by the lack of phylogenetic signal, which could be related with rapid speciation events after the Last Glacial Maximum. It is also possible that the species present in high altitudes are just descendents of different species that reached these environments and became adapted to them. Another possibility is the lack of resolution of the ITS and Trn-L sequences. Regardless the lack of resolution of the tree, we found a lack of phylogenetic agreement of the sequences and the number of chromosomes. On the other hand, our tree did not disagree with the morphological classification within the genus, which indicates that morphological characters retain phylogenetic signal in addition to the expected convergence.

P1505. Species delimitation withim the Zamia verschaffeltii Miq. species complex (Zamiaceae-Cycadales)

F. Nicolalde[1,2], A. P. Vovides[1], D. W. Stevenson[3];
[1]Instituo de Ecologia A. C., Xalapa, Mexico, [2]Red Latinoamericana de Botánica, Santiago de Chile, Chile, [3]The New York Botanical Garden, New York, NY, United States.

The cycad Zamia verschaffeltii Miq. (1870) was described from material collected in Mexico by Ferdinand Deppe and Christian Wilhelm Schiede, German plant collectors who explored and collected in Mexico and Central America between the years 1828 and 1829. However, owing to unprecisely recorded locality information on the holotype of Z. verschaffeltii the type locality still remains an enigma (Socorro), but it is suspected that it is within south eastern Mexico in the states of Veracruz, Tabasco or Chiapas where the following species of Zamia are known: Z. loddigessii, Z. cremnophila, Z. purpurea, Z. variegata, Z. lacandona, and Z. splendens the latter two species are thought to be in synonimy under Z. vershcaffeltii = Z. katzeriana. Two localities under the name "Socorro" have been detected, one in Tabasco and another in southern Veracruz. Preliminary results from morphometric and phylogenetic analysis indicates that Z. splendens is a different taxonomic entity to the Z. verschaffeltii concept observed by Miquel

P1506. Current research on the Mexican cycad flora

A. P. Vovides[1], J. González-Astorga[1], M. Pérez-Farrera[2], D. González[1], F. Nicolalde[1], C. Iglesias[1];
[1]Instituto de Ecología, A.C., Xalapa, Mexico, [2]Universidad de Ciencias y Artes del Estado de Chiapas, Tuxtla Gutierrez, Mexico.

Mexico is second world wide in cycad diversity with 45 species described to date among three genera: Ceratozamia, Dioon and Zamia. Advances on preliminary molecular phylogenies in the genera Ceratozamia and Dioon has indicated that good resolution for species delimitation is still problematic, but biogeographic inferences have been made. Multivariate analysis of morphological data is helping to clear up some taxonomic confusion in a Zamia species group in south eastern Mexico. Population genetics of two Dioon spp distributed along the Sierra Madre Oriental have revealed two distinct distribution patterns associated with genetic bottleneck effects and Pleistocene floristic refugia. Though chromosome number and karyotype is known to be highly variable in Zamia and conservative in Ceratozamia there appears to be a correlation in number of chromosome satellites with latitude in Ceratozamia. These topics are discussed in biogeographic and evolutionary terms.

P1507. Type specimens of Croatian endemic *Limonium* species (Plumbaginaceae)

S. BogdanoviÍ , B. MitiÍ ;
Faculty of Science, Zagreb, Croatia.

In Croatian flora the genus *Limonium* Mill. (Plumbaginaceae) is represented by 11 taxa. On the basis of literature, field and herbaria studies original type specimens has been traced in different herbaria (WU, W, ZA, BOLO and PRC). The historical review of taxa treatments and the typification process are briefly discussed for *Limonium cancellatum* (Bernh. ex Bertol.) O. Kuntze, *L. dictyophorum* (Tausch) Degen, *L. subanfractum* Trinajstic, *L. vestitum* (C. E. Salmon) C. E. Salmon and *L. vestitum* subsp. *brusnicense* Trinajstic. The specimen from the WU herbaria was selected as the lectotype of *L. vestitum*. Original holotype material of *L. cancellatum* is deposited in BOLO herbarium and of *L. subanfractum*, *L. vestitum* subsp. *brusnicense* in ZA herbarium. We found and discussed existence of two type specimens of the same species, firstly described as *L. dictyophorum* in PRC herbarium and than as *L. anfractum* in WU herbarium. According to the ICBN, specimen of *L. dictyophorum* was chosen as adequate type material.

P1508. Effects of farm manure, inorganic nitrogen and Rhizobium on yield of soybean (Glycine max L.)

G. Akbari, N. Schahbazian, A. Hejazi, I. Alahdadi;
University of Teheran, Abouraihan Campus, Department of Agronomy and Plant Breeding, Teheran, Islamic Republic of Iran.

An experiment was carried out for two years (2001 - 2002) to determine the effect of organic manure, inorganic nitrogen and *Rhizobium* bacteria on soybean 'Williams' yield, under semi - arid condition in the region of Varamin.The effect of organic manure in 3 levels inorganic nitrogen in 3 levels , and Rhizobium strains consisting of 3 commercial forms was investigated using a split plot design with 4 replications.

The results of yield analysis and other characteristics of soybean showed significant differences between factors and between the two years of experimentation. The results showed than soybean seed inoculation with bacteria strains has increased the crop yield and differences among strains were observed in different conditions.

Application of different levels of organic nitrogen led to different amount of yields in presence of nitrogen fertilizer levels, normal distribution of rain and timely sowing of crop in 2002.

The results of this experiment showed that application of organic nitrogen and inoculation of soybean seed with appropriate bacteria will lead to yield increase of this crop.

P1509. Regressive-informational model of plant diversity origin

S. B. Alya, K. N. Sarsenbaev;
research company, Almaty, Kazakhstan.

The model explains modern plant diversity on Earth. It is based on four statements. First, all plant diversity originates from several dozens of plant species (prototypes). In the whole history of Earth, plants accommodated to changes in atmosphere, temperature and soil chemical composition. They were transformed according to a set of multivariate information. Second, in genotype of modern plants there is an information not only about synthesis molecular components of cell, but also about mechanisms that assemble them to complex and organs, response reactions to environment and cosmos. Third, there are no meaningless nucleotide sequences in DNA. The information is coded not only by the nucleotide triplet but also by binary codes on DNA surface. Information transforms not only from DNA to proteins, but from different signals to DNA. Fourth, new plant species and subspecies were formed during the settlement on Earth by adapting to the environment conditions and simplifying genome prototypes' (sometimes complicating genome prototype). It led to habitus, morphology, physiology and biochemistry changes. The botanists register this as a new species appearance.

P1510. Plant Biodiversity of Nara Desert of Sindh, Pakistan, in terms of Microhabitat

G. R. Bhatti[1], R. Qureshi[1], M. Shah[2];
[1]Shah Abdul Latif University, Khairpur, Pakistan, [2]Pakistan Museum of Natural History, Islamabad, Pakistan.

One hundred sixty plant species, belonging to 118 genera and 45 families were collected from the Nara desert during 1998-2001 are identified. Of them, one species of gymnosperm, three sedges and twenty species of Poaceae (grasses) are determined. The checklist is arranged alphabetically along their vernacular names, family and habitat.

Statistically the area containing the 21.22 %, of the plant families, 7.81% of the genera and 2.94% of the total species of Pakistan has been so far revised by Ali et al. (1971-2002).

Six distinct habitats were identified for plant communities from the study area: Crest habitat (Top of the sand dune); Slopes/swale/flanks habitat; Sandy plains Habitat (*Tar-Tarai*- low laying flat areas); Lake/wetland habitat; Saline/Sodic Land and Hilly Tract.

Floristically the crest habitat possesses 14 species (8.75%) a less number of species as compared to the rest of habitat. The highest number of species 103 (66.25%) recorded from the Flat Habitat.

P1511. The threatened plants, lost habitats and endemic species in the flora of Sanliurfa (Turkey)

M. Aslan, E. Cetin;
Harran Universty, ķanlıurfa, Turkey.

The natural living areas (habitat) in our country, as if in the World, have been constantly dertroying and decreasing, because of the various antropogenic activities, This proses, have been limiting and the natural plants species, as weel as destroying the genetical sources must be prevented or become slow immediately. However, GAP Region has not been researched widely and the habitats of this region has been constantly changed. In the natural flora of the region, rare and endemic plant species have been concerned and factors which threated these species and danger categories have been observed. In this study, we investigated the feature of natural flora of GAP region. Recently, there has been increased harmful antropologic factors thretening the future of and the destroying the natural flora of the region. Therefore, the endemic species in the region have been under great danger of extinction.

P1512. The Morphology, Type, Frequency and Distribution of Calcium Crystals in Some Medicianl Plants of the Philippines

V. S. Tolentino;
Department of Biology, Ateneo de Manila University, School of Science and Engineering, Loyola Schools, Quezon City, Philippines.

The morphology, type, frequency and distribution of calcium crystals in some Philippine medicinal plants was determined using light microscopy. Representative plants from the Amaranthaceae, Solanaceae, Fabaceae, Cucurbitaceae, Umbelifferae, Cruciferae, Convulvulaceae and Asteraceae were examined. Capsicum frutescens, C. annum, and Datura arborea of the Solanaceae exhibited mainly calcium oxalate crystals in the form of druses, styloids, crystal sand and prismatic crystals. In the seed coats of Phaseolus vulgaris, the prismatic and kink crystals observed may supplement the protective role of the seed coat for the developing embryo. Druse crystals were observed in Iresine herbstii, Alternanthera ficoidea "versicolor", and A. ficoidea "amoena". Results from this study may not only aid in taxonomical classification of plants, but may also be useful indicators of the physical and chemical conditions of the cell environment the crystals were formed. Knowing the abundance of crystals in different parts of the plant body especially the edible and medicinal plants may guide consumers as to the plant part and recommended age of the leaf to be used

P1513. Phylogenetic reconstruction of *Croton* section C*yclostigma* reveals that it is a polyphyletic group

R. Riina, P. E. Berry, B. Van Ee;
Department of Botany, University of Wisconsin-Madison, Madison, WI, United States.

Croton sect. *Cyclostigma* form one of the most distinct groups within the genus *Croton.* Members of *Croton* occupy a great diversity of habitats, from arid vegetation to lowland and montane forests and are important colonizers of disturbed sites. *Croton* sect. *Cyclostigma* represents one of the few arborescent lineages within a predominantly shrubby genus. It is also distinct from many other *Croton* lineages by its ecological preference for more humid habitats, especially montane cloud forests and riversides. Several species in the section are commonly known as "dragon's blood" due to the presence of blood-red latex, which is widely used for medicinal purposes in several South American countries. The section as defined by Webster consists of 62 species centered in the Neotropics, but with some disjunct members in Africa and Madagascar. Based on ITS and chloroplast data this work shows that section *Cyclostigma* is not monophyletic, however a well supported "core Cyclostigma clade" is identified.The relative phylogenetic position of the section within the genus and the amphiatlantic distribution of the section is evaluated using a broader *Croton* molecular data set.

P1514. An Endemism of the Western of Lycian Toros (Babadag/Denizli) in Turkey

S. -. -. Oluk[1], **A. G. -. Balim**[2];
[1]Celal Bayar University, Manisa, Turkey, [2]Dokuz Eylul University, Izmir, Turkey.

The study area lies within 42° 00, 46° 60Ŋ north parallels and 28° 30Ŋ,29° 29Ŋ east longutitutes. It is in the C2 grid square, according to the system adopted by Davis. Babadag is named as a Lycian Toros which is as a part of the western of Toros Mountain by Regel. The elevation is 100 meters at Karacasu on the western of study area. The eastern is Cankurtaran village, 1000 meters. The marble which originated from Baba hill is undergoing to Dikmen in the south of the study area. These series are covered with schist at the surface in the Gökbel valey, Tatarpinar and Yamaardic hill. In the study area, There are 1066 taxa 163 of which are endemic species 15,1%. Six of them are vulnarable plants according to red data list for the Flora of Turkey. Endemic taxa occupie between 500 and 2300m. They can be found calcareous rocks and in forest or cultivated lands. Most of them in the study area occupie calcareous rocks located in asilvatic belt at the elevation of 1750-2308m althoug some endemic taxa develops on phyll rocks. Evran hill, Karababa, Akbaba and Baba hills are the most important places for endemic taxa.

P1515. Trapping Device Evolution of Predatious Fungi: Evidence from Ribosome DNA and Multiprotein Sequences

Y. Yang, E. Yang, **X. Liu**;
Key Laboratory of Systematic Mycology & Lichenology, Institute of Microbiology, Chinese Academy of Sciences, Beijing, China.

Nematode-trapping fungi produce special structures to capture nematodes. We performed a comprehensive phylogenetic analysis of predacious fungi to study the evolutionary relationships of trapping devices by using sequences from three protein-coding genes (RPB2, EF1-Ŭ, & ɓ-tublin) and rDNA ITS region. Phylogenetic trees resulted from Maximum-likelihood analysis suggested that there is a strong phylogenetic component for the evolution of trapping devices. We proposed an evolution trend for the trapping devices based on both our phylogenetic tree and morphological characters. (*i*) The simple sessile knob-like special cells were assumed to be the ancestor of trapping devices; (*i*) The simple sessile knob-like special cells were assumed to be the ancestor of trapping devices; (*ii*) Non-adhesive trap (constricting ring) was separated earlier from the adhesive traps (knob, stalked knob, hyphal branch, non-constricting ring and network); (*iii*) Among the adhesive traps, network was differentiated from the other traps; (*iv*) Then sessile knobs evolved into stalked knobs or non-constricting rings by the adhesive cells coiling or adhesive branches.

P1516. Distribution patterns and biodiversity in species of the genus Cousinia (sect. Cynaroideae)

F. Attar[1], A. Ghahreman[1], M. Assadi[2], M. Iranshahr[1];
[1]Central Herbarium of Tehran University, Tehran, Islamic Republic of Iran, [2]Institute of forests and rangelands, Tehran, Islamic Republic of Iran.

The *Cousinia* , with about 240 species, after Astragalus is the largest genus in the Flora of Iran. Nearly all of its species are found in arid zones, mostly in the Irano-Turanian region. A majority of the Cousinia species has a limited distribution and grows in small local areas. In the last researches done in 1972 and 1979 by Rechinger it led to dividing the *Cousinia* into 53 sections. The largest section is the sect. *Cynaroideae* with 88 species, of which 55 species are grown in Iran. The *Cynaroideae* section has the most morphologic variety among the genus. Recently we described 14 species from Iran. Based of our research this section includes 88 species in the world. 73 species of *Cynaroideae* were identified for Iran, of which 59 were endemic. After Iran, Iraq and Turkey have the biggest number on endemic species belonging to this section. The growth of 73 of the 88 species of *Cynaroideae* within Iranian borders is a testimony to the fact that Iran is only center of genetic diversity of the section.

P1517. Aponogeton satarensis, Trithuria konkanensis, Camptorrhiza indica: living witnesses for the Wagner's theory of Continental drift

S. R. Yadav;
University of Delhi, Delhi, India.

During past two decades, I described more than 20 species of flowering plants from Western Ghats which is among eight hottest hot spots in the world. Three monocot species Aponogeton satarensis (Aponogetonaceae), Camptorrhiza indica (Colchicaceae), Trithuria konkanensis (Hydatellaceae), are considered significant from biogeography standpoint. Cytogenetical investigations on A. satarensis and A. decaryi showed a close genetic relationship supporting the relation of Indian subcontinent to Madagascar. Morphological and cytogenetical investigations revealed a close relationship between Camtorrhiza indica and Iphigenia species. An occurrence of the Camptorrhiza strumorsa, the only other species of the genus in South Africa establishes relation of South Africa to Indian subcontinent. Discovery of Trithuria konkanensis of family Hydatellaceae has established the relation of Indian subcontinent to that of Australia. These three newly described monocot species are the living witnesses to support the Wagner's theory of continental drift.

P1518. Diversidade florística em ambientes distintos no Parque Nacional Vale do Catimbau, PE, Brasil.

M. F. Sales;
Universidade Federal Rural de Pernambuco, Recife, Brazil.

O Parque é considerado uma área de extrema importância biológica por apresentar vários ambientes, com diferentes tipos vegetacionais e uma flora bastante peculiar. Foram reconhecidos quatro tipos vegetacionais: rupestre; floresta úmida; arbustiva perenifólia; e caducifólia espinhosa (Caatinga). A flora vascular está formada por 370 espécies, distribuídas em 78 famílias, sendo 34 monocotiledóneas e as demais, dicotiledôneas. A família melhor representada em número de espécies foi Leguminosae com 59 espécies, sendo 25 Caesalpinioideae, 11 Mimosoideae e 23 Papilionoideae; seguidas de Euphorbiaceae (18), Asteraceae (11), Myrtaceae (10), Convolvulaceae (9), Malvaceae e Rubiaceae com 8. Os gêneros mais diversos foram *Croton* (Euphorbiaceae) 11 espécies, *Chamaecrista* (10) e *Senna* (7). Os ambientes com flora mais diversificada foram os rupestes e vegetação arbustiva perenifólia.

P1519. Floral diversity of African Marantaceae

A. Ley, R. Claßen-Bockhoff;
Institut für Spezielle Botanik und Botanischer Garten, Mainz, Germany.

The Marantaceae (31/530) are a pantropical family of herbaceous monocots characterised by a highly derived pollination mechanism. An explosive movement of the style activated by the contact of the pollinator with a "trigger" guarantees the precise pollen transfer. Studies on American and Asian Marantaceae have shown a variety of adaptations to different pollinators based on diversity in floral morphology but nothing is yet known about the pollination systems and the correlated floral diversity in the African species. This, however, would be of special interest as Africa is regarded as the primary centre of diversity. African Marantaceae (10/33) form phylogenetically two mayor clades (basal and advanced) and three isolated genera. To reconstruct adaptive radiation in Marantaceae, we started a project dealing with the evolution of African species including both molecular and ecological aspects. The poster presents the first photographic overview of the existing floral diversity with emphasis on the diversity in "trigger" morphology including first inferences about their phylogeny and pollination.

P1520. Molecular systematics of Martyniaceae using the ITS region of nuclear ribosomal DNA

R. Gutierrez;
School of Life Sciences, Arizona State University, Tempe, AZ, United States.

Acceptance of the group Martyniaceae as a valid family has long been questioned. Often placed in the Pedaliaceae, the Martyniaceae have been allied to numerous other families, including the Gesneriaceae, Bignoniaceae, Acanthaceae, and Verbenaceae. Internal relationships within the Martyniaceae have not been explored using molecular data. For this study, sequences of nuclear ribosomal DNA from the Internal Transcribed Spacer (ITS) region were used to examine these relationships. Several samples from eight families were included (Acanthaceae, Bignoniaceae, Gesneriaceae, Lamiaceae, Lentibulariaceae, Martyniaceae, Pedaliaceae, and Verbenaceae). Within the Martyniaceae, all four genera (*Craniolaria*, *Ibicella*, *Martynia*, *Proboscidea*) were sampled. The largest genus, the genus *Proboscidea*, was emphasized. The results of this study indicate that Martyniaceae is a distinct lineage. Within the Martyniaceae, the South American genera *Ibicella* and *Craniolaria* clustered, as did the North American genera *Proboscidea* and *Martynia*. Within *Proboscidea*, acceptance of three infrageneric groups is supported.

P1521. Biosystematic of African Celtis

A. A. T. sattarian, L. A. E. Maesen;
Wageningen university, Wageningen, Netherlands Antilles.

Celtidaceae, formerly Ulmaceae (Takahashi 1989) comprise ca. 180 species, classified in 9 genera, distibuted in the Northern hemisphere and in Africa. *Celtis* L. is one of the the most widely distributed tree genera in the world.In Africa 12 species are known: Some aims of this study are a revision of African *Celtis*, preparation of a conspectus of all *Celtis* species, producing an overall molecular phylogenetic hypothesis for Celtidaceae, and a phenology of *Celtis*. Methods used are loaning materials from different herbaria, study of macro-morphological and micro-morphological characters and observing phenology to understand seasonal ecophysiological response in *Celtis* by field observations in Wageningen Botanical Gardens, Molecular work will clarify relationships among species.

Two new species are described: *Celtis australiensis* Sattarian and *Celtis madagascariensis* Sattarian.

Endocarp characters proved to be important characters in African *Celtis,* Sunken area aperture in pollen grain as a main character in Celtis spp,all African *Celtis* pollen grains have been described.

P1522. A regional vascular plants catalogue from eastern Venezuela: Monagas State

R. M. Gonto[1], A. Fernandez[1], A. Larez[2];
[1]Universidad Central de Venezuela, Caracas, Venezuela, [2]Universidad de Oriente, Monagas, Venezuela.

Venezuela is known as a megadiverse country, with 17.000 different plant species.

Monagas state (28.900 km^2)in western Venezuela, within the Cordillera de la Costa as a northern boundary, the Orinoco river to the south, Venezuelan Llanos to the west and the Orinoco Delta to the east, reaches from 0 to 2600 masl. The state comprises ecosystems from mangrove formations, shrubby and open savannas, deciduous and humid forests, *Mauritia* palm swamps, wetlands, gallery forests, *Curatella* shrublands locally known as chaparrales and thorn scrubs. This is a poorly collected region. A check list made by the ’80 stimated to 1.676 species. Today, 1.333 species have been counted only for the Llanos formation below 400 masl. A survey of plants previous to the vascular flora of the state is in course. Preliminary results of the plant diversity of the state reaches 204 families, 1105 genres, and 2566 species.

Specimens are deposited at CAR, GUYN, IRBR, MY, MYF, UOJ and PORT herbaria.

P1523. A regional vascular plants catalogue from eastern Venezuela: Monagas State

R. M. Gonto[1], A. Fernandez[1], A. Larez[2];
[1]Universidad Central de Venezuela, Caracas, Venezuela, [2]Universidad de Oriente, Nucleo Monagas, Maturin, Venezuela.

Venezuela is known as a megadiverse country, with 17.000 different plant species.

Monagas state (28.900 km^2)in western Venezuela, within the Cordillera de la Costa as a northern boundary, the Orinoco river to the south, Venezuelan Llanos to the west and the Orinoco Delta to the east, reaches from 0 to 2600 masl. The state comprises ecosystems from mangrove formations, shrubby and open savannas, deciduous and humid forests, *Mauritia* palm swamps, wetlands, gallery forests, *Curatella* shrublands locally known as chaparrales and thorn scrubs. This is a poorly collected region. A check list made by the ’80 stimated to 1.676 species. Today, 1.333 species have been counted only for the Llanos formation below 400 masl. A survey of plants previous to the vascular flora of the state is in course. Preliminary results of the plant diversity of the state reaches 204 families, 1105 genres, and 2566 species.

Specimens are deposited at CAR, GUYN, IRBR, MY, MYF, UOJ and PORT herbaria.

P1524. Morphological approach on the Vitaceae phylogeny

C. Hanotin;
Museum National d'Histoire Naturelle, Paris, France.

Vitaceae are a family of mainly woody climbers characterized by the presence of leaf-opposed tendrils or inflorescences but with numerous exceptions. Floral differences and especially vegetative differences have historically been used to establish generic limits. However the relationships between genera have been proved difficult to establish.

This family is distributed worlwide and includes about 700 species parting in 14 genera. Vitis, Ampelopsis and Parthenocissus are mostly restricted to temperate areas. Vitis is concentrated in the northern hemisphere. Parthenocissus and Ampelopsis are asian and american genera. The remaining genera have predominantly tropical and sub-tropical distributions. I have focused on morphological characters to try to achieve a morphological phylogenetic reconstruction of the family. Futhermore I studied the delimation of the genera.

P1525. *Myxochlamys mullerensis* (Zingiberaceae), a new genus from Kalimantan, Indonesia

A. Takano[1], **H. Nagamasu**[2], H. Okada[3];
[1]Division of Natural History, Sanda, Hyogo, Japan, [2]The Kyoto University Museum, Kyoto, Japan, [3]Botanical Gardens, Katano, Osaka, Japan.

A new genus and species, *Myxochlamys mullerensis* (Zingiberaceae) is described from the Muller Range, Central Kalimantan, Indonesia. The inflorescence is terminal on a leafy shoot with few leaves arranged in a tuft, and filled with plenty of mucilage inside bracts. The bracts are free to the base, spirally arranged, densely imbricate and subtending a single flower. The flower is similar to that of *Boesenbergia* but the anther is versatile with two long spurs at the base of thecae. The versatile anthers are known in five genera in the family so far: *Camptandra, Cautleya, Curcuma, Paracautleya*, and *Roscoea*. However, phylogenetic analysis using ITS sequences suggested the new plant is more closely related to *Scaphochlamys* and *Distichochlamys*, although the clade was not so strongly supported. Morphologically, however, *Myxochlamys* differs from these two genera by having entire and concave labellum and versatile anther with two long spurs.

P1526. Modelling the potential distribution of plant species in Colombia using Mahalanobis distances

D. Armenteras[1,2];
[1]Instituto de Investigación de Recursos Biológicos Alexander von Humboldt, Bogota, Colombia, [2]King's College London, London, United Kingdom.

This work introduces a multivariate methodology for modelling the distribution of plant species in Colombia by means of integrating GIS with multivariate statistics. Predictive models represent an important tool to better understand the factors that control species distributions. Many of these have been developed in temperate areas, however poorly sampled tropical regions, where the highest biodiversity areas remain and models might be of major value, have hardly ever been considered. Primary inventory data exist in the best of cases as georeferenced coordinates from localities where specimens have been collected. There is rarely data which indicates absence or abundance of species. However, most of the current modelling approaches need the existence of both presence and absence data, and many of them are based only on biological tolerance to climate. The methodology here illustrated represents a step towards the achievement of an efficient use of the data already available in Colombia by providing a technique for modelling potential species distribution that utilizes only presence data based on Mahalanobis distances applied to two species of Palicourea.

P1527. The Middle Devonian proto-ovule *Runcaria heinzelinii* Stockmans 1968

P. Gerrienne[1], B. Meyer-Berthaud[2], M. Fairon-Demaret[1], M. Streel[1], P. Steemans[1];

[1]Université de Liège, Liège, Belgium, [2]Botanique et bioinformatique de l'architecture des plantes - CIRAD, Montpellier, France.

Contrasting hypotheses about the single/multiple, saltational/gradual origin of the seed habit, and identification of closest relatives to seed plants among progymnosperms are matters of considerable debate. We have identified a middle Givetian (Middle Devonian; approximately 385 million years ago) proto-ovule that pushes back the earliest evidence of seeds by about 20 million years. *Runcaria heinzelinii* Stockmans 1968 is a small radially symmetrical proto-ovule surrounded by a cupule. It possesses an indehiscent megasporangium bearing a distal columnar extension, differing from that of all early preovules by its extensive length and closed apex protruding above a multilobed spiraling integument. This morphology suggests a reproductive mechanism that combines anemophilous pollination and dissolution of sporangial cells to allow fertilization. *Runcaria* displays a highly derived morphology compared to that of progymnosperm sporangia which sheds new light on the order of character addition leading to the seed. It suggests that the seed syndrome originated earlier than the middle Givetian, when all known progymnosperms were aneurophytaleans.

P1528. Comparison of two morphological *Stratiotes aloides* forms

C. Toma;
Academy of Physical Education, Katowice, Poland.

Stratiotes aloides forms in Wielkie Slosineckie Lake situated in Poland were examined. The investigation was aimed at demonstrating differences between the floating form of *S. aloides* and the submerged one. 40 specimens and 909 leaves of *S. aloides* were examined. The following plant attributes were examined: width, length, sex, number of generative and vegetative organs, dry mass of whole plants and their organs. The examined attributes of leaves: leaf apex angle; leaf width measured 3 cm from the base, 10 cm from the base and 10 cm from the top; leaf area; cellular wall thickness; number of vascular bundles, and number of chloroplasts. The leaf area was determined with a image analyzer Met-Ilo 8. Leaf cells were examined with the use of a confocal and optical microscope. Water and bottom deposits from the places of specimen collection were analysed. The results confirm the occurrence of the two morphological forms of *S. aloides* in Wielkie Slosineckie Lake as well as the morphological and anatomical differentiation between them.

P1529. Male and female gametes from some woody plants: isolation and characterization

W. Li[1], X. Cheng[2], X. Xu[3];
[1]Chinese Acdemy of Forestry, Beijing, China, [2]chinese acdemy of forestry, Beijing, China, [3]Institut de la Recherche Interdisciplinaire de Toulouse, Toulouse, France.

Isolated viable gametes are prerequisite for *in vitro* fertilization and available for cytological studies. The isolation and manipulation of viable gametes has been technically challenging for woody plants. By enzymatic-osmotic shock method, we have successfully isolated viable gametes from several woody species.

1. Sperms formation and positional shift among components of the male germ unit were observed in *Paeonia suffruticosa* after inoculated in a BK medium with 12.5% sucrose. After enzymatic digestion and osmotic shock, sperms were released from a subapical pore of pollen tubes and were FDA positive
2. Embryo sacs/egg apparates were isolated from *Populus euphratica* by enzymatic digestion and squash. Stereofeatures of fertilization were observed during isolation. The cutinized covers of nucellus and interguments showed the structural obstacles to the isolation of egg cell. 3. Archegonia of *Pinus tabulaeformis* were isolated from enzymatic solution via an osmotic shock. Egg cells were released at 18h, and were FDA positive. In the protein inclusions that are bounded by a double membrane, there are trapped plastids, mitochondria and polyribosomes.

P1530. Diversity of Stingless bee (*Trigona collina* Smith) 's florae in Diciduous Forest of Doi Mon Long at Queen sirikit Botanic Garden, Chiang Mai, Thailand by Pollen Load analysis

W. Dejtisakdi[1], N. Juntawong[1], W. Arlelop[1], S. Masuthon[1], T. Santisuk[2], S. Wongsiri[3];
[1]Department of Botany, Kasetsart Univ., Bangkok, Thailand,
[2]Department of Forestry, Kasetsart Univ., Bangkok, Thailand,
[3]Department of Science, Chulalongkorn Univ., Bangkok, Thailand.

Abstract

Changing of environment effects the balance of ecosystem which leads to the decrease of Stingless bee (*Trigona collina* Smith *)* population in Thailand. This study could clarify the food plant species for Stingless bee in the deciduous forest of Queen Sirikit Botanic Garden, Chiang Mai province. The result will be useful for the conservation management of this bee species. Following the acetolysis technique, 20 plant species were recorded as food plants of the bees according to their external morphology. These are in the family : Mimosaceae, Asteraceae, Loranthaceae, Euphorbiaceae, Sapindaceae and Juglandaceae. the Pollen number 2 (P2) was *Tridax procumbens* L., (P3) was *Croton oblongifolius* Roxb., (P11) was *Litchi chinensis* Sorm., (P16) was *Mimosa pigra* L., (P18) was *Engelhardtia spicata* BI. and (P20) was *Helixanthera sp*. The higher abundance of the meliferoius plant species was recorded between January-March, whereas fewer supply was found during July-September. Moreover, the number of food plant species was not possitively correlated with the number of flowering plants. This phenomena exhibited the preference behavior of the bee.

P1531. The foliar anatomy of forest climax tree species in relation to forest development in 0range Kloof, Table Mountain, South Africa.

C. N. M. Hlwatika, **R. B. Bhat**;
Walter Sisulu University, Mthatha, South Africa.

This investigation deals with the foliar features and functional anatomy of four forest climax tree species growing in a forest and the adjoining fynbos protected from disturbance for over 50 years. These foliar features, anatomical and morphological, were investigated within the forest interior, forest margin and the adjoining fynbos, and between the stream and non-stream habitats on Table Mountain. The aim of the investigation was to understand the functional significance of foliar anatomy in forest ecotonal dynamics. The foliage of the forest climax species displayed a distinctively thin cuticle. Results suggest that the forest climax species predominantly possess foliage acclimated to one set of environmental conditions - the forest interior. The predominant lack of significance differences between leaf characters of any given tree species in the forest climax and in the forest margin suggest ecological similarities between these environments. It appears that a lack of adaptive ability both anatomically and morphologically restricts the colonisation of the forest-adjoining fynbos by forest climatic tree species.

P1532. Application of Molecular Markers on Nomenclature for Ornamental Peach

D. Hu[1], Z. Zhang[1], D. Zhang[2], Q. Zhang[3], J. Li[4];
[1]Beijing Botanical Garden, Beijing, China, [2]Landscape Horticulture, University of Maine, Orono, ME, United States, [3]College of Landscape Horticulture, Beijing Forestry University, Beijing, China, [4]Arnold Arboretum of Harvard University, Boston, MA, United States.

Ornamental peach (*Prunus persica* (L.) Batsch) is a popular ornamental plant with many published and new taxa. Unfortunately, its nomenclature and classification in the literature are contradictory and confusing, which limited further breeding and development. Molecular markers have been increasingly applied for distinguishing different taxa by producing robust, reliable and objective data for taxon descriptions. DNA fingerprinting library of all 51 available ornamental peach taxa has been established by using six EcoRI/MseI primer combinations of AFLP data. Among the 51 collected taxa, 32 cultivars derived from two species are legitimate taxa. These molecular data, particularly unique bands and band patterns of a taxon, could apply for identifying and supporting the legitimate taxon of ornamental peach. Application of AFLP data on nomenclature provides an example to aid future naming of ornamental taxa based on *International Code of Nomenclature for Cultivated Plants*. To include molecular data into the articles of ICNCP, recommendation provisions based on ornamental peach AFLP analysis were proposed.

P1533. Morphological and genetic diversity of endemic genus *Boninia* in the Bonin (Ogasawara) Islands, Japan

S. Katoh, H. Kato;
Makino Herbarium, Graduate School of Science, Tokyo Metropolitan University, Tokyo, Japan.

Boninia is one of two endemic genera found on Bonin (Ogasawara) islands located in the northwestern Pacific Ocean.

Boninia glabra, *B. grisea* and *B. grisea* var. *crassifolia* have been described, occupying a diversity of mesic to xeric habitats from sea cliffs to mountain ridge above 900 meters.

Morphological analysis based on 19 morphological characters was performed in total of eight populations of three taxa. The PCA analysis and the phenogram of cluster analysis revealed existence of morphological subgroups within *B. grisea* populations, on the other hand, each of *B. glabra* and *B. grisea* var. *crassifolia* formed a coherent cluster.

Genetic diversities within and among populations were examined using AFLPs. Analysis of molecular variance showed that 72.8% of variability was partitioned among individuals within populations. In the NJ analysis, there was hardly any structure and none of taxa formed distinct groups.

Morphological and genetic diversification within *B. grisea* could suggest incipient form of adaptive radiation, and disagreement of morphological and genetic boundaries of the other two taxa implies recent divergence.

P1534. The Database of Vascular Plants of Sichuan and Chongqing in the southwest of China

X. Gao;
Chengdu Institute of Biology, CAS, Chengdu, China.

There are more than 11,000 species of Vascular plants in Sichuan province and Chongqing City (VPSC) in the southwest of China. One of the famous biodiversity “hot-spot” areas- Hengduan Mountains is located in Western Sichuan and Eastern Xizang. A database of these species has been set up in recent years. VPSC is a part of the biodiversity information system project in the southwest of China supported by Chinese Academy of Sciences. VPSC provides an online information search. The species names and associated information including Chinese names, local names, images, distributions, resource use and related publications will be available.

In the database, the species names are based on the recently publications, such as Flora of China, especially monographs of revision. Some important synonymous in Flora Reipublicae Popularis Sinicae and Flora Sichuanica are cited.

Full Chinese information has been available in the database, and full English information will be available in the recent months.

P1535. Miquel's new taxa of the flowering plants described from Japan in Prolusio Florae Japonicae and some other works

H. Ohba[1], S. Akiyama[2], G. Thijsse[3];
[1]University of Tokyo, Tokyo, Japan, [2]National Science Museum, Tokyo, Japan, [3]National Herbarium of the Netherlands, Leiden, The Netherlands.

Dr. F. A. W. Miquel (1811--1871) studied the collections of Japanese plants collected by Phillip Franz von Siebold and his successors kept in the Rijksherbarium, Leiden (L). He described many new taxa based on those collections in *Prolusio Florae Japonicae* in his *Annales Musei Botanici Lugduno-Batavi*, and in other works between 1850 and 1868, but did not typify them in the present sense, since the type concept was not practice at that time. In studying the Japanese flora, there is a need to clarify Miquel’s taxa and to lectotypify them. The labels of the collections studied by Miquel usually give the locality only as “Japonia,” and the name of the collector. The specimens also bear Miquel’s determination. Additionally, some specimens have labels with the original information in Japanese or other languages, which are useful for identifying the cited specimens in Miquel’s articles.

As aid to those studying the Japanese flora, we have prepared a list of the taxa from Japan described by Miquel and have lectotypified a number of names for which a type specimen was not previously designated.

P1536. Sexual systems of tree species in two tropical forests of Brazil

C. C. Castro, R. R. Rodrigues;
Escola Superior de Agricultura Luiz de Queiroz, Piracicaba, Brazil.

The distribution of sexual functions within and between individuals in plant populations are reproductive strategies that seem to be shaped by selective pressures such as the pollination ecology and the mating systems. The great majority of tree species is hermaphrodite, being generally followed by the dioecy and monoecy. The objective of this study is to characterize the distribution of sexual systems of tree species in 10ha. of a Restinga forest and 10ha. of Cerrado forest in SE Brazil. Sexual systems were determined through the observation of morphological and functional male and female elements of flowers. The majority of the species studied were classified as hermaphrodite, being followed by dioecy and monoecy, what corroborates the patterns discussed above. Dioecious families recorded here were also recorded in other tropical environments, and generally presented small flowers. We found some evidences of androdioecy and ginodioecy, but a larger sample is necessary to draw any definitive conclusions.

P1537. Diversity Arrays Technology (DArT™): a promising DNA microarray-based comparative technique for molecular systematics and DNA barcoding

K. E. James[1], J. C. Vogel[1], A. Newton[1], N. Pedersen[1], A. Kilian[2];
[1]The Natural History Museum, London, United Kingdom, [2]Diversity Arrays Technology Pty Limited, Canberra, Australia.

Conventional techniques in molecular systematics typically involve time-consuming labor components that, while not prohibitive, limit the rate of scientific progress and pose a special challenge to comprehensive efforts like DNA barcoding. Developed to map variation within crop species, Diversity Arrays Technology (DArT™) rapidly identifies and genotypes hundreds of DNA polymorphisms that differentiate closely related organisms. Because DArT does not require prior sequence information, it is suitable for non-model organism research, potentially bridging the gap between genome-era biotechnology and studies of the natural world. To explore DArT as a tool for systematics and DNA barcoding, we commissioned Diversity Arrays Technology Pty Ltd to generate DArT data for two test sets of ferns and bryophytes. We examine the capacity of DArT data to resolve relationships, and we test DArT against specific challenges like hybridization and polyploidy, which seem likely to complicate barcoding. We discuss the potential applications of DArT in different arenas of plant research and propose a strategy for using DArT as a complementary tool for DNA barcoding.

P1538. Phylogenetic relationship of the Collemataceae(Lecanorales) family inferred from mSSU and nLSU rDNA sequences

M. A. G. Otálora[1], G. Aragón[1], I. Martínez[1], M. C. Molina[1], M. C. Molina[1], H. O'Brien[2], F. Lutzoni[2];
[1]Universidad Rey Juan Carlos, Madrid, Spain, [2]Duke University, Durham, NC, United States.

Collemataceae is a family of lichenized ascomycetes comprising the genera Collema F.H. Wigg., and Leptogium (Ach.) Gray, both with septate spores, and Physma A. Massal., Staurolemma Körb., and Ramalodium Nyl., which all have simple spores. The generic concept in this family is based on the presence or absence of a eucortex. Collema is divided according to the nature of the proper exciple, spore shape and thallus size. Leptogium is classified by, presence/absence of tomentum and lower cortex, spore shape and thallus anatomy. However, phylogenetic studies of Lecanorales suggest that Collema and Leptogium are not monophyletic. In order to evaluate relationships and re-circumscribe the genera in this family using monophyly as the grouping criterion, we have conducted phylogenetic analyses on mtSSU and nucLSU rDNA sequences from species representing the morphological diversity recorded for these two genera. Members of the Placynthiaceae and Pannariaceae were used as outgroup taxa for this study. Our results suggest that the early evolution of the Collema-Leptogium complex was associated with differential ecological requirements and thallus size.

P1539. Report of a new Lepanthes from Colombia

J. C. Farfán Camargo, E. C. Buitrago Delgado;
Instituto de Ciencias Naturales, Universidad Nacional de Colombia, Bogota, Colombia.

It is presented the report of *Lepanthes magnifca* Luer from Colombia, this species was known solely of the Ecuadorian north-east, but recently it was collected in the south-west of Colombia in Nariño Department between 1100 and 1300 meters of altitude. *Lepanthes* is the fourth genus more diverse from Colombian with 277 species; most species inhabit cloud forests where the temperature is low and humidity high. A significant number of species are limited in distribution, resulting in high levels of endemism, near 40 % of species are endemic of Colombia, but due to the present situation of the Andean forests most of the populations they are very low, therefore many of the species can be in extinction danger. Few it is known systematics, ecology, reproductive Biology and taxonomy of *Lepanthes*.

P1540. Phylogenetic analysis of *Calathea* Subgenus *Microcephalum*

L. S. Suárez S., G. Galeano, F. González, J. Kress, F. Borschsenius;
National University of Colombia, Bogota, Colombia.

The family Marantaceae is composed for 31 genera and near 530 species. The genus with the greatest number of species in the family is *Calathea*, with around 300 species. Calathea in the monograph for the family consist of four subgeneras: *Eucalathea, Macropus* , *Pseudophrynium* and *Microcephalum*. This subgenus is conformed by the smallest species of *Calathea,* one of them have an extensively distributed in the Neotrópico (*Calathea micans*) and the remaning seven species occurring in (*C. compacta, C. curaraya, C. dicephala, C. fucata, C. microcephala, C. pearcei, C. undulata*). The most revelant morphological character used to distinguish *Microcephalum* are small inflorescences with few bracts.

The goal of this work is to conduct a cladistics analysis based on morphological, anatomical and molecular (*matK* ,*trnL-F* y *trnK* 3') data in order to better understand the evolution and classification of the members in Subgenus *Microcephalum* and propose a phylogenetic hypothesis for this subgenus inside *Calathea*.

P1541. Show me the stone cells and I can see where you picked that Dionysia!

I. Trift, A. A. Anderberg;
Swedish Museum of Natural History, Stockholm, Sweden.

The phylogeny of the genus Dionysia (Primulaceae) based on sequence data from ca 50 species differs from earlier classifications. The genus Dionysia (mostly tufts or cushion-forming subshrubs) grows in mountains in the Middle East. When cladograms are projected onto a distribution map, a distinct eastern-western pattern can be seen.

Many morphological characters in Dionysia are size-dependent, and thus a reduction in size in several clades have resulted in homologies. Leaf stone cells (sclereids) is a size-independent character that contains much informative variation. Our study indicates that only for two types of stone cells have parallel evolution produced forms that look really similar. Other types of stone cells are limited to single clades. Bundles of terminal stone cells are characteristic of one western clade, and diffused stone cells appear only in eastern species, with one exception.

Leaf stone cells provide phylogenetic information and are very useful when trying to determine the position of a newly discovered species of Dionysia

P1542. Haustorium type, endophytic system form and vegetative reproduction in four *Scurrula* L. species from Nepal

M. P. Devkota[1], G. Glatzel[2], C. Calvin[3];
[1]Botany Department, Amrit Campus, Thamel, Kathmandu, Nepal, [2]Institute of Forest Ecology, BOKU, Vienna, Austria, [3]Department of Biology, Portland State University, Portland, OR, United States.

Epicortical roots (ER) occurred in all *Scurrula* species regardless of host or elevation. Primary and secondary haustoria evoked a wood-rose response by host. Wood-rose form varied between and within species. Primary haustorium structural differences allowed classification into (1) flanging endophyte, (2) flanging endophyte with radial shafts, and, (3) sinker endophyte. *Scurrula elata* and *S. gracilifolia* differed in haustorial form on different hosts, and *S. elata* had the widest host range due to its specific haustorial and endophytic system plasticity. Epicortical roots of *Scurrula* resembled those of other Old World species in origin, morphology and branching pattern, but differed from those of New World species. The formation of secondary haustoria and root-borne shoots by ERs was common, but their frequency varied depending on the age of the mistletoe and the length and vigour of epicortical roots.

P1542a. Systematics of *Lambertia* Sm. (Proteaceae)

A. Spooner[1,2];
[1]Edith Cowan University, Joondalup, Perth, Australia, [2]Western Australian Herbarium, Perth, Australia.

Lambertia Sm., (Subfamily Grevilleoideae, Tribe Macadamieae, Subtribe Lambertiinae) is an Australian genus of 10 species, with nine species in the south-west of Western Australia and the remaining one in eastern Australia. It includes three critically endangered species (*L. echinata* R.Br., *L. fairallii* Keighery and *L. orbifolia* C.A.Gardner) and two poorly known taxa (*L. multiflora* Lindl. and *L. rariflora* Meisn.). Despite limited recent taxonomic and genetic work a number of important taxonomic, evolutionary and biographical questions remain. This project aims to resolve taxonomic issues with particular reference to the threatened taxa and to produce a phylogeny of the genus. The relationships between sub-species, especially those which are separated geographically or for which preliminary molecular analysis indicates differences, will be addressed and the monophyly of *Lambertia* and its relationships with putative sister taxa will be investigated.

P1543. Ranunculus glacialis and Ranunculus alpestris: sexual reproduction in a high mountain environment

J. Wagner, G. Steinacher, S. Erler, G. Geisler;
Institute of Botany, Innsbruck, Austria.

The duration of the growing season is the most important factor limiting plant life in high alpine and arctic habitats. Depending on relief and snow accumulation in winter, 3-5 months in the alpine belt and 1-3 months in the nival belt can be used for growth and reproduction in the mountains of the temperate zone. In a survey on different mountain species in the alpine and subnival zone, R.alpestris and R.glacialis showed a particularly rapid and efficient seed production. Anthesis started 10 to 14 days after snowmelt. Stigmas were receptive as soon as flower buds opened so that seed development could start immediately after pollination. In R.alpestris fruits began to disperse already 24 days after anthesis, in R.glacialis the period of seed development ranged between 28 and 36 days. Seed set was around 53% in R.alpestris but attained up to 82% in R.glacialis. In both species, flower preformation for the following year coincides with the period of seed development. After fruit dispersal, leaves soon become senescent and die back. Thus, to complete the reproductive cycle, a growing period of 6-7 weeks per year is sufficient for both species.

P1544. Life strategy of the subnival species of Cerastium (Caryophyllaceae) from the Central Greater Caucasus and the Alps

M. Akhalkatsi[1], J. Wagner[2], L. Kobakhidze[1];
[1]Institute of Botany, Georgian Academy of Sciences, Tbilisi, Georgia,
[2]Institute of Botany, University Innsbruck, Innsbruck, Austria.

Life history and reproductive biology (number and sizes of flowers, ovules and seeds, seed set, embryology) have been studied in Cerastium kazbek from the Caucasus and C. uniflorum from the Alps. They are perennial herbs. C. kazbek reaches upper distribution limit of flowering plants in the Caucasus, 4000 m a.s.l., and is almost absent below 3000 m. C. uniflorum grows between 1900-3400 m a.s.l. Flower primordia are formed in early spring under snow cover. After snow melting flower buds start to develop. The first flowers open in the end of June in C. kazbek and end of July in C. uniflorum. Flowering is not simultaneous in C. kazbek and new buds are formed basipetally. The first fruits mature in August-September. Seed dispersal continues until October, when new snow cover ceases vegetative cycle. C. kazbek enters winter bearing fruits, flowers and buds in different developmental stages. The aboveground parts of the plant are frozen except basal leaves, which stay green during winter.

P1545. Sexual and clonal reproduction in the alpine Geum reptans: effects on demography, genetic variation and population differentiation

J. Stoecklin, A. R. Pluess, T. Weppler;
Botanical Institute, Basel, Switzerland.

Spatially isolated populations are more the rule than the exception in alpine plant life. Selection has resulted in a high frequency of long-lived species that rely on clonal growth for population dynamics. We studied the importance of sexual vs. clonal reproduction in a pioneer plant from glacier foreland for its local and spatial dynamics. A main focus was to test whether variation in reproductive behavior depends on population origin from successional stage and elevation. With RAPD-PCR we measured genetic diversity, differentiation and gene flow among populations with distances ranging from 0.2 to 208 km. In field and greenhouse experiments we tested how population origin and environment affect reproduction. Matrix modeling suggests that in Geum reptans sexual reproduction is equally important for population dynamics as clonal reproduction. Genetic diversity in populations was high and irrespective of population origin, populations were moderately differentiated. Results from experiments suggest limited adaptation to contrasting habitats and a high potential to maintain growth and reproduction under a large range of habitat conditions.

P1546. Breeding systems and rarity: pollination requirements and micro- and macro-distribution patterns in New Zealand forget-me-nots (*Myosotis* spp).

A. W. Robertson[1], A. M. Brandon[2];
[1]Massey University, NZ, Palmerston North, New Zealand, [2]Department of Conservation, Hamilton, New Zealand.

The alpine forget-me-nots (*Myosotis* spp) of New Zealand are all self-compatible, but fall into two breeding types - autonomous selfers, and pollinator-requiring species. This separation has apparently led to fundamental differences in distribution patterns. The pollinator-dependent species are all range-restricted, in some cases to the state of being point-endemics. These species tend to show poor reproductive success at low densities (i.e. they suffer from Allee effects), while the selfers are often in small sparse populations, but are more widespread and in these species seed set is not affected by the density of the population. We show that one character - herkogamy (the distance between anthers and stigma) accurately predicts geographic range of 33 species. Thus, our work demonstrates the importance of knowledge of breeding systems of rare plants for understanding conservation status and distribution pattern.

P1547. Breeding system of high mountain plant species in the European Alps

U. Ladinig, G. Steinacher, G. Geisler, J. Wagner;
Institute of Botany, Innsbruck, Austria.

In our study we investigated four alpine species (Saxifraga androsacea, S.caesia, S.moschata, Ranunculus alpestris) and three nival species (Saxifraga bryoides, Ranunculus glacialis, Cerastium uniflorum). All Saxifrages showed a mixed mating system with the highest reproductive success after natural pollination (mean S/O ratio 0.5-0.6). After natural selfing, the S/O ratio ranged between 0.1 and 0.4, but artificial selfing could markedly increase seed set. Apomixis seemed to be irrelevant in these species.

C.uniflorum turned out to be a clear outcrosser (mean S/O ratio 0.6) yielding no seeds by natural selfing and apomixis. The efficiency of artificial selfing was with 15% rather low, signifying a high degree of self incompatibility. R.glacialis attained S/O ratios of up to 0.8 after outcrossing, but only up to 0.12 after selfing and apomixis. R.alpestris showed a rather flexible breeding system: natural crossing and natural selfing led to about the same reproductive success (S/O ratio about 0.4) and about 20 percent of flowers performed apomixis. In total it could be shown that all species except for R.alpestris strongly depend on pollination by insects.

P1548. Conditions affecting recruitment of seedlish of Espeletia grandiflora in Parque Nacional Natural Chingaza, (Colombia).

F. F. Botero, J. L. Arias, J. A. Garcia, M. A. López;
Universidad Nacional de Colombia, Bogotá D.C., Colombia.

ABSTRACT

In this study two sites were sampled to evaluate conditions influencing recruitment of seedlish of *Espeletia* in Parque Nacional Natural Chingaza (Cundinamarca, Colombia). As results, we could find more microsites on second sampling, down on slope's gradient. This can be explained because of water streams that run down by the slope, carry seeds and deposit them at the end of the slope or in places with smaller slope. Most of sites for implantation corresponded to free-spaces in *Calamagrostis effusa* matrix occasioned by falling of *E. grandiflora*'s plants and necromass present, where seed are trapped and deposited. It was also found that size of microsites is directly related with number of seedlish which get implanted. Another factor that seems to play an important role is distance to mother plant, being more frequents seedlish in places near to source, given that mother plants modify microenvironmental conditions generating special conditions which favor implantation because seeds are covered and protected from low temperatures.

Then, implantation is determined by slope, diversity of microsites, and distance to plant mother.

P1549. Life history traits and population dynamic of *Saxifraga aizoides* in an alpine succession

S. Marcante;
University, Innsbruck, Austria.

Saxifraga aizoides is a pioneer species on the earliest stages of deglaciated terrain (moraines of 1971) on the foreland of the Rotmoos glacier (Central Alps, Tyrol, Austria). *Saxifraga* can be regarded as target species for investigating both the colonization mechanisms as well as the population dynamics. The ongoing project (2003-2007) is analysing the life history traits of this species along three different moraines. This poster will show the first results of soil seed bank, seed rain, germination ability and growth studies of *Saxifraga aizoides*.

20 permanent plots of 1 m^2 were established per moraine stage (moraines 1971, 1923, 1858 and one site beyond the terminal moraine) during the summer 2004. In each plot 5 soil samples were collected, a seed trap was installed, individuals of *Saxifraga* were marked and counted and several fruits were collected for germination experiments.

Saxifraga aizoides seems to have permanent soil seeds banks and to be well dispersed along the two young moraine stages. The regeneration of the population seems to be successfully on the 1971 moraine (612 seedlings) but not on the 1923 moraine (0 seedlings).

P1550. Reproductive biology of subalpine endemic *Minuartia nifensis* Mc Neill from Turkey

S. Gucel, O. Secmen;
Ege Univeristy Botanic Garden and Herbarium Center, Izmir, Turkey.

The *Minuartia nifensis* species found in Turkey, is one of the 16 members which belong to the *Xeralsine* subsection of the *Minuartia* section of the *Caryophyllaceae* family. The *Minuartia nifensis* species was first discovered on the Nif mountain peak by Reino Alava in the year 1966. In 1969, Mc Neill who had been doing research on the *Xeralsine* subsection, categorized this species as a distinct endemic one that can be found only on the Nif mountain (Davis 1988).

As indicated by John Mc Neill, the taxonomy of this subsection, of which *Minuartia nifensis* is a member, is extremely complicated and its area of existence within Turkey is still unclear. Mc Neill suspected that the reproductive biology of the group to which *Minuartia nifensis* belongs was somewhat unusual and wondered about the possibility of agamospermy.

This study has several goals. The first goal is to determine the population growth areas and estimate the number of individuals. The next one is to update the IUCN category of *Minuartia nifensis*, with the aid of the acquired data and to determine the reproductive biology. And the final goal is to develop specific conservation strategies.

P1551. Is there a female advantage in seed weight in gynodioecious Mountain Thyme along altitudinal gradients?

U. Landergott[1], J. Thompson[2], J. J. Schneller[1], **R. Holderegger**[3];
[1]Institute of Systematic Botany, University of Zürich, Zürich, Switzerland, [2]Centre D'Ecologie Fonctionelle et Evolutive CNRS, Montpellier, France, [3]WSL Swiss Federal Research Institute, Birmensdorf, Switzerland.

The frequency of females of gynodioecious *Thymus praecox* increases along altitudinal gradients in the Alps, maybe caused by a female advantage in seed weight at higher altitudes. Two sources of variation in seed weight were detected: (1) allocation of resources within fruits (linear decrease in weight with increasing seed number) and (2) altitude (heavier seeds at higher elevations). A transplant experiment showed genotypic differentiation for heavier seeds at higher altitudes. This could allow selection to act on the sex ratio with a stronger female advantage at higher altitudes. Indeed, females of *T. praecox* provisioned seeds better than hermaphrodites, but the relative advantage was constant at different altitudes. Moreover, hermaphrodites set less and thus heavier seeds, while females set more but lighter seeds. This counteracted the postulated female advantage from seed provisioning. Hence, no correlation between female advantage and current sex ratios was found, and the importance of genotypic differentiation in seed weight along altitudinal gradients for the maintenance of current sex ratios in Mountain Thyme is still not clear.

P1552. Genetic diversity in two glacier forelands in the Central Alps

C. Raffl Wallinger;
University of Innbruck, Innsbruck, Austria.

Glacier forelands offer the possibility to investigate the development of a newly formed ecosystem from the very beginning. So far little is known about the population dynamics of early settling species occurring there. The knowledge of genetic diversity within and among glacier foreland populations may contribute to a better understanding of the colonisation processes. *Saxifraga aizoides* is a dominant early colonising species, highly abundant within two parallel glacier valleys in the research area in the Oetztal (Central Alps, Tyrol, Austria). 16 populations of *Saxifraga aizoides* from different moraine stages (dated 1923, 1872, and 1858) and the adjacent valley slopes were exemplary investigated by an AFLP marker system. 209 fragments could be amplified, of which 92.8 % were polymorphic. The data were analysed using the AMOVA technique to test the variation within populations and among them as well as between the different glacier valleys. Furthermore, allocation procedures (AFLPOP) were performed to gain conclusive insights in the colonisation history.

P1553. Is there apospory in sunflower?

O. N. Voronova;
Komarov Botanical Institute, S.Petersburg, Russian Federation.

The phenomenon of apospory is interested in selection and genetic aspects (Batygina, 1999); in relation to this some data about formation of additional embryo sacs [AES] in sunflower are presented.

The ovule is tenuinucellate, with one integument, integumentary tapetum [IT] and one embryo sac [ES] that develops according Polygonum-type.

The *Helianthus annuus* (line VIR116) was pollinated by *H. occidentalis.* Temporal fixations of ovule permit to reveal AES at different time after pollination (from 50 m. to 56 h.). The 83 ovule were investigated and the AES were found in 15 of them. The penetration of pollen tubes into the ovules was not occurred. Almost all AES units are similar to those in ES except antipodals. They are not arranged linearly and have smaller sizes, spherical form and dark stained cytoplasm. The AES are not surrounded by IT, have the irregular form and located behind ES, but do not adjoin to it.

The data allow supposing that AES, founded in VIR116, can be of aposporic origin.

P1554. Apogamety and genetic heterogeneity in genus *Allium* L. (Alliaceae L.)

G. Y. Vinogradova, T. B. Batygina, G. E. Titova;
Komarov Botanical Institute, St.Petersburg, Russian Federation.

Polyembryony and connected with its apogamety is cause of genetic heterogeneity, since embryos arising in one seed (twins and triplets) have different inheritance (uniparental, biparental). Apogamety is rare phenomenon, because its reasons, origin and genesis of adventitious embryos are poorly understood. In genus *Allium* the both form of apogamety are found. Comparative cytoembryological investigation of ovule, embryo sac and adventitious embryos genesis in two species *Allium* with synergidal (*A. schoenoprasum*) and antipodal (*A. ramosum*) apogamety is carried out. It was revealed that during embryo sac development the synergid (*A. schoenoprasum*) or antipod (*A. ramosum*) becomes egg-like. Development of zygotic and adventitious embryos is similar (Onagrad-type). Owing to competition most of adventitious embryos degenerate in early stages. The frequency of polyembryony in mature seeds is 0,1 % in A.schoenoprasum and 6 % in A ramosum. Also various deviations in embryo sac development in A. ramosum are found. Perhaps, the adventitious embryos are appeared in seed due to the interaction different factors (genetic, physiological, ecological etc.).

P1555. Sexual reproduction as a factor influencing population genetic structure in agamic complex of Hieracium subgenus Pilosella

R. Rosenbaumová[1,2], F. Krahulec[2];
[1]Department of Botany, Charles University, Prague, Czech Republic,
[2]Institute of Botany, Academy of Sciences of the Czech Republic, PrŢhonice, Czech Republic.

Significance of sexual reproduction in populations of facultative apomicts is investigated. Model system consisting of hexaploid apomictic *Hieracium bauhini*, tetraploid sexual *H. pilosella* (parent accessions), their natural hybrids, and their artificially generated hybrids is used. Crossing experiments between parental accessions were carried out to quantify apomixis, sexuality and haploid parthenogenesis in *H. bauhini*; 95.47% of progeny was produced by apomixis, 2.47% of progeny were BII hybrids, 0.41% were BIII hybrids, and 1.65% were trihaploids in this accession. Mating system of particular progeny was estimated by emasculation experiments. Almost all BII hybrids were sexual and almost all trihaploids were apomicts; some selection acts here. Mating system has not been estimated in BIII hybrid. Experimental backcrossing of artificial hybrids is planned to examine the role of such hybrids in hybridisations in natural populations. It is also planned to compare artificial hybrids (with known origin) with natural hybrids of unknown origin. This will enable us to detect processes that could contribute to the origin of hybrids in the field.

P1556. Apomictic Taxa in the Vegetation of Central Europe

T. Gregor;
Hochschule Vechta, Institut für Didaktik der Naturwissenschaften, 49377 Vechta, Germany.

Predominantly agamospermous species account for more than 1/3 of Central Europe?s Higher Plants.

The presence of apomictic taxa was evaluated in 200.000 phytosociological relevés. 10 ecological qualities (water supply; calcium & magnesium supply; nutrient supply; environment dynamics; hemeroby; frequency of stresstolerant species; frequency of salt tolerant species; altitude; vegetation height; frequency of annuals) were rated in 143 syntaxonomical alliances in a 5-step scale and correlated with the number of apomicts.

Corrected mean numbers of apomicts vary from 0 to 1.9 per relevé and alliance. Rang correlations revealed significant data only for the traits altitude (more apomicts than expected), water (less apomicts), and salt (less apomicts). Apomicts do not predominantly occur in habitats with under average competition. They do not have larger ranges than related amphimicts. No explanation can be presented for the above average numbers of apomicts in high altitude habitats. Absence of apomicts from the species-poor habitats with high values for the traits water and salt might be artifacts.

P1557. Evolution of new apomictic interspecific hybrids from a sexual diploid *Allium senescens* var. *minor*

K. Oh[1], C. Jung[1], H. Kim[1], M. Lee[1], J. Sung[1], C. Park[1], B. Kim[2], D. Suh[1];
[1]Yeongnam Agricultural Research Institute, NICS, RDA, Milyang, Republic of Korea, [2]Research Management Bureau, RDA, Suwon, Republic of Korea.

All known apomictic species in nature are polyploid. To understand evolution of an apomictic hexaploid species *Allium senescens* (AS), we focused on a diploid sexual species *A. senescens* var. *minor* (ASM). Two species are taxonomically very near and the seed setting of their interspecific hybrid is normal. We harvested seeds of ASM which were planted near with AS and tetraploid interspecific hybrids from a cross between ASM and AS. Among 192 seedlings of ASM, 16 plants (8%) are triploid and 2 plants (1%) are tetraploids. Result of karyotype suggests that triploids and tetraploids are not developed by ASM itself but developed by contribution of foreign genome. All 88 flowered diploid plants are sexual but 2 of 15 flowered triploid plants and 1 flowered tetraploid plant showed parthenogenetic embryogenesis. The shape of parthenogenetic embryo developed from egg cell or antipodal cell is same with that of AS. Triploid, tetraploid and pentaploid AS or ASM x AS interspecific hybrid could be developed naturally by open pollination of sexual plant with pollen from different ploidy plant. Through the process apomixis also delivered and expressed in polyploid plant.

P1558. Relevance of clonal propagation of perennial plants in the semiarid Valley of Zapotitlán, Puebla, México.

M. D. García Suárez[1], J. L. Gómez Olivares[2], H. Serrano[2];
[1]Biology Department. Universidad Autónoma Metropolitana Iztapalapa México, D.F., Mexico City 09340, Mexico, [2]Dept. Health Sciences. Universidad Autónoma Metropolitana Iztapalapa México, D.F., Mexico City 09340, Mexico.

Plant survival in arid and semiarid environments represents a challenge due to harsh conditions. Vegetative reproduction operates as a safe strategy to perpetuate genotype. The clonal propagation of perennial plants was registered in 50 x 50 m permanent quadrants in the Zapotitlán Valley, in order to evaluate ist efficiency and the different alternatives of vegetative propagation that these plants present. We found that the most common reproductive strategy was the formation of basal shoots some examples are: *Agave marmorata, Agave macroacantha, Tillandsia dasyliriifolia, Tillandsia califanii, Echinocactus platyacanthus* and *Ferocactus latispinus;* rhizomatous shoots *Hechtia aff. podantha, Agave marmorata, Agave macroacantha;* buds *Yucca periculosa, Coriphanta radians;* bulbils *Agave marmorata, Agave macroacantha;* cladodes *Opuntia sp.* For some of these species, vegetative propagation has proved to be more efficient than seed propagation, allowing their survival in this extreme environment.

P1559. Structural and biochemical aspects of the life strategy of *Colchicum autumnale* L.

L. Franková[1], K. Bóka[2], O. Gašparíková[1], M. Pšenák[3];
[1]Institute of Botany, SAS, Bratislava, Slovakia, [2]ELTE University, Budapest, Hungary, [3]Comenius University, Faculty of Pharmacy, Bratislava, Slovakia.

Colchicum autumnale is a clonal, hysteranthous geophyte. Starch is the main storage material of ripe corm. 2/3 of starch of mother corm is reutilized during autumnal developmental stage, supporting development of shoot and flowers when the net production of reduced carbon does not exist at all. This decline was paralleled by increase in total amylolytic activity, consisting mainly of Ŭ-amylase, ƀ-amylase and Ŭ-glucosidase activities. Sucrose, glucose and fructose were the only free sugars detected in the corms, with maximum level during winter season. Using native PAGE a specific protein complex was identified in all organs of the plant. The rest of starch was completely reallocated from the mother to daughter corm during the photosynthetically active stage. Structural analyses showed the presence of sclerenchymatic tissue in the protuberance, helping the new corm to penetrate through the soil. On the boundary of new corm and shoot a meristematic layer was recognized. This layer is later on changed to abscission zone, which initiates the dying back of above-ground part regularly at the end of annual life-cycle. Supported by grant VEGA No. 1/1275/04.

P1560. Clonality on narrow endemic and relict *Dianthus callizonus* Schott et Kotschy in Romanian Carpathians

M. Onete, A. Paunescu;
Institute of Biology of the Romanian Academy, Bucharest, Romania.

Dianthus callizonus (The Little Carnation of Piatra Craiului) has its distribution in alpine and subalpine areas in Piatra Craiului Massif from Romanian Carpathians, on fixed and semifixed calcareous screes, grasslands. Due to the geomorphological and climate characteristics of the Massif, *D. callizonus* is a rare, relict and endemic species; limited resources can be invested either for sexual or for vegetative reproduction. Being included in different plant associations and having modular construction, the growth strategy may be realized by differences in the spatial arrangement and size of shoots, producing buds on horizontal roots and plagiotropic shoots which annually renew the aerial shoot system, adaptively associated with the stressful conditions of the habitats. Its distribution and maintenance in Piatra Craiului Massif depend on its pronounced capacity to expend laterally for reaching more areas inside of a very fragmented habitat and to resist in the same area.

P1561. Natural regeneration system of Cryptomeria japonica in a natural forest

K. Mishima[1], K. Takata[1], A. Makita[2], S. Sawada[3];
[1]Akita Prefectural University, Noshiro, Japan, [2]Akita Prefectural University, Akita, Japan, [3]Akita Prefecture Forest Technology Center, Akita, Japan.

Asexual propagation, such as layering and sprouting, plays an important role in regeneration system in a natural forest of Cryptomeria japonica. Especially, in regions along the Japan Sea, branches are pressed down to the ground by heavy snowfalls every year, and rooted. In order to understand regeneration system of Cryptomeria japonica in natural forest, we investigated spatial extension of clones, ratio of sexual and asexual propagations by field investigation and DNA analysis using microsatellite makers.

We established three study plots (P1, P2 and P3) in different forest condition in Akita prefecture, Japan. In plot P1, P2 and P3 all of individuals over 1.3 m in height were investigated for the position in a plot, tree height and diameter of breast height, and needles were sampled for DNA analysis. In each of the plots, core plots (PC1, PC2 and PC3) were established, and all of individuals were analyzed in the same way.

As a result, different regeneration types were detected in each study plot. This result suggested that each study plot is at a different regeneration stage.

P1562. Subterranean development of seedlings into clonal plants

A. Hirschfeld, **N. Pütz**;
Division of Biology and Education, 49377 Vechta, Germany.

Subterranean systems of perennials are a complex of organs, their structural components following functional necessities. Our TLP examinations make it possible to observe the underground progress from the seedling to an adult system, enabling us to describe unknown details, such as the transition from a turnip to a secondary fibrous root system in Potentilla inclinata.

Growth dynamics follow a three-step progress: (A) establishment of the seedling, (B) survival of an unfavourable season and preservation of site, and (C) cloning in the following seasons, combined with vegetative dispersal.

Furthermore, the development of subterranean systems is a dynamic with two kinetic processes: the vertical movement during seedling establishment brings the innovation buds to a safe soil position, and the horizontal movement during dispersal conquers new sites.

Thus, the "Three steps of progress" provide a fundamental background for acquiring an overall understanding of subterranean plant behaviour.

P1563. Potential costs of division of labor in clonal plants: effects of severing stolon connections between specialized ramets in *Trifolium repens*.

M. C. Sampaio[1,2], A. Smit-Tiekstra[1], **J. F. Stuefer**[1];
[1]Radboud University Nijmegen, Nijmegen, The Netherlands,
[2]Universidade Federal do Rio de Janeiro, Rio de Janeiro, Brazil.

Connected ramets of clonal plants can morphologically specialize in the uptake of locally abundant resources and exchange local surpluses among them. This phenomenon, termed division of labor, can markedly increase whole-clone performance in undisturbed habitats by enhancing the efficiency of resource extraction from heterogeneous environments. However, division of labor also makes cooperating ramets dependent on each other as they rely on internal resource imported from connected partner ramets. Disrupting stolon connections between specialized ramets should therefore result in potentially costs in terms of ramet mortality and reduced plant growth. We tested this hypothesis in a greenhouse experiment in which we exposed *Trifolium repens* to heterogeneous environments, where the availability of water and light was negatively correlated in space. After specialization we severed the connections between ramets and studied the survival and growth of disconnected clone parts. We found significant costs of specialization in terms of plant performance. We will argue that specialization costs may select against division of labor in disturbed habitats.

P1564. Within-tussock genotypic diversity: Identifying seedling establishment in *Carex sempervirens* tussocks using RAPDs

F. Yu[1], J. Schneller[2], B. Krüsi[1], M. Schütz[1], O. Wildi[1];
[1]Swiss Federal Institute of Forest, Snow and Landscape Research, Birmensdorf, Switzerland, [2]Institute of Systematic Botany, University of Zürich, Zürich, Switzerland.

Carex sempervirens Vill. (evergreen sedge) can form tussocks consisting of densely packed tillers. Previous studies have shown that seedlings of many other plant species can establish themselves within tussocks of *C. sempervirens*. A question, therefore, rises: Can seedlings of *C. sempervirens* themselves establish also within its tussocks, thereby forming multi-genotypic 'clones'? If they can, is the chance to establish new genotypes (seedlings) higher in weak tussocks than in similar-sized vigorous ones? Comparable number of *C. sempervirens* tillers have been sampled from 12 large, vigorous tussocks (basal diameter [mean ± 1 SD], 31 ± 2 cm; tiller cover [mean ± 1 SD], 24 ± 6%) and 12 large, weak ones (basal diameter, 30 ± 2 cm; tiller cover, 88 ± 9%). Randomly amplified polymorphic DNA (RAPD) markers were used to identify genotypes of the sampled tillers. A preliminary study shows that a *C. sempervirens* tussock can consist of more than one genotype, suggesting that seedlings of *C. sempervirens* may establish themselves within its own tussocks.

P1565. Influence of clonal structure on the selfing rate in *Vaccinium myrtillus* L.

A. Jacquemart, T. Albert;
Université catholique de Louvain, Louvain-la-Neuve, Belgium.

Clonal growth, which allows the multiplication of flowering shoots of the same genetic indivicual, can lead to a large floral display and may thus increase the rate of selfing through geitonogamy as a consequence of the increase in the number of flowers visited in succession. The aim of our study is to analyse the combined effect of the diversity and the spatial distribution of clones within *Vaccinium myrtillus* patches on the rate of geitonogamy by a direct estimation of the selfing rate using RAPD markers. Four mother plants were selected within patches characterised by a contrasted clonal structure. The selfing rate was significantly lower for the two mother plants situated within patches characterised by a higher number of clones and a more intermingled distribution of clones. Therefore, in clonal plant species that are not fully self-fertile such as *V. myrtillus*, an increase in the number of clones within a patch and/or an increase in the intermingling of clones could allow a species to have a large multiclonal patch size, and thus a large floral display to attract pollinators, while reducing the effect on the rate of geitonogamy.

P1566. Pteridophytic Flora of Central Himalayas : Rare and Endangered Elements and their Conservation

H. C. Pande;
Botanical Survey of India, Dehradun, India.

On the Indian subcontinent the Himalayas are one of the important centers of plant diversity and richness. The forest area in this region is ever decreasing. Out of the 500 fern species in the Himalayas, this region harbours 350 species. About 10% species of them are endemic. The tree trunk and branches are heavily laden with ferns. Forest destructions have caused huge damage to epiphytic fern vegetation mainly consisting of Polypodioid, Davalloid, Asplenoid, Vittarioid and Hymenophylloid members. Mining and construction of roads in the study area has caused tremendous loss to terrestrial ferns. Common species are becoming rare while the rare species are being completely lost to the Himalayan flora. The list of endangered species of ferns and fern allies in the Himalayas run to about 23. By and large our major concerns today should be to direct our efforts in conservation of members of *Psilotum, Hupergia, Osmunda, Cyathea, Botrychium, Athyrium, Lepisorus, Plagiogyria, Asplenium, Acrophorus, Ctenopters, Dryopteris, Polystichum,* which are in the state of immediate danger of depletion.

P1567. Genetic Biodiversity of Laurus azorica (Seub.) Franco in Macaronesia

B. Rudolph[1], L. Bartsch[1], I. Galinsky[1], Á. M. González Rodríguez[2], Á. B. Fernández López[3], C. Neff[4], J. G. Rohwer[1];
[1]University of Hamburg, Biocenter Klein Flottbek, Hamburg, Germany, [2]Dpto. Biología Vegetal, Facultad de Farmacia, La Laguna, Tenerife, Spain, [3]Parque Nacional de Garajonay, San Sebastián de La Gomera, Spain, [4]University of Karlsruhe, Institute of Geography and Geoecology, Karlsruhe, Germany.

Laurus azorica (Lauraceae) is the canopy plant of the Macaronesian laurel forest, an evergreen cloud forest relic of the European and North African Tertiary flora. This shady tree creates optimal conditions for a variety of endemic and endangered island species. It shows different morphotypes in different forest regions (Kunkel 1977) but their genetic background is still unknown. In this study we will analyse the genetic diversity of L. azorica, in order to improve its separation from its sister L. nobilis and to reconstruct its immigration, its expansion and its genetic diversity dynamics. So far leaf samples were collected from fragmented forest regions (Tenerife), a larger protected area (La Gomera) and in a natural forest (Azores), and analysed using AFLP markers. Additionally the development of SSR markers is in progress, to investigate population dynamics. These molecular analyses will allow us to look at several questions concerning conservation genetics of L. azorica.

P1568. Molecular and biochemical characterization of three different ecotypes of *Oreganum vulgare* grown in Albania.

A. Bacu, F. Babani, E. Kongjika;
Biological Research Institute, Tirana, Albania.

Three albanian ecotypes of *Oreganum vulgare* were undergone RAPD analysis and GC analysis.Genomic DNA was isolated from leaves of individual plants according to Gene Elute Plant Miniprep Kit, Sigma. PCR amplifications were carried out according to [Verde, 2002]. The composition of the essential oils was completed via GC. Buds were put in a media (MS, NAA, GA3) while during subculturing and rooting this media (MS) was added BAP : NAA.
The ecotypes collected in the areas of Peza, Llogara and Gjirokastra showed genetic polymorphism. The comparison of the constituents in three different vegetative phases showed differences especially in the quantity of thymol and carvacrole. The "in vitro" propagation of the ecotypes showed that the selected media offered optimal conditions for the growth of plantlets; and that ecotypes differed in the rate of development and rooting. Based on the results of the RAPD analysis, essential oils composition, and their attitude toward the "in vitro" propagation conditions we conclude that these ecotypes differ from each other and that they can not be grouped into groups of similarity.

P1569. Influence of human damage actions and soil characteristics in the establishment and development of secondary forest in sand coastal plain vegetation (Restinga Forest) of the littoral area in the state of São Paulo, Brazil

R. M. Reis-Duate[1], J. C. Casagrande[1], O. A. Silva[1], L. M. Barbosa[1], C. A. Sato[1], M. S. Galvão-Bueno[2];
[1]Bioscience Institute, Rio Claro, Brazil, [2]Natural History Institute Pau Brasil, São Paulo, Brazil.

The sand coastal plain vegetation (Restinga Forest) has been described as an ecosystem associated with the Atlantic Forest, constituted of mosaics. The restinga forest is one of the most fragile and susceptible ecosystems, showing low resilience to human damage. This work was carried out in the Anchieta island, a State Park in the city of Ubatuba in the northern coast of the state of São Paulo, Brazil (45º02' - 45º05' W and 23º31' - 23º34' S). The soil umidity associated with the type and intensity of human damage actions, as well as the natural time regeneration, creating the soil fertility patterns, determined the vegetation physiognomies found in the mosaic of that secondary forest. Based on such information and the plasticity of the most representative plant species, was suggested a model of plantation for natural recovery of gallery forest in Restinga ecosystems.

P1570. Uneven partitioning of genetic variation in chloroplast microsatellites of Swiss stone pine populations along the European mountain range

M. Höhn[1], P. Ábrán[2], G. Bisztray[1], A. Buonamici[3], K. Cseke[1], F. Gugerli[4], F. Sebastiani[3], G. G. Vendramin[5];
[1]Corvinus University of Budapest, Budapest, Hungary, [2]Environmental Protection Agency Mures, Targu Mures, Romania, [3]Dipartimento di Biotecnologie Agrarie, Laboratorio Genexpress, Università degli Studi, Sesto Fiorentino (Firenze), Italy, [4]WSL Swiss Federal Research Institute, Birmensdorf, Switzerland, [5]Istituto di Genetica Vegetale, CNR, Sesto Fiorentino (Firenze), Italy.

Pinus cembra is an important element of European mountain forests. The few regional studies available to date are inconclusive regarding population processes that have led to the current pattern of genetic diversity. We sampled 19 natural populations from the Swiss Alps, representing the central part of the species' natural range, and 9 peripheral populations from the Tatra and Carpathians. Peripheral populations are expected to diverge from central populations as a result of the interwoven effects of isolation, genetic drift, and natural selection. Three chloroplast microsatellites yielded high levels of haplotypic variation in most populations. In spite of their limited size, the peripheral populations from the Carpathians also displayed high variation, with the most variable population found in the South Carpathians. As expected, the two study regions were genetically separated, and differentiation among populations was lower in the central Alps than in the Carpathians Therefore the gene pool of the Carpathian populations represents an important component of the genetic resources of *P. cembra* deserving special attention in conservation efforts.

P1571. The relict isolated population of Siberian Spruce (*Picea obovata* Ledeb.) at North-East of Asia.

E. A. Andrianova, O. A. Mochalova;
Institute of biologic problem of the North, Magadan, Russian Federation.

The relict isolated population of Siberian Spruce (Picea obovata Ledeb.) is situated at the northern coast of the Okhotsk Sea, at the Yama River basin (59^{0}48’ and 59^{0}32’N, 153^{0}20’ and 153^{0}57’E). This remote refuge is located more than 650 km from the main range of Picea obovata, and in fact, is the extreme North-East refuge of this important forest species. This enclave of the Spruce forest is about than 60 km^2. In spite of long term investigations, it is still a question about precision boundary Spruce distribution.

There is an “island” of the dark-coniferous forests in light-coniferous (“yakutian”) and shrub-pine (“beringian”) habitats. This refuge serves as a stronghold for a variety of rare and relict plants. Spruce forests have most complex floristic composition and structure among all forest types at the northern coast of the Okhotsk Sea. The spruce patches have a tendency to increase its spread in the Yama valley, however this growth of range is limited by some features of landscape and severe climate conductions which influence the seed ability of trees. It appears, that come individual spruce trees demonstrate growth in conditions far from ecological optimum.

P1572. Modern state of stone exposure’s vegetation in the steppe zone of European part of Russia

M. M. Sereda, O. N. Demina;
Research Scientific Institute of Biology, Rostov on Don, Russian Federation.

Rich experience in investigation of stone steppes and exposures is accumulated in Russia. However, this object concerns with interests of floristic, phytocenology, steppe science, biogeography, phytosozology etc, therefore some necessity is hutched to elaborate the complex of methods for observation of this societies with involving of some modern approaches to the vegetation’s classification, geomorphology, mapping and monitoring.

Last years we have comprehensively investigated stone steppes of Eastern Don bass. The great experience is received in vegetation’s classification with application of dominant and ecoloco-floristical approaches, the geobotanical maps are elaborated with the GIS technologies of model arrays of stone steppe in its base. Especially for gully systems the original method of geobotanical profiles is elaborated. The great number of endemic and relict species is also revealed.

P1573. Biodiversity of Black Microcolonial Fungi isolated from Antalya/Turkey (Side, Perge, Termessos) and their biodeterioration-potential

H. Sert[1,2], K. Sterflinger[1];
[1]University of Natural Resources and Applied Life Sciences, Austrian Center of Biological Resources and Applied Mycology (ACBR), Vienna, Austria, [2]Akdeniz University, Faculty of Arts and Sciences, Dep. of Biology, Antalya, Turkey.

Abstract

In this study rock surfaces of archaeological sites in Antalya were investigated with focus on black fungi for the first time. Black, meristematic fungi were isolated from surfaces of historical marble monuments in Antalya (Side, Perge, Termessos). Their morphology was characterized, their diversity was documented and the taxonomy and phylogeny of new isolates was clarified based on molecular methods, that is, by sequencing parts of the small ribosomal subunit (18 S) and internal transcribed spacer regions. From a total of around 250 samples 111 different fungal strains were isolated. In 72 of 111 strains the rDNA sequencing data and the lack of homologies in “Genbank” gave stong evidence that 72 of 111 strains have to be described as new species and/or genera. All of them, however, clustered within the ascomycete orders of Dothideales or Chaetothyriales. Field studies show that these organisms cause color changes, black spots, crater shaped lesions as well as chipping and exfoliation of the rock surfaces in Antalya and thus they have to be regarded as a serious threat for the antique cultural heritage in Turkey.

P1574. Phylogenetic relationships in the complex *Galactia-Collaea-Camptosema* (Diocleinae-Phaseoleae-Papilionoideae-Leguminosae) from southern South America

S. M. Sede[1], D. Tosto[1], L. Poggio[2], **R. H. Fortunato**[3];
[1]Facultad de Ciencias Exactas y Naturales, UBA, Buenos Aires, Argentina, [2]CONICET / Facultad de Ciencias Exactas y Naturales, UBA, Buenos Aires, Argentina, [3]CONICET / INTA, Castelar, prov. Buenos Aires, Argentina.

The genera *Galactia* P. Browne (pantropical), *Camptosema* Hook. & Arn. (neotropical) and *Collaea* DC. (neotropical) are grouped in a complex with exomorphological similarities and different criteria were adopted to delimit them. The phylogenetic hypothesis based on morphological characters do not support the monophyly of *Galactia* and *Camptosema*. Southern South American species were studied including those which generate conflict in the generic delimitation of the complex. The aim of this study was to analyze the phylogenetic relationships of the species by the parsimony method using nuclear (ITS) and chloroplast (trnL-trnF IGS) sequence data. The results obtained did not corroborate the monophyly of *Galactia* and *Camptosema* in agreement with the previous phylogenetic analyses based on morphological characters. The chromosome characteristics of the group were also evaluated and new records for the conflictive species are reported. The results of this study together with the morphological revision point out the necessity of reviewing the generic circumscription of the complex.

P1575. The populations of Seabuckthorn from Zarafshan nature reserve of Uzbekistan as a initial gernplasme for breeding

F. J. Kabulova;
Samarkand State university, Samarkand, Uzbekistan.

Seabuckthorn is considered as a valuable fruite and medicinal plant in Uzbekistan.

The area of distribution located mainly in a repairian forests of Zarafshan, Ak-darya and Karadarya rivers. Zarafshan natural reserve is also considered as a principal area of distribution with total area as 64 hectare.

The natural plantations consist of shrubby and tree form with 2,5-10 m of height. The habitus is differed by shape, type and density as well. The fruits are also differed by their color (yellow, yellow-orange, orange, red-orange and red), size (small,medium, large) and shape (round, oval, cylindrical).

The total weit of 100 fruits are from 5 to 20 g. In wild populations it were identified forms with a few thorns and red color. This forms are very interesting for further breeding form. It was determined higher content of fatty oil and caratenoids in this form. The obtained results will help to develop better ways of preservation this plant in the region.

P1576. Mapping quantitative trait loci in multiple populations of *Arabidopsis thaliana* identifies natural allelic variation for trichome density

V. Symonds, A. Lloyd;
University of Texas-Austin, Austin, TX, United States.

The genetic and molecular bases of complex traits are poorly understood. A common approach to this problem is the use of whole-genome scans to identify polygenes, or quantitative trait loci (QTL). The results of such analyses provide estimates of several genetic parameters that may underlie phenotypic variation, including the number of loci, the type and magnitude of their effects, interactions between genes (epistasis), and gene-by-environment interactions. This collection of parameters is often referred to as the “genetic architecture” of a trait. Because these parameters are largely population specific, however, we investigated the potential for variation in genetic architecture by mapping QTL for trichome density in four experimental populations of *Arabidopsis thaliana*. Our mapping results identify nine QTL of significant effect. Through a candidate gene approach, we have cloned one of these QTL. At this locus, we have revealed extensive molecular variation, some of which determines trichome density variation among natural accessions. We shall provide mapping results, comparative analyses, and interpretations of these findings.

P1577. Genetic Variation in Natural Populations of Ricinus communis L : Indirect Ploidy Level Approach

A. S. A. Alhammadi;
University of Sanaa, Sanaa, Yemen.

Abstract

This study aims at finding the cause of the genetic variation observed in natural population of *Ricinus communis* L plant. The hypothesis of different ploidy level was tested using indirect approach. Samples of seeds from populations differing in morphological traits were collected from different localities. The collected seeds were grown in the same experimental field under the same environmental conditions Two groups of traits were compared. These traits usually used as indirect indicators of differences in ploidy level in flowering plants. The first group included time to germination, plant height, Plant color, time to flowering, flower size, number of fruits per inflorescence, and 100 seeds weight. All these traits have shown significant statistical difference. Other group of traits was stomatal density stomata size and number of chloroplast in the guard cells

The results indicate that the cause of the genetic variation in two populations of *Ricinus communis* L is difference in chromosome number. Direct estimation of ploidy level is recommended before initiating any genetic or breeding program using these populations

P1578. Transformer-3: Automating population genetic analysis.

M. Baccarani-Rosas, J. Caujapé-Castells;
Jardín Botánico Canario "Viera y Clavijo", Las Palmas de Gran Canaria, Spain.

The genotyping and the processing of molecular population genetic co-dominant markers need become error-free and much less time consuming in order to implement higher accuracy and urgency in the growing number of applications of this kind of data. In this contribution we introduce Transformer-3, a versatile, user-friendly, proof-reading software that processes drawn interpretations of molecular patterns and genotype or binary matrices introduced by the user to calculate the parameters related to the probabilities of allelic loss and to generate the input files needed to run the programs of most widespread use in population genetics for any possible grouping of populations. The program, still in beta version, is suitable for codominant (allozyme or microsatellite) and dominant (AFLP, RFLP and RAPDs) molecular data for up to 66,000 individuals divided into a maximum of 50 populations. Transformer-3 is programmed in visual basic using a Microsoft Excel® sheet, so it will run in any computer that can contain the Microsoft Office® package. Copies of the current beta version will be made available upon request to the authors.

P1579. Molecular characterization of an Olive (*Olea europea* L.) cultivar from Abruzzo region

E. Albertini[1], R. Torricelli1[1], S. Ancillotti[1], L. Pollastri[2], **F. Veronesi**[1];
[1]Plant Biology and Agro-environmental and Animal Biotechnology Department, Perugia, Italy, [2]ARSSA, Pescara, Italy.

Olive (*Olea europea* L., 2n=2x=46), an oil-producing tree, is considered the most important fruit crop throughout the Mediterranean Basin and it is characterized by a large number of varieties, most of which behave in a self-incompatible way. Within a Mediterranean overall cultivation of about 2000 cultivars Italy plays a primary role with its 500 cultivars and, with its 45,248 ha cultivated with olive, the Abruzzo Region is one of the most important areas of olive cultivation in Italy. There are at least 21 cultivars of olive identified in Abruzzo. Within these, Dritta is one of the most popular cultivar because of its medium-high yield in oil (18-20%) that is of high organoleptic quality. Since the characteristics of an olive oil, as well as of other crop-derived products, depends both on the area of cultivation and genetic constitution of cultivars, a germplasm characterization represent a key factor for the traceability of the final product. Here we report molecular characterization of 21 accessions of DRITTA cultivar compared with 8 of the most cultivated varieties in the Abruzzo region.

P1580. Multiple evolution of monoecy from dioecy in Momordica (Cucurbitaceae)

H. Schäfer, S. S. Renner;
Ludwig Maximilians University, Munich, Germany.

The African/Asian genus Momordica comprises 47 species, all with unisexual flowers. Phylogenetic analyses of chloroplast gene, intron, and spacer sequences from all species show that Momordica is monophyletic and sister to the Asian Siraitia, Indofevillea, Baijiania, and Thladiantha, all dioecious. The eight Asian Momordica species also are dioecious. Of the 39 African species, 20 are dioecious and 19 monoecious, and monoecy apparently evolved five times. Pollinator discrimination against female individuals may be among the selective factors favoring monoecy: With the exception of the widely cultivated M. balsamina and M. charantia, Momordica species are pollinated by Ctenoplectra bees, which obtain pollen, nectar, and fatty oils from the male flowers. Female flowers are similar in morphology, but almost or entirely rewardless. Where Momordica occurs at low densities, such as in savannas, pollinators may avoid females, favoring cosexuality. Species of humid forests are mostly dioecious. Fieldwork will test this hypothesis.

P1581. Assessment of genetic variation of common juniper (Juniperus communis L.) in Luxembourg

C. Steinbach, T. Helminger, G. Colling, S. Hermant, L. Griz, A. Bonniot;
Musée national d'histoire naturelle, Luxembourg, Luxembourg.

In order to assess the conservation value of small stands of common juniper (Juniperus communis L.), we studied the genetic population structure of this rare shrub in Luxembourg. In 10 populations spread throughout the range, we sampled up to fifteen plants along transects. To test for genetic structuring within the populations, more than one transect was used in the largest populations.

Most genetic variance was found within populations (81% of total variance), although there was a significant genetic differentiation (RAPD patterns) between populations (10%) ($P < 0.05$) and among transects within populations (9%) ($P < 0.002$). The mean number of individuals exchanged per generation between transects (Nem = 1.06) and the similar amount of variance within and between populations indicate a moderate gene flow within the study region. This could be explained by wind pollination and seed dispersal by birds. It might also reflect a wider distribution of this long-lived plant in the recent past before changes in agricultural practices led to increased fragmentation of its habitat.

P1582. High levels of genetic diversity in *Dioon caputoi* De Luca, Sabato and Vázquez Torres (Zamiaceae, Cycadales) a narowly distributed species of Puebla, México.

D. Cabrera-Toledo, J. A. González-Astorga, A. P. Vovides;
Instituto de Ecología, A.C, Xalapa, Mexico.

The amount and distribution of genetic diversity within and among four populations of *Dioon caputoi*, a narrowly distributed cycad of Puebla state in México, was determinated. High levels of genetic variability was found (P = 78.95%; A = 1.91; H_e= 0.350), compared with other species of cycad in the Zamiaceae. In spite of the small population sizes (between 50 and 120 individuals) there was no significant global nor local inbreeding (F_{it}= -0.242 ± 0.09; F_{is}= -0.379 ± 0.08, respectively). Rather, a significant excess of observed heterocigosity with respect to Hardy-Weinberg equilibrium expectations was obtained in the four populations studied. However, since the analysis of bottleneck showed a significant deviation from the mutation-genetic drift equilibrium model in the four populations (that is, a transient excess of heterosigosity) this high level of genetic diversity could be explained as a recent reduction in population sizes. Biogeographical and ecological implications are discussed.

P1583. Allozyme diversity of diploid and dysploid species of *Delphinium* series *Fissa* (Ranunculaceae) in the W Mediterranean area

M. Orellana, J. López-Pujol, A. M. Rovira, J. Simon, C. Blanché, M. Bosch;
Laboratori de Botànica, Facultat de Farmàcia, Universitat de Barcelona, Barcelona, Spain.

The genetic diversity and population structure of *Delphinium* series *Fissa* taxa (Ranunculaceae) in the Western Mediterranean area is assessed using allozyme electrophoresis. This group comprises four taxa (*D. bolosii*, *D. mansanetianum, D. fissum* subsp. *fissum* and *D. fissum* subsp*. sordidum*), most of them narrow endemic and endangered plants. Dysploid (2n=18) and diploid (2n=16) species have been reported for this series.Within the 12 surveyed populations, a total of 15 loci were interpreted and 30 alleles were identified. Low levels of genetic diversity were found for all taxa, the most diverse was the dysploid *D. bolosii* (P=28.9%, A=1.4 and H_e=0.104) and the less diverse *D. mansanetianum* (P=6.7%, A=1.2 and H_e=0.071). High levels of divergence were estimated for *D. f fissum* subsp*. sordidum* populations, while a taxa-specific allele (*Idh-1b*) was found for *D. fissum* subsp*. fissum*. Nei's genetic identity index was also calculated suggesting a close relationship between the recently described *D. mansanetianum* and *D. bolosii*. Given their threatened status, these data are helpful for management strategies and conservation plans for these taxa.

P1584. Simple sequence repeat (SSR) analysis for assessment of genetic variability in apricot cultivars

F. Maghuly[1], E. Borroto[1], S. Leopold[1], A. Pedryc[2], H. Katinger[1], M. Laimer[1];
[1]IAM, Vienna, Austria, [2]Corvinus University, Budapest, Hungary.

The genetic diversity of apricot (*Prunus armeniaca*, 2n =16) was studied using SSR markers. A total of 129 apricot cultivars from different geographic origins of Corvinus University (Budapest, Hungary) and BOKU (Vienna, Austria) were selected. Thirty microsatellites primer pairs, developed in apricot were used. Ten of them amplified polymorphic patterns, which was useful to investigate patterns of variation in apricot cultivars.

The UPGMA dendrogram based on the genetic distance reflected the grouping of cultivars in agreement with their geographic origin and pedigree. Eastern European cultivars (Hungarian) belong to four subgroups, which share the same parentals in their pedigrees. Three subgroups of the Hungarian cultivars seem to be more closely related to the Western European than to the Central Asian cultivars, while one subgroup more close to the Central Asian group.

Asian and American cultivars were intermediate showing a different genetic basis than the Eastern European cultivars.

The implications of these data for the use of SSR fingerprints in breeder´s rights protection and apricot breeding are discussed.

P1585. RAPD variation of the regional endemic *Saxifraga rosacea* subsp. *sponhemica* in Europe

T. Walisch[1], S. Hermant[1], G. Colling[1], D. Matthies[2];
[1]Musée National d'Histoire Naturelle, Luxembourg, Luxembourg,
[2]Phillips-Universität Marburg, Marburg, Germany.

We studied the genetic population structure of the rare rock plant *Saxifraga rosacea* ssp. *sponhemica* which occurs in naturally isolated populations in several European countries. In 34 populations we sampled up to fourteen plants each along transects. To test for genetic structuring within the populations, more than one transect was used in four large populations. There was strong genetic differentiation (RAPD patterns) among countries (15% of total variation), among populations within countries (21%) and between transects within populations (11%) (all P < 0.001). The strong genetic variation among populations and the mean number of individuals exchanged per generation between transects (Nem = 0.27) indicates that gene flow is low. The significant genetic differentiation between transects within populations indicates little gene flow even within populations. Possible explanations for the generally low gene flow are pollinator behaviour and restricted dispersal of the seeds. Genetic differentiation among all 38 transects (pairwise PhiST) was related to geographic distance (Mantel test, r=0.539, P<0.0001).

P1586. Genetic variability and fertility of *Vriesea gigantea* (Bromeliaceae) populations from the Rainforest in South Brazil

C. P. da Silva, F. Bered, G. M. Paggi, E. K. dos Santos, M. H. B. Zanettini;
Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil.

Vriesea gigantea Gaud. is a bromeliad species occuring in the Atlantic Rainforest, eastern Brazil. Little is known about the genetic variability, fertility and viability of bromeliads populations. The aims of this study are: to describe the genetic variability by using SSR molecular markers in populations of *V. gigantea*, and to analyze the fertility and viability of these populations throughout meiotic behaviour in pollen-mother-cells, pollen viability, and seeds germination. Five SSR primers developed by Boneh et al. (2003) for *Tillandsia* and *Guzmania* genus will be used. The primers were tested on 12 individuals from different locations in the south Brazil. Three primers have amplified positively (EB6 -3alleles; E6 -2alleles; and P2P19 -8alleles) under the same PCR conditions described by the authors. The heterozigosity observed to each primer were: 0.125, 0.8, and 0.875, repectively. Optimazed PCR conditions are being developed to the others two pair primers (CT5 and E19). These results are promising for the utilization of these markers to study genetic variability of related species of *Tillandsia* and *Guzmania* genus such as *V. gigantea*.

P1587. Genetic investigation of African willows along the Blue and the main Nile rivers in the confluent region of Khartoum (Sudan)

N. B. Hamza[1], J. Glössl[1], E. A. Elsheikh[2], C. Arnold[3,1];
[1]Institute of Applied Genetics and Cell Biology, 1190 Vienna, Austria,
[2]Seed Research Center, Ministry of Science& Technology, Khartoum, Sudan, [3]National Centre of Competence in Research (NCCR) Plant Survival, Neuchâtel, Switzerland.

The recent increase of human activity along the Nile deeply affects this floodplain ecosystem. Willows represent a reliable solution to the decontamination of water as well as the stabilisation of the riverbanks. However, till now little is known about the genetics of both native Salix subserrata Willd. and S. murielii Skan. The ploidy level of both species was determined using flow cytometry. At the chloroplast level, one haplotype of each species was identified by sequencing of five regions of the chloroplast, PCR-RFLP and SSCP. The nuclear genome was analysed using microsatellite primers originally developed for Salix burjatica and Populus sp. The results show the presence of vegetative reproduction, as 13 % were clones. Multivariate analysis (PCA) of the genetic data reveals hybridisation and introgression of both species in the studied areas. Results of microsatellites analysis show a low genetic differentiation among the investigated populations (FST value= 0.13). This low genetic diversity might be attributed to the high gene flow between populations, through pollen flow and/or seed dispersal rather than to the quite low vegetative reproduction.

P1588. Molecular evidences for repeated hybridization events as the origin of the genus × *Crepidiastrixeris* (Asteraceae) using RAPDs and ITS data

Y. Saito[1,2], M. Möller[3], G. Kokubugata[4,1], T. Katsuyama[5], W. Marubashi[1], T. Iwashina[4,1];
[1]Ibaraki University, Ibaraki, Japan, [2]National Scence Museum, Tokyo, Ibaraki, Japan, [3]Royal Botanic Garden Edinburgh, Edinburgh, Scotland, United Kingdom, [4]National Science Museum, Tokyo, Ibaraki, Japan, [5]Kanagawa Prefectural Museum of Natural History, Kanagawa, Japan.

The hybrid origin of × *Crepidiastrixeris denticulato-platyphylla* was investigated using RAPDs and ITS sequence data. The putative parents *Paraixeris denticulata* and *Crepidiastrum platyphyllum* represent separate species, irrespective of geographic origin. The combined occurrence of species-specific RAPD markers from *P. denticulata* and *C. platyphyllum* in × *C. denticulato-platyphylla* established unambiguously a hybrid origin between the two taxa. This is in line with the occurrence of a combination of morphological characters, such as plant habit and floret numbers. The parent taxa differed by 7 nucleotide substitutions and two indel events from each other in the ITS region. The hybrids showed sequence additively and mostly represented F_1 plants, with the exception of two plants which were of putative F2 origin. The present study suggests that × *C. denticulato-platyphylla* exists due to frequent hybridization between the two species of *P. denticulata* and *C. platyphyllum*.

P1589. Genetic diversity studies on *Mallotus philippinensis* Muell. (-A Dye yielding plant) using Isozyme data

R. Siva, K. V.Krishnamurthy;
Bharathidasan University, Trichirappalli, India.

Isozyme analysis has been applied widely to characterize the patterns of genetic differentiation in plant species. Genetic characterization of natural resources is an essential step for a better understanding of genetic resources for the implementation of in situ and ex situ conservation activities. So adequate knowledge about the plant is necessary for planning sustainable development of any region like India, where the flora is rich in diversity and endemism. *Mallotus philippinensis*, belongs to the family Euphorbiaceae, yielding red colour dye from its fruit was used in ancient India, by the Hindu silk dyer. Genetic diversity was assessed on seeds collected from 10 different locations and twelve different enzyme systems were screened and forty two putative loci were totally resolved with sufficient consistency and clarity. Cluster analysis showing the great genetic variations among the population. The outcome of this study, it is hoped, would help to exploit populations that would show the greatest genetic diversity for improving the dye content through future studies. Also these results have important implications for the conservation strategy.

P1590. Genetic structure of an ectomycorrhizal fungus *Chroogomphus rutilus* population in a *Pinus tabulaeformis* forest

L. D. Guo, W. X. Huai;
Systematic Mycology & Lichenology Laboratory, Institute of Microbiology, Chinese Academy of Sciences, Beijing, China.

The genetic structure of an ectomycorrhizal fungus *Chroogomphus rutilus* population was evaluated in a *Pinus tabulaeformis* stand at Dongling Mountain of north China using random amplified microsatellite (RAMS) markers. Two hundred and ten sporocarps were collected at two stands and divided into 108 genets analyzed by three 5'-anchored RAMS primers. Among these genets, 75 (69.4%) were represented by single sporocarps, the other 33 comprised multiple sporocarps. The genetic diversity as determined by Shannon-Weaver diversity index was 2.92 in this population, furthermore, there were similar diversity indices within stand A (2.89) and stand B (2.92). The largest genet is up to 450 m. The genets within a similar group located close to each other. The results indicate that *C. rutilus* population in mature forest stands can comprise large genets or small genets, and suggest that it is very important to spread *via* below-ground mycelia, as well as sexual spore propagation in the life history of the *C. rutilus* population.

P1591. Morphometric circumscription of species and infraspecific taxa in Tunisian *Pseudophrys* (*Ophrys*, Orchidaceae)

S. Bernardos[1], A. Crespí[2], F. Amich[1];
[1]University of Salamanca, Salamanca, Spain, [2]University of Trás-os-Montes e Alto Douro, Vila Real, Portugal.

The section *Pseudophrys* is a taxonomically critical species complex with pronounced morphological variation, suggesting the need for further taxonomic evaluation, specially in Mediterranean Africa, a centre of radiation for orchids of this section of the genus *Ophrys*. The taxonomy of *Pseudophrys* in Tunisia has been controversial. A multivariate analysis has been performed in order to study the polymorphisms of the twelve species represented in Tunisia. Extensive observations in the field and analysis of morphological characters show that most of the characters used by previous authors for distinguishing the species are variable between or even within populations. To determine characters distinguishing different species and to examine their circumscription, we performed morphometric analyses on three different subsets, one with all the currently recognized species, other two containing the closely related *Ophrys eleonorae*/*O. vallesiana*, and *O. africana*/*O. gazella*. These populations were treated as Operational Taxonomic Units (OTUs) and studied using cluster analysis, principal component analysis and canonical discriminant analysis.

P1592. Genetic diversity of Kentucky bluegrass (*Poa pratensis* L.) populations evaluated by RAPD markers

M. Be o, J. Brindza;
Slovak University of Agriculture, Nitra, Slovakia.

Random amplified polymorphic DNA (RAPD) markers were used to measure genetic diversity in germplasm collection of Kentucky bluegrass (*Poa pratensis* L.). Total of 20 populations (local varietes and cultivars) were collected from Slovakia, Czech Republic and Ukraine. From 12 tested primers, a 23 bands (in average 12 bands per population) was detected by two 10-mer RAPD primers PP2 5´CCgCAgTCTg3´ and PP3 5´ACATCgCCCA3´. Nei and Li´s index of the genetic distance was used to class diversity between populations. This index showed low genetic diversity, in average was 0,288, but second primer PP3 detected higher genetic diversity. Cluster analysis UPGMA was used to illustrate the diversity of genetic material. This analysis detected 4 populations (South Ukraine, 63/718, 63/721 and Maly Slizovnik) with high genetic diversity. They created different cluster of all populations. Optimalized PCR RAPD reaction and RAPD primers PP2 and PP3 could be used to detect genetic diversity between populations and could be used in plant breeding program of Kentucky bluegrass.

P1593. Isozyme variation in natural populations of *Pterocarpus macrocarpus* Kurz. in Vietnam

H. T. T. Tran;
Institute of Agricultural Genetics, Hanoi, Viet Nam.

ABSTRACT

We analysed genetic variation within and between populations of *Pterocarpus marcrocarpus* from Vietnam to improve conservation of genetic resources of this hardwood species. A total of 651 seedlings from 61 trees and from three locations were tested at 10 polymorphic loci. Of 11 isoenzymes investigated, malate dehydrogenase (MDH), peroxidase (POD) and esterase (EST) were polymorphic at all 10 loci. Percentage of polymorphic loci per population ranged from 54% to 64.5% with a mean of 60.5%. Within each family, the frequency of isoenzyme phenotypes ranged from 0 to 1 with a mean of 0.5276 per locus. An UPGMA tree was constructed based on the Euclidean distance matrix and isoenzyme variation. This showed no association with geographical distance but evidence for isolation along longitudinal gradient. A Neighbor Joining (NJ) tree was constructed based on isoenzyme phenotypes and this showed one family (Nghe An) was dispersed from other two families (Tay Ninh and Yokdon). An ordination plot of the principal coordinate analysis confirmed these results.

P1594. Spatial differentiation and estimation of immigration rates with a stepping-stone structure for Fagus crenata populations in Japan

K. Kitamura[1], H. Tachida[2], K. Takenaka[3];
[1]Hokkaido Research Center, Forestry and Forest Products Research Institute, Sapporo, Japan, [2]Kyushu University, Fukuoka, Japan, [3]Hokkaido University, Sapporo, Japan.

Spatial genetic substructurings of a local Fagus crenata (Siebold's beech) population in central Honshu (Japan) was analyzed by 13 allozyme loci. This beech forest has been rapidly deteriorating by air pollution and feeding pressure of sika deers. Spatial autocorrelation analysis revealed positive significant values within small distance classes and negative in farther classes. Twelve patch populations were discriminated within the local population, and a simulation analysis was conducted using the stepping-stone model to estimate the migration rate among patch populations. The population migration rate (Nm=2.7) was revealed to be larger than one migrant every other generation, which indicates that the population differentiation is not significant. Although the model analysis demonstrated a sufficient gene flow between neighboring patch populations, the severe damage to local populations may cause the fragmentation of patch populations.

P1595. Morphological variation of Spiraea (Rosaceae) from Siberia and the Far East (Russia).

T. A. Polyakova;
Amur Botanical Garden, Blagoveschensk, Russian Federation.

About 17 kinds of Spiraea grows in territory of Siberia and the Far East Russia. Various forms of variability of morphological attributes of disputable kinds are investigated. Variability within the limits of one plant of metric attributes of the kinds concerning to miscellaneous sections of Spiraea, is characterized by close parameters that testifies to specificity of attributes and presence of the general laws of variability. The analysis of variability of metric attributes between plants of one population and between populations specifies specificity of kinds. The majority of metric attributes (the length of a sheet, width of a sheet, length of kidneys etc.) the investigated kinds are characterized by the expressed variability in east and southeast directions. Geographical law in variability of qualitative attributes (color of axes of inflorescences etc.) it is not revealed.

P1596. Vegetation survey of the northwest part of the Šar-Planina Mt.

L. T. O. Amidzic, V. S. J. Mitrovic, P. M. L. Lazarevic;
Institute for Nature Conservation of Serbia, Belgrade, Serbia and Montenegro.

Šar-Planina Mt. belongs to the Central Balkans' massif and is 85 km long. The main ridge is about 2,500 m high. The southern slopes of the massif belong to Macedonia, the northern and northwest ones to Serbia, while the smaller part of the southwest slopes to Albania. Specific geographic location, where the Mediterranean and continental influences clash and imbue, the great relative height difference, the variety of geological base, outstanding soil plasticity with the dominating glacial morphology, rich floristic composition, as well as entanglement of different ecological conditions constantly changing in a small area, have produced an extreme vegetation variousness of the region. By long-range terrain research of the Šar-Planina Mt., as well as revision and grouping of all so far obtained plot data, 222 vegetation units, i.e. 136 plant associations classified into 47 alliances, 23 orders and 16 classes have been found. In the paper shall be given their syntaxsonomic survey.

P1596a. Large scale AFLP screening of natural populations provides the basis for the analysis of the molecular mechanisms underlying biodiversity - the case of *Melampyrum* (Orobanchaceae)

J. Wunder[1], M. Li[1], G. Bissoli[1], H. Saedler[2], C. Varotto[1];
[1]CSBT, Center for the Study of Biodiversity – Trentino, San Michele all'Adige, Italy, [2]Max-Planck-Institut for Plant Breeding Research, Cologne, Germany.

Analyses of mutants and “ecotypes” using mainly seedbank material cover only a small part of the variation present in natural populations. By contrast, in nature there is a large range of variation, encompassing an unknown number of distinct ecotypes, varieties and mutants.

Within the 6 species of *Melampyrum* known in Trentino/Italy, AFLP analyses revealed considerable genetic distances within and between populations as well as differences between species concerning population- and meta-population structure. Beside several morphological and ecological traits varying between populations and species also a flower-mutant independently appearing in different populations was discovered. Furthermore there is a lack of correlation between morphological and genetic distances between the species to the point that even a 7th species was found.

While genomic-based AFLP provides the basis to define the populations or species to be compared, other techniques, like cDNA-AFLP are used to identify the genes involved in the traits analyzed.

A summary of our approach to trace the molecular mechanisms underlying biodiversity by analysing natural populations is given.

P1597. Genetic diversity of an invasive plant *Eupatorium adenophorum* analyzed by AFLP marker

S. Qiang;
Weed Research Laboratory, Nanjing Agricultural University, Nanjing, China.

Crofton weed(*Eupatorium adenophorum*) is a damaging invasive weed that has been established in more than 30 tropical and subtropical countries worldwide. AFLP technique was used to analyze genetic diversity of 24 populations of Crofton weed collected from 24 locations in China and Australia. AFLP analysis produced 509 scorable bands, of which 77.01% were polymorphic. The related diversity indexes: na was 1.50, H 0.29 and I 0.42, indicating that genetic diversity is very rich. The cluster analysis showed that in Yunnan Province first invaded in China, it had great genetic variability among geographically close or far populations because all ones sampled in this province could be classified into eight groups. In other newly-invaded areas, genetic diversity was simple and distinctly related to the geographically close populations collected from the place of Yunnan, which spreading seeds by wind resulted in. Moreover, water can carry the seeds to far regions from the seed-produced place.

P1598. After the bottleneck: patterns of introduction and rapid evolutionary change in an invasive grass

H. Meimberg, J. I. Hammond, E. K. Espeland, T. W. Park, K. J. Rice, J. K. McKay;
University of California, Davis; Department of Plant Sciences and Center of Population Biology, Davis, CA, United States.

Barbed goatgrass, *Aegilops triuncialis*, closely related to cultivated wheat, is a cleistogamous allopolyploid annual grass with a native range from the Mediterranean to Afghanistan. Ae. triuncialis was first introduced into California in 1914 and is now considered to be a serious noxious range weed. It is found more commonly on infertile soils, such as serpentine outcrops, than in richer zonal soils. This makes goatgrass a threat to fragile habitat types.

Using nuclear and chloroplast loci we examined the history of invasion of *Ae. triuncialis* into California. Analysis of 170 accessions from California and Eurasia indicates that a strong bottleneck occurred during its introduction.

Of 38 species wide genotypes, 2 are present in California, and these 2

appear to separate into two broad groups. This indicates that there were two separate introductions.

The ability of *Ae. triuncalis* to invade serpentine soils, a habitat that is not occupied by goatgrass in its native range, suggests the possibility that some lineages adapted to new habitats following range expansion. Ecological and molecular studies to answer this question are currently underway.

P1599. Does allelopathy explain the invasion success of Solidago canadensis?

D. Abhilasha, J. Joshi, H. Brandl;
Institute of Environmental Sciences, Zürich, Switzerland.

The success of plant invaders has been tried to explain by the loss of natural enemies in the newly invaded range leading to compensatory release and enabling the species to allocate their energy into growth and reproduction instead of defence. However, in *S. canadensis* s.l. L. such a compensatory release has not been found in a comparative study. A further mechanism explaining the success of invasive weeds may be the production of chemical, allelopathic compounds by the invader that have harmful effects on plant neighbours that have not been co-evolved. We took root extracts of *S. canadensis* and performed thin layer chromatography to recognize the compounds. The compounds were individually tested on filter paper on their putative negative impacts on germination of seeds of competing plant species in the invasive range of *S. canadensis*. In addition, in a pot experiment, competing plant species were grown with *S. canadensis* either with activated carbon in the soil adsorbing the allelopathic compounds or without to check whether allelopathic effects of *S. canadensis* might lead to a competitive advantage

P1600. Evolution of increased competitive ability

G. Jakobs;
Geobotanical Institute ETH, Zurich, Switzerland.

The invasion success of introduced species depends on the interaction of habitat invasibility and species' invasiveness. There is increasing evidence that not only the intrinsic plant characteristics, but also post-introduction evolutionary changes are essential. They require a high additive genetic variance, which appears to be common among traits facilitating invasion. Adaptive evolutionary changes have been demonstrated for a number of plant species, although the driving forces or selective factors appear to differ in different environments.

Among other selection pressures, the absence of specific herbivores in the introduced range can be fundamental and, as postulated in the **E**volution of **i**ncreased **c**ompetitive **a**bility (EICA)-hypothesis, may lead to an altered trade-off between herbivore defence and competitive ability. Generalist herbivores may have the opposite effect, causing a selection for better-defended genotypes rather than highly competitive ones. Both theories seem to apply for some species and under certain environmental conditions.

P1601. Microsatellite isolation in native (C. prolifera) and invasive (C. taxifolia) Caulerpa sp in the Mediterranean sea

E. Varela-Álvarez[1], A. Lago-Lestón[1], F. Alberto[1], G. Pearson[1], C. Duarte[2], N. Marbá[2];
[1]CCMAR-CIMAR, Faro, Portugal, [2]IMEDEA, CSIC-UIB, Esporles, Mallorca, Spain.

Caulerpales are clonal marine algae, which often act as invasive species. Over the past decade, C. taxifolia has spread in along the Mediterranean coast, presently occurring at 70 sites and covering nearly 3000 hectares of subtidal area. About 60 km of coastline are currently affected and there is concern about the potential reduction in biodiversity and changes in coastal ecosystem functions. Information about population mechanisms of population maintenance and spreading in both species areis largely lacking In order to assess clonal structure and genetic diversity of recently established populations of the invasive species C. taxifolia in comparison with populations of the native C prolifera in the Mediterranean, new genetic markers (microsatellites) are being developed. Two genomic libraries enriched for microsatellite dinucleotide repeats have been constructed per for each Caulerp a sp. Several microsatellite sequences have been obtained and the levels of polymorphism within those sequences are being tested.

P1602. Genetic differentiation between native and introduced populations of the South African ragwort *Senecio inaequidens*

O. Bossdorf[1,2], A. Winkler[2], D. Prati[2];
[1]SUNY, Stony Brook, NY, United States, [2]UFZ Centre for Environmental Research, Halle, Germany.

Invasive species often evolve rapidly in response to the novel biotic and abiotic conditions in their introduced range. Such evolutionary changes might play an important role in the success of some invasive species. Here, we investigated whether introduced European populations of the South African ragwort *Senecio inaequidens* have genetically diverged from native populations. We carried out a common garden experiment where 12 South African and 11 European populations were grown at two levels of nutrient availability, as well as in the presence or absence of a generalist herbivore. We found that, in contrast to a current hypothesis, plants from introduced populations had a sigificantly lower fitness, and they were more resistant to herbivory. Moreover, introduced populations were less genetically variable, but displayed greater plasticity in response to fertilization. We argue that in order to understand the invasion success of *Senecio inaequidens*, its pathways of introduction must be taken into account. Overall, our data support a model in which both adaptive evolution and phenotypic plasticity contribute to invasion success.

P1603. Increased susceptibility to enemies following introduction in the invasive plant *Silene latifolia*.

A. Biere[1], J. A. Elzinga[1], L. M. Wolfe[2];
[1]Netherlands Institute of Ecology, NIOO-KNAW, Heteren, The Netherlands, [2]Georgia Southern University, Statesboro, GA, United States.

One of the influential hypotheses why species become invasive in their introduced ranges is that release from natural enemies allows them to shift investment from traits involved in defense to traits enhancing growth, reproduction and competitive ability. The invasive plant *Silene latifolia* was introduced from Europe (EU) into North America (NA) approximately 200 years ago and experiences lower damage by natural enemies in the introduced range. A common garden experiment in Europe, using seeds from 20 EU and 20 NA populations reveals (1) genetically-based differences in life history beween plants from EU and NA populations; plants from NA have evolved a weedy, invasive phenotype that flowers two weeks earlier and has a two- to three-fold higher reproductive potential; (2) higher susceptibility of plants from NA populations to fungal infection, fruit predation, and aphid infestation, suggesting that the invasive NA phenotype has evolved at the expense of the loss of defensive abilities.

P1604. Molecular evidence for multiple introductions of garlic mustard (Alliaria petiolata, Brassicaceae) to North America

W. Durka[1], O. Bossdorf[2], D. Prati[1], H. Auge[1];
[1]UFZ - Environmental Research Centre, Halle, Germany, [2]State University of New York at Stony Brook, New York 11794-5245, NY, United States.

Invasive species offer excellent model systems for studying rapid evolutionary change. Molecular markers can provide information about pathways of introduction, the amount of genetic variation introduced and the extent to which founder effects and inbreeding after bottlenecks may have contributed to evolutionary change. We studied microsatellite variation among and within 27 native and 26 introduced populations of garlic mustard (Alliaria petiolata), a European herb invasive in North America. Overall, introduced populations were genetically less diverse. However, considerable variation was present and when compared to the likely source regions no bottleneck was evident. The high allelic diversity in the introduced range strongly suggests multiple introductions. Out of six European regions, the British Isles, Northern Europe and Central Europe had significantly higher proportions of alleles in common with the introduced range, and are therefore the most likely source regions. The analyses will be updated by the results of ongoing investigations using chloroplast DNA markers from which we hope to get more insight into the pathways of introduction.

P1605. Genetic variation among native and invasive populations of Senecio jacobaea and its correlation with invasive traits

J. Joshi[1], K. Van den Hof[2], K. Vrieling[2];
[1]Institute of Environmental Sciences, University of Zurich, Zurich, Switzerland, [2]Institute of Biology, Leiden University, Leiden, The Netherlands.

Senecio jacobaea is native in Europe and has become a noxious weed in North America, Australia, and New Zealand. In a comparative study using AFLP data, genetic diversity among invasive populations from North America, Australia and New Zealand was substantially smaller than among native populations. Invasive populations all belonged to the same chemotype whereas the genetically more diverse native populations could be separated into two distinct chemotypes. Invasive populations had a higher performance, i.e. showed higher vegetative and reproductive growth in comparative experiments and also produced more pyrrolizidine alkaloids, their main antiherbivory compound. Compared with natives that have to deal with an array of both specialist and generalist enemies, invasive populations benefited from high protection against a generalist herbivore, but lost additional protection against chemically adapted specialist herbivores absent in the invaded areas.

P1606. Similarity in the adaptation of life-history traits to latitude and genetic differentiation between native and introduced populations of *Mimulus guttatus*

M. van Kleunen, M. Fischer;
Institute for Biochemistry and Biology, Potsdam, Germany.

Latitudinal similarity and post-introduction evolution may be important for plant invasions. In a common environment, we compared life-history traits of plants of *Mimulus guttatus* from its non-native ranges in New Zealand and Scotland with plants from the whole latitudinal gradient in its native range in North America. While phenology was not affected by the latitude of origin, plants from higher latitude produced fewer flowers but more and longer stolons. These latitudinal clines did not differ between the native and non-native plants, indicating that non-native plants have the same reproductive allocation as native plants from similar latitude. Plants from the non-native ranges, however, had larger flowers and produced more branches than the ones from the native range, indicating that they have evolved differently. Moreover, populations from the non-native range had lower heritable genetic variation for time to anthesis and anther-stigma separation than the ones from the native range, indicating a lower potential for their evolution in the non-native ranges. We conclude that evolutionary processes play an important role in the invasion by *M. guttatus*.

P1607. Cultigenes as a source for neophyta? - Feral oilseed rape and its putative natural hybrids in northern Germany

B. Elling, B. Neuffer;
Universität Osnabrück, Biologie, Spezielle Botanik, Osnabrück, Germany.

Oilseed rape is well-known for its innate characteristic of establishing feral populations outside cultivated areas. Furthermore, hybridisation between *B. napus* and its close relatives such as *B. rapa, B. oleraceae* and *Raphanus spec.* under field conditions has been well documented. Populations of feral oilseed rape, close relatives and potential hybrid populations in Osnabrück and its surroundings are recorded in this study. Out of 77 populations sampled in the area under study during the first vegetation period, two populations have been identified as potential hybrids by morphological and cytological (chromosome number, flow cytometry) analyses. Populations are investigated by flow cytometry in order to identify hybrids of different ploidy levels from various provenances. In addition molecular markers are also applied to compare inter- and intra-population variability of oilseed rape and to analyse relationships between feral populations, putative hybrids and cultivated varieties. To check the persistence of feral oilseed rape populations the area is going to be monitored during several vegetation periods.

P1608. Comparison of native and invasive populations of Senecio inaequidens for vegetative and reproductive traits in a control common garden experiment

M. Alleaume-Benharira[1], I. Chuine[2], L. Lafuma-Mery[1], **S. Maurice**[1], O. Ronce[1];
[1]ISEM, Montpellier, France, [2]CEFE-CNRS, Montpellier, France.

Senecio inaequidens, a South African species, has accidentally been introduced into several sites in Europe where it has become an invasive. Its range now extends from the Mediterranean coast to Denmark.

Only tetraploid individuals are found in Europe whereas diploids and tetraploids are present in Africa. We compared vegetative and reproductive traits of individuals sampled as seeds in two tetraploid populations from South Africa, two populations from France and two populations from the Netherlands, these two latter countries representing two different introductions.

Seedlings were planted outdoors in Montpellier France into three different environments: control (Mediterranean-type), heated (night screens and heating cables) and water supplied (Dutch mean precipitations).

Mean character values did not show differences between Africa and Europe. Several significant interactions between environments and countries were found, showing that plasticity for those characters varies with the country of origin. These experimental data will be used to develop a process-based biogeography model to predict the spread of *Senecio inaequidens* in Europe.

P1609. Polymorphism in seed of *Acer pseudoplatanus* L.: differences in responses to phytohormones and stratification

D. Djunisijevic, M. Djukic;
Faculty of Forestry, Belgrade, Serbia and Montenegro.

Seed mass, as most relevant measure of seed size occupies important position in the ecology of a species. It links the ecology of reproduction and seedling establishment with the ecology of vegetative growth (Leishman &Westoby, 1992). Maternal factors can markedly influence seed dormancy breaking and germination requirements. Production of two or more different types of seeds by a species (seed polymorphism) is found in a number of species (Gutterman, 2000).This phenomenon regulates temporal distribution of seed germination.

Strong invasive properties made sycamore one of the most common tree species in urban areas of Europe. In this species were identified two general type of inflorescence (protogynous and protandrous inflorescence). Morphological differences and fruit size variations in infructescens, between protogynous and protandrous individuals were reported, (Binggeli, 1990).

The results show differences in responses to phytohormones and stratification of two seed types. It was found that stored GA significantly influences germination of large seeds in contrast to small, where *de novo* synthesis of GA is necessary to complete germination.

P1610. Dispersal pattern of asexual and sexual propagules in bryophytes

M. Pohjamo[1], S. Laaka-Lindberg[2], H. Korpelainen[1];
[1]University of Helsinki, 00014 Helsinki, Finland, [2]Lammi Biological Station, Lammi, Finland.

Dispersal ability is of great importance for plants, which commonly occupy spatially limited habitat patches. Bryophyte dispersal has been thought to take place primarily by spores. Another potential mechanism is dispersal by asexual diaspores and leaf fragments. In this presentation, we report results concerning the dispersal of spores and gemmae in the leafy hepatic *Anastrophyllum hellerianum* in Southern Finland. *A. hellerianum* is a dioicous epixylic hepatic which reproduces both sexually by spores and asexually by one-celled gemmae. Lower reproduction investment is required for asexual than sexual reproduction in *A. hellerianum*. As the production of spores is rare, the ability of species to colonize new substrate patches by frequently produced gemmae is crucial. The study was conducted both in a natural habitat and in an artificial set-up without background dispersal. Traps were distributed in different directions at distances of 0-10 m from the parent colony. The results indicate that asexual gemmae may function in dispersal over relatively long distances, which is comparable to the dispersal of spores on a local scale.

P1611. A seed pool approach to tracking acorn movementby acorn woodpeckers

D. Grivet[1], P. E. Smouse[2], V. L. Sork[1];
[1]Dept of Ecology and Evolutionary Biology and Institute of the Environment, University of California, Los Angeles, CA, United States, [2]Department of Ecology, Evolution & Natural Resources, Rutgers University, New Brunswick, NJ, United States.

Animals are the principle vectors of seed dispersal for many plant species. Unfortunately, tracking animals and dispersed seeds is a long-standing challenge. We introduce a novel approach that uses maternally-inherited seed tissue to quantify the genetic structure of dispersed seed pools. This approach measures the genetic variability within and among seed pools, without requiring a highly polymorphic battery of markers, or the locations and genotypes of all possible seed parents. We demonstrate this approach with the specific case of seed transport of valley oak (*Quercus lobata*) acorns by acorn woodpeckers (*Melanerpes formicivorus*). These territorial birds store acorns in drilled holes in the bark of trees called granaries. An analysis of 3 microsatellites derived from maternally-inherited DNA in seed coats from acorns stored in different granaries shows extremely high genetic structure in the seed pool among granaries, a low number of effective seed donors per granary, and restricted seed movement. Our findings provide insight into the foraging and seed-dispersal behavior of acorn woodpeckers, with an approach that can be widely extended to other systems.

P1612. Successful colonization and survival of tropical macrophyte *Pistia stratiotes* in thermal waters of temperate zone

N. Sajna, M. Kaligaric, M. Haler;
Biology Dept., Maribor, Slovenia.

Temporary occurrence of *Pistia stratiotes* outside the tropical or subtropical zone is not rare, but winter survival outdoors was not reported so far. Few plants were spotted on the thermal waters near Catež (Slovenia, 45°53´N 15°37´E) in 2001 for the first time. The species might have been introduced by incidental release of specimens used as ornamental pond plant. In 2002 it spread out and formed dense mats, which in 2003 completely covered the 25ha surface of two natural thermal water bodies with temperature values between 25°C and 31°C whole year round.A gradient of declining nutrients was perceived and correlated with leaf traits, plant biomass, plant density and flowering. Extremely large plant size (rosettes diameter up to 64cm) was observed, probably due to favourable nutrient status, temperature conditions and longer photoperiod as within its natural range. Plants bloom and produce viable seeds, which were already present in the water sediment in 2004. The seasonal changes in biomass follow the local climate, having the peak in summer and strong decline in winter, when most of leaves decay, but many small rosettes survive and resprout quickly in early spring.

P1613. Sex Allocation Bias in Hermaphrodite Plants: Effects of Local Resource Competition and Seed Dormancy.

T. Tsuchimatsu, M. Ito;
Department of General Systems Studies, University of Tokyo, Tokyo, Japan.

We developed a general model that describes the relationships between sex allocation and spatial/time dispersal of plants. Sex allocation tends to be male biased in animals when daughters don't quite disperse than sons because they must compete with daughters or between mother and daughters for locally limited resources (local resource competition [LRC]; Clark, 1978). We applied LRC effect to hermaphrodite plants and developed a game model to examine whether local resource competition with relative seeds effect the ESS sex allocation. We found that e.g. when selfing rate is relatively low and pollen are relatively easy to disperse out of their patches than seeds, ESS sex allocation becomes more male biased. In addition, most plants' seeds are known to have partial dormancy. Dormancy is understood as not only a bet-hedging strategy for an unpredictable environment, but also offspring dispersal strategy over time axis. To develop more general and practical model, we also analyzed whether ESS sex allocation changes when considering a certain seed dormancy rate further.

P1614. Gene flow, pollen competition, and introgression among cultivated and wild populations of *Lobelia cardinalis*

L. M. Johnson[1,2];
[1]University of Virginia, Charlottesville, VA, United States, [2]Christopher Newport University, Newport News, VA, United States.

To understand risks to local adaptation due to influx of genes from non-local populations of *Lobelia cardinalis*, I evaluated the potential for gene dispersal from small plantings into wild populations, probability of hybridization and consequences of introgression. The likelihood of gene movement from ornamental plants to wild populations is high, and chances of establishment of hybrids in natural populations are good.

Pollinators did not discriminate between local and non-local pollen, fertilizing half the flowers 1 km from a pollen source. Testing siring ability of non-local pollen donor populations showed that pollen source affected the percentage of locally-sired offspring, but direction of bias was not consistent among donors. A field experiment with hybrids of local and non-local populations revealed a high likelihood of hybrid establishment. While local parentals out-survived other parentals, F_1 hybrids survived even better. Hybrid generations reproduced in the field, allowing introgression of non-local traits. A parallel study in controlled conditions showed little genetic differentiation among parentals and among resultant hybrids.

P1615. Natural hybridization in mangroves: molecular approach to hybrid identification, maternity confirmation and introgression

M. Sun;
The University of Hong Kong, Hong Kong, Hong Kong Special Administrative Region of China.

Interspecific natural hybridization is important in plant evolution. The occurrence of natural hybridization is not random, and varies in frequency among families and genera. Natural hybrids are only known in three genera of major mangrove families, recognized based on morphological criteria. Many morphological traits are subject to environmental influences, and to complications arising from character convergence and homoplasy, so neutral molecular markers should be used to verify natural hybridization, introgression and maternity. Natural hybridization in three major mangrove genera, Bruguiera, Rhizophora, and Sonneratia, was examined using ISSR, cpDNA and ITS sequences. All natural hybrids in these genera, resulting from interspecific hybridization between closely related taxa, were confirmed. The maternal species involved in the hybridization were identified. The suitability of ISSR markers was shown for detecting introgression in Bruguiera populations that occupy a wide geographical area. The evolutionary consequences of potential gene flow among sympatric species through introgressive hybridization are discussed.

P1616. A microsatellite analysis of the genus Micromeria Benth. (Lamiaceae) in Macaronesia

T. Abele, H. Meimberg, C. Bräuchler, G. Heubl;
Department Biology I, Section: Biodiversity Research, Systematic Botany, LMU, Munich, Germany.

Macaronesia shows high plant species diversity. Adaptive radiation isassumed as one reason for the high amount of endemic taxa for several plantgroups. One example is the genus *Micromeria* with 16 species recognised in Macaronesia. Most are narrow endemics, only few are distributed onmore thanone island. ISSR fingerprints and sequencing of single copy genes indicate that radiation took place on each island separately, and morphological features used for species delimitation probably evolved independently several times. A microsatellite analysis using about 350 samples was performed to determine the amount of gene flow between species and populations. Additionally the extent to which similarity between species from one island in fingerprint pattern and sequence, is influenced by introgressions and hybridization should be tested. First results confirm our assumption on the radiation of Micromeria. In some cases it is indicated that former divided species were homogenised by hybridisation, so inter island colonisation might have occurred more frequently as indicated by molecular analysis.

P1617. Detecting a consequence of flowering-plant density on the inter-line crossing rate utilizing the F_1 seed production system of a brassicaceous vegetable

A. Konuma[1], A. Horisaki[2], N. Tanaka[2], S. Niikura[2];
[1]National Institute for Agro-Environmental Sciences, Tsukuba, Japan, [2]Tohoku Seed Co., Utsunomiya, Japan.

F_1 hybrid seed is a main supply source of seed for vegetable production. These are produced by crossing of two different inbred lines as parents, which express heterosis, utilizing insect pollinators in field. It is often observed that the inter-line crossing rate fluctuates over years, and it may cause economic loss. In ecological studies of wild plants, it is reported that reducing seed production or lower outcrossing rate per individual plant tends to be observed in lower flowering-density or smaller population. Behavior of pollinator may responsible for the phenomena. It appears that fluctuation of inter-line crossing rate in F_1 hybrid seed production is caused by the same mechanism of lower outcrossing rate in wild plant. The matter in F_1 seed production is equivalent to a major subject in plant ecology. Therefore, ecological study utilizing F_1 seed production system may beneficial for both plant ecology and agricultural production. In this paper, we present our current study regarding a consequence of flowering-plant density on outcrossing, which utilized artificial population employing two inbred lines of *Brassica rapa*.

P1618. Cytogenetic and molecular characterization of *Narcissus x perezlarae* (Amaryllidaceae) and its putative progenitors

I. Marques[1], M. Martins Loucao[1], G. Nieto Feliner[2], J. Fuertes Aguilar[3];
[1]Universidade de Lisboa. Museu Nacional de Historia Natural. Jardim Botanico, Lisboa, Portugal, [2]Real Jardin Botanico. Plaza de Murillo 2. 28014, Madrid, Spain, [3]Real Jardin Botanico. PLaza de Murillo 2. 28014, Madrid, Spain.

Studies of ecological and evolutionary consequences of hybridization rely on accurate methods of hybrid identification. In *Narcissus,* with ca.70 species distributed in the Mediterranean area, several natural hybrids have been reported, among them *Narcissus x perezlarae*. Based on morphological and cytological characters, this taxon was proposed to be the result of interspecific hybridization between *N. serotinus* (2n=10, 30) and *N. cavanillesii* (2n=28). *N. serotinus* is distributed throughout the Mediterranean coast while *N. cavanillesii* is restricted to SW Iberia and N Morocco. The disjunct occurrence of *N. x perezlarae* (SW Iberian quadrant, N Morocco and Valencia in E Spain) suggests a polytopic origin and a potential evolutionary role beyond a sporadic occurrence. We report the chromosome number of *N. x perezlarae* (2n=29) in all the populations sampled, including those from Valencia, where one of the putative parents is absent. To verify its hypothesized origin, we also present preliminary data on sequence variation from four chloroplast regions (*ndhf*, *trn*L-F, *psb*A-*trn*H, *atp*B-*rbc*L) in a wide sample of wild hybrids and putative progenitors.

P1619. Hybrid speciation and evolution in UK Sorbus taxa

A. Robertson[1], T. C. Rich[2], S. A. Harris[3], L. Houston[1], S. Allen[1], C. Roberts[1], S. J. Hiscock[1];
[1]School of Biological Sciences, Bristol, United Kingdom, [2]National Museums & Galleries of Wales, Cardiff, United Kingdom, [3]University of Oxford, Oxford, United Kingdom.

Understanding the processes that have given rise to polyploid hybrid taxa is central to our understanding of plant evolution. Within the Avon Gorge, UK, there are three sexual diploid Sorbus species; Sorbus aucuparia, S. aria, and S. torminalis, one primary diploid hybrid, S. x thuringiaca, and five polyploid apomictic taxa (S. bristoliensis, S. wilmottiana, S. anglica, S. porrigentiformis and S. eminens). In this study we are using a range of genetic markers (nuclear and chloroplast) in a population analysis to elucidate the origins and breeding systems of these Avon Gorge Sorbus taxa. To gain insights into hybrid formation, and determine the basis of the reproductive barriers that drive speciation, we are combining our molecular marker assays with a comprehensive study of breeding behaviour using controlled pollinations between the different taxa. An understanding of the genetic and reproductive relationships among the Sorbus taxa in this speciation ‘hot-spot’ will allow us to make recommendations for the conservation of this unique biodiversity.

P1620. Consequences of genetic introgression from foreign provenances into local plant populations

L. Crémieux, A. Bischoff, T. Steinger, **H. Mueller-Schaerer**;
University of Fribourg, Department of Biology, Unit Ecology and Evolution, Fribourg, Switzerland.

Many restoration and habitat creation schemes involve sowing of seed mixtures to create species-rich communities. However, the geographical origin of the seed material used is still controversial. Besides the poor adaptation to local site conditions, one risk of introducing foreign populations is genetic introgression into native populations, which can reduce the fitness of locally adapted populations through outbreeding depression. We are studying the effects of gene flow from foreign provenances into local plant populations in Lotus corniculatus and Plantago lanceolata. Two generations of hybrids (F1 and F2) were made between local Swiss plants and plants of English and Czech origin, as well as plants from a contrasting habitat on a local level. The results of a field experiment, comparing the performance of the progeny of crosses between geographically or environmentally distant populations to that of within-population crosses, will be presented. Resistance of the hybrids to insect herbivores and pathogens will also be discussed.

P1621. Morphological variation in different generations of volunteer *Brassica rapa*

T. D'Hertefeldt[1], M. Young[2], G. Squire[2], J. Russell[2];
[1]Plant ecology and systematics, Lund university, Lund, Sweden,
[2]Scottish Crop Research Institute, Invergowrie, United Kingdom.

The aim of this study was to compare variation in morphological traits of volunteer compared to crop plants of *Brassica rapa*, and to investigate if volunteer plants adopted a more weed-like morphology over time. We studied variation in morphological traits (flower size, hairiness and leaf colour) in a 5-year-old volunteer *B. rapa* population. Volunteer morphology differed significantly from that of crop plants, especially with regards to hairiness and leaf colour. Subsequently, *Brassica napus* and *B. rapa* were allowed to reproduce spontaneously in the field for one year after which morphological variation of the progeny was studied. The morphological variation in F1 plants appeared lower than for the volunteer *B. rapa*. A pilot microsatellite study showed indications of gene flow from *B. napus*. The combined effects of gene flow and local selection on the possibility for local adaptation in weedy populations will be discussed.

P1622. Asymmetrical crossability on interspecific cross and backcross between Hemerocallis fulva and H. citrina.

A. Yasumoto, T. Yahara;
Department of Biology, Kyushu University, Fukuoka, Japan.

Evolutionary outcomes could be affected by asymmetrical gene flow when young allopatric species come into contact and hybridize. The study of crossability on both interspecific cross and backcross is necessary to assess the asymmetrical gene flow. To examine asymmetrical crossability on both cross, we use Hemerocallis fulva and H. citrina, which are distributed in sympatry and sometimes hybridized on Hirado Island (Japan). Flowers of these species were hand-pollinated by conspecific, interspecific and F1 hybrid pollen. Seed set of interspecific cross was lower than that of conspecific when H. fulva was used as maternal plants, but no difference was found when H. citrina was used as maternal plants. Seed set of backcross was lower than that of conspecific cross irrespective of maternal species. Consequently, crossability was asymmetric when the two species were crossed but symmetric when pollen of F1 hybrids was backcrossed to either of parental species.

P1623. Characterization and identification of microsatellites in Hemerocallis

T. Miyake;
Department of Biology, Kyushu University, Fukuoka, Japan.

Hemerocallis fulva (Liliaceae) and H. citrina show distinct pollination syndromes. Hemerocallis fulva, having orange perianth, is mainly pollinated by butterflies or bees and flowers exclusively in daytime, while H. citrina, having sweet-scented lemon-yellow perianth, is pollinated by nocturnal hawkmoths and flowers exclusively at night. Thus, co-flowering overlap, appearing in the morning and at dusk, is short in a day. Although these apparent ethological and temporal isolations limit gene flow between the two species, hybrid populations are recorded in several localities in Japan. To evaluate gene flow in hybrid populations and between the two species, I developed microsatellite markers. Their level of variability and identifying polymorphisms will be evaluated and presented. Then, the frequencies of diagnostic alleles in one hybrid population will be evaluated.

P1624. Meet the ancestor: molecular data reveal that Tragopogon porrifolius, one of the diploid parents of T. mirus, may be polyphyletic

E. V. Mavrodiev, D. Soltis, P. Soltis;
University of Florida, Gainesville, FL, United States.

Tragopogon mirus (Asteraceae) is a recently formed allotetraploid from North America; its diploid parents, T. dubius and T. porrifolius, were introduced from Europe in the early 1900s. ITS and ETS sequence data reveal that “T. porrifolius” comprises several genetically distinct lineages. The diploid “T. porrifolius” contribution to T. mirus appears in a different major clade of Tragopogon than other collections of T. porrifolius. This distinctive genotype is morphologically and karyologically distinct from other T. porrifolius and should perhaps be referred to as T. eriospermus (= T. sativus). This entity is widespread in North America and Europe (= cultivated salsify). Other subspecies of T. porrifolius (ssp. australis, ssp. cupani, and ssp. longirostris) appear in two closely related subclades. Sequence data indicate that T. cupani comprises both diploid and allopolyploid populations. Ssp. longirostris has also been introduced to North America. Thus, T. porrifolius is likely polyphyletic. Because of the vagaries surrounding ITS/ETS sequences, additional sequences are needed to test the extent of polyphyly of T. porrifolius.

P1625. An AFLP analysis for relationships of a putative hybrid species Diplazium yakumontanum and related species (Woodsiaceae).

C. Park[1], T. Yahara[1], M. Takamiya[2];
[1]Laboratory of Ecology Science, Department of Biology, Faculty of Science, Kyushu University, Fukuoka, Japan, [2]Department of Environmental Science, Graduate School of Science and Technology, Kumamoto University, Kumamoto, Japan.

Interspecific hybridization is known to be a common phenomenon in vascular plants and provides variation that facilitates adaptation. *Diplazium* Sw. is a polymorphic fern genus including many hybrid taxa, Approximately 60 Japanese taxa have simple, simply pinnate to bipinnatifid, and bi- to tripinnate leaves, and putative hybrids among these taxa cause taxonomic confusion. *Diplazium yakumonntanum* (tetraploid, 2n=164) is a Japanese endemic species and it is inferred from a hybrid species between *D. nipponicum* (triploid, 2n=123 and tetraploid, 2n=164) and *D. Petri* (tetraploid, 2n=164). The aim of this research is to study the genetic relationships between tetraploid hybrid species *Diplazium yakumonntanum* and parental species, and find specific marker of these species using amplified fragment length polymorphism (AFLP). We discuss the utility of these specific markers for finding the origin of the genomes in the tetraploid hybrid species.

P1626. Hybridization between Strobilanthes glandulifera and S. tashiroi (Acanthaceae) in Okinawa Island, Japan

D. Seok, J. Murata;
Botanical Gardens, Graduate School of Science, The University of Tokyo, Tokyo, Japan.

Natural hybridization among two sympatric species of *Strobilanthes* from Okinawa Island, Japan was investigated. *Strobilanthes glandulifera,* which has a monocarpic life history strategy, and *S. tashiroi,* which has a polycarpic life history strategy, can be readily distinguished by morphological characters, including pollen morphology. However, natural populations in the Motobu Peninsula of Okinawa-jima, where *S. glandulifera* and *S. tashiroi* are found in sympatry, have characteristics that appear to be intermediate or intermixed between *S. glandulifera* and *S. tashiroi.* It is likely that these individuals originated through a cross between *S. glandulifera* and *S. tashiroi.* Sequences analysis of nuclear ribosomal internal transcribed spacer (ITS) regions and combined chloroplast DNA regions (*mat*K gene and *trn*L(UAA)-*trn*F(GAA), *trn*T(UGU)-*trn*L(UAA), and *atp*B-*rbc*L spacer regions) suggest that putative hybrid originated from hybridization between *S. glandulifera* and *S. tashiroi*. This is the first report of a natural hybrid in the genus *Strobilanthes*.

P1627. Studies of *Potamogeton* hybrids identified in Polish populations using morphological, biochemical and molecular methods

J. Zalewska-Galosz[1], M. Ronikier[2];
[1]Institute of Botany, Jagiellonian University, Krakow, Poland, [2]Institute of Botany, Polish Academy of Science, Krakow, Poland.

Clonal but also sexual reproduction, autogamy, lack of prezygotic isolations between species and capacity of long-distance spreading lead to the hybridisation within the genus *Potamogeton*. Once created hybrid often forms vigorous, long-persistent, clonal population. Some of them are partly fertile so introgression of genomic components from one taxon into another could be observed. Identification of *Potamogeton* hybrids based on the comparative morphology and anatomy solely is difficult and sometimes misleading, therefore it should be supported by biochemical or molecular data. Selected *Potamogeton* hybrids and their putative parents from Polish populations (both linear- and broad-leaved) have been studied by isozymes analysis, restriction fragment length polymorphism analysis (RFLP) of chloroplast DNA and of the nuclear rDNA ITS region to support the morphological and anatomical evidence. Methods are presented and the results are discussed.

P1628. Multidisciplinary evidence for differentation-hybridization-cycles in the evolution of the polyploid complex Achillea millefolium agg.

F. Ehrendorfer[1], Y. Guo[1], M. van Loo[1], R. Mittermayr[2], J. Saukel[2];
[1]Institute of Botany, Department of Systematics and Evolutionary Botany, Faculty of Life Sciences, University of Vienna, A-1030, Rennweg 14, Vienna, Austria, [2]Department of Pharmacognosy, Faculty of Life Sciences, University of Vienna, A-1090 Althanstrasse 14, Vienna, Austria.

The polyploid complex of *Achillea millefolium* agg. consists of allogamous perennial herbs. It can be subdivided into 20-30 closely related taxa, growing in very diverse habitats of the Northern Hemisphere. Taxa form several reticulate lines ascending from diploids to high polyploids (2x - 4x - 6x - 8x). Representative samples (66 populations, 27 taxa) of the aggregate and its suspected hybrid links with other clades were studied with the help of DNA sequences (ITS, *trn*L-F), AFLP, plastid haplotypes (PCR-RFLP), cytogenetics, phyto-chemistry (essential oils, sesquiterpen-lactones), morphometry, etc. On the diploid level these data suggest general relationships and document basal genetic divergence and radiation. Polyploid taxa are of multiple and hybrid origin as revealed by specific AFLP bands and specific plastid haplotypes shared with their assumed diploid progenitors. The appearance of new specific AFLP and plastid markers in 4x-taxa signals new genetic differentiation and is followed by horizontal hybrid transfer between 4x-taxa. Comparable cycles of differentiation and hybridization are repeated on the 6x and higher ploidy levels.

P1629. Hybridization, introgression, polyploidization and the origin of the apomictic *Ranunculus cassubicus* complex

O. Paun, J. Greilhuber, T. Stuessy, E. Hörandl;
Faculty of Life Sciences, Vienna, Austria.

The role of hybridization, auto- or allopolyploidy, and introgression of apomixis genes in the origin of apomictic complexes is still under debate. The *Ranunculus cassubicus* complex, comprising diploid or autotetraploid sexual and polyploid apomictic taxa, provides a model system for study. Isozyme, AFLP and SSR data clearly indicate an unique ancient hybrid origin of hexaploid apomictic *R. carpaticola* populations from NW. Slovakia, involving sexual autotetraploid *R. cassubicifolius* from the northern pre-Alps, and diploid sexual *R. carpaticola* from C. Slovakia. Although both parents occur mainly in forests, the apomicts occupy border zones and tend to establish in adjacent man-made meadows. Introgression from other distinct microspecies from meadows contributes to the origin of new genotypes and might confer on the hybrids a broader ecological tolerance than either parent. Polyploidy is a springboard for the origin of new hybrids, but appears to result in apomixis only in combination with hybridization. Apomixis, in turn, has permitted perpetuation and establishment of ecologically divergent hybrid genotypes.

P1630. Reticulate evolution in angiosperms: exploring network reconstruction methods.

B. Vriesendorp, F. T. Bakker;
Nationaal Herbarium Nederland, Wageningen, The Netherlands.

Reticulation, i.e. the occurrence of hybridization and introgression, is thought to be of major importance in the evolution of flowering plants. Since reticulate patterns cannot be reconstructed in a bifurcating phylogenetic tree, there is a need for methods that can reconstruct such patterns in angiosperms at the species-level.
In this study we compared current available methods for network reconstruction, such as T-rex and NeighborNet. Using simulated data for these programs is not yet feasible, therefore their performance in detecting and representing hybrid taxa was tested using published 'real' DNA sequence data. The hybrid hypothesis in these studies was based on incongruence between different (DNA) data sets. We combined these data sets and compared the resulting output from the different network programs with the originally published trees. Also, we tested the output against our expectations about placement of a hybrid in a network. The question of how to interpret these networks in a meaningful biological way is discussed, as well as their added value compared with exploration of incongruent datasets using traditional phylogenetic methods.

P1631. Gene flow, hybridization, and divergence between Hawaiian Dubautia species

J. M. Cruse-Sanders, E. Friar;
Rancho Santa Ana Botanic Garden, Claremont, CA, United States.

This study used microsatellites and paternity analysis to estimate pollen movement at a fine scale between *Dubautia arborea* and *D. ciliolata*. A well-documented hybrid zone occurs in the transitional habitat of Waipahoehoe Gulch on the slopes of Mauna Kea, Hawaii, and contains plants that represent a continuous morphological spectrum between the parental species. The two species are fully interfertile and occur in parapatry, but maintain distinct morphologies and ecological specialization. A core region within the hybrid zone was designated and every individual plant mapped and sampled for genetic analysis. Seeds from 15 maternal plants were collected, germinated, and genotyped using eight microsatellite loci. Additionally, 30 plants from adjacent pure populations of the parental species were genotyped. Within the active hybrid zone, mating appeared to be random with respect to plant phenotype, generating a wide array of intermediate forms. Therefore, gene flow was expected to follow an isolation by distance model. Results are interpreted in light of the role of hybridization in ecological divergence and the evolution of adaptive traits.

P1632. Hybridization of *Goodyera chejuensis* (Orchidaceae) inferred from Molecular evidence

C. S. Lee[1], **N. S. Lee**[1], S. H. Yeau[2];
[1]Dept. of Life Sciences, Ewha Womans University, Seoul, Republic of Korea, [2]Dept. of Science Education, Ewha Womans University, Seoul, Republic of Korea.

Goodyera × *jejuensis* S. Kim, a recently described orchid endemic to Korea, shares many morphological characters and grows in a sympatry with both both *G. schlelechtendaliana* Reichb. fil and *G. velutina* Maxim., raising the possibility that *G.* × *jejuensis* was originated from hybridization of *G. schlelechtendaliana* and *G. velutina.* To verify the hypothesis, the ITS sequence of nrDNA, and psbA-trnH, trnSG and trnL of cpDNA for 32 accessions from 6 taxa of *Goodyera* were analyzed. In the ITS regions of *G.* × *chejuensis,* four single nucleotide polymorphisms sites were observed, at positions 102 (G/A), 440 (A/G), 464 (C/T), and 642 (A/T). Of these, *G.* × *chejuensis* shares species-specific character states with *G. schlelechtendaliana* at three sites, positions 102 (G), 440 (G), and 464 (C). Also, *G.* × *chejuensis* shares two species-specific character states with *G. velutina* at positions 653 (A) and 512 (T) in the ITS region. *Goodyera* × *chejuensis* and *G. schlelechtendaliana* share 10 and 39 species-specific character states in trnH-psbA and trnSG of cp DNA, respectively. Our molecular data suggest that *G.* x *chejuensis* was originated from hybridization between *G. schlelechtendaliana* and *G. velutina.*

P1633. Hybrid origin and expansion of tetraploid *Achillea* taxa from E Asia to N America: DNA-based, morphological and ecogeographical evidence

M. van Loo[1], Y. P. Guo[1], C. Vogl[2], F. Ehrendorfer[1];
[1]Department of Systematic and Evolutionary Botany, Faculty of Life Sciences, University of Vienna, Austria, [2]Institute of Animal Breeding and Genetics, University of Veterinary Medicine, Austria.

A group of 2x- and 4x-taxa of herbaceous perennial *Achillea* (Asteraceae) in E Asia has been studied by DNA-analyses (sequencing, AFLP, cpDNA PCR-RFLP) and other multidisciplinary methods. *A. acuminata*-2x belongs to *A.* sect. *Ptarmica*. *A. asiatica*-2x is an eastern member of the *A. millefolium* aggregate in sect. *Achillea*. *A. alpina*-4x and *A. wilsoniana*-4x form a nearly continuous morphological, ecological, and geographical link between the two very different diploids. A NJ genetic distance analysis of AFLP data clearly demonstrates an intermediate position of the 4x- between the two 2x-taxa. 5 plastid haplotypes were detected by PCR-RFLP analyses in these species. *A. alpina*-4x and *A. wilsoniana*-4x share one haplotype only with *A. asiatica*-2x. On the basis of all these evidence and previous cpDNA *trnL-F* and nrITS sequence data, the two allotetraploids are regarded as products of a possibly Pleistocene hybridization between an *A. acuminata*-like ancestor as father and an *A. asiatica*-like as mother. This was followed by considerable secondary genetic diversification on the 4x level and expansions from Asia into the large area of northern N America.

P1634. Investigating ancient homoploid hybridisation patterns within the genus *Diphasiastrum*

S. M. D. Aagaard[1], N. Wikström[1], J. Vogel[2];
[1]Evolutionary Biology Centre, Uppsala University, Uppsala, Sweden, [2]The Natural History Museum, London, United Kingdom.

Several defined species within the genus *Diphasiastrum* are considered to be of hybrid origin. These assumptions are primarily based on observations of populations with intermediate morphology and high rates of spore abortion in both Europe and North-America. Cytological and molecular support for these theories is, however, lacking. The main goal of this project is to investigate and estimate the frequency of speciation through hybridisation within this genus. This primarily implies investigating congruence between cpDNA - and nuclear single copy gene sequences (LEAFY, RNA polymerase and phosphoglucose isomerase, PGI) to identify parental lineages of the putative hybrid species. As *Diphasiastrum* is known as a genus with notoriously uncountable chromosomes, assessing ploidal level is crucial to define what kind of hybridisation events that have occurred, i.e. if the hybrids are either homoploid or allopolyploid. Such data will be obtained using Quantitative Feulgen photocytometry. Furthermore, microsatellite - and allozyme markers will be used for a more detailed study at population level.

P1635. Reproductive isolation in Mediterranean deceptive orchids

G. Scopece[1], A. M. Nardella[1], C. Lexer[2], A. Widmer[3], S. Cozzolino[1];
[1]Università "Federico II", Naples, Italy, [2]Royal Botanic Gardens, Kew, London, United Kingdom, [3]ETH Zuerich, Zuerich, Switzerland.

The maintenance of species boundary among related sympatric species is clearly dependent on the strength of reproductive isolation. Orchid flowers are often highly specialised to attract and fit their pollinators, suggesting a prominent rule for pre-mating reproductive isolation in maintaining species boundaries. To investigate the presence and the strength of post-mating barriers in Mediterranean orchids we performed a large number of interspecific crossing experiments and analysed fruit set production and seed viability. Then we tested the relationship between reproductive isolation and genetic distance for post-mating pre-zygotic barriers and for post-zygotic barriers. Results clearly indicate that post-mating barriers (both pre-zygotic and post-zygotic), including late post-zygotic barriers, as hybrid sterility, largely contribute to prevent gene flow among co-flowering food deceptive orchids with a generalized pollination compared with other orchid groups with an highly specialised pollination biology like the sexually deceptive *Ophrys*.

P1636. F1-dominated hybrid zones: can genome-habitat interaction alone maintain species barriers?

R. I. Milne[1], R. J. Abbott[2];
[1]Institute of Molecular Plant Sciences, University of Edinburgh, Edinburgh, United Kingdom, [2]Institute of Environmental and Evolutionary Biology, University of St Andrews, St Andrews, United Kingdom.

F1-dominated hybrid zones (**F1DZ**s) are hybrid zones in which F1 hybrids are highly fertile and make up most or all of the hybrid population. In such cases hybrid zone population structure varies dramatically according to habitat - in undisturbed habitats intermediate between those of the parents, most or all hybrids are F1s; where the habitat is disturbed or otherwise atypical, most hybrids are post-F1s. Because post-F1s are required for gene flow between the parents, this implies that genome-habitat interaction maintains species barriers in F1DZs. F1DZs were probably far more common before human interference began. Hybrid zones between *Rhododendron ferrugineum* (Acid soils) and *R. hirsutum* (Basic soils) are unique among published examples: F1s occur intermixed with both parents and a very few post-F1s on a mosaic of soil types. Here soil pH appears to determine where each genotype class grows. Implications for how species barriers might arise and be maintained are discussed.

P1637. Evolution of Cuphea spp. during domestication

A. A. Jaradat[1,2];
[1]Agricultural Research Service, Morris, MN, United States, [2]Dept. of Agronomy & Plant Genetics, University of Minnesota, MN, United States.

Cuphea, a semi-domesticated crop, is a potential source of oil suitable for industrial uses. Indeterminacy, seed shattering and post-harvest dormancy constitute its domestication syndrome. PSR23, a selection from a *Cuphea viscosissima* Jacq. x *Cuphea lanceolata* f. *silenoides* W.T. Aiton cross, was assessed for seed, capsule, and plant morphological and physiological characters. PSR23 germplasm produced during six consecutive years showed a reduced genetic diversity favoring characters better suited to cultivation. Morphological and physiological divergence of PSR23 from its wild progenitors increased as indicated by consistent and gradual differences in the principal components structure, and by smaller fractal dimensions of seeds, capsules and mature plants. Directional selection through agricultural practices increased the frequency of tall and more erect genotypes, heavier and more circular seed with reduced post-harvest dormancy and higher germination index as compared with the wild progenitors. Indehiscence and determinacy are critical to fully domesticate PSR23. Stabilizing selection will be needed to maintain the domesticated crop.

P1638. Investigation of durability of four types of natural fibre-polyethylene composites against the fungus coriolus versicolor

s. pourabbasi[1], A. Karimi[2], D. Parsapajooh[2], M. Tajvidi[2];
[1]Islamic azad university of malayer branch, Malayer, Islamic Republic of Iran, [2]University of tehran, karaj, Islamic Republic of Iran.

In order to study the durability of four types of natural fiber-polyethylene composites containing kenaf, rice hulls, newsprint and wood flour as the reinforcement at 25% and 50% by weight against *Coriolus versicolor,* available specimens of the composites were sampled.

After preparing the specimens and culture medium (Malt Extract Agar), specimens were contaminated with cultured fungus(laboratory conditions 22C, 75% relative humidity)for fourteen weeks. After this period, weight reduction, water absorption of specimens were measured and compared with control samples.The results showed that weight reduction of samples after contamination with fungus was significant.The composites containing 50% uncompatabilized wood flour had the highest weight reduction and the composites containing 25% with 1% compatabilized wood flour had the least weight reduction as compared with other types of composites.

The highest Water absorption of samples, after contamination with fungus has been observed in the composites containing 50% uncompatabilized wood flour and the composites containing 25% with 1% compatabilized wood flour had the least water absorption.

P1639. Natural hybridization in Betula in Iceland

A. Thor Thorsson[1], A. Sigurgeirsson[2], K. Anamthawat-Jonsson[1];
[1]Department of Biology, University of Iceland, Askja-The Natural Science Building, Reykjavik, Iceland, [2]Icelandic Forest Research, Mógilsá, Reykjavik, Iceland.

Betula (birch) is a genus of some fifty species distributed throughout northern temperate regions. In Iceland, two *Betula* species coexist, *B. nana* (2n=28, diploid dwarf birch) and *B. pubescens* (4n=56, tetraploid downy birch). Downy birch is the major tree species forming natural woodlands in Iceland, which today cover only one percent of the total land area. The morphology of Icelandic birch is extremely variable, evidently due to introgressive hybridization. Such introgression (gene flow) could only occur via interspecific hybridization and repeated backcrossing of the hybrids. Flowering periods of the two species overlap significantly in Iceland, due to a short growing season, allowing interspecific hybridization to take place in birch. Our result show that about 10% of examined birch plants are triploid hybrids (3n=42). This is a much higher frequency than has been expected. The populations showed continuous morphological variation connecting the species, but karyotypically they consisted of only three types of plants, diploids, triploids and tetraploids. No aneuploids were found. Some of the tetraploid plants had *B. pubescens* morphology as expected, but most of them had intermediate characters. Most of the diploid plants had *B. nana* morphology, but some were intermediates and a few had *B. pubescens* morphology. The triploid plants were either intermediates or they resembled one of the two species. Introgressive hybridization in birch is clearly a continuing process, probably as a means of survival in a difficult environment. The aim of this research is to evaluate the extent and the possible role of natural hybridization between *B. pubescens* and *B. nana* in natural woodlands in Iceland*.*

P1640. The genetic variation of Licuala and Cyrtostachys, Palmae, in the Tasek Merimbun Heritage Park in Borneo Island.

J. Miyamoto, M. Nakayama, E. Arima, N. M. Watanabe, E. Suzuki;
Kagoshima University, Kagoshima, Japan.

Licuala is a fan-leaved palm and Cyrtostachys is a feather-leaved palm that distribute mainly in South East Asia. We studied their RAPDs patterns in the northwestern part of Borneo Island. The aim is to know the genetic variation of their populations in the natural habitats. Leaves of 168 plants of Licuala and 189 of Cyrtostachys were collected in the Tasek Merimbun Heritage Park in Brunei Darussalam. Genomic DNAs were extracted and the DNA segments were amplified by using six oligonicleotide primers. The cluster analysis was made by using data of the absence-presence of electrophoretic bands. As a result, 115 polymorphic fragments were amplified and two major clusters were recognized in Licuala. One cluster consisted of L. paludosa Griff and the other was an unknown taxon. In C.renda, 74 polymorphic fragments were recognized. Populations showing wide genetic variations located in a forest that included complicated microhabitats with swamps and dry slopes.

P1641. Molecular markers as a tool for identification plant dispersal in river corridors: An example of Sparganium erectum

T. Fer[1], M. Pfosser[2];
[1]Department of Botany, Prague, Czech Republic,
[2]Oberösterreichisches Landesmuseum, Linz, Austria.

Rivers represent linear corridors in landscape. All possible suitable sites for water plants are connected by the stream flow and species can migrate along the linear structure downstream. Transport of both vegetative and generative diasporas is possible. But it is still the question how numerous and how far diasporas can be dispersed.

We used AFLP markers to distinguish vegetative and generative dispersal, and to identify long-distance dispersal in river system.

258 samples from 66 populations of *Sparganium erectum* from the two river basins in Czech Republic were analysed. Based on AFLP analysis we can state the following: (1) vegetative dispersal is more frequent in lower parts of rivers, (2) generative dispersal is important factor in establishment of new localities, (3) populations in lower parts of rivers are genetically more diverse, genotypes are dispersed downstream, (4) more than a half of total variability is found within populations, (5) low correlation between genetic and geographic distance implies strong effect of water streams in dispersal processes of river plants.

P1642. Differences among European populations of Silene latifolia for sexually-dimorphic traits in response to water availability

D. L. Bell, L. F. Delph;
Indiana University, Bloomington, IN, United States.

To understand evolution in natural populations it is important to determine the ecological factors, e.g., water availability, that contribute to population differentiation. In this study we grew five European *Silene latifolia* populations in two moisture treatments to determine if they differ for floral, physiological, and leaf traits. A French population had many small flowers, an effect especially pronounced for males. In contrast, a Czech population had few very large flowers. The small-flowered French population dramatically increased flower number in the moist treatment from the dry treatment while the other populations had modest increases. This population also had the highest water use efficiency (WUE; which was correlated with leaf thickness) across both treatments. The large-flowered Czech population had high WUE in dry conditions but low WUE in moist conditions, which suggests that the population can alter WUE but continue to produce large flowers, which are generally considered costly. The differences between populations for WUE may be the result of contrasting patterns of selection on leaf traits via differences in water availability.

P1643. The maitenance of cyto-nuclear gynodioecy in wild radish (Raphanus sativus): relative seed fitness between females and hermaphrodites based on molecular genotyping

K. Murayama;
Department of Biology, Kyushu University, Fukuoka, Japan.

In gynodioecious breeding system, sex determination often involved cytoplasmic male sterile (CMS) genes and nuclear genes restoring male function. In R. sativus, Ogura cytotype is responsible for CMS and has been well analyzed at molecular level. Thus, whether hermaphrodites have a CMS gene or not is easily surveyed using an Ogura-specific marker. To test the theoretical prediction that females should have at least a slight female advantage over hermaphrodites, I compared seed fitness among the three genotypes: females, hermaphrodites with CMS gene and those without it. Neither many quantity parameters nor seed germination rate differed among the genotypes. In fruit set and total weight in fruits and seeds, hermaphrodites without CMS gene achieved significantly large values than the females. These results suggest no seed fitness advantage of females in R. sativus. However, I found females invested larger proportion in fruit and seed production than hermaphrodites despite their small plant biomass. If there is a metapopulation structure including populations where females grow as much as hermaphrodites, cyto-nuclear gynodioecy is to be maintained.

P1644. Effect of predispersal seed predation and population size on population dynamics of two species of genus *Aster*

J. Rothanzl[1], Z. Münzbergová[2,1];
[1]Faculty of Science, Charles University, Prague, Czech Republic,
[2]Institute of Botany, Academy of Sciences of the Czech Republic, PrŢhonice, Czech Republic.

European landscapes are highly fragmented. As a result many plant and animal populations are small and isolated. Isolation and small population size can have negative effect on reproduction and survival of populations due to e.g. low pollinator attraction. On the other hand, small population size can have also positive effects such as lower attraction of herbivores and thus lower herbivore damage.

We studied relationship between population size, plant performance and herbivory using species from genus *Aster* and its monophagous herbivores from genus *Coleophora* as model species. To test dispersal ability of the herbivore, we attempt to estimate genetic relatedness between the herbivore populations.

The results show higher density of the herbivore and consequently higher seed damage in larger populations. This effect is however compensated by higher seed production in larger population resulting in non-significant relationship between population size and number of intact seeds.

P1645. Ecological and genetic differentiation in an endangered aquatic species *Nymphoides coreana* (Lev.) Hara in Japan

Y. Shibayama[1], Y. Kadono[2];
[1]The University of Tokyo, Tokyo, Japan, [2]Kobe University, Kobe, Japan.

Nymphoides coreana (Lev.) Hara is an endangered aquatic plant and now its distribution is geographically isolated by the loss of many populations. The species has proven to be an inbreeder by autogamous pollination. The obligate selfing and geographical isolation may lead to the genetic and ecological differentiation among populations. Our field survey and cultivation experiments have shown that the populations in the paddy fields are annual and, on the other hand, those in irrigation ponds are perennial. Flower size was the smallest but the size and weight of the seeds were the largest in the plants from paddy fields. Germination rate of the seeds was the highest under light and anaerobic conditions in the plants from irrigation ponds but it was highest irrespective of light condition under anaerobic condition in the plants from paddy fields. Allozyme analysis has also shown the occurrence of distinct geographic variation among the populations of *N. coreana*. These results show that some ecotypes occur within the populations of *N. coreana* in Japan.

P1646. Genetic diversity at the northern edge of the distribution of *Anthyllis montana* ssp. *jacquinii* (Fabaceae)

M. Kropf;
Institute of Botany, BOKU University, Vienna, Austria.

Taxonomically, the mountain species *Anthyllis montana* L. might be best treated as two subspecies with a western and eastern distribution area in Europe, respectively. As part of the eastern subspecies *jacquinii* a small number of populations in Austria is at the northern-most limit of the species' distribution. These populations are highly isolated, patchy structured, to some extent individual-poor, and as a consequence thereof, are considered to be threatened. Seven populations of *Anthyllis montana* in Austria went already extinct.

For conservation management, a molecular analysis utilising AFLP fingerprints and chloroplast PCR-RFLPs will be performed to characterise levels of genetic diversity. The remaining Austrian populations have been sampled and will be compared to more southern (i.e. "central") populations from Slovenia in a hierarchically structured approach including subpopulational patches. Correlations between genetic diversity and population size will be tested to uncover Austrian populations which might be most critically endangered.

P1647. Demography of Betula fruticosa Pall. in dependence from types of habitat, Vitimskoye upland, East Siberia

I. R. Sekulich;
Institute of General and Experimental Biology, Ulan-Ude, Russian Federation.

On the Vitimskoye upland one of the basic dominant of shrub vegetation is Betula fruticosa Pall.

The extremely continental climate and continuous spreading of permafrost are determining factor in forming of ecological conditions for Betula fruticosa.

In demography structure the maximal number of specimens of generative age have been marked in all coenopopulations of Betula fruticosa. The large number of pregenerative specimens of Betula fruticosa have been marked in communities where the frost cracking is observed. The sites of naked ground, which are basic microecotope for regeneration of Betula fruticosa, are formed there. The limiting factor for regeneration of Betula fruticosa is supermoistening or lack of moisture. For example, in community are located to negative forms of a relief with the difficult drainage, and in community are located dry southern slopes, quantity of young specimens very low.

P1648. Preliminary insights in demographic monitoring of the endangered woody Cruciferae *Vella pseudocytisus* in Spain

F. Domínguez, E. del Valle, P. R. Pulido, J. A. Calleja, H. Sainz, **J. C. Moreno-Saiz**;
Deparmento de Biología (Botánica), Universidad Autónoma de Madrid, Madrid, Spain.

The scrubby member of the Cruciferae family *Vella pseudocytisus* L. is endemic to the Western Mediterranean basin and consists in two subspecies in peninsular Spain: *pseudocytisus* and *paui* Gómez Campo. Both taxa live under continental climate, on gypsum soils and their habitats range from open semi-natural steppic scrublands to artificial slopes between cereal croplands. Their extant populations have been fragmented and equally catalogued as Endangered in the recent Spanish Red Data Book, in stead of they were protected in their corresponding regional laws of plant conservation.

From 2001 demographic monitoring has been developed in several locations of both subspecies, distant 300 km apart. Their futures seem to be compromised as a slight decline has been projected for both. The nearly absent recruitment and the reduced survival of the juveniles observed are commented taking into account the high germination rate experienced in the lab. The possible effect of the past cycle of dry (*bad*) years is discussed taking into account differences both in regional conditions and precipitations regimes.

P1649. Variability of one year old seedlings of Pinus peuce Griseb.

B. Nikolic, M. Veselinovic, B. Batos, R. Djokovic;
Institute of forestry, Belgrade, Serbia and Montenegro.

Seedlings of Macedonian pine were obtained from stored seed harvested in two successive years from artificial forest plantation near Ivanjica, Serbia. The seed was sowed in containers in mixture of soil, peat and sand after standard presowing wet-cold treatement (six months at +4ºC in refrigerator). Differences between measured characteristics of one year old seedlings (the length of main root, the length of all roots, the mass of air-dried roots, the root collar diameter, the height of seedling, the length of primary needles and the length of secondary needles and the mass of air-dried green part of seedlings) according to age of seed harvesting and according to individual trees were discussed. These results were compared with those obtained from two weeks old seedlings of the same origin (trees). Differences between half-sib lines were proved by statistic metods (descriptive sta., anova).

P1650. Investigations of Helleborus purpurascens Waldst. & Kit. (Ranunculaceae) in Ukraine.

V. Korotchenko;
Institute of Ecology of the Carpathians N.A.S. of Ukraine, Lviv, Ukraine.

H. purpurascens is the East-Carpathian species, the tertiary relict, endemit, for which the natural rarity is proper. The plant has medicine properties due to contains of cardioglycosides, which have a cardiotonic effect.

The investigations on onthomorphogenesis features, natural populations structure and chemistry (for a contains of toxic metals and microelements) were conducted.

At the first an investigation of natural grow places of H. purpurascens on the population level was conducted in Ukraine.

There were studied mountain and lowland populations of H. purpurascens, which are on the distribution limit within Ukraine.

On the way of population investigations main population parameters, such as area dispersal, number, age individual status, age spectres character, onthogenesis features, vitality, reproduction and restoration, phytomass storage, were studied. Changes of these parameters and population strategy were studied too in the antropogenic pressure conditions.

A chemical monitoring of heavy metals contains in the plant matherial - roots with rhizoma from diverse natural grow places (mountain and lowland) is accompanied.

P1651. Demographical structure of populations of *Adenocarpus gibbsianus* Castr. & Talavera (Leguminosae). Influences of the reproductive success.

R. Casimiro-Soriguer, J. L. García-Castaño, C. de Vega, R. Berjano, M. Á. Ortiz, A. Terrab, F. Balao, J. Cano, S. Talavera;
Departamento de Biología Vegetal y Ecología, Universidad de Sevilla, Sevilla, Spain.

Adenocarpus gibbsianus Castr. & Talavera (Leguminosae) is an endemic species occurring in SW Spain paleodunes that shows only 3 populations as well as some scattered individuals. This so low number of populations makes this species very sensitive to any instability in their demography. To assess their structure as well as their regeneration capacity, and so the stability of this species, we counted the number of individuals belonging to the seedling, vegetative and reproductive stages in every population as well as their change in three consecutive years. Two populations showed an apparently stable structure whereas very little recruitment was observed in the third one. Additionally we tried to guess if a differential reproductive effort, estimated as the number of seeds produced, could explain these differences but no apparent relationship was found. So, whereas two populations looked stable, the other one behaved as a fossil population in spite of its important reproductive potentiality, suffering strangulation in the younger stages. To avoid wasting resources, *in situ* conservation of this species should pivot on the most stable populations.

P1652. Population biology of herbaceous plants infected by systemic fungal pathogens

T. Koubek;
Faculty of Science, Praha, Czech Republic.

The range and dynamics of natural plant populations can be significantly influenced by interactions with other trophic levels such as herbivores and pathogens. The latter has been brought into focus only in last few years, but the results are striking. The systemic fungal pathogens can influence their hosts in various ways, e.g. by altering growth, fertility, interactions with herbivores etc.

To broaden this knowledge, I started to investigate two systems - Scorzonera humilis with its smut fungus Ustilago scorzonerae and Falcaria vulgaris with its rust fungus Puccinia sii-falcariae. The study includes field observations of populations, in which both healthy and diseased plants were marked, measured and will be followed for several years. The data are going to be processed using matrix modelling to find the most sensitive stages in life cycle of the host under pressure of the pathogen. There will be also greenhouse experiments carried out to verify and explain the outcome of the field observations. The poster is aimed to present some of my first year's data on Falcaria vulgaris and prospects of the work. I hope to get answers for some of still unanswered questions.

P1653. Demography of *Dioon edule* in central Veracruz Mexico

P. Octavio-Aguilar[1], J. González-Astorga[1], A. P. Vovides[2];
[1]Laboratorio de Genética de Poblaciones. Instituto de Ecología A.C., Xalapa, Veracruz., Mexico, [2]Laboratorio de Biología Evolutiva de Cycadales. Instituto de Ecología A.C., Xalapa, Veracruz., Mexico.

The demographic dynamics of one well conserved and two fragmented populations of the cycad *Dioon edule* Lindl (Zamiaceae) were studied using projection matrix modelling. Density and spatial distribution patterns differed between populations according to seed dispersal traits. In all scenarios the population growth rate (ə) was most sensitive to changes in the abundance of adult plants. The elasticity reproductive component (F) for the three populations was zero and stasis values (L) were higher than expected. *Dioon edule* behaves like a tree life-form species according to Caswell. The specie's response to different management conditions suggests that the conservation of adult plants is critical for the species survival. This may be true for all cycad species. It was detected that habitat disturbance influences the population dynamics of *D. edule*, especially in the persistence of adult plants. The results are discussed with vision for practical conservation management.

P1654. Maximum entropy method as a tool for exploring spatial population structures

K. Lájer;
Institute of Biology, Pécs, Hungary.

The spatial probability distributions of shoots in plant communities were modeled. The vegetation potentials at a given point depend on the distance of the nearest individual of species i:

where *s* denotes the number of occurring species. We suppose the spatial means of these remain constant. The vegetation is in a stationary state if the corresponding distribution p($\underline{v}$) is the most likely, namely realized by the most of the possible configurations.

The method was applied to a Bottle Sedge stand *(Equiseto limosi-Caricetum rostratae)* and a Slender Sedge stand *(Caricetum elato-lasiocarpae).*

The distribution of Carex rostrata was independent on that of Equisetum fluviatile. In the case of Carex rostrata we obtain the following probability density function for :

where is the lattice constant within tufts.

This means that the sedge shoots take place according to a Poisson distribution on a fractal of dimension Ŭ= 1.5494. The Lagrange parameter = 0.18166 is proportional to the shoot density on the fractal.

For Carex lasiocarpa we have similar results but this species interacts with Carex elata. This causes some distortion in spatial structure, accounted for by the model.

P1655. Is dormancy induced by stress?

T. Kull[1], R. P. Shefferson[2], K. Tali[1];
[1]Institute of Agricultural and Environmental Sciences, Tartu, Estonia, [2]Department of Integrative Biology, University of California, Berkeley, CA, United States.

Dormancy is a poorly understood life history phenomenon in which a mature perennial plant fails to sprout any aboveground tissue in one or more growing seasons. It occurs among several plant families, but generally occurs in rare plants with difficult growing requirements, most often described in orchids. As such, experimental studies to address the nature of this condition have so far been lacking. We defoliated and shaded individuals of Cypripedium calceolus and Cephalanthera longifolia in five populations in Estonia in 2002 and 2003 to ascertain whether dormancy is a potentially adaptive means of dealing with environmental stress resulting in low photosynthesis. Sighting data was analyzed with mark-recapture statistics in order to estimate dormancy and survival likelihoods, otherwise not estimable in an unbiased fashion.

Dormancy appears an adaptive condition, allowing the plant to buffer environmental stress without increasing mortality risk, though the differences in response to treatment suggest that dormancy may have a different life-history context for each species.

P1656. Population structure of Apium repens in Belgium

A. C. M. Ronse;
National Botanic Garden of Belgium, Meise, Belgium.

Apium repens (Jacq.) Lag. is a low creeping perennial umbellifer with a mainly European distribution, that is rare throughout its distribution area. It has been included in the European Habitat Directive 92/43/EEG as wild species that should be protected integrally in the European Union. It has been found to subsist in Belgium in five populations of very inequal size and in different habitat types (Ronse & Vanhecke 2004). In four populations a demographic study has been carried out since 2003, with monthly measurements of individual plants during six months each year. This poster presents results concerning the population structure of *A. repens* at different locations and its evolution with time. Moreover, the influence of some climatic and other abiotic variables on population structure and on reproduction is investigated.

References

Ronse A. & Vanhecke L. 2004. The conservation biology of creeping marshwort (Apium repens) in Belgium: aims, methods and first results. Scripta Bot. Belg. 29: 147-150.

P1657. Demographic structure of fern populations in South Siberia

I. I. Gureyeva;
Tomsk State University, Tomsk, Russian Federation.

Population demography of 6 forest and 4 rocky ferns was studied. The results reveal, that the long-term existence and stability of fern populations in native conditions is ensured by coexistence of gametophyte and sporophyte subpopulations, duration of sporophyte life and sporophyte ability to vegetative propagation. The main peculiarity of the forest fern populations is ecological separation of gametophyte and sporophyte subpopulations. Gametophyte subpopulations of Dryopteris expansa, D.carthusiana, and D.filix-mas develop on rotten windfall; sporophytes of these species are able to effective vegetative propagation by young offsprings. Gametophytes of Athyrium distentifolium, A.filix-femina, Phegopteis connectilis and Gymnocarpium dryopteris prefer the naked plantless soil. Sporophyte subpopulations demonstrate a complex age composition of individuals, gametophyte subpopulations have a complex sex structure. Gametophytes and sporophytes of the rocky ferns (Cryptogramma stellerii, Cystopteris fragilis, Polypodium sibiricum, Asplenium ruta-muraria) grow together and do not form as a rule separate subpopulations.

P1658. How does a gypsophyte reproduce? Factors controlling the reproductive output of Helianthemum squamatum.

C. F. Aragón, M. J. Albert, L. Giménez-Benavides, A. L. Luzuriaga, A. Escudero;
Rey Juan Carlos University, Móstoles, Madrid, Spain.

We have examined the relationships among flowering phenology, plant size and reproductive output in the endemic Iberian gypsophyte Helianthemum squamatum, in two contrasting environments (north and south slope aspects) for a two-year period.

Survival rate of reproductive plants was less than fifty per cent, but plants persisting the second year increased noticeably their fruit and seed production. First flowering and peak flowering dates happened earlier in the south-facing slope, where flowering intensity and synchrony also were higher. Plants reproductive behaviour not only was different in the two studied environments but it also varied between years.

Our results suggest that microevolutionary processes may be ocurring in this species as a consequence of the pronounced environmental heterogeneity.

This kind of studies may help to clarify some aspects of gyspum community strategies and, they also can improve our knowledge about the potential response of this systems to climate change.

P1659. The effects of grassland management on the growth and viability of populations of the endangered, long-lived plant *Scorzonera humilis*

G. Colling[1,2], D. Matthies[3];
[1]Musée national d'histoire naturelle, Luxembourg, Luxembourg, [2]Institut für Umweltwissenschaften, Universität Zürich, Switzerland, [3]Pflanzenökologie, Fachbereich Biologie, Philipps-Universität Marburg, Germany.

We studied growth and viability of five populations of the long-lived plant *Scorzonera humilis*, a characteristic species of wet, nutrient-poor grasslands in relation to agricultural intensification. To investigate the effects of fertilisation and different cutting regimes on the population viability of *S. humilis* we carried out an experiment that simulated different agricultural practices at one study site. Projections based on mean transition matrices over several years indicated that populations at nutrient-poor sites would grow ($\lambda > 1$), whereas populations at nutrient-rich sites would decline continuously ($\lambda < 1$), if conditions stayed the same. Stochastic simulations showed that the extinction risk for a medium-sized population at a nutrient-poor site is very low, whereas the long-term survival even of large populations at nutrient-rich sites is unlikely if favourable conditions for recruitment are not restored. The experiment showed that a combination of fertilizing and early cutting drives populations quickly to extinction.

P1660. Ramet demography of *Allium oleraceum* (Liliaceae), common European geophyte

M. Duchoslav;
Department of Botany, Palacký University, Olomouc, Czech Republic.

Allium oleraceum is a perennial geophyte with annually renewed bulb. Sexual reproduction is extremely rare but species spreads via underground daughter bulbs and bulbils within inflorescence. Demographic data were collected from three populations that occurred in contrasting habitats (forest, scrub and rocks) for 6 years. Ramets were classified both by their size and flowering status. Overall, the population growth rate (lambda) ranged from a low of 0.45 to a high of 1.27. Abortion rate of flower scapes was high in forest population (90-100%) but lower in other populations (30-70%). Populations showed unimodal population structures but were dominated by different stages - sterile ramets of a middle size or juveniles. Elasticity values associated with reproduction (bulbils+seeds) contributed to 3-11% of lambda and were more important in less shaded populations. Although stasis and progression transitions made approximately equal and dominant contributions to lambda (40-56%), progression was more important in less shaded populations. Clonal growth via daughter bulbs contributed more to lambda in forest population (5%) than in other ones (less than 2%).

P1661. Population dynamics of *Abies hickelii* (Flous et Gaussen) (Pinaceae), an endangered species exposed to burning and harvest on the Pico de Orizaba Mountain, Veracruz, México.

C. H. Ávila-Bello[1], L. López-Mata[2], M. Mandujano[3];
[1]facultad de Ingeniería en Sistemas de Producción Agropecuaria, Acayucan, Mexico, [2]Colegio de Postgraduados, Texcoco, México, Mexico, [3]Instituto de Ecología-UNAM, México, City, Mexico.

Abstract

Abies hickelii is a fir species endemic to Chiapas, Oaxaca and Veracruz; its area of distribution is used for grazing and logging. To assess if the species is truly endangered we study the population dynamics of *A. hickelii* on the Pico de Orizaba Mountain, Veracruz using Lefkovitch transition matrices. Data on saplings, juveniles, adult trees and fecundity, were taken from six permanent 1000 m^2 plots. Lambda (λ) was 0.99, indicating that the population is very close to numerical equilibrium but decreasing, so the species could be considered as endangered; the stages at which λ is most sensitive are Juvenile II and Adult I. The GLF demographic triangle indicates that the species invests 99% of elasticity in survival. Effects of fires and harvest on trees were simulated for different persistence, transition and fecundity probability values. Lambda is quite sensitive to changes in Juvenile II tree survival and harvest, making this stage the bottleneck for population growth. Survival makes the greatest contribution to λ. Reproductive rates concentrate in the adult stage. Logging reduced transition rates from juveniles to adults and had the greatest effect on λ.

P1662. Age structure and vitality of Dentaria quinquefolia M. B. coenopopulations in phytocoenosis of the Mountainous Crimea

L. P. Vakhrusheva, L. A. Bagrova;
Vernadsky Taurida National University, Simferopol, Ukraine.

Dentaria quinquefolia M.B. coenopopulations were studied in 3 areas covered by Querceto- Carpinetum mercurialidosum association: 1 - without anthropogenic press; 2 - collection for bunches; 3 - recreation, plant collection, pasture. In the Area 1, age spectrum is complete; juvenile, immature, virginil specimens give in total 52.2%, generative 39.8%, senile 8.0%. Plant height is 43.2 ± 0.8 cm, inflorescence length is 8.9 ± 1.4 cm, leaf length is 33.4 ± 0.9 cm. In the Area 2, pre-generative specimens contain 21.4%, generative 41.7%, senile 36.9%. Plant height is 29.4 ± 1.2 cm; inflorescence length is 5.1 ± 1.7 cm; leaf length is 22.4 ± 1.8 cm. In the Area 3, only subsenile (40%) and senile (60%) plants grow; height is 20,7 ±1,3 cm, leaf length is 14.5 ±1,8 cm. Anthropogenic press has destroyed the age strucutre of the coenopopulation, suppressed vitality and self-sustaining ability. The degree of destruction of nature population of Dentaria quinquefolia M.B.depends on quantity of anthropogenic press.

P1663. Fertility analysis of *Vriesea gigantea* (Gauldchaud, 1864), Bromeliaceae.

F. Bered, G. M. Paggi, E. K. dos Santos, C. P. da Silva, L. C. T. da Silveira, M. H. B. Zanettini;
Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil.

The breeding system and fertility are related with genetic diversity of natural populations. Little is known about reproductive biology of bromeliads populations. This study aims to assess plant fertility and seed viability of *Vriesea gigantea*. Four populations from south of Brazil have been investigated. In each population five plants (mother-plants = MP) were sampled. From each MP 90 seeds were used for fertility analysis. Seeds were sterilized and placed on ½ MS medium with B5 vitamins. Plant fertility were assessed considering: (a) reproductive potential (total number of flowers per plant); (b) fruits production (% fruits = total number of fruits per plant/total number of flowers per plant x 100); (c) the number of seeds per fruit were estimated from 5 fruits of 10 MP sampled randomly. Data were analyzed using ANOVA and means compared by Tukey test. Seeds were mostly viable: after 15 days 94% were germinated. The mean of flowers per plant were 155 (ranging from 45 - 267), the fruit production ranged from 6.3 to 95.5%, and the number of seeds per fruit ranged from 0 to 708. The results showed significative differences among plants and populations.

P1664. Morphophysiological dormancy, germination and recruitment of *Leucopogon* (Ericaceae): implications for functional types and species persistence in a fire prone region

M. K. J. Ooi;
Institute for Conservation Biology, University of Wollongong, Wollongong, Australia.

In fire prone regions, obligate seeding species depend on regeneration from seed, and seedling recruitment is a particularly critical phase for their persistence. To maximise recruitment, obligate seeders are assumed to primarily have dormancy related to fire cues. This study, conducted in southeastern Australia, investigated the dormancy and recruitment of obligate-seeding *Leucopogon* shrub species, including the threatened *L. exolasius*. All species had morphophysiological dormancy, which was not broken by direct fire cues. However, a post-fire flush of emergence occurred and was always restricted to autumn, irrespective of the timing of the fire, or that rainfall is aseasonal. Seedling growth was significantly reduced for delayed emergents. These results show that *Leucopogon* germination and recruitment could vary considerably in response to the fire regime, compared to other species within the same functional group. There are likely to be many other morphophysiologically dormant species in this, and other, fire-prone regions. It is possible that these species may tolerate fire, rather than be specifically adapted to it.

P1665. Recolonization potential of bryophyte fragments in hydrologically restored rich fens

K. Mälson, H. Rydin;
Evolutionary biology centre, Uppsala, Sweden.

Fragmentation (mainly due to drainage) of rich fen patches in the landscape may cause dispersal limitation for plants occurring in the biotope. Specific bryophyte species are often frequent and abundant in rich fens with undisturbed hydrology. For these reasons we initiated a reintroduction study, using fragments of *Campylium stellatum*, *Pseudocalliergon trifarium*, *Scorpidium cossonii* and *S. scorpioides*, in combination with different kinds of soil disturbances and treatments (such as mowing, addition of lime etc.). Desiccation protection was also tested. The study was performed in a hydrologically restored rich fen. To evaluate the growth potential of the gametophyte fragments a greenhouse experiment was performed. Comparison was made to evaluate fragment establishment and growth potential of the four moss species, which represent different growth forms. Fragments of different parts of the gametophyte were tested. Preliminary results show similar responses in all four tested species, with a higher survival rate in the greenhouse experiment compared to the field study and a positive response in growth and survival rate with addition of lime.

P1666. Seed germination in Mangifera indica Haden and Manila varieties.

C. M. Barbosa, C. C. P. Rios, D. E. Flores, L. F. Pérez, F. J. P. Fernández, L. G. Ponce de León;
Universidad Autónoma Metropolitana Iztapalapa, Mexico, Mexico.

Haden and Manila are monoembryonic and polyembryonic varieties of mango respectively. In Manila variety one zygotic embryo and several nucellar embryos are present in the same seed. To compare germination capacity of these different embryos, mango fruits were collected in Sinaloa, Mexico during June of 2003 and July 2004. The seeds were characterized and sowed at 25 ± 2°C with photoperiod 12/12h. Radicle's protrusion was daily quantified. The germination processes takes in 16 days. Seed germination occurs 3 to 5 days earlier in Haden than in Manila. In 2003 sample, 100% of Manila seeds germinate, at least one embryo germinating from each seed. In 2004 germination capacity was 60%. In samples of both years there were one to five germinated embryos by seed. In the other hand germination capacity in Haden was 75% and 99% respectively, with only one embryo germinating by seed. Differences in germination capacity were discussed taking account differences in seed characterization and harvest periods. Identification of genetic origin of embryos could be useful to evaluate the vigor value and to make recommendations for seedlings establishment.

P1667. The effect of fragmentation on the soil seed bank of dry meadows

D. Laubhann, K. G. Bernhardt;
University of Natural Resources and Applied Life Sciences, Department of Integrative Biology, Institute of Botany, Vienna, Austria.

One of the main threats of dry meadows is their isolation. Hence, we investigated the effect of fragmentation on the seed bank. Our study sites were six slopes between terraced vineyards covered with dry meadows. For the soil seed bank investigation we used the seedling emergence method. The average seed density was very low (max. 5556 seeds/m²). We compared the vegetation and the seed bank by using the Sörensen index (SI). Although the vegetation of all slopes is similar (SI = 0,45 to 0,80), the seed banks of the slopes show differences (SI = 0,21 to 0,59). Comparing the vegetation with the seed banks of the same slope, we found low similarity, too (SI = 0,22 to 0,40). While the similarity of the present vegetation is a result of nowadays management, differences in the composition of the seed banks might be caused by the history. For the small seed density and the difference between the vegetation and the seed bank of the same slope we hypothesis that on fragmented habitats there are smaller populations with low seed amount and seed mass. This might lead to the disability to built up a well developed seed bank. To confirm this hypothesis further investigations will be done.

P1668. Soil seed bank in limestone grasslands on Miechowska Upland (southern Poland)

B. Grzybowska;
Institute of Botany, Jagiellonian University, Krakow, Poland.

The soil seed bank and vegetation were studied in two limestone grasslands (Inuletum ensifoliae, Festuco-Brometea), over a 2-year period. At both sites 4 permanent plots (25m^2 each) were established in patches representing different successional stages: initial grassland, well developed, overgrown by shrubs and a proximate oldfield colonized by xerothermic species. The soil samples were collected in summer and autumn each year and the seed bank size and composition were determined by two methods: greenhouse germination over a 6-month period and seed extraction by washing. The seed density varied from 950 seeds/m^2 in overgrown grassland to 12000 in oldfields (mainly *Hypericum perforatum*). Over 60 species were found in the seed bank of both sites. Among them 12 were present only in the seed bank. The species richness of soil seed bank was the highest in oldfields (30 species), the lowest in initial grassland (10). The viable seeds of xerothermic species e.g. *Inula ensifolia*, *Linum hirsutum*, *L. catharticum* were found in soil also in overgrown plots. This suggests that soil seed bank can play a certain role in the restoration of such grassland after shrub removal.

P1669. Prairie species from a temperate environment exhibit positive germination responses to smoke treatments

L. V. Jefferson, M. Pennacchio, K. Havens;
Institute for Plant Conservation, Chicago Botanic Garden, Glencoe, IL, United States.

Fire has been a natural disturbance in grassland ecosystems since the Holocene period. In the Midwestern USA, for example, fire determines, in part, the structure of the landscape as prairie, savanna or woodland. Prairies require a high fire frequency to reduce the encroachment of woodland species. In other fire-prone environments (Australian, South African and American Mediterranean ecosystems), seeds will only germinate in response to fire-related cues such as smoke. Without these cues, the seed may remain dormant. The effect of smoke on prairie seeds had not previously been investigated.

This study treated seed of prairie species with aerosol smoke and smoke water under glasshouse and field conditions to identify which species were stimulated by smoke. The results were mixed; some species experienced increased or decreased germination percentages while others were unaffected. The results of this study suggest that the positive effect of smoke on seed germination extends further than that of Mediterranean environments. Some species from temperate environments that are historically prone to fire produce seeds that germinate in response to smoke.

P1670. Berg´s hypothesis revisited: Flower integration in populations of Narcissus papyraceus (Amaryllidaceae) with contrasted pollinators.

R. Perez-Barrales, J. Arroyo;
University of Seville, Sevilla, Spain.

It was postulated long time ago (Berg RL 1959, 1960) that species pollinated by specialist pollinators (the ones that exert more selective pressures, should present flower traits tightly correlated, compared to flowers pollinated by generalist pollinators (less selective preassures). Adittionally, the first kind of species would show less variation, as result of stabilizing selection on these traits. However, the available studies support or reject the hypothesis, probably because of the lack of precise knowledge on the pollination biology of the species or adequate population sampling. Here, we report data on pollination biology, flower and vegetative trait correlation (the last one as control) of a winter flowering species, Narcissus papyraceus, which presents geographically separated populations, pollinated mainly by hoverflies or moths. Populations pollinated by moths tend to show highly correlated and integrated flower morphology compared to those pollinated by hoverflies, as Berg predicted.

P1671. Floral Morphology, Flower Longevity, and Nectar Secretion Patterns of the Holoparasitic Plant *Cytinus hypocistis* (L.) L. (Cytinaceae) Growing on Three Different Hosts

C. de Vega, M. Arista, P. L. Ortiz, S. Talavera;
Departamento de Biología Vegetal y Ecología, Universidad de Sevilla, Sevilla, Spain.

Floral morphology, flower life span, and patterns of nectar production were examined in the monoecious *Cytinus hypocistis*, a root holoparasite of some species of Cistaceae. Variations of these features were analyzed in six populations on three hosts, two on *Cistus ladanifer*, two on *Cistus salviifolious,* and two on *Halimium halimifolium*. In all the populations the female flowers were bigger, opened earlier, and secreted a more concentrated nectar than the male flowers. Flower life span ranged from 4 to 9 days and, regardless of the host, in some populations female flowers lasted more than male flowers, whereas in other populations we encountered the opposite outcome. The amounts of nectar secreted in 24 hours ranged from 0.03 to 8.72 µ l, and nectar concentration varied from 12% to 50%. Nectar secretion differed among plants and populations, but it was the same among hosts. It was noticeable that, in spite the huge variations, all the monitored flowers had some quantity of nectar at any hour of the day.

Although this study is based only on some floral characteristics, our results do not allow us to suggest ecological races of *C. hypocistis* associated to each host.

P1672. Nocturnal anthesis of caper: Does time matter?

A. F. Argiropoulos, **S. T. Rhizopoulou**;
Section of Botany, Athens, Greece.

Caper (*Capparis spinosa* L.) is a winter-deciduous, invasive plant; its flowers consisting of four green sepals, four white petals, numerous purplish stamens and a flexible style last for 12 hours, during anthesis that coincides the dry summer. Nocturnal, floral advertisement presents adaptations to prevent the warming effect of exposure to solar radiation and to avoid the evaporative cooling of floral tissues at the expense of water. Stomata on surfaces of sepals and of petals may be involved to the cooling of flower. Petals contain vacuolated parenchyma cells with large intercellular space. Filaments and style densely packed with small cells are related to cell wall material that provides strength. By blossoming released at sunset, the species avoids water expenditure, minimizes exposure of flowers to diurnal solar radiation and to elevated, damaging temperatures. Corollas grow close to the ground, where midday temperatures can exceed 40 °C. In turn, white corollas are exposed to visits of pollinators by remaining turgid overnight. This may be partially due to a decline in the solute potential of petals, *via* withdrawal of water from other floral tissues.

P1673. Nystinastic movements do not necessarily involve an increase in net pre-emergent reproductive success. The case of Silene colorata Poiret (Caryophyllaceae)

A. Terrab[1], J. García-Castaño[2], R. Berjano[2], C. de Vega[2], F. Balao[2], R. Casimiro-Soriguer[2], S. Talavera[2];
[1]Institute of Botany, Vienna, Austria, [2]Universidad de Sevilla, Sevilla, Spain.

Silene colorata Poiret (Caryophyllaceae) draws pollinator attention only by night by means of nystinastic movements but can be pollinated by both diurnal and nocturnal insects. We set an experiment to test the final influence of these temporally segregated pollinators and found that nocturnal fruit-set was higher than diurnal one but, additionally, that flowers exposed in daylight hours suffered damage due to Bombus activity; as this damage avoided a successful pollination, the found difference vanished once it was included as a covariate. Thus a higher fruit-set in individuals exposed by night was due to a lower flower damage and not to a higher pollination; anyway, as the number of visits by night was lower than by day, nocturnal pollination was more efficient. No difference among treatments was found for the seed-set, i.e. the number of ovules fecundated, once flowers had been pollinated, was the same. These data do not support the hypothesis that the flower display is an adaptation to attract pollinators increasing the fruit-set. On the other way round, by means of less conspicuous flowers, this species could avoid attracting predators when more abundant.

P1674. Butterfly pollinators select for short flowers in the carnation Dianthus carthusianorum

D. Bloch, A. Erhardt;
Institute of Environmental Sciences, Basel, Switzerland.

Interactions with pollinators have resulted in a spectacular diversity of flowering plants. Pollinator-mediated selection has repeatedly been shown, but most quantitative studies have taken only floral *or* pollinator traits into consideration. We conducted field surveys and experiments, measuring variation in flower tube length of the butterfly-pollinated *D. carthusianorum* and pollen deposition of two pollinating butterfly species with varying proboscis lengths. We found that (1) seed set is pollinator limited in the field, a precondition for pollinator-mediated selection, (2) selection depends on the mechanical interaction between flowers and pollinating butterflies, and (3) both experimental butterfly pollinators select for shorter reproductive floral parts (anthers and stigma lobes) and hence for shorter flowers. This study shows not only how quantitative morphological traits of flowers and pollinators affect floral selection, but demonstrates also a process counteracting an evolutionary race between proboscis length and flower depth. These results may explain the rarity of very deep flowers.

P1675. How pollinators, seed predators and grazers influence selection on floral display of *Primula farinosa*.

D. Vanhoenacker[1], J. Ågren[2], J. Ehrlén[1];
[1]Stockholm University, Stockholm, Sweden, [2]Uppsala University, Uppsala, Sweden.

Floral display characters may influence the attractiveness to pollinators, but also the risk of damage by seed predators and grazers. We examined how biotic interactions influence selection on scape length of *Primula farinosa*. This perennial herb is dimorphic for scape length and produces either a regular or a very short scape. We studied four populations over two years on Öland in Sweden. At fruit maturation we measured fruit initiation, seed predation and proportion of grazed plants. To estimate the role of pollinators in the process of fruit initiation, we supplementally hand pollinated half of the study plants. Short-scaped plants of *P. farinosa* had in most cases lower fruit initiation than long-scaped plants and they were in general more pollen limited. However they were less susceptible to grazing and seed predators. Because of variation in the magnitude of these morph-specific differences, the relative fruit set of the two scape morphs varied significantly among populations. As intensive grazing influences the habitat, we also discuss how the scape-morph specific interactions with pollinators and fruit predators might be affected by vegetation height.

P1676. Floral evolution along altitudinal gradients in *Campanula rotundifolia* (Campanulaceae)

J. Maad, W. S. Armbruster;
Norwegian University of Science and Technology, Trondheim, Norway.

We investigated patterns and mechanisms of floral evolution in the perennial *Campanula rotundifolia* (Campanulaceae) along altitudinal gradients in Norway. Flower size was explored in 16 populations at altitudes between 240 and 1100 m a.s.l. We estimated phenotypic selection on four morphological characters through three fitness components in two of the populations. Flower length covaried positively with elevation. Plants in a high-elevation population (800 m a.s.l.) were shorter and produced fewer, but larger, flowers than in a low-elevation population (510 m a.s.l.). Seed set per capsule was higher in the high than the low population, but seed set per shoot did not differ. Selection on flower size was generally through seed set per capsule, while selection on plant size was through capsule number and did not differ in strength between the two populations. Pollinators probably caused the observed selection, although we do not know whether selection on flower size was generated by variation in the visitation rate or in pollination efficiency per visit. Selection mediated by pollinators may contribute to the evolution of larger flowers at higher elevations.

P1677. Assessment of genetic variability in some Iranian sweet oranges (Citrus sinensis [L.] Osbeck) and mandarins (Citrus reticulata Blanco) using SSR markers

B. Golein[1,2], A. Talaie[2], Z. Zamani[2];
[1]Citrus research Institute, Ramsar, Islamic Republic of Iran, [2]Tehran University, Faculty of Agriculture, Karaj, Islamic Republic of Iran.

The genetic variability of 8 sweet oranges and 6 mandarins accessions was evaluated using simple sequence repeats (SSRs) analysis. In total, 52 putative alleles were detected using 7 primer pairs. The number of putative alleles per primer pair ranged from 3 to 10 with an average of 7.42. Polymorphic information content (PIC) value changed from 0.505 to 0.950. Microsatellite markers discriminated variation within mandarins, but low variation observed between sweet oranges.

A UPGMA phenetic tree was constructed and one main sweet orange group consisting of three sub-groups and four main mandarin groups were identified.

Results showed that; the majority of local sweet orange accessions probably have a narrow genetic base suggesting that the observed morphological polymorphism within the group must be associated with somatic mutations or they may be single clone with different names, which were not exactly detected by these markers. Studies with more microsatellite markers or other molecular markers may be more precise in determination of genetic variability among selected genotypes.

P1678. Molecular biological studies on *Digitalis lanata* Ehrh. populations

K. Pozsonyi;
University of Pécs, Pécs, Hungary.

Digitalis lanata Ehrh. populations were selected in the Mecsek, in a mountain of south Hungary, in the Great Hungarian Plain and a Digitalis ferruginea population in Italy. These plants were dried at room temperature and the DNA was isolated from the samples. The samples were prepared with several primers (OPN, OPO, OPP and OPW-primers), an F-buffer and a Taq-polimerase. The samples were tested and studied by RAPD-technique. The samples were developed on agarose gel. After developement photos of the gels were taken at UV light. The bands were evaluated by comparison to the marker bands. In the DNA-patterns altogether 2-4 bands per plant were detected. The plant DNA-patterns contained uniform and unique bands equally. The unique bands of the populations refer to polymorph primers. On the basis of these results the plant populations could be classified into groups. This classification of genotype by RAPD can be related to the phenotype and the ecological habitat of the leafy foxglove populations.

P1679. Interspecific genetic diversity in European oak populations based on the fragment length analysis of a single beta-tubulin gene

I. Porth[1], P. Garnier-Gere[2], A. Kremer[2], **K. Burg**[1];
[1]ARCSeibersdorf research GmbH, Department of Bioresources, Seibersdorf, Austria, [2]INRA BIOGECO, Cestas, France.

The genus Quercus is characterised by a high variability of traits and the tendency to hybridize without significant mating barrier. For the two highly intercrossing species Quercus robur L. and Q. petraea (Matt.) Liebl., diversity studies showed low interspecific genetic variation. In this study we report the isolation of a TUB homologue of A. thaliana from oak, which proved to be highly polymorph in natural populations. Two alleles were found to be selectively associated with either sessile or pedunculate oak. Population differentiation based on allele frequencies of TUB was significant within nine out of 10 investigated continous mixed oak stands. A correlation between specific alleles and differentiation was assumed by the above-average contribution of the two indicated alleles to the overall Fst value. Differences in the segregation of TUB were detected within a Q. petraea intraspecific and an interspecific cross attributed to the inheritance of the “petraea” specific allele. Hence, differences in gene flow detected in artificial hybrids as well as in natural oak populations could be explained by a hybridisation barrier between Q. robur and Q. petraea.

P1680. Analysis of genetic diversity of Iranian pistachio (*P. vera*) cultivars based on RAPD and morphological markers

S. Mirzaei[1], M. Bahar[2], B. Sharifnabi[2], A. Tajabadipour[3];
[1]International center For Sciences, High Technology & environmental Sciences, Kerman, Islamic Republic of Iran, [2]Isfahan University of Technology, Isfahan, Islamic Republic of Iran, [3]Iranian Pistachio Research Institute, Kerman, Islamic Republic of Iran.

The Random Amplified Polymorphic DNA (RAPD) technique and morphological markers were employed for characterization and determination of genetic relationship in some of the major Iranian pistachio (*P. vera* L.) cultivars. Among 77 primers, only 15 primers revealed polymorphism among the cultivars. Based on Jaccard’s similarity coefficient and UPGMA algorithm, cluster analysis, placed the pistachio genotypes in three main groups including; cultivated *P. vera*, wild *P. vera* and *P. mutica*. Cluster analysis results indicated that Gholamrezaei and Momtaz cultivars were identical. Wild *P. vera* named Sarakhs was closely classified with Italiaei cultivar. This strengthened the postulate which says the Iranian commercial pistachio cultivars were originated from sarakhs variety. Cluster analysis of 29 morphological quantitative traits and 17 qualitative ones showed concordance between grouping pattern of these data and those ones of RAPD.
Keywords: RAPD, Genetic diversity and pistachio

P1681. Genetic variation and phylogeographical patterns in *Alsophila podophylla* from southern China based on cpDNA a*tp*B-*rbc*L sequence data

T. Wang;
Sun Yat-sen University, Guangzhou, China.

CpDNA *atp*B-*rbc*L intergenic spacers of individuals of *Alsophila podophylla*, collected from eight populations distributed in Hainan and Guangdong Province, southern China, were sequenced. Sequences were assessed as evolutionarily neutral. Eight haplotypes were identified based on a statistical parsimony algorithm. A high level of haplotype diversity and a low nucleotide diversity were detected. Populations from Hainan shared common haplotypes with those from Guangdong. A network and a NJ tree constructed from haplotypes both suggested a close genetic relationship among populations distributed in Hainan and Guangdong. F_{ST} , *Nm*, AMOVA, and DNA divergence data consistently indicated that no geographical differentiation occured at the interregional level. Geographic isolation has not yet resulted in population differentiations within the populations in Hainan and Guangdong. Phylogeographical patterns demonstrate a ‘star-like’ feature. The majority of haplotypes coalesced near the tip of the NJ tree. Moreover, a demographic signature of population expansion was also detected by mismatch distribution analysis.

P1682. Genetic diversity of two *Ephedra distachya* populations in the Alps

E. Zippel;
Botanic Garden and Botanical Museum Berlin-Dahlem, Berlin, Germany.

The genus Ephedra occurs in Europe with nine species. In the Alps, *Ephedra distachya* s.l. (including *Ephedra helvetica*) is a rare species of the central alpine dry valleys such as in Wallis, Switzerland or the Durance Valley in Eastern France. During the Pleistocene with its great glaciers in the central Alps, *Ephedra distachya* probably survived in the unglaciate parts of the Provencial Alps. After this period, their migration routes, delimitation of infraspecific taxa, their taxonomic relevance and relationships between populations are still unknown. For example, in the literature the few occurrences in South Tyrol were assigned to two or three taxa on the basis of differences in the form of the micropyle of the female flower . This poster reports the initial findings of a molecular study of *Ephedra* populations inthe Wallis, Switzerland and Vinschgau, Italy. They reveal little genetic variation between the investigated populations and suggest that both populations belong to one taxon.

P1683. Molecular Variation in *Cordyceps sinensis* on the Tibetan Plateau

Y. J. Yao, L. Jiao, Y. Jiang, C. H. Dong, Y. Zhan;
Systematic Mycology and Lichenology Laboratory, Institute of Microbiology, Chinese Academy of Science, Beijing, China.

Cordyceps sinensis is a fungus growing on larvae of moths and endemic on the Tibetan Plateau with patched distributions. It is one of the most valued herbs in the Traditional Chinese Medicine. DNA was extracted from stroma, sclerotium and living strain of fruitbodies collected over the Plateau, and 53 ITS sequences were obtained from 33 samples. Combined with the 118 sequences retrieved from the GenBank, excluding 83 of ambiguous locality, repeated submission or unreliable sequence readings, analysis of 88 sequences revealed no difference in sequences from stroma, sclerotium and living strain from the same individual, apart from an occasional 8 bp deletion. Thirty-one haplotypes were identified with pairwise distance ranging from 0.00205 to 0.02664. Two major clades were found in the phylogenetic tree, with samples from Yunnan in one and those from Sichuan, Qinghai and Xizang in the other. However, the molecular variation of ITS sequences within *C. sinensis* is much lower than that among species. It is concluded that diverse host species of *Hepialus*, over 30 reported, and vast geographic separation have not induced much variation in ITS sequences of *C. sinensis*.

P1684. Allozyme variation in five natural populations of *Juniperus sabina* L. in Spain

P. KosiŒski[1,2], A. Wojnicka-Póğorak[3], A. BoratyŒski[1], A. Romo[4];
[1]Institute of Dendrology, Kórnik, Poland, [2]August Cieszkowski Agriculture University, Department of Botany, PoznaŒ, Poland, [3]A. Mickiewicz University, PoznaŒ, Poland, [4]Botanical Institute, Barcelona, Spain.

J. sabina is a small dioecious, wind-pollinated shrub with usually more or less prostrate habit, scale-like leaves and fleshy cones. It occurs on mountain areas of Eurasia and shows notably fragmented distribution pattern. Nine loci were assayed applying starch gel electrophoresis for five parental (fleshy husks of cones) and four progeny populations (embryos). All enzyme systems proved to be polymorphic both to parental and descendent plants. Locus DIA appeared to be most monomorphic whereas locus SHDH was most variable. Population from the Betic Cordillera was most genetically diverse. A small differentiation among populations and large variation within populations were reflected by small value of GST. All groups of embryos are characterized by an excess of homozygotes relative to Hardy-Weinberg equilibrium. Excess of heterozygotes was observed in case of mature individuals and only population from Sierra de Albarracín showed not large surplus of homozygotes. Mean values of observed heterozygosity of parental populations keep level with other coniferous plants. Nei's genetic distance reflected geographical distribution of populations.

P1685. Genetic diversity of holm oak (*Quercus ilex* subsp. *rotundifolia* (Lam) O. Schwarz) in Portugal

C. M. Sousa-Correia, N. Maxted, B. Ford-Lloyd;
University of Birmingham, School of Biosciences, Birmingham, United Kingdom.

Q. ilex subsp. *rotundifolia* and *Q. suber*, keystone species of traditional Mediterranean silvi-agroecosystems, cover 2-2.5 million ha in the Iberian Peninsula and occupy critical areas in terms of soil and water resources. There has been a severe decline of these species during the last century, resulting from deforestation, unfavorable climatic factors, epidemics and overgrazing, which prevented regeneration. Long-term sustainability of these silvi-agroecosystems is further threatened by global warming. Knowledge of the distribution of genetic diversity is critical to the development of effective species conservation and utilization, and for the long-term sustainability of these ecosystems. In this study, regional genetic variation of holm oak was investigated using SSRs. Mean genetic diversity was high. A significant F_{ST} value and positive F_{IS} value indicate some differentiation among populations and only a low level of inbreeding. The results suggest high outcrossing rates, but also differentiation among populations and relatedness among trees of the same population resulting from common origin and adaptation.

P1686. Using RAPD and AFLP markers for molecular characterization of a *Theobroma* genus germplasm bank

Y. A. Moreno[1], **L. Melgarejo - Muñoz**[2], M. Hernández[1], L. Quintero[1], G. Vargas[1];
[1]Instituto Amazónico de Investigaciones Científicas - SINCHI, Bogotá, Colombia, [2]Departamento de Biologia, Universidad Nacional de Colombia, Bogotá, Colombia.

RAPD and AFLP markers were compared in terms of their discriminative capability and genetic relationship establishment among 65 *T. grandiflorum* and 16 *T. bicolor* materials from an *ex situ Theobroma* germplasm bank (Guaviare, Colombia). Similarity and principal component analyses were done for 117 RAPD and 375 AFLP bands. A low congruence in the results for each marker was determined from differences in dendrograms and correlations of similarity values. The analysis of AFLP markers showed a higher correspondence than RAPD with the agronomic groups of some *T. grandiflorum* materials and ecotype classification of *T. bicolor* materials. When the analysis implies materials from both species, the expected heterozygosity values were highest for RAPD (0.30) than AFLP markers (0.25), this value were not significantly different for the independent analysis of species. The marker index values indicate the highest overall utility of AFLP markers system for materials discrimination. This is particularly important for *T. bicolor* materials due the high similarity values estimative (0.9 - 1.0) found by RAPD markers, as a consequence of its low polymorphic markers fraction.

P1687. Inventory and economical value of genotypes from naturally widespread population of black mullbery (Morus nigra L.) in Slovakia

J. Holecyova, J. Brindza, R. Ostrovsky, A. Urbanovic, B. Mikuska;
Slovak University of Agriculture, Nitra, Slovakia.

Monitoring and inventory of widespread genotypes from the black mulberry population (Morus nigra L.) in Slovakia was detected by GIS technology. Most of the genotypes exceeded the age of 200 years. By experimental study of 480 genotypes were determined traits variability on the level of trees, leaves, flowers, fruits and seeds.

Leaves length was in the range 34 - 217 mm, width 36 - 193 mm and the stem length 4 - 46 mm. In the fruit level were determined weight in the range from 34 to 127 g, length 8.1 - 34.4 mm, width 5.3 - 25.2. There was evaluated juice yield (75%), content of vitamin C (11.09 - 14.95 mg/100g), pigments, sugars and organic acids also. Experimental data are utilized for developing the descriptor list. Basic data about genotypes with image documentation are processed in information system GENOTYPDATA Morus nigra L. using ICT.

P1688. Assessing the genetic diversity of *Goeztea elegans*, an endangered Caribbean Tree, based on AFLP data

S. Planas[1], E. Santiago[2];
[1]Departamento de Biologia-Universidad de Puerto Rico-Rio Piedras, San Juan, Puerto Rico, [2]Herbario-Jardín Botánico, Universidad de Puerto Rico, San Juan, Puerto Rico.

Recent advances in molecular technology have opened a new chapter in species conservation efforts, as well as in population biology. One of such techniques is the amplification fragment length polymorphism (AFLP), based on the selective PCR amplification of restriction fragments from a total digest of genomic DNA. We investigated levels of genetic diversity within and among the last remaining populations of *Goetzea elegans* Wydler (Solanaceae), a highly endangered tree species endemic to Puerto Rico. We used an AFLP protocol based on infrared detection of AFLP fragments and the number of polymorphic fragments obtained were visualized and scored using LI-COR automated DNA analyzer and the SAGAmx software. Current results indicate the presence of both, intra and inter-population polymorphism that allows developing a preliminary assessment on the current genetic diversity of the species. The data obtained in this work have important implications for conservation and future breeding programs of this and other rare plants of the Caribbean.

P1689. Development of microsatellite (SSR) markers in *Phaseolus radiatus* (mungbean) and their application on diversity assessment

Y. Park[1], J. Lee[2], K. Ma[1], J. Yu[1], J. Lee[1], A. Dixit[1], J. Kwag[1], E. Cho[1];
[1]National Institute of Agricultural Biotechnology, Suwon, Republic of Korea, [2]National Institute of Crop Science, Suwon, Republic of Korea.

Microsatellites (SSR) are the most useful genetic markers today. Because of their high polymorphism and relative ease of scoring, the demand for these markers is increased rapidly. We have developed a simple, fast and efficient procedure for generating highly SSR- enriched library from genomic DNA of mungbean (*Phaseolus radiatus*). The successful construction of SSR-enriched library relies mainly upon high ratio of SSR containing clones, low redundancy and sufficient number of flanking sequences for primer designing. The library constructed by our new procedure contains up to 80% SSR positive clones. Direct sequencing of randomly selected clones for primer designing facilitated to the fast development of 87 SSR primers. Genetic profiling of 80 selective accessions of mungbean with 24 developed SSR primers has been successfully conducted to date. The efficiency of SSR development and diversity of mungbean collection using SSR markers will be discussed based on germplasm management and genetic diversity.

P1690. Sex determination and sex chromosome evolution in Silene dioecious species

M. Nicolas[1], G. Marais[2], V. Hykelova[3], B. Janousek[3], V. Laporte[4], B. Vyskot[3], D. Mouchiroud[2], I. Negrutiu[1], D. Charlesworth[4], F. Moneger[1];
[1]Laboratoire Reproduction et Développement des Plantes, Lyon, France, [2]Laboratoire de Biométrie et Biologie Evolutive, Lyon, France, [3]Laboratory of Plant Developmental Genetics, Brno, Czech Republic, [4]Institute of Cell, Edinburgh, United Kingdom.

Most flowering plants are hermaphrodite. Dioecious species, having separate male and female individuals represent only ~4% of angiosperm species. The Silene genus (Caryophyllaceae) contains a clade of dioecious species (including S. latifolia, S. dioica and S. diclinis) whose sex determination is based on a XY sex chromosome system with a male-determining Y. This genus is thus well-suited as a model for studying plant sex chromosome evolution.

Sex chromosomes are thought to evolve from an ancestral pair of autosome, between which recombination in the sex determining region has ceased. Sex chromosome evolution, and the causes of recombination arrest and Y degeneration, have been studied in animals. Thanks to 4 genes isolated in sex chromosome of S. latifolia, it is now possible to do similar studies in the plant kingdom. We first demonstrated that these 4 genes have an orthologs on sex chromosomes in S. dioica and S. diclinis, suggesting a common and recent, origin of sex chromosomes. We also mapped the 4 genes on the X chromosome and compared divergence of gene pairs between the X and Y copies. We discuss the results of this analysis and compare them with animal systems.

P1691. An evaluation of microsatellite markers in identification of zygotic seedlings in *Citrus* breeding programs

B. Golein[1,2], Z. Zamani[2], A. Talaie[2], A. Ebadi[2];
[1]Citrus Research Institute, Ramsar, Islamic Republic of Iran, [2]Tehran University, Faculty of Agriculture, Karaj, Islamic Republic of Iran.

Microsatellites or SSRs (simple sequence repeat) have been employed as reliable markers in the plants genome analysis. In citrus breeding and genetic programs, it is very important to distinguish between zygotic and nucellar seedlings in order to eliminate unwanted genotypes. This study details the properties of four example SSRs markers that were isolated from ‘‘Lisbon’’ lemon (*Citrus limon*) using the bead-enrichement method for distinguishing zygotic from nucellar seedlings of a cross between ‘‘Page’’ mandarin (as female) and some *Citrus* cultivars (as male). Four SSRs loci including *AMB2*, *AMB5*, *AMB8* and *AMB10* were tested for amplification of target loci both within the parents and progeny. The results indicate that more than 90% of target loci in each experienced genome can be amplified by tested primers, so it shows that SSRs flanking primers to be conserved in every genome tested. In addition, SSR analysis for the identification of hybrids derived from the cross of polyembryonic citrus cultivars was efficient and the genotype of every plant could be unmistakably assessed.

P1692. Study of Sexual Reproductive system in Marigold (*Calendula officinalis*) and evaluating of Cross-pollination

A. Mohamadi[1], M. R. Naroui Rad[2];
[1]Plant breeding , Zabol University, Zabol, Islamic Republic of Iran, [2]Research Center of Agriculture& Natural Resources, Zabol, Islamic Republic of Iran.

Morphological study of *Calendula officinalis* can be important for increasing of essential oil and other components. In order to investigate of sexual structure and reproductive system of marigold an experiment was conducted during 2001 growing season at Hamadan, Iran. In this study, were evaluated sexual structure of flowers, types of florets, morphological structure of seed and percent of cross-pollination.Resulted floret included two types. The outer-floret names ligular capitule that it has sterile female organs.The inner floret names tubular capitule that it has both sterile female and hermaphrodite organs. Stigma is two branches shapes and male organs have three continuous stament.Results showed that the percent of cross-pollination at 95% of confidence interval is 94.73 ± 1.13.

P1693. GENERATIVE CELL SPECIFIC 1 is essential for angiosperm fertilization

T. Mori[1], H. Kuroiwa[1], T. Higashiyama[2], T. Kuroiwa[1];
[1]Rikkyo (St.Paul's) University, Tokyo, Japan, [2]University of Tokyo, Tokyo, Japan.

The double fertilization process in angiosperms is based on delivery of a pair of sperm cells by pollen tube elongation toward each embryo sac enclosing egg and central cells. Several studies have revealed gametophyte interaction mechanisms, however, nothing is known about the gamete interaction. In this study, we identified a novel protein, designated GCS1 (GENERATIVE CELL SPECIFIC 1), using generative cells isolated from lily (Lilium longiflorum) pollen. GCS1 possesses a C-terminus transmembrane domain, and immunological approaches showed that it is accumulated during the late gametogenesis and localized on the plasma membrane. Arabidopsis gcs1 mutant showed the serious male sterility. This finding would be the first report of the gamete interaction factor essential for the successful angiosperm fertilization. Noteworthily, GCS1 homologues were identified in algae, slime mold and parasites, and the gamete specific expression was revealed in such non-angiosperm species. Our findings might give some important clues to understand the evolution in the gamete interaction.

P1694. Pollination ecology and visitors diversity of *Monotagma plurispicatum* (Körn.) K. Schum. (Marantaceae) in a tropical Atlantic rainforest remnant, Northeastern Brazil

E. Palli[1], I. C. Machado[2], P. Cara[2], C. Erbar[1], P. Leins[1];
[1]Ruprecht-Karls University, Heidelberg, Germany, [2]Federal University of Pernambuco, Recife, Brazil.

A case history of the herbaceous ***Monotagma plurispicatum*** was realized from February to April 2005 in a natural population of two different border sites of an Atlantic rainforest remnant with 3500ha in extent (8^{o} 30' S, 35^{o} 50' W), in Alagoas state, northeastern Brazil. The study was focused on floral biology, pollination mechanism, reproductive system and nectar production of the species. With an entomophilous syndrom, *Monotagma* presents axilar inflorescence with hermaphrodite flowers of white color and diurnal anthesis and offers nectar as unique floral resource. Characterized by secondary pollen presentation, the flowers show a highly precise and irreversible explosive mechanism to discharge the pollen. Inspite of presenting a considerable range of visitors, only those who are able to release this mechanism can be considered as effective pollinators, such as two species of Euglossinae bees (genus *Euglossa*) and one hummingbird (*Phaethornis ruber* - Trochilinae). Differences between the two studied areas concerning richness and frequency of the visitors indicates that forest fragmentation could have an impact on the pollination ecology of the species.

P1695. Carpenter Bee Pollination In Two Crotalaria Species (Fabaceae)

P. R. Srungavarapu;
Environmental Sciences, Andhra University, Visakhapatnam, India.

Crotalaria laburnifolia L. and *C. verrucosa* L. are perennial shrubs with robust growth during rainy season. They flower year-long with concentrated flowering during August-September. The terminal racemes produce yellow flowers in *C. laburnifolia* and blue flowers in *C. verrucosa*. In both, the flowers are characteristically papilionaceous representing flag-shaped blossoms with pump type pollen presentation mechanism. The flowers are nectariferous, open from noon to evening time with a maximum percentage at 1500-1600 h and were visited regularly by carpenter bees (*Xylocopa latipes* and *X. pubescens*) during the period of anthesis and occasionally by digger bees and leafcutter bees at any time of the day for collecting nectar. The flowers were frequented more by juvenile carpenter bees than their adult ones and the probing behaviour resulted in sternotribic pollination. The bees showed inter-plant foraging activity in quest of more nectar. As both *Crotalaria* species are self-compatible, the nectar-feeding activity of bees, especially carpenter bees has been considered to be effecting both self- and cross-pollination.

P1696. Estimating selection on floral traits through male fertility in a large natural population of *Mimulus guttatus* by using the neighborhood model

M. van Kleunen[1], **J. Burczyk**[2];
[1]Institute for Biochemistry and Biology, Potsdam, Germany,
[2]Department of Genetics, Bydgoszcz University, Bydgoszcz, Poland.

Most methods for studying selection through male fitness using genetic markers require that all potential males in the population are sampled. We used the neighborhood model, which also considers outcrossing with non-sampled background males, to estimate paternal selection gradients on floral traits in a large natural population of *Mimulus guttatus*. Multivariate analyses indicated that male mating success declined with distance from and depended on the direction to the mother plants, and that there is directional selection for plants with fewer open flowers which have more elongated corollas, smaller anthers, a smaller anther-stigma separation, more red dots on the corolla and a larger fluctuating asymmetry therein. However, for most of these traits there was also stabilizing selection for intermediate optima. The large number of significant selection gradients in our study shows that even in relatively large natural populations where not all males can be sampled, it is possible to detect significant paternal selection gradients when the analyses are based on the neighborhood model.

P1697. Fruit set of the endemic *Barlia metlesicsiana* (Orchidaceae) on Tenerife Island

K. Bernhardt[1], E. Sommerkamp[2], M. Kropf[1];
[1]Institute of Botany, BOKU University, Vienna, Austria, [2]Grupo Orquideófilo Canarias, Puerto de la Cruz, Tenerife, Spain.

The distribution of the orchid species *Barlia metlesicsiana* W.Teschner is restricted to the Canary Island Tenerife. Only two populations are reported from the western part of the island: Santiago del Teide and Chio/ Guia de Isora.

Both populations are characterised by a patchy population structure with several subpopulations and individuals growing solitary, and therefore, plants are difficult to reach for pollinators. We analysed 230 individuals of four subpopulations representing both known populations. Overall, one third of the analysed plants flowered in 2004. Portions of flowering individuals ranges from 19.0-56.3% in four subpopulations with an average of 26% of all flowers (n = 1805) producing matured capsules as a measure of pollination success. Additionally, we recorded plant height, leaf characteristics, and flower number per plant. Correlations reveal no significant relationship between plant height or flower number ("floral display") and individual proportions of fruit set indicating almost random pollination success. As effective pollinator the bumble-bee *Bombus canariensis* Pérez was observed.

P1698. Sex ratio and differences between male and female specimens in *Taxus baccata*

G. Iszkulo, A. K. Jasinska;
Polish Academy of Sciences, Kornik, Poland.

Sex ratio in 4 natural and 1 spontaneous semi-natural populations of *Taxus baccata* were verified in Poland and Ukraine during 2003. The aim of the study was to verify the hypotheses, that: 1) sex ratio depends on a) the average age of population, b) environmental conditions, 2) dimensions of trees and needle characters of male and female individuals are different. The sex was verified on the plots within of all 5 populations on the basis of presence of micro- and/or macrostribili. Sex ratio, counted as quotient of female and male specimen numbers, varied from 0.49 in the oldest to 1.12 in the medium aged population. Sex ratio correlated statistically significantly with the average yearly precipitation. The male individuals were higher and thicker than female ones, but the female individuals have longer needles than male. It was concluded, that female individuals, have probably higher reproductive costs and can to lose the competition with the male ones.

P1699. Genetic and molecular analysis of trichome density using naturally occurring variation among Arabidopsis thaliana accessions

J. Hilscher[1], U. I. Im[1], C. Schlötterer[2], M. T. Hauser[1];
[1]Institute of Applied Genetics and Cell Biology, BOKU - University of Natural Resources and Applied Life Sciences, Vienna, Austria,
[2]Institute of Animal Breeding and Genetics, University of Veterinary Medicine, Vienna, Austria.

Arabidopsis thaliana trichomes are single epidermal cells present on leaves, stems, petioles and sepals. The morphological and mechanical features of trichomes can influence many aspects of plant physiology and ecology and thus may be of selective importance.

Genetic studies identified a well defined set of genes including (MYB related and bHLH-like) transcription factors and a WD40 repeat protein that regulate trichome initiation. The current model of de novo trichome patterning involves the action of activators and inhibitors, which account for the regular spacing through local self-activation and lateral inhibiton. Furthermore, across *A. thaliana* accessions trichome density on leaves shows a wide variation. We exploited the natural occurring variation for mapping novel modulators of trichome density in a QTL analysis. We chose a F2 mating design, based on a cross between two extreme A. thaliana accessions, with low and a high trichome density. Molecular and population genetic analyses of candidate loci will contribute to the understanding of trichome patterning and of adaptive processes acting on this trait.

Supported by the FWF and WWTF

P1700. Life history plasticity to irradiance during seedling establishment in *Picea omorika*

D. P. Pemac[1], J. Ducic[2], B. Tucic[1];
[1]Institute for Biological Research "Sinisa Stankovic", Belgrade, Serbia and Montenegro, [2]Ministry for science and enviromental protection, Belgrade, Serbia and Montenegro.

The adaptive value of life history plasticity to irradiance has been tested in *Picea omorika* seedlings from a synthetic population comprising 21 maternal families from six natural populations. Phenotypic variation induced by two distinct light intensities was explored for three juvenile traits: days from germination to cotyledon opening (DGTOC), days from cotyledon opening to epicotyl appearance (DCTOE), and epicotyl length at six weeks (EPL6). Ambient light conditions affected significantly DCTOE and EPL6, but not DGTOC. Phenotypic selection analysis revealed that canalization of DGTOC was favoured by selection, but entailed a fitness cost under both light levels. The plasticity of DCTOE to irradiance was diagnosed as maladaptive. The existence of heritable variation for plasticity was revealed for all of the traits studied. However, since DGTOC and DCTOE were involved in a genetic trade-off, these traits would never reach their optimal values across radiation environments.

P1701. Adaptive plastic responses to an irradiance gradient in the *Iris pumila* plants from exposed and shaded habitats

S. N. Avramov, D. P. Pemac, B. Tucic;
Institute for Biological Research "Sinisa Stankovic", Belgrade, Serbia and Montenegro.

Plasticity of *Iris pumila* leaf traits (three morphological and five anatomical) to irradiance was explored under growth-room conditions. Siblings from 28 full-sib families from an open and a shaded population responded similarly to changes in light availability: morphological traits gradually increased, while anatomical traits decreased with light reduction. Comparisons of the induced phenotypes with those favored by selection at each light level revealed that a larger leaf size and an increased SLA were functionally beneficial on light-deprived conditions. A medium stomatal density was also adaptive at high light in the open population. Plasticity costs were detected for two anatomical traits at low irradiance in the open population, as well as one morphological trait at medium light, and one anatomical trait under high irradiance in the shaded population. The cost of canalization was recognized for two anatomical traits at high and low light, and one morphological at low irradiance.

P1702. Phenotypic plasticity and genetic differentiation of *Diplotaxis erucoides* (Brassicaceae) populations in Sicily

P. Unterluggauer, K. G. Bernhardt, M. Kropf;
Institut für Botanik, Universität für Bodenkultur, Wien, Austria.

Diplotaxis erucoides is a wide-spread species in the mediterranean area. Particularly, in arable fields it occurs with at least two flowering generations per year (winter-annual, summer-annual). Different phenotypes are found according to the different environmental conditions of humid winters and arid summers. The present study aims to quantify the phenotypic differences among the generations and to estimate the extent of their genetic differentiation. The soil seed bank is included to illuminate the genetic diversity and composition of the belowground subpopulations in relation to the genetic constitution of the aboveground subpopulations. In Sicily seven populations were sampled (30 individuals / generation, soil samples). Phenotypic variation is assessed by morphological traits as height, branching, fruit production, leaf characteristics and life history traits like speed of development (common garden experiment). Genetic variation is analysed using AFLP technique. Correlation of phenotypic and genetic variation will indicate, to what extent phenotypic differences among generations are due to plasticity or ecotypic differentiation.

P1703. Individual variability of mineral content in relation to plant size in experimental populations of two herbaceous species

E. KomosiŒska[1], U. Wierzchowska[1], B. GruszczyŒska[1], P. Mňdrzycki[2], M. Zachwatowicz[3], **T. Wyszomirski**[1];
[1]Warsaw University, Institute of Botany, Warsaw, Poland, [2]Warsaw University of Ecology and Management, Faculty of Ecology, Warsaw, Poland, [3]Warsaw University, Faculty of Geography and Regional Studies, Warsaw, Poland.

Populations of white mustard (Sinapis alba) and small balsam (Impatiens parviflora) were grown in glasshouse conditions, each species at two population densities. Measurements of individual size taken at harvest included: stem height and diameter, aboveground dry mass, leaf area, crown projection area etc. Concentrations of N, P, K, Ca, Mg, Na, Mn, Fe and Zn in leaves and stems were determined. Patterns of size-concentration relationships differed both across species and densities. The percentage of variation in element concentration explained by the set of size measurements ranged from about 0% (N and P in low-density Impatiens) to 39% (N in Sinapis and high-density Impatiens), to 64% (Zn in high-density Impatiens). Direction of some mass-concentration relationships depended on density (e.g. mass-K correlation: negative in low-density, and positive in high-density Impatiens). Also, various measures of size related differently to particular concentrations (e.g. for Zn in high-density Impatiens: strong positive partial correlation with mass and negative with plant height) Detailed results are presented in relation to plant size allometry.

P1704. MAM Variation Determines Glucosinolate Profiles in Arabidopsis lyrata ssp. petraea.

A. J. Heidel, M. J. Clauss, J. Kroymann, T. Mitchell-Olds;
Max Planck Institute for Chemical Ecology, Jena, Germany.

Glucosinolates are chemical defenses against insect herbivores and are present in the Capparales. Methylthioalkylmalate synthase (MAM) is required for side chain elongation in Met-derived glucosinolate biosynthesis in *Arabidopsis thaliana*. MAM variation and its evolutionary dynamics in natural populations are unknown, so we investigated whether MAM variation explains glucosinolate variation in a natural population of *A. lyrata* ssp. *petraea* in Central Europe. Using microsatellite markers to distinguish MAM alleles, we crossed individuals within the natural population, genotyped the progeny and determined that the MAM alleles from 6 of 16 crosses associate with particular glucosinolate profiles. Some alleles associate with longer chain glucosinolate while other alleles associate with shorter chain glucosinolates. Therefore there are variable MAM alleles within a population determining glucosinolate content. This provides a useful system to study the evolution of a resistance phenotypic trait since the underlying genetic variation that causes the phenotypic variation is known.

P1705. Evolution of plant defenses in Arabidopsis lyrata within the context of a natural herbivore community

M. J. Clauss, T. Mitchell-Olds;
Department of Genetics and Evolution, Jena, Germany.

Herbivory can have significant impact on plant fitness, and plant defenses evolve in response to herbivore-mediated selection. In the Brassicaceae, both trichomes and plant secondary compounds such as glucosinolates function as defenses against herbivores, and respond to artificial selection in model and crop species. However, we know little about the evolutionary dynamics of the integrated defense phenotype in natural populations. For one natural population of Arabidopsis lyrata, an out-crossing perennial herb closely related to A. thaliana, we quantified the ecological role of herbivory in the field, characterized defense-related phenotypes, and assessed the genetic basis of defense. Herbivory during three years of field observations was imposed by a diverse and varying suite of insects and mollusks. Only the abundance of Lepidopteran and Heteropteran larvae was significantly positively correlated with tissue loss and negatively correlated with flowering in A. lyrata. Using specialist and generalist Lepidopteran larvae in bioassays of plant resistance in the laboratory, we found a genetic basis in resistance to multiple herbivores. In a quantitative genetic study sampling widely from the above population, we found significant heritability for trichome density and glucosinolate composition. Whereas resistance to Trichoplusia ni (a generalist) was significantly correlated with glucosinolate concentration, resistance to Plutella xylostella (a specialist) was correlated with trichomes density. Thus, significant genetic variation for different mechanisms of defense are segregating within this single population of A. lyrata. Genetic correlations among alternative defenses are weak, and do not appear to constrain the independent evolution different components of the complex plant defense phenotype in response to a multi-species herbivore community.

P1706. Temporal abundance patterns of the desert annual plant *Allionia incarnata* related to rainfall and temperature, and effects of predation by the harvester ant *Pogonomyrmex rugosus.*

S. Rivas Arancibia, R. Guzmán Mendoza, A. Zavala Hurtado;
Universidad Autónoma Metropolitana- Iztapalapa, México City, Mexico.

Desert annual plants must adjust their developmental patterns to short and unpredictable rain events. Also, seeds are prone to be gathered by consumers and dispersers, controlling their distribution and abundance patterns. In Mexican deserts, *Allionia incarnata* is one of the first annual plant to appear in the rainy season and is a main resource for harvester ants. We describe abundance patterns of *A. incarnata* during five years in three permanent sites at the semiarid Zapotitlán Valley, México. In one of these sites, we explored the impact of the harvester ant *Pogonomyrmex rugosus* on the dynamics of *A. incarnata*. Using Generalized Linear Models we adjusted abundance response surfaces related to temperature and rainfall. It was found in ample temperature (20 - 30°C) and rainfall (20 - 80 mm) ranges with differences related to soil water retention capacities. We found a 9 % of *A. incarnata* in the soil seed bank, and a 23.4% of predated seeds by *P. rugosus*. This highlights the relevance of seed predation as a controlling factor in the dynamics of desert annual plants. Finally, we discuss the adjusting of life-history traits of this species to a bet hedging strategy.

P1707. Biology, ecology and invasion characteristics of Campylopus introflexus in the Czech Republic

E. Loskotova;
Faculty of Science, Charles University, Prague, Czech Republic.

The poster summarizes project aims and preliminary results of a study on the moss *Campylopus introflexus* (Dicranaceae) in Central Europe. *C. introflexus* is one of the most strongly invasive species of bryophytes in Europe. The species appears to be native in the Southern Hemisphere. In Europe, it was collected for the first time in the British Isles in 1941. The moss has expanded eastward and the first collection in the Czech Republic is dated 1988. New localities have been recorded with growing frequency. Today, 23 localities are known in the Czech Republic, but a thorough survey of this critical moss does not exist.

The author's research is based on monitoring phytogeography (east boundary of actual spread), life history (reproduction, competitive abilities, etc.), and ecology (microclimatic characteristics, substrate requirements, etc.). Genetic patterns in the Czech populations are being studied by molecular methods (isozymes, RAPD). In vitro cultivation and cryopreservation of samples is also part of the methodology.

P1708. Genetic diversity of *Sphagnum fimbriatum* in the northern and southern hemispheres

B. E. Itten, J. Schneller, E. Urmi;
Institute for Systematic Botany, Zurich, Switzerland.

Sphagnum fimbriatum (Sphagnopsida, Bryophyta) is a bipolar species that occurs in the northern and southern temperate zones (Eurasia, North America, South America, New Zealand). In some areas of Central Europe *S. fimbriatum* is rare. In Switzerland it is included in the red list of endangered bryophytes.

The aim of this study is to test the genetic variability within and among populations in order to assess whether:

a) There is a positive correlation between population size and genetic variability,

b) the current distribution in Switzerland is a consequence of fragmentation of populations,

c) the world-wide differences in abundance correlate with differences in genetic diversity.

DNA from twenty-two European populations was amplified with RAPD markers and the data analysed with hierarchical analysis of molecular variance. The genetic distances/similarities between pairs of populations were calculated.

The higher partition of the variation is found within populations. That might be due to large effective population sizes, or multiple colonization events.

Additionally seven Argentine populations were analysed and compared with the European ones.

P1709. Genetic diversity of *Sphagnum subsecundum agg.* populations in Portugal

M. Ricca[1], T. Azevedo[1], A. Séneca[1,2];
[1]CIBIO/ICETA - University of Porto, Porto, Portugal, [2]Dept. of Botany of FCUP - University of Porto, Porto, Portugal.

Over the past 20 years, studies have revealed levels of genetic variation in bryophytes that are similar to those found in vascular plants. This has led many to question the traditional view of bryophyte evolution, which holds that these organisms have a low evolutionary rate. The morphological similarities through time and space are partly explained by the presence of physiological and biochemical, rather than morphological, evolution (creating sibling species) and convergent evolution.

The *Sphagnum subsecundum agg* is a species complex taxonomic challenging as the morphological traits used to distinguish the species, in some areas of its European distribution, overlap and many plants present intermediate forms. Therefore population studies will allow understand more about its dynamics and clarify the taxonomic relations. In Portugal, these taxa are the most abundant sphagna, but reproduce more mainly through gametophore fragmentation; rarely it's possible to observe capsules. The main aim of this work is to compare genetic diversity patterns using ISSR of different populations.

P1710. Differences in the diaspore bank of bryophytes between two grassland types: the role of the life-strategies

Z. Hock, P. Szövényi, Z. Tóth;
Eötvös Loránd University of Sciences, Budapest, Hungary.

Diaspore bank of bryophytes in open and closed grasslands on dolomite rock has been investigated by means of seasonally collected soil samples. These habitats differ in vegetation structure and microclimate. The total cover of bryophytes at the surface and in the soil samples was complementary: closed sites, dominated by perennials, had greater cover values at the surface (lack of long-lived propagules), while colonist-dominated open sites showed higher cover in the soil samples (abundant stored, long-lived propagules, potential dormancy). However, cover values in both samples types were greatly influenced by the sampling date, since some species had different abundances depending on habitat type and/or sampling date. The number of species in soil samples of closed sites with more even conditions was slightly higher, which can be explained by the additional presence of perennials. Species absent or rare at both sites were detected in soil samples, however some frequently and abundantly sporulating species were absent from the diaspore bank. Differences in patterns detected at the two sites can mostly be explained by their different life-strategy spectrum.

P1711. Darwinian selection on a selfing locus

K. K. Shimizu, M. D. Purugganan;
North Carolina State University, Raleigh, NC, United States.

The evolutionary transition from outcrossing to selfing is one of the most prevalent trends in flowering plants. In 1876, Charles Darwin proposed the reproductive assurance model to explain it, suggesting that selfing can be evolutionarily advantageous when pollinators or mates are scarce in spite of inbreeding depression. It was shown that a model plant *Arabidopsis thaliana* became a selfer by the loss of self-incompatibility genes *SRK* and *SCR*. The *pseudoSCR1* gene in 21 *A. thaliana* accessions has low levels of nucleotide diversity. This indicates that positive directional selection has driven the evolutionary fixation of the pseudogene allele of *SCR*. Coalescent simulation showed that the event most probably occurred at the range expansion ~17,000 years ago owing to the glacial retreats. These results support Darwin's model, since rapid expansion would be accompanied by scarcities of mates and thus selfing plants would have a selective advantage during long-distance dispersals.

P1712. An investigation of the inheritance procedure and estimating the number of controlling genes of some traits related to grain yield in barley *(Hordeum vulgare)* Afzal/Radical cross

A. Baghizadeh[1], **M. Naghavi**[2];
[1]international center of science, high tachnology & enviromental science, Mahan, Islamic Republic of Iran, [2]Tehran University, Tehran, Islamic Republic of Iran.

In order to study inheritance of traits related to grain yield in barley, F_1, F_2 and F_3 generations were made from Afzal/Radical cross. Parents along with F_1, F_2 and F_3 generations were planted in a randomized complete block, design with three replications. Head weight, head length, number of heads, number of spikelets per spike, awn length, hundred grain weight, grains per head and straw yield per head in different generations were recorded. Analysis of variance indicated that mean squares of generations were statistically significant for all the traits. Then, generation mean analysis was performed for all the traits. The results showed that additive, dominance and epistasis effects were effective for all the traits except awn length. Recently trait was controlled with only additive and dominance effects. Also, results indicated that dominance variance was the most important for inheritance of all the traits. Average broadsense heritabilities where between%69-89% for all the traits. The number of genes for the traits were estimated to be between one and five.

P1713. Development of the microalgae communities in the phytotelmata of *Sarracenia purpurea* L.

C. Gebühr[1], E. Pohlon[1], A. R. Schmidt[2], K. Küsel[1];
[1]Institute for Ecology, Jena, Germany, [2]Institute of Palaeontology, Berlin, Germany.

The phytotelmata of Sarracenia purpurea are colonized by a variety of organisms including bacteria, microalgae, protozoa, and invertebrates. However, the microbial food web and the role of microalgae in pitcher plants are still poorly understood. The aim of this study was to determine the structure and the succession of the algal communities in an allochthonous population of S. purpurea in a fen (Saxonia, Germany) within one year. More than 100 taxa of microalgae were found in the phytotelmata representing up to 97 % of the total living biomass. Within one plant, different phytotelmata harboured different algae communites. Approximately 50,000 algae per ml water fluid were present in young phytotelmata, dominated by Chrysophyceae, whereas 200,000 algae per ml water fluid were present in one year old phytotelmata, mostly dominated by Chlorophyceae. In contrast, Bacillariophyceae dominated in the fen. The colonization pattern in exposed sterile artificial pitchers were similar to those observed in the phytotelmata. Thus, the colonization of the pitchers seemed to be randomly and not affected by plant - phytotelm community interactions.

P1714. Comparison of molecular phylogenetic reconstruction of different loci in Nepenthaceae

H. Meimberg, G. Heubl;
Department Biology I, Section: Biodiversity Research, Systematic Botany, LMU, Munich, Germany.

The Malay Archipelago is considered as a center of secondary diversity of Nepenthaceae, the pitcher plants of the Old World tropics. Recent analysis of the cpDNA trnK intron supports this hypothesis showing all species as neighbor group to the isolated species from Sri Lanka, Seychelles and Madagascar. Accordingly, an origin of recent Nepenthaceae in the Indian Subcontinent is indicated.

In the course of our study, we identified a translocated pseudogene copy of the trnK gene in the Nepenthaceae which we assume to be located in the mitochondria. In addition a nuclear single copy gene was analyzed. Comparison between the three datasets allows new insights concerning the evolution of Nepenthaceae. Obviously recent Nepenthaceae underwent a bottleneck and inconsistencies in the phylogenetic reconstruction of the data sets indicate that the evolution of the group was influenced by hybridization and introgressions. One monophyly of species from Borneo and Sulawesi shows a high distance to the rest of the taxa using non cpDNA data sets. This indicates that the cpDNA phylogeny could be misleading and an origin of recent Nepenthaceae on the Sunda Shelf is feasible.

P1715. Pedological and microclimatic requirements of *Drosophyllum lusitanicum*

M. Peroutka, W. Adlassnig, W. Pois, G. Eder, I. K. Lichtscheidl;
Faculty of Life Science, Vienna, Austria.

Unlike the majority of carnivorous plants, *Drosophyllum lusitanicum* colonizes hot and arid sites in the Western Mediterranean. Soil requirements and the enduring of severe drought stress in summer are controversially discussed in literature.

We compare soil composition, microclimate, trapping activity and further physiological parameters of plants from natural sites in different developmental stages. *Drosophyllum* roots only in acid soil but never in the calcareous bedrock, contradictory reports are caused by inaccurate sampling. It tolerates very low concentrations of all macronutrients.

The macro- and microclimate are very harsh during the day; wind is the only factor significantly decreased by the plant population. In summer, water neither from rainfalls nor from soil is available. Nonetheless plants are green, produce trapping mucilage and proteases. We show that water supply comes from the daily dew and is taken in by cuticular pores on the leaves. *Drosophyllum* is vivid and fruits in all stages of succession, but germination was only observed on pioneer sites. Preservation of open and oligotrophic sites is essential for the survival of this species.

P1716. Phosphatase Activity in Glandular Structures of Carnivorous Plant Traps

B. J. Pğachno, A. Jankun;
The Jagiellonian University, Institute of Botany, Department of Plant Cytology and Embryology, Kraków, Poland.

Phosphatase activity was studied in situ in glandular hairs and glands of carnivorous plants, especially in the *Utricularia* genus, as well as in species of other carnivorous genera. For the visualization of the phosphatase activity the ELF (Enzyme Labelled Fluorescence) - 97 phosphatase substrate was used. The phosphatase activity was found in internal trap hairs of 19 *Utricularia* species from 11 sections, in various internal hairs of Genlisea traps (both members of the subgenus Tayloria and Genlisea), both stalked and sessile hairs of *Pinguicula*, sessile hairs of *Byblis linifora*, emergences of *Drosera*, and in glands of *Cephalotus*, *Brocchinia reducta* and *Nepenthes*. Taking into account intensive and commonly found activity of the phosphatase in glandular structures of carnivorous plant traps in these taxa, digested animals are important source of phosphorus for these plants.

P1717. Microflora in the Traps of Pitcher Plants

E. Mayer, W. Adlassnig, M. Peroutka, I. K. Lichtscheidl;
Institution of Cell Imaging and Ultrastructural Research, Vienna, Austria.

Carnivorous pitcher plants supplement their nutrition by trapping and digesting insects in fluid filled traps. It is a matter of debate if digestion is performed by the plant or by bacteria. Interestingly, the traps are not only killing animals, but host diverse communities of animals and microorganisms.

Whereas many studies on trap bound arthropods exist, only little is known about protists and microorganisms in the digestive fluid. We observe microorganisms in the fluid of three genera of pitcher plants (*Nepenthes*, *Cephalotus* and *Sarracenia*) and study the physiological properties of 44 strands of bacteria and fungi.

We find significant differences in the microflora of these three genera (*Nepenthes*: bacteria, yeasts, filamentous fungi; *Sarracenia*: bacteria, yeasts, protozoans; *Cephalotus*: bacteria, filamentous fungi, algae, moss protonemata). Concerning digestion, we find proteolytic activity in 6 strands of bacteria, 4 acidify the pitcher fluid, 3 degrade sulfur.

Our results show that digestion is significantly supported by microbial action. Furthermore, pitchers are a complex micro-ecosystem for bacteria, fungi, protozoans and algae.

P1718. The mucilage of *Drosera*, a carnivorous plant, habitat or battlefield for bacteria?

K. Pranjií [1], H. Daims[2], K. Stöcker[2], I. K. Lichtscheidl[1];
[1]Institution of Cell Imaging and Ultrastructure Research, Vienna, Austria, [2]Institution of Microbial Ecology, Vienna, Austria.

Introduction: Carnivorous plants have developed unique strategies to compensate for limited nutrient availability in their habitats by capturing small animals. *Drosera*, a carnivorous plant, produces and secretes mucilage containing digestive enzymes to break down captured prey. It is still unknown if microorganisms contribute to this digestion process or if the degradation of prey is done by the plant alone.

Material and Method: We combined microscopical and molecular techniques like *Fluorescence In Situ Hybridisation*, PCR-amplification of 16S rRNA genes and *Field Emission Scanning Electron Microscopy* to detect and identify bacteria on the tentacles and in the mucilage of different *Drosera* species.

Results: The number of bacteria in the mucilage and on the epidermal leave surfaces of *Drosera* was very low. The amount and identity of the detected bacteria did not correlate with vegetation period or *Drosera* species. After the addition of bacteria into the mucilage disintegration of bacterial cell membrane within a few minutes, followed by cell lyses, was observed. Therefore we proposed that these bacteria were airborne contaminants rather than symbionts.

P1719. Pharmaceutical study of *Aldrovanda vesiculosa* trap movement

A. N. Ivanova, L. E. Muravnik;
Komarov Botanical Institute RAS, St.-Petersburg, Russian Federation.

Successive phases of *A. vesiculosa* trap lobe movement were studied. Stimulation by bristle (BS) or feeding with boiled egg-white (FS) was used to induce trap movement while plants were incubated in chemical solutions. After incubation in 0.01 mM $LaCl_2$ or 0.1 mM EGTA shutting, narrowing and opening of the trap were inhibited both after BS and FS that indicated Ca^{2+} role in trap lobes movement. Incubation in 0.05 mM LiCl for more than 3 hr prevented shutting and opening after BS that may indicate inositol-3-phosphatase involvement in those processes. Open traps closed spontaneously but shut traps half-opened after 30 min incubation in 0.01 mM $HgCl_2$. Pre-incubation in 5 mM mercaptoethanol prevented spontaneous shutting in $HgCl_2$ solution may propose involvement of Hg-sensitive aquaporins in trap shutting. 0.01 mM monensin prevented opening of traps after FS. It didn't affect shutting and opening after BS either narrowing after FS. Thus only opening after FS could be decided to result from cell growth. Study of *A. vesiculosa* trap lobe cell ultrastructure confirmed stated assumption.

P1720. Morphology and nrITS phylogeny of the genus Pinguicula (Lentibulariaceae), with special attention to embryo evolution

G. V. Degtjareva[1], S. J. Casper[2], F. H. Hellwig[2], A. R. Schmidt[2], D. D. Sokoloff[1];
[1]Moscow State University, Moscow, Russian Federation, [2]Institut für Spezielle Botanik, Friedrich-Schiller-Universität, Jena, Germany.

The family Lentibulariaceae is characterised by great variability of embryo structure, including cotyledon number. In this respect, the family is probably unique among other families of Lamiales. The genus Pinguicula which comprises about 80 species is especially interesting due to co-existence of species with monocotyledoneous and dicotyledoneous embryos (Haccius & Hartle-Baude 1957). To elucidate putative evolutionary history of embryo, we have analysed nrITS sequences in 31 Pinguicula species from Old and New World. Besides, we have studied seed (including embryo) morphology and anatomy in 22 species. Our molecular phylogenetic data are largely congruent with data on the same DNA region produced by Shimai & Kondo (2004), although they studied only 21 species. We suggest that cotyledon number was quite unstable in the evolution of Pinguicula. Some features of seed coat structure and flower morphology are much more congruent to nrITS phylogenetic data than cotyledon number.

P1721. Complex organisation of the waxy zone in pitchers of Nepenthes alata Blanco (Nepenthaceae)

E. Gorb[1], K. Haas[2], A. Henrich[2], S. Enders[1], N. Barbakadse[1], S. Gorb[1];
[1]MPI for Metals Research, Stuttgart, Germany, [2]University of Hohenheim, Stuttgart, Germany.

The waxy zone inside pitchers in most Nepenthes species is covered with a thick layer of epicuticular wax and was reported to serve mainly for animal trapping and retention. In N. alata, two layers of waxes are distinguished. These layers differ in their structure, chemical composition and mechanical properties, and they decrease the attachment of insects in different ways. The lower layer is composed of highly interconnected irregular platelets, whereas the upper one consists of densely arranged separate membraneous platelets bearing a pedicel-like "foot". These morphological distinctions are caused primarily by differences in the chemical composition of waxes. The waxes exhibit different mechanical properties: the wax of the lower layer is harder and stiffer than that of the upper layer. Moreover, crystals of the upper layer are very brittle and may be easily detached or broken to tiny pieces. The laboratory experiments showed that both wax layers reduce the attachment force of insects. Both layers lead to the reduction of the contact area of insects' feet with the plant surface. Additionally, crystals of the upper layer contaminate insects' adhesive organs.

P1722. The behaviour of *Drosera rotundifolia* L. (Droseraceae) trapping leaves in natural habitats

P. A. Volkova[1], T. E. Volkova[2], K. N. Markvichyova[1], A. B. Shipunov[3];
[1]Moscow State University, Moscow, Russian Federation, [2]All-Russian Academy of External Trade, Moscow, Russian Federation, [3]Institute of Information Technologies, Moscow, Russian Federation.

Our aim was to investigate the influence of weather conditions and prey on the leaf-trapping behaviour of insectivorous plant *Drosera rotundifolia* (Droseraceae) in the natural habitat.

Continuous, non-manipulative observations on two sundew plants in Northern Russia and two plants in Middle Russia lasted 72 hours each. We estimated the shape of the leaf blade, the degree of slime secretion, percentage of curved margin tentacles and the number of captured prey for each of sixteen leaves chosen for the study.

Our observations show that different characteristics of leaf blade changed independently both on each other and on the presence of prey. The correlated behaviour of leaf blades from different plants also indirectly shows the absence of dependence between trapping leaves behaviour and prey. However, our experiments with artificial feeding in natural conditions show clear leaf reaction to the prey.

We propose that in natural undisturbed conditions changes of the leaf blade characteristics are casual and are augmented by the external factors such as relative air humidity, atmosphere pressure and presence of the prey on the leaf blade.

P1723. Respiration study in aquatic carnivorous plants: turions, traps and leaves

L. Adamec;
Institute of Botany, TŚeboŔ, Czech Republic.

Respiration at 4 and 20^{o}C was compared in dormant autumnal turions of aquatic plants *Hydrocharis morsus-ranae* and *Caldesia parnassifolia* and aquatic carnivorous plants *Aldrovanda vesiculosa, Utricularia australis, U. ochroleuca* and *U. bremii* and after breaking imposed dormancy in the spring. Respiration rate at 20^{o}C was 1.3-4.6 mmol/kg$_{\text{FW}}$.h in dormant turions and slightly increased (1.7-5.2 mmol/kg$_{\text{FW}}$.h) in the spring. However, non-dormant "turions" of (sub)tropical Australian *Aldrovanda* populations and American temperate *Utricularia inflata* and *U. purpurea* respired 7.6-11.3 mmol/kg$_{\text{FW}}$.h. Respiration rate of traps of 6 temperate aquatic *Utricularia* species (5.1-8.6 mmol/kg$_{\text{FW}}$.h) was 70-120 % greater than that in leaves or shoots. But net photosynthetic rate in photosynthetic leaves/shoots (40-117 mmol/kg$_{\text{FW}}$.h) exceeded that in traps by 7-10 times. Thus, *Utricularia* traps represent a great metabolic cost for the plants.

P1724. Carnivory Timed to Flowering in Triggerplants (Stylidium; Stylidiaceae)

D. W. Darnowski[1], D. M. Carroll[2];
[1]Indiana University Southeast, New Albany, IN, United States, [2]Rush University Medical Center, Chicago, IL, United States.

Australia's Triggerplants (Stylidium spp.; Stylidiaceae) 1) share habitat (wet, low nutrient soils) with accepted genera of carnivorous (Drosera, Utricularia, Cephalotus) and subcarnivorous/protocarnivorous (Byblis) plants and 2) possess glandular hairs which trap insects. Several lines of evidence were found to support the hypothesis that triggerplants are carnivorous: 1) trapping rates (prey m-2) for triggerplants and for accepted genera of carnivorous and subcarnivorous plants were very similar at three sites separated by 1500 km; 2) triggerplants, like Drosera capensis and unlike non-carnivorous plants, produced proteases in an inducible fashion when prey-trapping was simulated using yeast extract. This was true for plants flowering on soil as well as for plants flowering in vitro, the latter possibility excluding digestion by microorganisms on the plant surface. Therefore, triggerplants are carnivorous. It is very interesting that this carnivory is timed to just before and during flowering.

P1725. Photosystem-II damage and repair cycle in chloroplasts

A. Melis;
Dept. of Plant & Microbial Biology, Berkeley, CA, United States.

The mechanism of a photosystem-II (PSII) damage and repair cycle in chloroplasts will be discussed. Photo-oxidative damage to the PSII reaction center occurs in every organism of oxygenic photosynthesis. An elaborate repair mechanism has evolved that rectifies this irreversible photoinhibition and restores the PSII charge separation activity. The repair entails several enzymatic reactions for the selective removal and replacement of the inactivated D1/32 kD reaction center protein (the chloroplast-encoded psbA gene product) from the massive (>1,000 kD) water-oxidizing and oxygen-evolving PSII holocomplex. Evidence will be presented for the conformational status of PSII during D1 turnover. The composition of a PSII repair intermediate that occurs in the thylakoid membrane will also be discussed. This repair process is unique in the annals of biology; nothing analogous in complexity and specificity has been reported in other systems. Elucidation of the mechanism may reveal hitherto unknown reactions for the selective replacement of a protein from within multi-protein complexes. This may have applications in agriculture, medicine and other fields.

P1726. Impact of long-term salinity and oxidative stress on photosynthesis, growth, cellular antioxidants and medicinal quality of *Artemisia annua* L.

M. I. Qureshi[1], M. Z. Abdin[1], S. Qadir[1], M. Iqbal[2];
[1]Centre for Transgenic Plant Development, Jamia Hamdard, New Delhi, India, [2]Department of Botany, Jamia Hamdard, New Delhi, India.

In plants, salinity alters osmoregulation, ionic balance, stomatal behavior, photosynthetic rate and oxyradical generation. In response, plants try to cope with them by strengthening the cellular antioxidant system and status of osmolytes. We studied impact of the long-term salinity and oxidative stress on photosynthesis (P_n), growth, cellular antioxidants, proline and medicinal quality of *Artemisia annua* L. which yields artemisinin, effective against both drug-resistant and cerebral malaria-causing strains of *P. falciparum* and the cancer. Under salinity, *A. annua* showed reduced P_n and biomass accumulation. Contents of TBARS, proline, GSSG, DAs and activities of SOD, APx and GR increased but GSH and As declined. Artemisinin content increased initially (98%; 160 mM NaCl) but declined with progression of time. Thus, salinity causes oxidative stress in *A. annua*, reducing P_n, growth, Asc and GSH but increased contents of proline and glutathione (GSH+GSSG), and activities of antioxidant enzymes provide a certain level of tolerance. An increase in artemisinin content might be due to rapid conversion of its precursors by oxyradicals into artemisinin.

P1727. Photophysiological comparison of two green algae (Nephroselmis olivacea, Pedinomonas minor)

K. Flieger, R. Goss, C. Wilhelm;
Institute of Biology I, Leipzig, Germany.

We have examined two green algae with regard to different light conditions, like different growth illuminations, as well as short-time exposure to high light. The first one, Pedinomonas minor, is not able to de-epoxidize violaxanthin and therefore also shows a very small NPQ, mostly consistent of qI. The second one, Nephroselmis olivacea, exhibits a typical violaxanthin xanthophyll cycle and also shows a strong NPQ, resulting from qE.

Analyses of the carotenoid biosynthesis show that in both algae the pool of xanthophyll cycle pigments is raised following treatment with excessive light. The activation of the carotenoid biosynthesis in light is significantly higher in Pedinomonas than in Nephroselmis. The comparison of growth rates of both algae shows that Pedinomonas seems to be even better adapted to grow, under stronger illumination than Nephroselmis, although Pedinomonas is lacking the photoprotective mechanism xanthophyll cycle.

P1728. Functional Role of Pigments in Nigrescent Leaves

J. B. Hatier, K. S. Gould;
SBS, Auckland University, Auckland, New Zealand.

Black-leaved plants should not exist. Theory predicts that the intense pigmentation would light-starve a leaf by absorbing energy that might otherwise be employed in photosynthesis. Although rare in nature, there are some species with extremely dark pigmented leaves. Not only do they survive but anecdotal evidence suggests that such plants are particularly robust against environmental stress. Mondo grass (*Ophiopogon planiscarpus*) was chosen because both green and black phenotypes were present in one species.

Experiments on optical properties as well as the functional significance of pigments, notably anthocyanin, were conducted on both morphs. Green and black mondo grasses were exposed to varying levels of increasing irradiance and temperature. Daily measurements of lipid peroxidation, antioxidant enzyme activity and total phenolic scavenging capacities were recorded.

The data suggests that the black morph provides a superior protection against photoinhibition and attributable to its total phenolic composition, possesses a higher scavenging capacity of reactive oxygen species.

P1729. Lipid influence on the enzymatic deepoxidation of xanthophylls

A. Vieler[1], R. Goss[1], C. Wilhelm[1], J. Grzyb[2], D. Latowski[2], K. Strzalka[2];
[1]University of Leipzig, Leipzig, Germany, [2]Jagiellonien University, Krakow, Poland.

We applied in vitro enzyme assays to analyse the influence membrane lipids on the deepoxidation reaction performed by the enzymes violaxanthin deepoxidase (VDE) and diadinoxanthin deepoxidase (DDE). Both enzymes exhibit high activities in presence of the non-bilayer forming lipids MGDG and PE. The DDE reaction rates saturate at lipid/pigment ratios (L/P) of 15, for optimal VDE-activity an L/P of 29 is required. These results correlate perfectly with the solubility properties of the two xanthophylls diadinoxanthin (Ddx) and violaxanthin (Vx) in these two lipids. Whereas Ddx is completely dissolved at a L/P of 15, for Vx a L/P of 29 is necessary. In the presence of bilayer forming lipids like DGDG and PC both enzymes revealed significantly decreased reaction rates, which cannot be explained by the strongly decreased substrate solubility in these lipids. Even at lipid concentrations that guarantee a completely dissolved substrate, reaction rates do not reach those observed in MGDG or PE. We therefore conclude that both the presence of non-bilayer forming lipids promotes substrate solubilisation and the structures provided are crucial for enzyme activity.

P1730. Terpenoid induction and oxidative damage in *Arabidopsis thaliana* plants

A. M. Sanchez-Moreiras, M. Huang, J. Gershenzon, D. Tholl, C. Abel;
Max Planck Institute for Chemical Ecology, Jena, Germany.

Many plants release volatile monoterpenes (C10) and sesquiterpenes (C15)from their foliage, but the physiological role of these substances is not well studied. Different abiotic conditions were used to test the effect of oxidative damage on the leaves (rosette stage) of *Arabidopsis thaliana* plants, and the changes in volatile profile were measured. The wild types WS and Columbia (Col-0) were exposed to high light, high temperature, and different concentrations of herbicides (like Paraquat, Bromoxynil, Acifluorfen, etc.) in order to see oxidative damage by measuring "in situ" superoxide and hydrogen peroxide accumulation (before visible symptoms appear), lipid peroxidation (MDA accumulation), and total H_2O_2 concentration. The use of Arabidopsis transgenic lines overexpressing various terpene biosynthetic genes and GUS-promoter fusion constructs allowed the manipulation of terpene levels to study their role during the plant stress response. This research will help in the understanding of the relation between terpenoids and the defence against oxidative stress.

P1731. How to localize subcellular glutathione in plants?

M. Müller, G. Zellnig, B. Zechmann;
Institute of Plant Sciences, Graz, Austria.

Glutathione (GSH) is the most abundant member of the group of ɔ-glutamylcysteinyl tripeptides. It is considered to be a major redox buffer and to have a broad spectrum of functions in plants. While biochemical pathways involving GSH are known in some detail, there is considerable uncertainty about which tissues, cells and organelles are involved in glutathione metabolism.

In this study different methods (bimanes, immuno-fluorescence microscopy and TEM immunogold cytochemistry) were used to visualize and to investigate changes in the subcellular distribution of GSH in various plant tissues. In combination with digital image analysis quantification of GSH contents within different organelles was possible for the first time, showing steep gradients of glutathione levels between different cellular compartments (e.g. high levels in mitochondria vs. low levels in plastids). Differences in the distribution of GSH within tissues and cells during GSH modulation indicate that GSH concentrations are the product of an equilibrium between synthesis, degradation, usage, and short- and long-distance transport.

This work was supported by FWF, Project P16273-B06.

P1732. Photoprotective mechanisms in foliose lichens have sufficient capacity to cope with a short-term high light stress

M. Bartak[1], H. Vrablikova[1], P. Vaczi[1], J. Hajek[1], J. Stepigova[1], P. Ilik[2];
[1]Masaryk University, Department of Plant Physiology and Anatomy, Brno, Czech Republic, [2]Laboratory of Biophysics, Faculty of Science, Palacky University, Olomouc, Czech Republic.

Response of photosynthetic parameters of *Lasallia pustulata* and *Umbilicaria antarctica* to a short-term (30 min) high light (HL, 1 500 micromols m-2 s-1) stress was studied. Photoprotective mechanisms activated during HL exposure and consequent recovery were monitored fluorometrically (OJIP induction, quenching analysis, Chl fluorescence imaging), spectrophotometrically (APX - ascorbate peroxidase), and chromatographically (Z, V - zea-, violaxanthin, GSH - glutathione). HL induced an increase of Chl fluorescence levels O and J indicating decreased effectivity of electron flow in PS II. Fv/Fm and ū$_{II}$ dropped to 70 and 80 %, more apparently at thallus margins. In dark, Fv/Fm and ū$_{II}$ showed fast (1 h) and slow (10 h) phase of recovery. HL induced NPQ increment by the factors of 6 (*U. antarctica*) and 8 (*L. pustulata*). Fast decrease of NPQ during dark recovery related linearly to Z conversion to V. After HL treatment, total GSH decreased. Proportion of its oxidized form (GSSG) increased. In conclusion, hydrated U. antarctica and L. pustulata had sufficient capacity of photoprotective mechanisms to cope with HL stress. The latter species had a higher pool of total GSH.

P1733. Electron flows in chloroplasts under high temperature

N. L. Pshybytko;
Institute of Biophysics and Cell Engineering, Minsk, Belarus.

The aim of our investigation was the study of protective role of cyclic electron transport around PSII under high temperature. The effects of heat shock (40°C, 3 h) on the photosynthetic activity of 7-day-old barley seedlings were studied. Analysis of dark delay kinetics of chlorophyll *a* fluorescence (Fv) indicated thermoinduced suppression of linear electron flow due to increase of plastoquinone pool reduction. Taking into account the data on excessive reduction of plastoquinone pool and unchanged level of photochemical quenching of Fv it could be supposed that cyclic electron flow through PS II is accelerated by heat shock. This assumption was confirmed by the increase of content of Cyt_{HP} b_{559}

that mediates this electron transfer. Antimycin A as the inhibitor of electron flow from Cyt b_{559} increased the plastoqiunone pool reduction. The most strong effect in stressed leaves indicated that cyclic electron flow around PSII decreased level of plastoqiunone pool reduction and protected electron transport chain from overreduction.

P1734. The induction of the synthesis of small heat-shock proteins of 14,5 and 16 kDa in suspension cultured tobacco cells in response to elevated ambient temperatures is mediated by changes in membrane fluidity and enhanced production of hydrogen peroxide

H. Koenigshofer[1], **H. Loeppert**[1], H. Tromballa[2];
[1]Institute of Botany, Univ. of Natural Resources and Applied Life Sciences, Vienna, Austria, [2]Institute of Physical Chemistry, Univ. Vienna, Vienna, Austria.

The synthesis of heat-shock proteins (HSPs) is a fundamental reaction in all organisms to protect cells against heat injury and other adverse environmental impacts. With regard to the regulation of HSP synthesis under heat stress, the initial events that detect an increase in the ambient temperature and transduce it into a cellular signal are still a matter of debate. In this study, the involvement of physical properties of the cellular membranes and related oxidative processes in sensing a temperature upshift and inducing HSP synthesis were characterized in tobacco BY2 cells. We found that the overall increase in membrane fluidity by the addition of benzyl alcohol decreased the threshold temperature for the maximal activation of the synthesis of two small HSPs (14,5 and 16 kDa) in tobacco cells from 32°C to 28°C. This shift in HSP induction to lower temperatures by the membrane fluidizing effect of benzyl alcohol was paralleled with the enhanced production of H_2O_2. Our results provide evidence that alterations in the membrane fluid state take part in the perception of elevated temperatures and transmit the temperature signal by stimulating the generation of H_2O_2.

P1735. The NADP-ME family of *A. thaliana*: Specific biochemical properties and expression patterns suggest different roles for each isoform

M. C. Gerrard Wheeler[1], M. A. Tronconi[1], M. I. Zanor[2], M. F. Drincovich[1], C. S. Andreo[1], **U. I. Flügge**[3], V. G. Maurino[3];
[1]Centro de Estudios Fotosintéticos y Bioquímicos, Universidad Nacional de Rosario, Rosario, Argentina, [2]Max Planck Institute for Molecular Plant Physiology, Golm, Germany, [3]Botanisches Institut, Universität zu Köln, Cologne, Germany.

The A. thaliana genome encodes four NADP-malic enzyme isoforms. NADP-ME1-3 are localized to the cytosol while NADP-ME4 is localized to plastids as shown by assays of GFP fusion proteins. AtNADP-ME recombinant isozymes are functional and depicted differential kinetic and structural properties. NADP-ME2 exhibits the highest specific activity, while NADP-ME3 and 4 showed the highest activities towards NADP and malate, respectively. NADP-ME4 exists in equilibrium of active tetramers and dimers, while the cytosolic counterparts are present in higher oligomeric states. Comparative enzymatic activity assays in T-DNA insertion mutants and developmental studies of promoter activities indicate that NADP-ME2 is responsible for the major part of NADP-ME activity in Arabidopsis. NADP-ME2 and 4 show a constitutive pattern of expression, while expression of NADP-ME1 and 3 is under control of developmental and cell-specific signals. Studies with the insertional mutants indicates that NADP-ME2 is essential for survival under high light stress. Based on these findings, arguments for novel roles for some members of the NADP-ME family in A. thaliana are presented.

P1736. An in vivo anti-oxidant function of anthocyanins in red leaves is evident only when the pigments reside in the vicinity of the oxy-radical source

F. Kytridis, Y. Manetas;
University of Patras, Patras, Greece.

Anthocyanins are considered as powerful anti-oxidants in vitro and such a function has also been proposed to explain their transient presence in some leaves. We argued that the likely anti-oxidant role should be enhanced when anthocyanins are located in the vicinity of oxy-radical formation, i.e. the leaf mesophyll cells and we designed experiments to this aim. We used plants with intraspecies variation in the express of the anthocyanic trait having anthocyanins either in the epidermal or mesophyll cells. We also compared young red and mature green leaves. In all cases, oxy-radical production was photosynthetically induced by red light (which by-passes anthocyanins) after application of methylviologen. The protective function of anthocyanins was assessed by measuring photosystem II efficiency by chlorophyll fluorescence methods. The results indicate an anti-oxidant role only when anthocyanins reside within the mesophyll cells.

P1737. Winter wheat leaf glycolipid characteristics at the oxidation stress condition induced by hydrogen peroxide.

N. Musienko, L. Batsmanova, O. Sytar;
National Taras Shevchenko university of Kyiv, Kyiv, Ukraine.

The results of studies devolted the winter wheat plant adaptive reaction to the the oxidation stress induced by hydrogen peroxide.
The oxidation stress developing at exogenous hydrogen peroxide action was studied in wheat photosynthesizing tissues basing on lipid peroxidation product (primery - lipid hydroperoxides and secondary - TBA-active products) accumulation and antioxidative enzyme (superoxidedismutase and catalase) activity changing. It was found that oxidative stress intensity increased proportionally according to the oxidant concentration growth.
A set of hydrogen peroxide dose from low to high impact upon photosynthetic pigments and glycolipids was investigated. Hydrogen peroxide action peculiarities upon native systems and chloroplast isolated were studied.
Photosynthesizing tissue lipid-pigment complex and pro-antioxidation system parameters allow to screen winter wheat various variety for their tolerance against oxidative damage.

P1738. Free radicals in abiotically stressed plants investigated by EPR spectroscopy

T. G. Reichenauer, K. Pirker, B. A. Goodman;
ARC Seibersdorf research, Seibersdorf, Austria.

Free radicals are generated in normal metabolism and are controlled by redox reactions involving small antioxidant molecules and enzymes. Stress conditions affect the balance between free radicals and antioxidants, and stress-induced free radicals are usually inferred from changes in antioxidant levels in tissues. However, depending on the nature, magnitude and duration of the stress and plant genetic factors, these may be either increase or decrease. Direct investigation of free radicals in stressed tissues has been little investigated because of their transient nature and the lack of readily available analytical methods.
EPR spectroscopy is able to detect free radicals in biological tissues, and we report its use to study free radicals in tissues of plants that had been exposed to various abiotic stresses. Results show that stresses, in addition to influencing free radical levels *in vivo*, can affect the generation of stable free radicals during storage of processed products.

P1739. Effect of free air ozone fumigation on glutathione and total soluble sugars in adult beech trees.

M. Alexou, K. Haberer, H. Rennenberg;
Insitute of Forest Botany and Tree Physiology, Chair of Tree Physiology, Freiburg i.Br., Germany.

Total and oxidised glutathione (GSSG) and total soluble sugars were analysed in sun and shade leaves as well fine roots of beech trees (Fagus sylvatica) exposed to free air ozone fumigation ($1xO_3$, $2xO_3$) in Kranzberg forest, Bavaria during the vegetation seasons of 2003 and 2004.
Changes in these parameters depended especially on seasonality and exposition of the leaves rather than ozone fumigation treament ($1xO_3$ vs $2xO_3$), which led to a significant difference only in the case of GSSG. The correlations between the particular ozone exposure (SUM0, AOT40, COU) and the parameters investigated are higher in shade than in sun leaves.
The fact that 2003 was a very dry year affected the parameters measured and their correlations with ozone. Apparently, drought and ozone in combination increased the oxidative stress for the trees. However, beech showed a resistence that was higher than expected.

P1740. Photochemical activity of two Mediterranean evergreen species under spring, summer and winter conditions.

C. Arena, L. Vitale, A. Virzo De Santo;
Università degli Studi di Napoli, Federico II, Napoli, Italy.

Plants of Mediterranean-type ecosystems are exposed during the year to adverse climatic conditions specially in summer and in winter. In this work the influence of seasonal climatic changes on thermal and photochemical processes was studied in *Quercus ilex* L. and *Laurus nobilis* L. Gas exchange and chl *a* fluorescence measurements were performed in situ on attached leaves at the actual seasonal temperature and relative humidity conditions and at 1000 PPFD. In both species A_N and gt_{H2O} were highest in May compared to February and July; the lowest values were found in July when leaf temperatures were the highest and precipitation was low. F_{PSII} decreased significantly in February compared to May and July both in *L. nobilis* and *Q. ilex*. F_{PSII} did not differ between May and July. The highest ETR/A_N found in summer for *Q. ilex* compared to *L. nobilis* indicated a major utilization of reductants to alternative sinks to photosynthesis. In February, the highest NPQ and the lowest ETR/A_N in both species suggest that thermal dissipation represents the main dissipative process of the excess excitation energy when photochemical pathways are reduced by low temperatures.

P1741. Chilling in the dark of two different pepper varieties (*Capsicum annuum*): a possible role of endophytes in stress response

C. Naglreiter, T. G. Reichenauer;
ARC Seibersdorf research GmbH, Seibersdorf, Austria.

Two different pepper varieties (*Capsicum annuum*) a cold-tolerant var. Ziegenhorn bello (ZB) and a cold-sensitive var. Milder Spiral (MS) were cultivated at 23/18°C day/night temperature in a climate chamber.

Half of the plants were inoculated with endophytes (Arthrobacter sp. strain ZB04) isolated from from var. Ziegenhorn Bello.

One part of the plants was exposed to chilling temperatures during one night at 6°C and a second time one night at 4°C two weeks later.

Photosynthetic and chlorophyll fluorescence parameters were measured during chilling and the following days until full recovery. Chilling at 4°C had a much bigger influence on photosynthetic performance than at 6°C. Net rate of photosynthesis and actual photochemical capacity (F_v/F_m) were significantly reduced and ground fluorescence was increased shortly after chilling in both varieties independent of inoculation. Inoculation with the endophyte strain resulted in an increase in F_v/F_m in non-chilled plants. Analysis of carotenoid content of the leaves is under progress during submission of this abstract.

P1742. Analyzing biological diversity of plant ozone sensitivity can reveal mechanisms behind adaptation to polluted environment

H. Kollist[1,2], J. Kangasjärvi[1];
[1]Division of Plant Biology, Department of Biological and Environmental Sciences, University of Helsinki, Helsinki, Finland, [2]Institute of Botany and Ecology, University of Tartu, Tartu, Estonia.

Here we address the natural variation of ozone (O_3) sensitivity/tolerance among *Arabidopsis* ecotypes. Commonly only single or couple of clones have been used to study O_3 response of different species. Since plant-specific responses may greatly differ, it is possible that different individuals of the same species utilize different biological processes to cope with oxidative stress generated by elevated O_3. We have undertaken to screen the sensitivity/tolerance of about 100 *Arabidopsis* ecotypes collected throughout the world. This has revealed dramatic differences in O_3-sensitivity among ecotypes adapted to different background environmental conditions. Selected most sensitive/tolerant ecotypes are used for further analysis aiming to identify which biological processes are behind the diversity in their adaptation and acclimation to climate change. These analyses include O_3-induced changes in stomatal opening, concentration of antioxidants, induction of plant stress hormones and emission of volatile organic compounds. To map the genes that are activated by O_3 we use arabidopsis DNA-arrays that enable simultaneous analysis of 25000 genes.

P1743. Function of a borate exter complex in the heterocysts of *Anabaena variabilis*.

D. Malek[1], S. Jacoby[1], M. Aulhorn[1], E. Artamanova[2], E. Lobakova[2], R. Ehwald[1];
[1]Humboldt-University, Berlin, Germany, [2]Lomonossov University, Moscow, Russian Federation.

Boric acid (B), an essential nutrient of azototrophic cyanobacteria, is bound with high affinity to heterocysts (ca. 50 µmol/g dry weight) at pH>3 in the presence of Ca^{2+}. The B-ligand was not extracted with methanol/chloroform and found to be resistant to alkaline treatment, but it was degraded by acid hydrolysis. Azototrophic growth was sustained by 0.2 µM soluble B. B complexed in senescent heterocysts could not be re-utilised. Due to mechanic instability of the contact between heterocysts and vegetative cells, azototrophic cultures were stressed by shearing (shaken vessels). A strict requirement of N assimilation on B occured if cultures of the strain ATCC 29413 were agitated at low cell densities (OD < 0.5). This strain was able to grow on non-shaken B-free medium or in shaken cultures at a high cell density (OD > 0.8). The strain PCC 7119 was highly sensitive to shearing stress and did not grow azototrophically on B-free non-shaken medium. O_2 pressure did not effect B-requirement. It is assumed, that the B complex cross-links the heterocyst specific polysaccharide and is essential for metabolite transfer between the N- and C-assimilating cells.

P1744. Consequences of the expression of Glycolate oxidase in plastids of A. thaliana in the context of a biotechnological approach to reduce photorespiratory losses.

H. Fahnenstich, V. Maurino, U. I. Flügge;
Department of Botany, University of Cologne, 50931 Köln, Germany.

During the course of the C2 oxidative pathway glycolate-2-P is recycled to glycerate-3-P and CO_2 and NH_3 are released inside the mitochondria. Due to the loss of fixed carbon photorespiration is considered as a wasteful process, although photoprotective properties were reported. We attempt to introduce catabolic pathways for glycolate in *A. thaliana* to release CO_2 inside the plastids. This would create autoregulatory cycles, which could attenuate photorespiration. In each cycle, the expression of three transgenes inside the chloroplasts is required. The first step of both pathways is catalyzed by glycolate oxidase (GO), yielding glyoxylate and H_2O_2. GO plants are characterized by retarded growth and yellowish leaves. To elucidate whether H_2O_2 or glyoxylate is responsible for the observed phenotype, transgenic plants co-expressing GO and *E. coli* catalase (KatE) or GO and the second enzyme of each pathway were produced. Co-expression of KatE alleviates the GO phenotype and demonstrates that the chloroplastic endogenous machinery that detoxifies H_2O_2 is overloaded when KatE is not overexpressed. The analysis of these transformants will be presented..

P1745. Short Circuiting Photorespiration

C. Josirley[1], A. J. Keys[1], P. J. Madgwick[1], P. J. Lea[2], M. A. J. Parry[1];
[1]Rothamsted Research, Herts, United Kingdom, [2]Lancaster University, Lancaster, United Kingdom.

Transgenic tobacco plants have been generated with the aim of by-passing part of the photorespiratory cycle that converts glycine to serine. The plants have been transformed with the genes encoding glyoxylate carboligase (gcl: EC 4.1.1.47), which converts glyoxylate to tartronate semialdehyde and CO_2, and hydroxypyruvate isomerase (hyi: EC 5.3.1.22), which converts tartronate semialdehyde to hydroxypyruvate. These enzymes are targeted to the peroxisome where they should 'short circuit' photorespiratory metabolism and decrease the energy requirements for photosynthesis by avoiding the release of ammonia. Under high CO_2 the plants had no obvious visible phenotype but under bright light and at ambient CO_2, necrotic lesions developed on the leaf lamina of the transgenic lines. We report the molecular, metabolomic and physiological characterisation of these plants.

P1746. Single-cell C_4 photosynthesis in marine diatoms?

R. C. Leegood[1], E. Granum[1], J. A. Raven[2], K. Brown[2];
[1]University of Sheffield, Sheffield, United Kingdom, [2]University of Dundee, Dundee, United Kingdom.

Marine diatoms are estimated to fix as much carbon as all of the terrestrial rain forests. Their productivity is enhanced by a CO_2-concentrating mechanism, but whether it is based on direct acquisition of inorganic carbon or on single-cell C4 photosynthesis is still a matter of controversy. In a C4 pathway phosphoenolpyruvate carboxylase (PEPC) could act as primary carboxylase in the cytoplasm and phosphoenolpyruvate carboxykinase (PEPCK) or malic enzyme (ME) as decarboxylase in the chloroplast, releasing CO_2 for Rubisco. Whole genome sequencing of the marine diatom *Thalassiosira pseudonana* has revealed the presence of essential genes for a C4 pathway, including PEPC, PEPCK, NADP-ME and pyruvate-orthophosphate dikinase. These genes were cloned, and gene expression measured by quantitative RT-PCR. Furthermore, antibodies were raised against some of the corresponding proteins, and used for immunoblotting. To test the C4 pathway hypothesis, changes in transcript and protein levels were measured when the diatom was grown under different levels of C and N limitation.

P1747. The effects of neighbouring plants on stem height and diameter growth of *Chenopodium album*: wind or red/far-red?

H. Nagashima[1], T. Hirose[2];
[1]Nikko Botanical Gardens, The University of Tokyo, Nikko, Japan,
[2]Graduate School of Life Sciences, Tohoku University, Sendai, Japan.

The effects of height of neighbouring plants on plant morphology were studied with individually potted *Chenopodium album* plants. A stand was established by arranging pots, where target plants were lifted or lowered to create height differences between targets and neighbours in the stand. Plants that were lifted to overtop neighbours reduced the rate of stem elongation and increased stem diameter growth. Lowered plants that were overtopped by neighbours increased the stem elongation rate without change in diameter growth. In the second experiment, we studied environmental factors that are responsible for growth modification. Two stands were established as in the first experiment, but in one stand black-painted artificial plants were used as neighbours to eliminate R/FR effects on targets keeping PAR similar to the other stand. In each stand, a half of targets were fixed to supporting sticks to reduce swaying by wind. Targets were lifted or lowered as in the first experiment. Growth modification was found only in the stand with natural neighbours even if plants were fixed to sticks. We conclude that R/FR rather than wind is responsible for the growth modification.

P1748. Costs and benefits of photosynthetic light acclimation in response to gap formation in a cool-temperate deciduous forest

R. Oguchi[1], K. Hikosaka[1], T. Hiura[2], T. Hirose[1];
[1]Graduate School of Life Sciences, Tohoku University, Sendai, Japan,
[2]Tomakomai Research Station, Hokkaido University, Tomakomai, Japan.

Shade leaves increase their photosynthetic capacity (Pmax) in response to improved light environment after e.g. gap formation. To increase Pmax, however, additional space is necessary for chloroplasts to increase their volume and leaves must be thick. The objective of the present study is to assess costs and benefits of photosynthetic light acclimation in natural conditions. We created gaps by falling canopy trees in a cool-temperate deciduous forest and studied the changes in photosynthetic characteristics of understorey seedlings of Kalopanax pictus Nakai in response to gap formation. Data obtained in the field were applied to simulate photosynthetic rates under gap and understorey conditions. We found that Pmax increased by 27% after the gap formation, which led to 11% increase in daily carbon gain. This increase in carbon gain was greater than the amount of biomass invested for additional leaf thickness, suggesting that photosynthetic light acclimation is beneficial for growth and survival of understorey seedlings when gap formation occurs.

P1749. Canopy distribution of physiological traits in 4 to 8-year-old hoop pine (*Araucaria cunninghamii*) trees in relation to season, fertiliser application and growth

N. V. Prasolova[1], Z. Xu[1,2], C. L. Beadle[3], M. A. Hunt[4];
[1]Griffith University, Brisbane, Australia, [2]Griffith Centre for Forestry and Horticultural Research, Brisbane, Australia, [3]CSIRO Forestry and Forest Products, Hobart, Australia, [4]Queensland Forestry Research Institute, Gympie, Australia.

We examined the distribution of photosynthetic capacity (A_{max}), stomatal conductance (g_s), foliar N concentration, ŭ^{13}C and ŭ^{15}N, SLA, and maximum silhouette area ratio (R_{max}) in the canopy of 4 to 8-year-old trees two years after fertiliser application (0-300 kg N ha^{-1}) in summer and winter to establish the links between canopy gradients and the physiological traits.

Foliar N varied throughout the canopy and with fertiliser application and season. Patterns of foliar N, ŭ^{13}C and ŭ^{15}N were similar among fertiliser treatments and between seasons. Decreases in ŭ^{13}C and ŭ^{15}N along the branches were larger than those from upper to lower canopy. SLA in the upper outer was less than in the lower outer canopy. ŭ^{13}C was positively correlated with SLA. R_{max} increased with canopy depth. A_{max} and g_s decreased with canopy depth and from the outer to inner branchlets with a positive correlation between A_{max} and g_s. Instantaneous WUE was negatively related to g_s. ŭ^{15}N significantly reflected N fertiliser uptake and distribution, and was significantly lower at wet than dry sites. The findings have implications for scaling up leaf-level physiological measurements.

P1750. Nitrogen allocation and the fate of absorbed light in 21-year-old radiata pine trees

S. Posch[1,2], C. R. Warren[1], H. Guttenberger[2], M. A. Adams[3];
[1]School of Forest and Ecosystem Science, University of Melbourne, Creswick, Australia, [2]Institute of Plant Science, Karl-Franzens-University, Graz, Austria, [3]Centre for Excellence in Natural Resource Management, University of Western Australia, Nedlands, Australia.

The fate of absorbed light may be influenced by N fertiliser given that the photosynthetic machinery accounts for more than half of the N in a leaf. We investigated the distribution of absorbed light to dissipation and photochemistry in N fertilised (N+) and not fertilised (N0) 21-year-old *Pinus radiata* D. Don trees in the lower, mid and upper canopy. Chlorophyll fluorescence, photosynthesis, Rubisco, chlorophyll, N, and needle morphology were measured. Dissipation (NPQ) did not differ between the upper canopies of both treatments, but was significantly lower in the lower and mid canopy of N+ trees than in the lower and mid canopy of N0 trees. The proportion of light energy used in photochemistry (ū PSII) did not differ between the treatments. N+ trees used photochemical energy more efficiently for CO_2 fixation (ū PSII/ū CO_2) than N0 trees. The amount of excess light was significantly higher in the lower and mid canopy of N+ trees than in the lower and mid canopy of N0 trees. We conclude that N fertiliser increases the susceptibility of *Pinus radiata* to photoinhibition in the lower and mid canopy.

The Austrian Academy of Sciences is warmly thanked for financial support.

P1751. Fruit bearing branchlets are carbon autonomous in mature broad-leaved temperate forest trees

G. Hoch;
University of Basel, Basel, Switzerland.

The C source-sink relationship in fruit bearing branchlets of mature deciduous forest trees was manipulated, in order to evaluate the degree of C autonomy for fruit development. The treatments, which were applied by using a canopy crane, included girdling and half and complete defoliation of fruiting branchlets of *Carpinus betulus*, *Fagus sylvatica* and *Tilia platyphyllos*. Analyses of non-structural carbohydrate concentrations and a ^{13}C tracer experiment were performed to identify situations of C imbalance and changes in C acquisition pathways induced by the treatments.

All three species exhibited complete C autonomy of fruiting at the level of whole, undisturbed branchlets, since neither the total infructescence biomass, nor the individual fruit mass decreased on girdled, un-defoliated branchlets. On girdled, 100 % defoliated branchlets, fruit biomass relative to controls was still about 50 % in *Carpinus* and *Tilia*, but only 20 % in *Fagus*, which reflects the small proportions of photosynthetically active infructescence tissues in the latter species. Interestingly, *Tilia* branchlets hardly imported C to compensate for assimilate loss after defoliation.

P1752. Direct Identification of Chloroplast Photosytems in Aglaonema simplex var.metallica by cryo optical fluorescence microscopy

F. Vacha[1], V. Sarafis[2], L. Bumba[1], A. Zupkanova[1], I. Falat[1], C. Sheue[3];
[1]Institute of Plant Molecular Biology,Czech Academy of Sciences, Ceske BudeJovice, Czech Republic, [2]CHAPS ,UWS&School of Life Sciences, U.of Qld, South Penrith &St. Lucia, Australia, [3]Graduate Insititue of Bioresources,Pintiung University, Pintiung, Taiwan Republic of China.

Cryofluorescence microscopy at minus 196 C with an Olympus long range objective at 0.7 N.A was used to observe isolated leaf chloroplasts of Aglaonema simplex var. metallica. This species and variety of Agalonema is characterised by very dark green leaves..

Photosystem one is revealed by blue light excitation from ahigh pressure mercury vapour lamp to reside mainly in the intergranal regions with a peak at 730nm while Photosystem two is mainly in

the grana. with a peak at 680 nm..The 730 peak is absent at room temperatures
The chloroplasts have grana of up to 1.9 microns in width and are very long while the intergranal spaces are traversed with numerous membranes in a space approx.0.5 microns wide.This was revealed by bright field microscopy, followed by confocal fluorescence microscopy .
Standard Glutaraldehyde- formaldehyde fixation with post fixation in OsO4 showed the membranes and their disposition.
We suggest cryofluorescence microscopy is particularly useful in analysing the positioning of chloroplast photsoynthetic pigment complexes.

P1753. Heat responses of pigment-protein-complexes in chloroplasts from callus and leaves of sugar beet

L. Lehnhardt, H. Pufe, I. Baumann, K. Mielke, **G. Baumann**;
Universität Potsdam, Potsdam-Golm, Germany.

For green callus and leaves of sugar beet we previously investigated the effects of chilling and/or strong light on the compositions of proteins (SDS-PAGE) and pigments (HPLC) in chloroplast thylakoid fractions [fragmentation of thylakoids by detergents and separation into at least 7 distinct bands by native green gel elcetrophoresis]. Here we report how this composition is affected when leaves (and isolated leaf chloroplasts) or green callus (and isolated callus chloroplasts) were kept at 40 - 50 0C for 30 - 120 min [standard conditions 120 min 50 0C] prior to thylakoid preparation. In most cases temperature induced alterations of protein composition are similar to effects of strong light and chilling stress and are most pronounced in pre-treated chloroplast suspensions. After heat stress of callus chloroplasts, the pigment concentration in presumed photosystem I is drastically reduced in favour of complexes with lower molecular weights. Appearance of zeaxanthin and reduction of the amount of lutein in almost all pigment-protein-complexes are the most striking effects of heat stress on leaves, callus and chloroplast suspensions.

P1754. Some aspects of desiccation tolerance in *Boea hygroscopica* and *Sporobolus stapfianus*

A. Whittaker, T. Martinelli, A. Bochicchio, **C. Vazzana**;
Dipartimento di Scienze Agronomiche e Gestione del Territorio Agroforestale (DISAT), Florence, Italy.

The research presented was compiled through a series of collaborative studies between the University of Florence and the Universities of Pisa, Padova and Pavia (Italy) and Cape Town (South Africa). Desiccation-tolerant or 'resurrection' plants provide unique model systems to investigate metabolism in response to severe drought stress. Use of the desiccation-tolerant, dicotyledonous species *Boea hygroscopica* F. Muell (Gesneriaceae) and monocotyledonous species *Sporobolus stapfianus* Gandoger (Poaceae) as model systems was integral to the study of desiccation tolerance in the aforementioned collaborations.
Desiccation tolerance in 'resurrection plants' is dependent on the induction of various protective mechanisms during dehydration. Using the leaf material of both plant species, the present study focussed on aspects of desiccation tolerance pertaining to variations in drying conditions, to adaptive changes in cell structure and to antioxidant defence mechanisms. The accumulation of low molecular weight substances, with particular emphasis on aspects of sucrose and nitrogen metabolism, also formed part of the present investigation.

P1755. Change of photosynthetic capacity of *Alnus hirsuta* sapling grown in a free air CO_2 enrichment (FACE) system: comparing the proximate *Betula* spp. without symbiotic N_2 fixing micro-organism.

N. Eguchi[1], K. Karatsu[1], T. Ueda[2], K. Takagi[3], K. Sasa[3], T. Hiura[3], R. Funada[4], T. Koike[3];
[1]Graduate School of Environmental Science, Hokkaido University, Sapporo, Japan, [2]Hokkaido Dalton, Sapporo, Japan, [3]Hokkaido University Forests, Sapporo, Japan, [4]Faculty of Agriculture, Tokyo University of Agriculture and Technology, Fuchu-Tokyo, Japan.

To elucidate the differences of photosynthetic capacity between plants with N_2-fixing micro-organism (N_2-fixing plant) and non-N_2-fixing plants under high CO_2 concentration ($[CO_2]$), two-year-old *Alnus hirsuta* Turcz (N_2-fixing plant), *Betula platyphylla* var. *japonica* Hara and *B. maximowicziana* Regel (non-N_2-fixing plants) were grown with a free air CO_2 enrichment (FACE) system located in northern Japan. $[CO_2]$ was 500 µmol mol^{-1} in FACE. Two soil conditions were prepared in each FACE with brown forest soil (high nutrient) and volcanic ash soil (low nutrient). All but "*A. hirsuta* in volcanic ash soil" and "*B. maximowicziana* in brown forest soil" showed the depression of photosynthetic capacity under high $[CO_2]$; i.e. down-regulation. As for *A. hirsuta*, the reason was mainly due to the excessive accumulation of starch in foliage. As for *B. platyphylla* and *B. maximowicziana*, the reason was mainly due to the reduction of Rubisco concentration. We concluded that both "*A. hirsuta*" and "*B. platyphylla* and *B. maximowicziana*" have a possibility to show down-regulation, but the reason is species specific characteristics as related to symbiotic microbes.

P1756. Identification of Metallothionein as a Heavy Metal Tolerance Mechanism in *Sphagnum magellanicum*

S. Hicks, Z. E. Gagnon;
Marist College, Poughkeepsie, NY, United States.

Deposition of platinum group metals (PGMs), platinum, palladium and rhodium, from automobile catalytic converters has led to an increase in concentrations of these elements in the environment. Animals can tolerate some heavy metal accumulation by forming metallothionein (MT), metal-protein complexes. We studied *Sphagnum's* mechanism of tolerance to PGMs and cadmium. *Sphagnum* was grown on Rudolph's media containing one of the following metals: Pt^{IV}, Rh^{II}, Pd^{II} (0.1, 1, 10, 100 ppm) or Cd^{II} (0, 0.1, 1.0, 5.0 ppm). After four weeks of exposure plants were harvested. Toxicological tests demonstrated significant DNA damage and decreases in length and biomass of plants in all metals and exposure concentrations. Metal accumulation in tissues was analyzed using a graphite furnace atomic absorption spectrophotometer. There was a positive correlation between metal concentration in media and in plant tissues. MT concentrations were determined by matrix-assisted laser desorption-ionization time-of-flight (MALDI-TOF). The induction of MT positively correlated to metal concentrations indicates that MT plays an important role in heavy metal tolerance.

P1757. Defense characteristics of deciduous broad-leaved tree seedlings grown under factorial combination of two levels of CO_2 and nitrogen

T. Koike[1], S. Matsuki[2], T. Shibata[3], H. Tobita[4], K. Konno[5], M. Kitao[4], Y. Maruyama[4];
[1]Hokkaido University Forests, Sapporo, Japan, [2]JSPS fellow c/o Hokkaido Forestry Institute, Bibai, Japan, [3]Graduate School of Agriculture, Hokkaido University Forests, Sapporo, Japan, [4]Forestry & Forest Products Research Institute, Sapporo, Japan, [5]National Institute of Agrobiological Science, Tsukuba, Japan.

Mixed broad-leaved forests are abundant in several kinds of herbivore species in northern Japan. Herbivores are depending on leaf quality. However, the leaf qualities are changing with increasing atmospheric CO_2 and nitrogen deposition. Four species of deciduous broad-leaved tree seedlings (alder, birch, oak & maple) were raised in a factorial combination of two levels of CO_2 and nutrients to examine the foliar defense traits. To evaluate defense capacity of four species, we used wild silkworms as a bioassay. Except for alder, survival and longevity were shortest in silkworms fed with leaves at high CO_2 and infertile condition while those were longest in leaves treated with ambient CO_2 and fertile. Longevity of silkworm fed with alder leaves was longer when alder seedlings at high CO_2 and infertile. Except for alder, results suggest that birch, oak and maple supported the CNB hypothesis. In alder, activity of symbiotic microbe would be enhanced by greater amount of photosynthates that they received from the host plants at high CO_2. In this, *Frankia* sp. would increase amount of nitrogen in plants, which improved food quality for silkworms.

P1758. Vegetation composition and ecophysiological traits in differently degraded stands of sandy grassland

S. Veres[1], O. Mile[2], V. Oláh[2], G. Lakatos[3], I. Mészáros[2];
[1]University of Debrecen, Department of Agricultural Botany and Plant Physiology, Debrecen, Hungary, [2]University of Debrecen, Department of Botany, Debrecen, Hungary, [3]University of Debrecen, Department of Applied Ecology, Debrecen, Hungary.

Under the continental climate of Carpathian basin semiarid grasslands represent one of the widespread vegetation. Due to overgrazing and other disturbances most of the semiarid grasslands in Hungary are the mosaics of more or less degraded patches. Our work focused on the variations in the ecophysiological traits of the common dominant species in a moderately degraded (cover 60 %) and a strongly degraded stand (27%) of Potentillo-Festucetum pseudovinae community in summer. The reduction of soil moisture content species experienced significantly higher leaf water saturation deficit in the more open stand. Carotenoid pool was larger for all the species in the strongly degraded stand. The protective xanthophyll cycle pool was also higher in the latter stand and reached 30-33 % of the total carotenoid content. The potential photochemical efficiency (F_v/F_m) was lower for the monocot species. There was a decrease in the F_v/F_m values at noon, which was larger in the strongly degraded stand.

P1759. Above-ground and bellow-ground biomass in relation to grazing pressure on species-rich Dinaric karst pastures

S. Skornik[1], M. Kaligaric[1], M. Vidrih[2], J. Sedonja[1];
[1]Biology Dept., University of Maribor, Slovenia, [2]Dept. of Agriculture, University of Ljubljana, Slovenia.

One of the most common activities on secondary grasslands is pastoralism which affects grasslands within grazing regime. Light, moderate and intensive grazing were applied on species-rich nutrient-poor calcareous pastures on Vremscica (Dinaric Karst, SE Slovenia) for 8 years. One location has been abandoned for 8 years. Two-seasons sampling on plots and sub-plots included plant composition and biomass. No significant differences were perceived in species richness by different treatments, while species composition and biomass were significantly affected by grazing regimes. On intensively grazed plots plant composition indicates habitat-generalists, which invest less bellow rather above-ground. On extensively grazed plots plant composition indicate on habitat-specialists, "karstic" sub-Mediterranean species, adopted to summer hydric stress, which invest much more bellow- that aboveground (rhizomes, bulbs). We could conclude that community assemblage with different plant functional types is affected by different grazing pressure.

P1760. Ecophysiological responses to simulated climate change (drought or nocturnal warming) in a semiarid forest-steppe in Hungary

T. Kalapos[1], A. Mojzes[1], E. Kovács[2], E. Kovács-Láng[2];
[1]Department of Plant Taxonomy and Ecology, L. Eötvös University, Budapest, Hungary, [2]Ecological and Botanical Research Institute, Hungarian Academy of Sciences, Vácrátót, Hungary.

Ecophysiological responses to simulated climate change (drought or nocturnal warming) were studied in a semiarid temperate forest-steppe vegetation mosaic for three species representing three different functional types: *Cynodon dactylon* (L.)Pers. (perennial stoloniferous C4 grass), *Festuca vaginata* W. et K. (cold tolerant perennial C3 bunchgrass) and *Populus alba* L. (C3 deciduous tree, shrub-sized root sprouts colonize sand grasslands). Treatments caused only slight changes in plant physiological activity. There was a tendency for enhanced leaf photochemistry during the day in response to nighttime warming (~ 1°C increase of daily minimum temperature). Species reactions to extreme weather were more pronounced. The extremely dry and hot spring and early summer in 2003 caused lasting photoinhibition - and probably photodamage - for *F. vaginata* that led to an unprecedented dieback of the species in the area. No such changes were observed for the other two species. Different responses of the three functional types forecast compositional changes in the forest-steppe vegetation. Supported by EU FW5 EVK2-CT-2000-00094, NKFP-3B/0008/2002, OTKA T038028.

P1761. Leaf anatomical plasticity of *Brachypodium pinnatum* (L.) Beauv. in contrasting microhabitats in a semiarid forest-steppe vegetation mosaic

A. Mojzes[1], L. Han[1], T. Kalapos[1], K. Virágh[2];
[1]Department of Plant Taxonomy and Ecology, L. Eötvös University, Budapest, Hungary, [2]Ecological and Botanical Research Institute, Hungarian Academy of Sciences, Vácrátót, Hungary.

After felling natural xerothermic oakwoods in the forest-steppe loess regions of Hungary the perennial understorey grass *B. pinnatum* persists for decades from shade to full sun microhabitats. Variation in leaf anatomy was explored behind the species' highly plastic leaf photochemistry in response to habitat light regime in three typical microhabitats (full shade under oak canopy, half shade near shrubs, and in unshaded grassland) *in situ*, and for plants transplanted between these microsites. Intervenial lamina and mesophyll were 46-64% thicker in the grassland *in situ* than in oak subcanopy due to an additional layer and 25-32% greater height of mesophyll cells. Mesophyll thickness and the proportion of veins plus sclerenchyma were greatest in the grassland *in situ* exceeding that of full or half shade to full sun transfers. Outer bundle sheath tended to be the thickest in the grassland. Despite adjustments in leaf anatomy, plasticity at the shoot level and presumed cellular modifications may play the major role in medium-term light acclimation of *B. pinnatum* contributing to the species' success in secondary vegetation succession. Supported by OTKA T038028.

P1762. The role of rangelands of Uzbekistan in a global carbon cycling

M. G. Nasyrov;
Samarkand State University, Samarkand, Uzbekistan.

The vast areas of grazing lands in Uzbekistan are a believed to have a large potential to sequester carbon and mitigate the greenhouse effect. Although arid and semi-arid ecosystems are known to have substantially lower productivity than forests, it was hypothesized that the vast landscapes of Uzbekistan dominated by rangeland ecosystem could be an important contributor to the "missing sink"(Nasyrov, 2000). Thus, the main objective of this study was to document the daily magnitudes and growing season dynamics of net ecosystem CO_2 exchange (NEE) in representative rangelands of Uzbekistan

The obtained results indicated that net growing season CO_2 fluxes were positive at rangeland monitoring sites in Uzbekistan.

The sagebrush-ephemeroidal semidesert site at Karnap, Uzbekistan sequestered 698 g CO_2 m^2 season.

Given the vast area of rangelands, this rate of carbon assimilation can turn Uzbekistan rangelands into a significant CO_2 storage sink, and they can greatly contribute to reducing the global warming.

P1763. The response of functional plant groups in a semi-natural grassland to long-term CO_2 enrichment

J. B. Winkler;
GSF - National Research Centre for Environment and Health, Neuherberg, Germany.

The long-term responses of an oligotrophic semi-natural grassland to in situ free air carbon-dioxide enrichment (FACE) and different cutting frequencies were investigated since 1999. The area was neither artificially irrigated nor fertilised.

Significant stimulation of total above ground biomass production by elevated [CO_2] was only found after three years of CO_2 enrichment and again in 2003 when precipitation was only about 60 % of average precipitation.

Functional plant groups responded differently to CO_2 enrichment causing a clear shift in the botanical composition from 1999 to 2004 towards a higher proportion of legumes under elevated [CO_2].

In 2002 the lacking stimulation of above-ground biomass yield of the grasses could be explained by a down-regulation of V_{cmax} in the dominant grass species *Bromus erectus*, whereas in 2004 carboxylation activity was not affected by elevated [CO_2].

Our results corroborate that in a nutrient-poor grassland community the legumes are the most competitive functional plant group. It has, however, to be taken into account that varying climatic conditions superimpose the response of the plant community to the treatments.

P1764. Ultrastructural alterations in thalli of lichen *Peltigera aphthosa* and in its isolated phycobiont *Coccomyxa* induced by continuous darkness

T. A. Vlassova;
Moscow State University, Moscow, Russian Federation.

The influence of the continuous lack of the light on the thalli of foliose lichen *Peltigera aphthosa* maintained in the air-dry condition was studied by the electron microscopy. The stress conditions induced in the lichen thalli the diminishing of contacts between phycobiont and mycobiont and the gradual degradation of their cells. These alterations indicated the evident decrease of the metabolic activity and were similar to those observed in the lichens under some other stress conditions or in the senescent lichen thalli. It supposed also some degree of delichenization of symbionts.. The isolated cultures of *Coccomyxa*, phycobiont of *P. aphthosa*, in the dark conditions also underwent ultrastructural and consequently functional changes in comparison with cultures maintained in the light. However, the alterations in these delichenized cells had some specificity and varied in the different nutritional media. The possible significance of the lichenization and of the water and nutritional supply for response of phycobiont to stress is discussed.

P1765. Growth inhibitory activity of metabolites from lichen mycobionts on photobiont

N. Hamada[1], Y. Takenaka[2], T. Tanahashi[2];
[1]Osaka City Institute of Public Health and Environmental Sciences, Osaka, Japan, [2]Kobe Pharmaceutical University, Kobe, Japan.

Many novel metabolites, e.g. dibenzopyran, chromone, dibenzofuran, isocoumarin, were found in cultured mycobiont. Some mycobiont metabolites are different from lichen metabolites, and are thought to be often toxic to photobiont. Under mycobiont conditions, the normal metabolic pathway in the lichen seems to be inoperative, but the dormant metabolism is induced in the mycobiont, and is thought to have biological significance only for the mycobiont. In this paper, effect of metabolites isolated from mycobiont was examined on the algal growth in liquid medium with shaking for 14 days. The dry weight of Trebouxia erici cultured in BBM medium added 1 umol of different metabolites were compared with background. Graphislactone A, dibenzofurans, and chromones suppressed from 40% to 60% of the algal growth. On the other hand, graphenone, graphisquinones, and xanthones did not suppress any algal growth. Biological significance of mycobiont metabolites was discussed.

P1766. Lichen photobionts from granite outcrops of the South Ukraine

A. Voytsekhovich, T. Darienko;
Kholodny Institute of Botany, Kyiv, Ukraine.

Investigations of 15 widespread lichens, growing on granite outcrops along Pivdenniy Buh River in the southern part of Ukraine using cultural methods are conducted. Species of Trebouxia genus found to be photobionts in 14 species of lichens. Desmococcus olivaceus is photobiont of Dermatocarpon miniatum. It is established that in the South Ukraine such lichens as Aspicilia hoffmannii, Candelariella vitellina, Parmelia somloensis, Ramalina polymorpha and Umbilicaria grisea have one photobiont - Trebouxia showmanii, Caloplaca aractina and Physcia tribacea - T. simplex, Physcia tenella - T. phycobiontica, Ramalina pollinaria - T. erici. T. showmanii is the most widespread photobiont in plots studied. This species is characterized by the most stable growth in culture upon mineral medium. Besides, there were cases when T. showmanii formed mass growings on stones under natural conditions and in laboratory “wet camera”. The morphology and the life cycles of algae isolated into culture were studied in details. All mentioned above isolated photobionts were for the first time found for the investigated lichens.

P1767. A lichen lectin binds to an alfa-1,4-polygalactoside urease located in the homologous algal cell wall.

M. Sacristán, A. M. Millanes, M. E. Legaz, C. Vicente;
Complutense University, Madrid, Spain.

Recognition of an alga by a fungus is based on the production of fungal lectins with arginase activity. The algal receptor is a cell wall polygalactosylated urease. To study the binding of a lectin to its ligand, phycobionts from *E. prunastri* were used to digest the urease polygactoside with Ŭ- and ɓ-galactosidases. Arginase activity of the lectin was measured before and after incubation of algae with the protein. Sugars enzymatically removed from the cell wall were also measured and, finally, the binding of a FITC-lectin to isolated and enzymatically-treated algae was studied.

Algae treated with Ŭ-galactosidase contain the lowest arginase activity and produce the highest amount of sugar after incubation with the enzyme. Phycobionts incubated with FITC-arginase retain fluorescence in their cell walls that can be removed by addition of galactose. Non-fluorescent walls were observed after incubation of Ŭ-galactosidase-treated algae with FITC-labelled lectin, recovering low values of fluorescence by disrupting algal cells. This implies that the lectin enter algal cells without the polygalactoside attached to the ligand.

P1768. Lateral CO_2 diffusion contributes to photosynthesis of homobaric leaves under alternating lightflecks

R. Pieruschka, U. Schurr, **S. Jahnke**;
Forschungszentrum Jülich GmbH, Jülich, Germany.

The supply of leaves with CO_2 is generally considered from ambient air to the leaf interior but lateral gas fluxes inside leaves may also contribute to gas exchange. We speculated that, when only part of a homobaric leaf is illuminated, lateral flux of (respiratory) CO_2 from shaded to illuminated leaf areas may affect photosynthesis. Combined gas exchange and chlorophyll fluorescence imaging measurements were performed. Shaded leaves were alternately illuminated with a large and a small lightfleck. When stomatal conductance was low, calculated net assimilation rates (*A*) of homobaric leaves underneath the small lightfleck were substantially higher than underneath the large lightfleck, and electron requirement for CO_2 fixation (e/*A*) was clearly decreased by lateral CO_2 flux. All this was not observed in heterobaric leaves. Homobaric leaves can obviously refix respiratory CO_2 from (remote) shaded leaf areas and, consequently, enhance net CO_2 uptake under drought stress. We hypothesize that homobaric leaf anatomy was an advantageous trait in the past under conditions of low atmospheric CO_2 concentration, in particular, when combined with shortage of water.

P1769. Effect of elevated CO_2 on photosynthetic performance and dry matter accumulation in radish

W. F. Postl, J. I. Haumann, S. Holzleitner, S. Pichlmann, H. R. Bolhàr-Nordenkampf;
Ecocenter Vienna, Faculty of Life Sciences, 1091 Vienna, Austria.

Radish plants (*Raphanus sativus* L.) were grown from seeds in climatic chambers under a light intensity of 750 µmol.m^{-2}.s^{-1} and two different CO_2 concentrations: 380 (ambient) and 680 (elevated) µmol CO_2.mol^{-1} air respectively. Photosynthetic rates (A_{700}) were significantly higher under elevated CO_2 over the whole vegetation period (up to +65%). In contrast to plants grown under ambient CO_2, a decrease in A_{700} values in elevated CO_2 plants at the end of the cultivation period was obviously due to earlier senescence, which could also be seen from reduced carboxylation efficiency. As expected, water use efficiency (WUE) was significantly higher under elevated CO_2. This might mostly be due to lower transpiration rates in these plants (75-80% of ambient).

After 45 days elevated levels of CO_2 resulted in an increase in total dry matter accumulation of +56% in harvested plants, in which assimilate translocation into the hypocotyl tuber was apparently higher (+70%) than into the leaves (+16%). Nitrate content of the tuber was lower under elevated CO_2 compared to ambient CO_2, whereas converse relationship occurred regarding ascorbic acid content.

P1770. Effects of Open Top Chamber CO_2 Enrichment (OTC) on leaf characteristics and photosynthetic capacity of grapevine (Vitis vinifera L.).

J. M. Moutinho Pereira, C. M. Correia, B. M. Gonçalves, E. A. Bacelar, H. Ferreira;
CETAV, Vila Real, Portugal.

Vines in a vineyard of the cultivar Touriga Franca were exposed to 2 concentrations of CO_2 (ambient and 500 ppm) using an open-top chambers carbon dioxide enrichment (OTC) system which allowed the exposure of the plants to constant CO_2 concentrations during summer of 2004. Some physiological and leaf anatomical characteristics were substantially affected by CO_2 enrichment. Net CO_2 assimilation rate was significantly increased, whereas stomatal conductance (gs) was reduced in elevated CO_2, leading to improvements in intrinsic water use efficiency. The decrease in gs was associated with a reduction of stomatal density and with direct effects of CO_2 on the stomata guard cells. Palisade and spongy parenchyma thickness were significantly higher in leaves grown under elevated CO_2 conditions. Those preliminary values may contribute to predict the magnitude of grapevine responses to climate change in the Mediterranean area.

P1771. Deuterium Isotopomer Distribution in tree ring cellulose: Separation between climate and physiological signals

A. Augusti, T. Nicol, J. Schleucher;
Medical Biophysics Department, Umeå, Sweden.

Plant-climate interactions have a strong influence on global carbon cycle. We study these interactions retrospectively using tree rings. The abundance of the stable hydrogen isotope deuterium (D) in plant material is influenced by climate and physiology. The D abundance of meteoric water carries a climate signal, which is partly passed on to plant material. Besides this, the D abundance of plant material depends on D fractionations of plant biochemistry, which constitute physiological signals. If these signals can be separated, climate and physiological signals can be obtained in parallel, allowing to infer plant-climate interactions. Deuterium Nuclear Magnetic Resonance allows to measure the D abundance of each C-H group of cellulose, which is the key to separating climate and physiological signals. Results from a laboratory experiment identify C-H groups in tree ring cellulose that carry climate and physiological signals. Results from a tree ring series show that climate signals (winter and summer precipitation) can be extracted. Experiments on longer tree ring series are in progress, to reconstruct climate and study long-term CO_2 fertilisation.

P1772. Competition dominates the responsiveness of juvenile European beech and Norway spruce to elevated CO_2 and/or O3 concentrations

T. E. E. Grams[1], A. R. Kozovits[1,2], R. Matyssek[1];
[1]Ecophysiolology of Plants, TU München, Freising, Germany,
[2]Departamento de Ecologia, Universidade de Brasília, Brasília, Brazil.

A two-year phytotron study was conducted to investigate the intra- and interspecific competitive behavior of juvenile European beech and Norway spruce. Ambient and elevated carbon dioxide (CO_2) and ozone (O3) regimes were applied as stressors for provoking changes in resource budgets, growth and allocation to facilitate the competition analysis. The hypothesis tested was that the responsiveness of plants to CO_2 and O3 depends on the type of competition (i.e. intra- versus interspecific).

Spruce was a stronger competitor than beech as displayed by its higher aboveground biomass increments in mixed compared to monoculture. The responsiveness of the juvenile trees to the atmospheric treatments differed between species and was dominated by the type of competition: Spruce growth benefited from elevated CO_2 concentrations, while growth of beech suffered from the enhanced O3 regime. In general, interspecific competition enhanced these atmospheric treatment effects, supporting our hypotheses. Our study stresses that competition is an important factor driving the development and responses of plants to elevated CO_2 and/or O3.

P1773. Effects of elevated CO_2 on photosynthesis and biomass with radish.

H. Usuda;
Lab. of Chemistry, School of Medicine, Teikyo University, Hachioji, Japan.

The relationship between the rate of photosynthesis/leaf area and biomass is still not clear. Elevated CO_2 should have positive effect on C3 photosynthesis. We developed the system for simultaneous measurements of continuous monitoring of CO_2 exchange and growth analysis with whole plants to evaluate the impact of elevated CO_2 on whole plant photosynthesis and biomass (Plant Production Sci.7, 386-, 2004). A radish cultivar with a big storage root (White Cherrish) was grown under ambient (around 400 ppm) or elevated CO_2 (around 770 ppm). The effects of elevated CO_2 on the rate of photosynthesis with an individual leaf were also assessed. The results indicated that increase of dry matter by elevated CO_2 is due to higher photosynthesis/leaf area and bigger leaf area and higher rate of photosynthesis with increased leaf area does have positive effect on plant biomass of vegetative crops. Down regulation of photosynthesis with elevated CO_2 will be also discussed.

P1774. Effects Of Air Filtration On Egyptian Clover (Trifolium Alexandrinum L. Cv. Messkawy) Grown In Open-Top Chambers In A Rural Site In Egypt. I. Effects Of Ozone And Ozone Protectant Chemicals On Photosynthesis, Stomatal Conductance And Growth

I. A. Hassan[1], N. B. Bell[2], F. M. Marshall[2];
[1]Alexandria University, Alexandria, Egypt, [2]Imperial College, London University, United Kingdom.

An Egyptian variety of clover plants (Trifolium alexandrinum L. cv. Messkawy) were either untreated (control) or treated with soil drench of ethylenediurea (EDU) at 50, 100, 150, or 200 ppm or benomyl at 250, 350, 450 or 550 ppm for the whole growing season and sown in the soil either under Egyptian field conditions at a rural site in northern Egypt or in open top chambers receiving either charcoal filtered or no-filtered air. It was noticed that Both EDU and benomyl caused an increase in growth parameters and provided some protection against O3 visible injury symptoms, with EDU having better protection than benomyl. Moreover, photosynthetic rates were increased in treated plants while stomatal conductance did not show any significant difference from control plants under OTCs conditions. It is clear from the results of the present investigation that benomyl and EDU would be useful tools to assess the effects of ambient O3 on plants under Egyptian field conditions. The implications to Egyptian agriculture were discussed.

P1775. Influence of elevated atmospheric CO_2 concentration and temperature (+3°C) on photosynthesis, water relations, ontogenetic development and yield of *Triticum durum* L. and *Vicia faba* L.

R. Linke[1], H. R. Bolhàr-Nordenkampf[1], M. H. Meister[1], E. Pfundtner[2];
[1]University Vienna, Faculty of Life Sciences, Vienna, Austria, [2]Austrian Agency for Health and Food Safety (AGES), Vienna, Austria.

Plants of *Triticum durum* L. and *Vicia faba* L. were grown at present climatic conditions (365 mg $CO_2.m^{-3}$; CS 2002) and at predicted future climatic conditions (700 mg $CO_2.m^{-3}$; +3°C; CS 2100) in two growth chambers in which seasons were simulated. Additionally, plants were subjected to different water regimes (45% and 75% of WHC). Growth in CS 2100 significantly increased light saturated photosynthesis of both species. Leaf conductance of *T. durum* plants grown in CS 2100 was reduced in spring and increased in early summer and summer. Contrastingly, *V. faba* showed a decrease of leaf conductance throughout ontogeny. Plant development and biomass accumulation were accelerated in both plant species grown in CS 2100. In *T. durum* the ontogenetic difference between the climatic scenarios increased through ontogeny and finally reached 18 d at dead ripeness, causing a shortening of the various ontogenetic stages, especially the grain filling duration, resulting in a lower grain weight. In *V. faba* a difference of 7 days was already observed at vegetative growth stage and remained constant. An increase of seed dry weight per plant in CS 2100 was only found under mild drought stress.

P1776. Nitrogen use efficiency of a poplar plantation is increased under elevated CO_2

C. Calfapietra[1], B. Gielen[2], P. De Angelis[1], M. Lukac[3], M. C. Moscatelli[4], A. Lagomarsino[1], A. Polle[5], G. Scarascia Mugnozza[1], M. F. Cotrufo[6], M. Hoosbeek[7];
[1]University of Tuscia, Department of Forest Environment and Resources (DISAFRI), Viterbo, Italy, [2]University of Antwerpen, Campus Drie Eiken, Department of Biology, Research Group of Plant and Vegetation Ecology, Wilrijk, Belgium, [3]University of Wales, School of Agricultural and Forest Sciences, Bangor, United Kingdom, [4]University of Tuscia, Department of Agrobiology and Agrochemistry (DABAC), Viterbo, Italy, [5]Institut für Forstbotanik, Georg-August Universität, Göttingen, Germany, [6]Second University of Naples, Department of Environmental Sciences, Caserta, Italy, [7]Wageningen University, Laboratory of Soil Science and Geology, Department of Environmental Sciences, Wageningen, The Netherlands.

Growth of trees is largely regulated by N availability. When plants are exposed to elevated CO_2 concentrations they often exhibit enhanced growth with increased biomass accumulation, which in the long-term can result in an increased N uptake from the soil. In fact, N and C cycles are usually strictly related within plants and N metabolism is regulated by signals that are derived from C metabolism (Stitt et al., 1999). In this study we will present data from the POPFACE experiment where a short rotation poplar plantation has been exposed to a CO_2 concentration of 550 ppm from planting to canopy closure. In particular we found that elevated [CO_2] treatment induced a decrease of N concentration in all plant tissues and as a result of the the increased biomass production, the N use efficiency, that is the biomass produced per unit of N in the plant, was increased under elevated [CO_2]. Despite total N content in the plant tissues was not different between elevated and ambient [CO_2], N depletion in the soil was evident under elevated [CO_2] suggesting some possible mechanisms of N immobilization.

Stitt M, Krapp A (1999) Plant Cell Environ 22:583-621.

P1777. Sink-limitation as a possible reason for limited growth response of sugar beet under free air CO_2-enrichment ?

R. Manderscheid, A. Pacholski, **H. J. Weigel**;
Institute of Agroecology, Braunschweig, Germany.

Effects of elevated CO_2 concentrations (550 ppm) on a crop rotation are investigated within the free air carbon dioxide enrichment (FACE) experiment at Braunschweig, Germany (1). During two growing seasons it has been found that growth and yield responses of sugar beet plants to the high CO_2-treatments were small in comparison to what could be expected in comparison to responses of other crop species. In addition, at the end of the growing season, a decrease of leaf area index (LAI) was observed under FACE conditions. Partial shading of the sugar beet canopy prevented the decrease of LAI under FACE and resulted in a higher growth stimulation than under full sunlight conditions. The results provide evidence for a possible sink limitation of sugar beet growth under future atmospheric CO_2 levels.

P1778. The role of polyamines during induction of photosynthesis

N. E. Ioannidis[1], K. Kotzabasis[1,2];
[1]Department of Biology, University of crete, Heraklion, Greece,
[2]Department of Botany, Natural History Museum of Crete, Heraklion, Crete, Greece.

Before re-illuminated leaves, protoplasts or chloroplasts achieve a steady state photosynthesis there is an induction period lasting from a few seconds to a few minutes. We have followed induction both polarographically and physicochemically in the unicellular eucaryote *Scenedesmus obliquus* and its mutant that lacks light harvesting complex (wt-LHC) and we demonstrate that artificially altered endocellular polyamine levels affects induction. Specific fluxes and activities were also evaluated non invasively with JIP-Test. High endocellular levels of the polyamines delay photosynthetic induction and reduces maximum photosynthesis, estimated as rate of oxygen evolution. In the case of wt-LHC mutant polyamine-treated cells showed no inhibition during photosynthetic induction. The role of polyamines on the light harvesting complex size during induction is discussed.

P1779. The photochemical use of absorbed light by plants

J. I. Haumann, H. R. Bolhàr-Nordenkampf, R. B. Linke;
Ecocenter Vienna, Faculty of Life Sciences, 1091 Vienna, Austria.

To gain information on the current photochemical use (PCU) in leaves, signals of chlorophyll fluorescence were taken to interpret the responses to environmental stress. Predawn Fv/Fm values were used to quantify available photochemical capacity at the beginning of the day (100%). Measurements were taken at different time intervals to determine the capacity of recovery of electron transport on upper and lower leaf surface.

Green house grown radish plants showed surprisingly high PCU (up to 35%, calculated from values of light exposed and 15’ dark adapted leaves) under “photochilling” conditions (high light, low temperature). We found, however, also a great portion of photoinhibited centers (17% on upper surface), which did not manage to fully recover within 20 hours. Heat stress under low light conditions resulted in a severe inactivation of photosystems (more pronounced on lower surface) without considerable recovery.

Well watered rice plants exhibited 7 fold higher PCU than water stressed plants. This also corresponded to higher electron transport rates (ETR) in the former, nevertheless combined with a slightly higher amount of photoinhibited centers.

P1780. Determination of rhizome dry matter content of Iris pumila L. using a non-destructive method

Z. Popovic, A. Mijovic, B. Karadzic;
Institute for Biological Research "Sinisa Stankovic", Belgrade, Serbia and Montenegro.

Commonly used method for determination of dry matter content (which includes measuring of fresh, water saturated and dry mass of plant organs) could be unrecommendable in some cases. Classic approach with harvesting of rhizomes (oven-drying) could have undesirable consequences on the abundance and number of species on its natural site. In our investigation we observed the biomass production of rare and endangered Iris pumila L. in Deliblato Sand (Serbia). The fresh rhizomes of I.pumila were divided into smaller parts, and planted on the same site. The initial concentration of dry matter in this parts of rhizomes, was indirectly determined using a volumetric method (measuring the fresh mass and volume of rhizomes). On the basis of our results from measuring rhizomes of different clones and different age, we concluded that fresh matter concentration is a good predictor of dry matter content of this plant organ. Values of fresh matter concentration (g/cm3) obtained from volumetric method were highly correlated ($r=0.91$; $p<0.05$) with values of dry matter content (g/g) obtained with classic approach of measuring in control group of rhizomes.

P1781. Dynamics of two Mediterranean coastal ecosystems using NDVI from satellite images

A. Kyparissis, E. Levizou;
Laboratory of Botany, Department of Biological Applications and Technology, University of Ioannina, Ioannina, Greece.

Among the modern methods for monitoring ecosystem dynamics the use of satellite imaging has been attracted special interest during the recent years. The Normalized Difference Vegetation Index (NDVI), which can be extracted from such images, has been proved to show good correlation with plant productivity. NDVI represents a measure of leaf chlorophyll content and may be correlated with photosynthetic activity, Leaf Area Index (LAI) and the Fraction of Absorbed Photosynthetically Active Radiation (FAPAR). Consequently, NDVI may be used for monitoring ecosystem dynamics, as it may fluctuates due to intra-annual growing processes (e.g. leaf burst or senescence of deciduous plants), or due to inter-annual climate variability, either natural or anthropogenic. In this study, NDVI was used for monitoring the dynamics of two adjacent but different coastal ecosystems: a phryganic one, dominated by the semi-deciduous shrub *Phlomis fruticosa* and a forest with *Pinus pinea*. NDVI has been correlated with precipitation - the main stress factor in Mediterranean type ecosystems - in a 7-year time series.

P1782. Photosynthetic pigment contents in twigs of 24 trees assessed by *in vivo* reflectance spectroscopy consistently indicate low chlorophyll levels but high carotenoid/chlorophyll ratios

E. Levizou[1,2], Y. Manetas[2];
[1]Laboratory of Botany, Department of Biological applications and Technology, University of Ioannina, Ioannina, Greece, [2]Laboratory of Plant Physiology, Department of Biology, University of Patras, Patras, Greece.

Preliminary trials indicated that spectral reflectance indices used to assess non-destructively photosynthetic pigment levels in leaves can be safely used for twigs as well, provided that twig periderm could be easily peeled off. We hypothesized that pigment levels in twigs should be compatible to the shade adaptation syndrome, due to the highly light absorptive periderm. Therefore, we compared selected indices obtained from leaves and twigs of 24 species. Twigs consistently displayed lower chlorophyll but higher carotenoids/chlorophyll ratios. When the exposed and shaded sides of twigs were compared, no differences were found. The results were unexpected, indicating that shade may not be the primary factor shaping corticular pigment profiles. Based on the sparse available literature, we suggest that red light enrichment and/or the extremely high CO_2 levels in the stem interior may pose additional photoselective and/or photoprotective needs, necessitating increased carotenoids/chlorophyll ratios.

P1783. Dynamics of leaf and root growth measured by digital image sequence processing - endogenous control versus environmental impact

A. Walter, U. Schurr;
Institute of Chemistry and Dynamics of the Geosphere, ICG-III, Juelich, Germany.

For their outstanding importance, analyses of internal growth regulations and environmental impact thereon are long-standing topics in plant sciences. However, only with recent technological advancements, it has become feasible to study the dynamics of plant growth in temporal and spatial scales that enable to establish a framework of multi-scale models, linking macroscopic growth with molecular events. Digital image sequence processing has been used to calculate maps of growth rate distribution from time-lapse videos of expanding roots and leaves of dicot plants with high spatio-temporal resolution. The techniques have successfully been applied to a wide variety of species and questions, ranging from investigating the effects of external nutrient availability on growth dynamics in maize roots to identifying the genes controlling diel growth patterns in *Populus* leaves. On the basis of these results, the hypothesis is developed that the relative importance of endogenous control versus environmental impact on growth dynamics depends on the spatial and temporal variation of the environmental conditions to which the tissue is exposed.

P1784. Function of plant body odour: non-invasive assessment through phytohormones

M. Dicke, R. Gols, J. G. de Boer;
Wageningen University and Research Centre, Wageningen, The Netherlands.

Plant hormones mediate phenotypic plasticity in plants. Upon attack by herbivores plants produce phytohormones that are involved in signal transduction resulting in the emission of complex odour blends that may consist of hundreds of compounds. One of the effects of these volatiles is the attraction of natural enemies of the herbivores as a kind of ‘bodyguards’. Which of the volatiles released by plants function as such is mostly unknown, especially because it is difficult to make synthetic forms of the plant’s bouquets due to the large number of compounds and the unavailability of many of their constituents.

Addressing the ecological role of individual plant volatiles has been greatly enhanced by elucidating the involvement of phytohormones in the induction. This provides an important tool for understanding the contribution of individual plant volatiles in interactions with arthropods. In addition to an important contribution to fundamental knowledge, also novel developments in environmentally benign pest control may be gained. Phytohormones may be used to prime plants so as to enhance their induced defences in response to herbivory.

P1785. Spectral Reflectance Compared with Fluorescence and Absorption Measurements of Seagrasses

A. L. Thorhaug[1], G. P. Berlyn[2];
[1]Yale University, Miami, FL, United States, [2]Yale University, New Haven, CT, United States.

Comparison of three non-intrusive, efficient measurement techniques for physiological responses were carried out sequentially on the same seagrass specimens. The *Thalassia testudinum* specimens (12 specimens each measured 3 times on each of 2 blades) were incubated 24 hr at 32 and 16 ppt. The same specimens in sequence were measured first for fluorescence (after dark-adaptation.), then absorbance , finally spectral reflectance. Results showed that the spectral reflectance low salinity measurements were statistically-significantly different from normal seawater; however, absorbance and fluorescence measurements were not significantly-significant (high standard error). Additionally, spectral reflectance indices (first derivative, NDI, SIPI) delineated effects of the stressor. The questions of recording the entire spectrum of values via spectral reflectance rather than two or three spectral lines of values in fluorescence and absorbance measurements will be discussed, as will differences expected from various optical sensor diameters.

P1786. Leaf cooling curves: a method for estimating leaf temperature in the sun and its application.

A. Leigh, J. D. Close, A. B. Nicotra;
The Australian National University, Canberra, Australia.

The evolutionary significance of leaf size is commonly attributed to temperature regulation, with theory predicting that small leaves are adapted to hot, dry climates. This is because small leaves have small boundary layers and thus rapid heat transfer, so should therefore be more thermally coupled to ambient temperature than large leaves. A similar theory can be applied to lobed *versus* entire leaves of the same area. Understanding how different leaves cope with heat is important as high leaf temperatures can lead to leaf or plant death. Thermal imagery is increasingly used to estimate foliage temperature, yet a common problem is that leaves cannot accurately be measured in full sunlight because reflectance from the leaf can distort its true temperature. We have developed a method for estimating leaf temperature in the sun using thermal imagery to generate cooling curves. From these curves, the time constant for cooling, Ű can be calculated, from which the original temperature of the sunlit leaf can be extrapolated. Consistent with leaf boundary layer theory, we have found that Űvaries with leaf morphology.

P1787. Thermography- A Potential Technique in Plant Physiology Research

E. Marqués Alonso, **T. G. Reichenauer**;
ARC Seibersdorf research GmbH, Seibersdorf, Austria.

Infrared thermography has been applied to measure leaf/canopy temperatures giving information of the energy balance of plant leaves that correlates very strongly to the rate of evaporation which in turn is dependent on stomatal conductance. The Iwanow effect (a rapid initial opening of the stomata before a longer-term closure in conditions of water supply insufficiency) was assessed on fully-developed wheat leaves which were cut off from their stems. Infrared thermography was also performed on a field experiment for comparative assessment of presymptomatic visualization of phytotoxicity. A higher average temperature was obtained in one of the fungicide treatments in comparison with the control and a second fungicide treatment for all wheat cultivars screened. Infrared thermography has been proved to have the adequate sensitivity for studies on stomatal dynamics on single leaves. It could be also adapted for use in the field as it seems to be precise enough in outdoor conditions. As a remote technique it does not interfere with stomatal conductance when measurements are being carried out and allows the semiautomatic screening of large areas in a very short time.

P1788. Possible amplification of mature mRNAs in single cells of tomato callus aggregates by direct RT-PCR of cytosolic contents suctioned out with a micropipette

H. Toyoda, Y. Matsuda, T. Nonomura;
Kinki University, Nara, Japan.

Two-step PCR (RT-PCR and nested PCR) was applied to single-cell RT-PCR for detecting gene expression *in situ* in single selected cells of leaf-derived callus aggregates of tomato (*Lycopersicon esculentum* Mill, cv. Moneymaker). The cytoplasm from one cell was removed with a micropipette using a light microscope and directly subjected to RT-PCR, followed by nested PCR. This method to remove cytosolic contents prevented the introduction of genomic DNA into the RT-PCR, and only intron-spliced products were amplified when the intron-containing genes were used as PCR targets. In addition, transcription of the intron-free gene was possibly detected by simultaneously tracing the intron-containing and intron-free genes using mixed primers for the targeted genes. The present study indicated that some stimuli-activated genes, such as the acidic extracellular chitinase and TLC1-retrotransposon long terminal repeat genes, were constitutively transcribed in tomato callus cells.

P1789. Long and short-term responses to contrasting irradiances in Copaifera langsdorffii Desf. (Caesalpinaceae)

C. H. Prado, C. C. Ronquim;
UFSCar, São Carlos, Brazil.

It was compared long-term responses of growth and leaf nutrient content in potted young plants of Copaifera langsdorffii at open and shaded areas without water stress. When young plants were transplanted to field under the same irradiance conditions the photosynthesis (A), leaf water potential (Y), and potential photochemical efficiency (Fv/Fm) were measured during daily courses in wet and dry seasons to point out short-term responses of carbon and water balances. The greater biomass accumulation, height, and total leaf area were linked with higher photosynthetic capacity on area basis in open area. All young plants survived in shade and it seems to be related with fast and high biomass accumulation in root. Net photosynthesis value in shade increased periodically when bunches of direct light (sunflecks) reached the leaves. The sunflecks took place in larger amount at dry period, but they were more effective for carbon assimilation in the rainy season. The ability of young plants to persist by long-term in shade could explain the wide distribution of C. langsdorffii in different Cerrado physiognomies.

P1790. Photosynthetic Pathways in Bromeliaceae, Based on Carbon Isotope Ratios of 1873 Species

D. M. Crayn[1], J. A. C. Smith[2], K. Winter[3];
[1]National Herbarium of New South Wales, Sydney, Australia,

[2]University of Oxford, Oxford, United Kingdom, [3]Smithsonian Tropical Research Institute, Panama City, Panama.

In the largest single-family survey to date, photosynthetic pathway was investigated in 1873 species of Bromeliaceae, representing ca. 65 % of all species and 55 of the 56 genera, using plant carbon-isotope ratio (d13C). Whereas 902 species showed d13C values typical of C3 plants (values more negative than -23 ‰), 827 showed d13C values typical of plants performing crassulacean acid metabolism, or CAM (values less negative than -20 ‰). A small number (144) of species showed intermediate d13C values (-20 ‰ to -23 ‰). The distribution of d13C values was strongly bimodal, with clusters around -26 ‰ and -13 ‰. These results suggest that about 44 % of all bromeliad species may utilize the CAM pathway as their principal mode of photosynthesis, including members of nine genera not previously known to contain CAM species. Additional species with intermediate and C3-type d13C values may also possess the capacity for some nocturnal CO_2 uptake via CAM. There was a positive correlation between altitude and d13C for species showing C3-type d13C values only, the first demonstration of a differential response of C3 and CAM plants to altitude with respect to carbon-isotope composition.

P1791. Life-time measurements of net CO_2 exchange in the C3-CAM species Mesembryanthemum crystallinum

K. Winter;
Smithsonian Tropical Research Institute, Panama City, Panama.

Net CO_2 exchange of the annual, halophytic species Mesembryanthemum crystallinum was measured continually throughout the entire, approximately 5-month life cycle of plants grown either in the presence of 400 mM NaCl in the hydroponic root medium from day 34 onwards, or maintained in a non-saline root medium. In plants exposed to 400 mM NaCl, about 30 % of life-time carbon gain of whole shoots was derived from dark CO_2 fixation involving crassulacean acid metabolism (CAM). By contrast, in non-salt-treated plants life-time carbon gain of shoots resulted almost exclusively from CO_2 fixation in the light and nocturnal carbon balance remained negative on all measuring days. These results are not consistent with the widely expressed notion that the induction of CAM by high salinity in M. crystallinum merely represents an acceleration of normal plant-age related developmental processes. Rather, utilization of the CAM pathway for carbon acquisition in M. crystallinum is overwhelmingly, if not fully, under environmental control.

P1792. Characterization of *Arabidopsis thaliana* transgenic lines expressing high levels of maize NADP-malic enzyme.

M. Saigo[1], R. D'Andrea[1], V. G. Maurino[2], M. F. Drincovich[1], C. S. Andreo[1];
[1]CEFOBI – Facultad Ciencias Bioquímicas y Farmacéuticas, Rosario, Argentina, [2]Botanisches Institut der Universität zu Köln, Cologne, Germany.

Arabidopsis thaliana (Col-0) was transformed with the maize chloroplastic NADP-malic enzyme (NADP-ME) cDNA under the control of 35SCaMV promoter. This enzyme catalyzes the decarboxylation of malate, generating pyruvate, CO_2 and NADPH. The homozygous line with the highest expression level showed a 30-fold increase in NADP-ME activity. Plants grown under normal light intensity showed no major morphological differences compared to the wild type line. However, chlorophyll content as well as photosynthetic performance indicators like CO_2 assimilation, Fv/Fm and ū PSII were significantly lower for transgenic lines. These results suggest that the presence of a highly active NADP-ME in chloroplasts of *A. thaliana*, could have important effects on the reductive power balance of this organelle, diminishing the efficiency of the overall photosynthetic process. The transgenic plants obtained in the present work represent a useful tool to understand the regulation of plastid redox metabolism.

P1793. Photosynthetic activity and growth of seedlings of four oak (Quercus) species grown in a combination of light and water regimes

J. L. Quero[1], R. Villar[2], **T. Marañón**[3], R. Zamora[1];
[1]University of Granada, Granada, Spain, [2]University of Córdoba, Córdoba, Spain, [3]IRNASE, Sevilla, Spain.

Photosynthesis and respiration rates determine the carbon gain and plant growth. In this paper we present the results of an experiment growing seedlings of four Mediterranean *Quercus* species (*Q. canariensis*, *Q. ilex*, *Q. pyrenaica* and *Q. suber*) under contrasted conditions of light and water in a glasshouse. Maximum photosynthetic activity (A_{max}) was higher for *Q. pyrenaica* (mean of 8.45 µmol m^{-2} s^{-1}) and lower for *Q. canariensis* (5.57 µmol m^{-2} s^{-1}). There was a significant decrease of A_{max} for all the species when grown under deep shade (mean of 5.02 µmol m^{-2} s^{-1}), compared to full light treatment (7.92 µmol m^{-2} s^{-1}). There was also a significant decrease of A_{max} for all species when grown under drought stress (mean of 4.06 µmol m^{-2} s^{-1}), compared to watered plants (9.0 µmol m^{-2} s^{-1}). Interestingly the interaction of both factors, light and water, on the A_{max} was also significant. The photosynthetic values are related with other physiological (stomatal conductance, respiration, WUE) and morphological (SLA) variables, and their role determining relative growth rate of seedlings is investigated.

P1794. Additional synthesis of starch from sucrose in leaves of arabidopsis in the light

O. Keerberg, H. Ivanova, H. Keerberg, T. Pärnik;
Institute of Agricultural and Environmental Sciences, Harku, Estonia.

Accumulating during daytime starch is converted in the night into sucrose and consumed in respiratory, biosynthetic and transport processes. However in the light the degradation and conversion of starch are blocked. In pulse chase experiments with wild type plants and starchless mutants *pgm* or *adg1* of arabidopsis an increase of starch radioactivity during chase in nonradioactive medium in the light was detected. These findings suggest that starch was additionally synthesized from labeled cytosolic soluble photosynthates, preferentially from sucrose. Radiogasometric studies of gas exchange have revealed that sucrose is consumed also in photorespiratory decarboxylations. To be involved in photorespiration the products of sucrose degradation must be transported from cytosol into chloroplast. We presume that derived from sucrose hexoses are transported into chloroplast by hexose transporter and phosphorylated there in hexokinase reaction. The phosphorylated hexoses may be consumed either for additional synthesis of starch or incorporated into the reductive pentose phosphate cycle and, via this cycle, into the glycolate cycle.

P1795. Patchy acclimation of photosynthesis due to corresponding spatial heterogeneity in epidermal anthocyanin accumulation.

A. Kyzeridou, Y. Manetas, **Y. Petropoulou**;
University of Patras, Patras, Greece.

In the present study, we have examined the hypothesis that an epidermal anthocyanic screen predisposes the underlying chloroplasts to changes related to a shade acclimation syndrome. Variegated leaves of the tropical understorey species *Coleus blumei*, which have regions with high chlorophyll density and are covered by anthocyanin-rich or anthocyanin-less epidermis, were used. The anthocyanic patches were consistenly correlated with lower chlorophyll a/b and lower carotenoid/total chlorophyll ratios. In addition, imaging of chlorophyll fluorescence parameters (using a red LED source for both measuring, saturating and actinic illumination, i.e. measuring photosynthesis by light which by-passes the anthocyanic screen) indicated slightly, but statistically significant, lower maximum electron transport rates (ETRs) along photosystem II in the red patches. The results confirm the shade adaptation hypothesis of red leaves.

P1796. Control of respiration in photosynthesizing leaves of C-3 plants by irradiance and CO_2

T. Parnik, H. Ivanova, O. Keerberg;
Institute of Agricultural and Environmental Sciences, Harku, Estonia.

In leaves of seven C-3 species respiratory CO_2 fluxes from primary (Rrp) and stored (Rrs) photosynthates and total rate of respiration (Rr=Rrp+Rrs) were measured in the light under steady state photosynthesis. Respiration in the dark Rd was determined 40 min after switching off the light. Values of Rr were the same at low and high light, 130 and 650 µmol m^{-2} s^{-1}, respectively. Under high light Rrp was 25% higher and Rrs by the same extent lower than under low light. Rd also increased after exposure to high light. Rr was lower than Rd both at low and high irradiances. Light curves of CO_2 efflux indicated that inhibition of Rrs was initiated at very low irradiances, the initial rapid decline in the region from 0 to 100 µmol m^{-2} s^{-1} was followed by a slower decrease at higher irradiances. In leaves of *Helianthus annuus* the inhibition of Rrs was at 3000 µL L^{-1} CO_2 less pronounced than at 360 µL L^{-1}. In leaves of *Secale cereale* the increase of CO_2 concentration from

300 to 2300 µL L^{-1} did not change Rr but resulted in 2-fold decrease of the contribution of Rrp with concomitant increase of Rrs. Under very high CO_2 , 30 mL L^{-1}, the inhibition of Rrs by light was removed.

P1797. Effect of thinning on photosynthetic acclimation and its relation to leaf nitrogen in young stands of *Chamaecyparis obtusa*

Q. Han, M. Araki, Y. Chiba;
FFPRI, Tsukuba, Japan.

In order to distinguish carbon fixation benefited from forest management from non-human factors, we studied the changes in photosynthesis after thinning and analyzed its relation to leaf nitrogen. The study site was a 10-year-old *Chamaecyparis obtusa* stand (36°3'N, 140°7'E) with 4.24 m high. The forest density was 2778 trees ha^{-1}. Half of the trees was cut one by another in the thinned treatment in May 2004. The photosynthetic responses to CO_2 concentration were measured *in situ* in leaves in July and October to estimate V_{cmax}. Thinning improved light condition in the lower and middle crowns but not in the upper crown. Nitrogen content per area (*N*) did not change after thinning at all crown positions. Thinning caused an increase in V_{cmax} only in lower crown in June, and in both middle and lower crowns in October. The slope of the linear regression between *N* and V_{cmax} was different between thinned and non-thinned treatments in October, but not in June. These results indicate that photosynthetic acclimation in the first year after thinning might mainly depend on nitrogen partitioning within photosynthetic machinery, but not on nitrogen reallocation between leaves.

P1798. Effects of salt stress on soluble proteins, proline and carbohydrates content of two tomato cultivars under *in vitro* culture condition

F. Amini, A. Ehsanpour;
Isfahan University, Isfahan, Islamic Republic of Iran.

The effect of NaCl stress on soluble proteins, proline and carbohydrates of two tomato (*Lycopersicon esculentum* Mill.) cultivars Isfahani and Shirazy were studied. Seeds were germinated on medium containing only water agar and then transferred to MS medium supplimented with different concentrations of NaCl (0, 40, 80, 120 and 160 mM) for 24 days. Increasing of salinity resulted in increasing of soluble proteins in stem-leaf of cv. Isfahani but decreasing in cv. Shirazy. Soluble proteins in roots of both cultivars showed some variations. When the concentration of NaCl in the medium was increased, proline contents of stem-leaf and roots of both cultivars was increased significantly. However, cv. Shirazy showed higher amount of proline level. Total carbohydrate in stem-leaf and roots in both cv. Shirazy and cv. Isfahani was increased in response to increasing of salt concentration. It can be concluded that, proline content in compare with the soluble protein and carbohydrate level is genotype dependent and can be a reliable criteria for evaluation of salt tolerance in tomato cultivars Isfahani and Shirazi.

P1799. Polyamines regulate the sensitivity of photosynthetic apparatus to UV-B radiation through changes in the molecular organization of LHCII

L. Sfichi[1], K. Kotzabasis[1,2];
[1]Department of Biology, University of Crete, P.O. Box 2208, GR-71409 Heraklion, Crete, Greece, [2]Department of Botany, Natural History Museum of Crete, Heraklion, Crete, Greece.

The sensitivity of the photosynthetic apparatus to UV-B is influenced by the size of LHCII, which is regulated by thylakoid-associated polyamines, especially putrescine (Put) and spermine (Spm). In *wt* cultures of *Scenedesmus obliquus*, a decrease in the Put/Spm ratio in thylakoids led to the increase of LHCII size and, consequently, to a higher sensitivity of the photosynthetic apparatus to UV-B. Inversely, an increase in the Put/Spm ratio conferred a higher degree of tolerance to UV-B radiation. Experiments with the mutant *wt-LHC* (without LHCII) showed that the changes induced by UV-B in the photosynthetic apparatus were less pronounced as compared to the *wt* cultures, but the ability to recover the photosynthetic ability was significantly decreased. The results highlight the LHCII importance in the mechanism of sensitivity/tolerance to UV-B radiation. The role of polyamines in the response of a photosynthetic apparatus without LHCII to UV-B is discussed.

P1800. Photosynthetic leaf properties and UV-B protection of cloud forest trees along an altitudinal gradient

N. Velázquez-Rosas, A. Orozco-Segovia, R. Cruz-Ortega, E. Toledo-Alvarado;
Instituto de Ecología, México D. F., Mexico.

The cloud forest presents a great morphological and structural variation along altitudinal gradients, but information about functional responses is poor. Photosynthetic leaf properties, UV-screening absorbance, and sun and shade leaf characteristics were analyzed in *Vaccinium consanguineum*, *Podocarpus matudae*, *Ticodendron incognitum* and *Drimys granadensis* along their altitudinal distributions. Sun leaves had higher mass and nitrogen per unit area than shade leaves. Chlorophyll (a and b) concentrations, Cha/Chb ratio, and total carotenoids concentrations were similar in shade and sun leaves, but these parameters were affected by the altitudinal gradient. The proportion of nitrogen was measured and partitioned for thylakoids was lower for sun leaves in all species, resulting in different light harvesting capacities between leaves and altitudes. UV-screening absorbance was higher in sun leaves but with no changes related to the altitudinal gradient. Leaf properties were associated with radiation levels along the altitudinal gradient and may reflect CO_2 assimilation rates and protection against UV-B radiation.

P1801. Ultraviolet-B radiation induced changes on growth, photosynthesis and leaf anatomy of broad bean (Vicia faba L.)

C. M. Correia, J. M. Moutinho Pereira, E. L. Bacelar, B. M. Gonçalves, H. Ferreira;
University of Trás-os-Montes e Alto Douro, Vila Real, Portugal.

The effects of ultraviolet-B (UV-B) radiation on growth, yield, gas exchange rates, pigmentation, soluble sugars, soluble proteins and leaf anatomy of broad bean were investigated. The experiment simulated a 20% stratospheric ozone depletion over Northern Portugal. After 4 months of UV-B treatment, total plant biomass and yield of high UV-B plants were 47 and 56% lower compared to control plants. The decrease of biomass appeared to be the result of changes in morphological, anatomical, physiological and biochemical processes. Enhanced UV-B induced decreases in leaf area, net assimilation rate, photosynthetic and transpiration rate, stomatal conductance, soluble sugars and soluble protein concentration, leaf tissue thickness, as well as in the number and size of root nodules containing the rhizobial symbiont. Pigment analysis of leaf extracts showed no significant effects on accumulation of photosynthetic and UV-B absorbing pigments. Since growing conditions strongly affect plant response to UV-B radiation, further field studies are necessary to assess the interaction between UV-B exposure and environmental variability.

P1802. Susceptibility of Antarctic mosses to UV-B induced DNA damage

J. D. Turnbull, S. J. Leslie, J. Wasley, S. A. Robinson;
Institute of Conservation Biology, Wollongong, Australia.

Antarctic vegetation is exposed to elevated levels of UV-B radiation (UVBR) as a result of ozone depletion. Three species of co-occurring Antarctic bryophytes, *Bryum pseudotriquetrum, Grimmia antarctici* and *Ceratodon purpureus* were irradiated with artificial UV-B or UVA radiation in either a fully hydrated or desiccated state. Enzyme-linked immunosorbent assays found DNA damage in the form of cyclobutane pyrimidine dimers and 6,4-photoproducts to be specific to UVBR, and DNA damage was significantly higher in the endemic moss, *G.antarctici*, than the other 2 species. In all species, desiccated moss accumulated less damage than hydrated moss. In a season of low ozone depletion, field samples of the 3 species exposed to ambient levels of UV-BR were collected at noon. There was no evidence that DNA damage accumulated in response to field levels of UV-BR. This study demonstrates that desiccation can confer protection from UV-B induced DNA damage in all three species but that *G.antarctici* is potentially more vulnerable to elevated UV-BR than the other 2 species. Continuing ozone depletion events may thus have consequences for the endemic's future competitiveness.

P1803. Effects of solar UV-B exclusion on the physiology of two cultivars of grapevine (*Vitis vinifera* L.) from La Rioja (Spain)

E. Núñez-Olivera, **J. Martínez-Abaigar**, R. Tomás, S. Otero, M. Arróniz-Crespo;
Universidad de La Rioja, Logroño (La Rioja), Spain.

Plants of two cultivars of *Vitis vinifera* (Tempranillo and Viura) typical of La Rioja (Spain) were exposed for 15 days in the field to two radiation regimes: near ambient radiation, and near ambient radiation 95% depleted in UV-B. The responses of the two grapevine cultivars to the almost complete exclusion of solar UV-B were somewhat different. Viura plants were hardly affected, except for a decrease in methanol-extractable UV-absorbing compounds (MEUVACs) and a less intense action of the xanthophyll cycle. These responses were also found in cv. Tempranillo, together with an increase in the concentrations of chlorophyll and carotenoids and in SPAD values. Thus, solar UV-B seems to cause slight damage in Tempranillo plants, but the rest of the variables (photosynthetic pigment composition, chlorophyll fluorescence) remained unaffected. The damage displayed by cv. Tempranillo as compared to the unaltered cv. Viura could be related to the lower capacity of the former to increase MEUVACs under solar UV-B. In conclusion, both cultivars seem to be adapted to the high solar radiation typical of the Mediterranean climate.

P1804. Protection against a sub-Antarctic summer - photoprotective and UV-B screening pigments of Heard Island vascular plants.

N. M. Grant, J. D. Turnbull, M. Ayoub, S. A. Robinson;
Institute for Conservation Biology, University of Wollongong, Wollongong, Australia.

Two vascular plant species (hair grass *Deschampsia antarctica* and herb *Acaena magellanica*) from sub-Antarctic Heard Island were sampled on 5 days between December 2003 and February 2004. Chlorophyll fluorescence and leaf temperature were determined in the field over midday and photosynthetic tissue samples collected for subsequent analysis of photosynthetic and UV-B screening pigments. *D. antarctica* had low F_v/F_m values coupled with high photoprotective pigment ratios, indicating sustained photoprotection during the study period while *A. magellanica* showed little sign of photoprotection. *Acaena magellanica* contained more than 3 times the amount of UV-B screening pigments than *D. antarctica.* Photoprotective pigment content in both species was responsive to naturally occurring changes in temperature and PAR with *D. antarctica* showing low temperature xanthophyll-mediated photoprotection, whilst *A. magellanica* indicated potential for protection at higher temperatures. Trends in pigments levels and response to temperature and PAR are discussed in relation to photosynthetic acclimation, plant growth habit and survival under a changing climate.

P1805. Impact of elevated UV-B radiation in high altitudes on secondary metabolite profiles in flowering heads of Arnica montana

R. Spitaler[1], D. Schlorhaufer[2], I. Merfort[3], S. Bortenschlager[2], E. Ellmerer[4], H. Stuppner[1], C. Zidorn[1];
[1]Institut für Pharmazie, Universität Innsbruck, Innsbruck, Austria, [2]Institut für Botanik, Universität Innsbruck, Innsbruck, Austria, [3]Institut für Pharmazeutische Wissenschaften, Universität Freiburg, Freiburg, Germany, [4]Institut für Organische Chemie, Universität Innsbruck, Innsbruck, Austria.

The influence of intensified UV-B radiation at higher altitudes on the contents of secondary metabolites in flowering heads of *Arnica montana* was assessed. Plants of the cultivar ARBO were grown in nine experimental plots at altitudes between 590 and 2230 m at Mount Patscherkofel near Innsbruck/Austria.

The total contents of sesquiterpenoids and flavonoids were not positively correlated with altitude. However, the proportion of flavonoids with vicinal free hydroxyl groups on ring B to flavonoids lacking this feature significantly increased with elevation. Additionally, the level of phenolic acids also positively correlated with the altitude of the growing site. In particular, amounts of 1-methoxyoxaloyl-3,5-dicaffeoylquinic acid significantly increased at higher sites and samples from the summit region contained 75% more of this compound than samples from valley sites. The UV-B protective and radical scavenging activity of phenolics and their significance for plant life in environments with elevated UV-B radiation are discussed.

P1806. The effect of epibrassinosteroid and different bands of ultraviolet radiation on the pigments content in *Glycine max.L*

S. Enteshari[1,2], K. Kalantari[3], M. Ghorbanli[2];
[1]International center of Science,High Technology&Environmental Science, Kerman, Islamic Republic of Iran, [2]Department of Biology University for Teacher Education, Tehran, Islamic Republic of Iran, [3]Department of Biology ,Shahid Bahonar University, Kerman, Islamic Republic of Iran.

The effect of different bands of UVradiation and epibrassinosteroid treatment on the quantity of chlorophylls,carotenoids ,flavonoids and UVabsorbing compounds in leaves of *Glycine max* were studied. Study showed in those plants that treated with UV-A the contents of these pigments were not significantly different in comparison to the control.While UV-B andUV-C irradiation caused significant decrease in chlorophylls and carotenoid.Epibrassinosteroid moderated this redaction.The quantity of anthocyanine,flavonoids and UV-absorbing compounds in plants that were treated with UV-B,UV-C and epibrassinosteroid were increased significantly.Therefore we concluded that chlorophylls and carotenoids are sensitive against UV-BandUV-C and application of epirassinosteroids can protect plants against UV-radiation by increasing protective pigments .Flavonoid ,anthocyanine and UVabsorbing compounds have high absorption in UV spectrum of light and therefore could prevent penetration of UV to the more sensitive tissues.

P1807. Dynamics of phytohormone and carbohydrate pools in subterranean organs of wintering plants

E. B. Kirichenko, T. V. Voronkova, V. V. Kondratieva, O. V. Shelepova;
"N.V. Tsitsin" Main Botanical Garden, Moscow, Russian Federation.

During the last 30 years the wintering perennial plants in the central regions of RF are often subjected to severe low temperature diseases. The dynamics of morphological and physiological state of mint rhizomes and tillering nodes of cereals during winter period was studied. The important significance of the maintenance of shoot and root apical meristems in viable state for plant survival was shown. The high activity of carbohydrate and phytohormone metabolism in the subterranean organs of these herbaceous species was revealed. The dynamics of cytokinin / ABA and soluble carbohydrate / starch ratios reflected the thaw phenomena during the winter. The results of evaluation of resistance to winter stresses and snow mold of plastid apparatus for the varieties of perennial wheat and mint will be presented. The selected varieties of this species manifesting a high level of resistance to abiotical and biotical stresses during their life cycle will be characterized. This work was supported by the Ministry of Education and Sciences of RF (project LScSc-1864.2003.4) and by RAS (Program “Fundamental basis of biological resources management”).

P1808. Effect of winter desiccation on antioxidant enzymes and anthocyanins in Vaccinium myrtillus L.

M. Tahkokorpi, E. Taulavuori, K. Taulavuori, K. Laine;
Department of Biology, University of Oulu, P.O.Box 3000, 90014 Oulu, Finland.

Plants face exposure to reactive oxygen species during photosynthesis and cell signaling as well as under environmental stress. Glutathione S-transferases (GSTs), enzymes with multiple cellular functions, catalyse the glutathione-dependent defence reactions and scavenge oxidative stress metabolites by functioning as glutathione peroxidases. Furthermore, GSTs are involved in anthocyanin metabolism, in which they act as carrier proteins. The snow cover crucially protects northern plants from wintertime drought and photo-oxidation in spring. To study the effects of winter desiccation possibly following the predicted climatic warming in the northern boreal zone, bilberry (*Vaccinium myrtillus* L.) plants were exposed to drought and excess irradiation by artificially preventing the formation of a protective snow cover. Control plants wintered under the natural snow. Antioxidant enzyme activities and anthocyanins were determined during winter dormancy, spring, active growth and frost hardening. The winter desiccation induced oxidative state in current-year shoots during summer, which indicates a long-term response to photo-oxidative stress.

P1809. Winter adaptive chances in Magnolias while introduction in Ukraine

N. Taran[1], R. Palagecha[2];
[1]National Taras Shevchenko University, Kyiv, Ukraine, [2]Botanical garden of National Taras Shevchenko University, Kyiv, Ukraine.

Winter adaptive peculiarities of 10 Magnolia species while introduction in Ukraine was studied. The comparative analysis of quantitative contents of flavonoids (rutin and quercetin) during autumn-winter months (October-February) shown the majority flavonoids loosed in bark of M. salicifolia shoots (75%) and M. kobus (56%), the minority - in M. liliflora (26%).The content of glicolipids (MGDG) in bark *M. salicifolia* annual shoots was 46 % higher then in shoots of *M. Liliflora*. The shoots of *M. salicifolia* characterized by highest pool of SQDG while the lowest autumn temperature -3^{o}C. In winter months polar lipid components decrease while sterols quantity increase in bark shoots of *M. Liliflora*. The additional investigation of the secretory structure in annual shoots shown the secretory idioblasts accumulation in bark parenchyma. They are characterized by the specific colour of fluorescence from bright-yellow to yellow-green known as fluorescence typical for the natural phenolic and terpenoid fluorochromes.While wintering secretory accumulations which plants use for their physiological needs was observed.

P1810. Effect of polyols on photosynthetic response of foliose lichens to sub-zero temperature

J. Hajek, M. Bartak;
Department of Plant Physiology and Anatomy, Faculty of Science, Masaryk University, Brno, Czech Republic.

At sub-zero temperature, cryoprotective compounds help algal lichens to maintain physiological activity. An alga-produced ribitol and hyphal cortex-produced mannitol are main high-energy compounds located in a lichen thallus. We tested hypothesis whether physiological concentrations of ribitol and mannitol provide effective cryoprotection that is detectable at the level of primary photosynthetic processes. From fresh *Umbilicaria hirsuta* and *Lassalia pustulata*, circular segments (1.5 cm^2) were cut. Two hours before expostion to low temperature, the segments were treated by 3 different concentrations of ribitol or mannitol under room temperature. In temperature gradient cultivator, the segments were exposed to 3 temperatures (-18, -6, +6 ^{o}C) for 3 d at low light. Throughout the experiment, chlorophyll fluorescence parameters (F_V/F_M, ū$_{II}$, NPQ) were measured each 12 h using a kinetic fluorometric CCD camera. For both species, F_V/F_M, ū$_{II}$ decreased towards sub-zero temperature and also with lenght of exposition. Positive effect of polyols on F_V/F_M, ū$_{II}$ was apparent only at +6 ^{o}C. Species-speciffic response to polyol concentrations was also apparent.

P1811. Photosynthetic responses of the mangrove, *Avicennia marina* subsp. *australasica* to frost and chilling temperatures during a New Zealand winter

C. M. Beard, T. G. A. Green, W. B. Silvester, C. E. C. Gemmill;
The University of Waikato, Hamilton, New Zealand.

Avicennia marina subsp. *australasica,* New Zealand's only mangrove, is confined to sheltered coastlines of the northern North Island between Lat. 34^o and 38^{o}S*.* At its range limits, night frosts and chilling temperatures below 5^{o}C are a common occurrence during winter. Although *Avicennia* is mildly frost tolerant, both factors are considered important in determining the southern limit of this species in NZ. Over a 7 month period, including winter, we investigated the course of changes in foliar chlorophyll content and of impacts on the photosynthetic apparatus of *Avicennia* sun and shade and leaves. Marked decreases in the maximum potential of photosystem II (PSII) efficiency, net CO_2 assimilation rates and stomatal conductance were evident in all leaves. The extent of chlorophyll bleaching and reduced PSII efficiency in the sun leaves was consistent with photoinhibitory damage (chlorophyll a + b content declined to 76.3% and PSII efficiency to 43.7% of start values). It was concluded that physiological performance in *Avicennia* is significantly depressed by cold winter temperatures, and that critical damage can be sustained at temperatures above freezing level.

P1812. Effects of plant growth and photo-oxidative stress on leaf senescence of *Quercus crispula*

K. Ono, T. Hara;
The Institute of Low Temperature Science, Hokkaido University, Sapporo, Japan.

To investigate how plant growth and photo-oxidative stress affect leaf senescence, *Quercus crispula* seedlings were grown from seeds in growth chambers in combination of two light intensities and two temperatures. The photosynthetic rate, Fv/Fm, amount of xantophylls and dry weight of the seedlings were measured for indices of leaf senescence, photo-oxidative stress and plant growth. From the early stage of leaf senescence, Fv/Fm value was lower and the amount of xanthophylls and de-epoxidation rate were higher in plants grown under low temperature with high light than those in other growth conditions. The photosynthetic rate was higher in the early stage of senescence but decreased to a great extent in plants grown under high temperature with high light, with a considerable increase in plant dry weight. It was suggested that leaf senescence was affected by photo-oxidative stress under low temperature with high light and by plant growth under high temperature with high light.

P1813. Effect of Different Air and Root-zone Temperatures on Nitrogen Fixation and Nodulation of Annual Medics of Iran

M. Amini Dehaghi[1], K. Azizi[2], A. Rezaeinodehi[1];
[1]Faculty of Agricultural Sciences,University of Shahed, Tehran, Islamic Republic of Iran, [2]Faculty of Agriculture, Lorestan University, Khoram Abad, Islamic Republic of Iran.

Three annual medic cultivars (Medicago polymorpha cv. Santiago, Medicago radiata cv. Radiata, and Medicago rigidula cv. Rigidula), were evaluated for symbiosis traits under three levels of day/night air temperatures (DNAT, 15/10, 20/15, and 25/20 ±0.2°C) and four root-zone temperatures (RZT, 5, 10, 15, and 20±0.2°C). The result showed that low root zone temperature (RZT) and day/night air temperature (DNAT) had a severely reduction effect on root length, root dry matter and nodule formation. Plants did not produce any nodule in the root at 5°C RZT and all DNATs. The plants grown at RZT ranging from 10 to 20°C were found to fix some nitrogen. The 10°C RZT seem to be a thermal critical point for Medicago spp. nodulation and N2 fixation. DNAT also had the same effect on plant nitrogen fixation M. rigidula performs well in nodule formation and nitrogen fixation at low RZT. Therefore M. rigidula is probably the most promising for the production of herbage at low temperature. M. polymorpha was found to have a significant performance in moderate temperatures but was also found to be the most widespread species and thus may be of high priority in cultivar development.

P1814. Antifreeze Proteins Modify the Freezing Process in Planta

M. Griffith[1], C. Lumb[1], S. B. Wiseman[1], M. Wisniewski[2], R. W. Johnson[1], A. G. Marangoni[3];
[1]University of Waterloo, Waterloo, ON, Canada, [2]U. S. Department of Agriculture, Agricultural Research Service, Kearneysville, WV, United States, [3]University of Guelph, Guelph, ON, Canada.

The goal of this study was to determine how AFPs reduce freezing injury in cold-acclimated winter rye plants. Antifreeze activity was present in guttate obtained from cold-acclimated winter rye leaves, indicating that the AFPs are soluble in the apoplasm and can bind to the surface of intercellular ice. As shown by infrared video thermography, AFPs had no effect on supercooling of the leaves, but AFPs did lower the freezing temperature of the leaves by 0.3 to 1.2°C when an ice nucleator was present. In vitro studies showed that apoplastic proteins extracted from cold-acclimated winter rye leaves inhibited the recrystallization of ice and also slowed the rate of migration of ice through solution-saturated filter paper. We found that lactate dehydrogenase activity was higher after freezing in the presence of AFPs, but the same effect was obtained by adding bovine serum albumin, and that AFPs had no effect on unstacked thylakoid volume after freezing and thawing. We conclude that rye AFPs have no cryoprotective activity, rather they interact directly with ice *in planta* and reduce freezing injury by slowing the propagation and recrystallization of ice in the tissues.

P1815. Comparing photosynthetic, photoprotective and water relations parameters in winter-red and green phenotypes of *Cistus creticus*

P. Karageorgou, E. Levizou, **Y. Manetas**;
University of Patras, Patras, Greece.

The foliage of a considerable number of individuals in *Cistus creticus* turns red during winter after accumulation of anthocyanins. In contrast, other individuals occupying the same habitat remain green throughout the year. When green, the leaves of both phenotypes have similar photosynthetic pigment levels, water potential and stomatal conductance, but PSII effective photochemical yield and corresponding electron transport rates are slightly lower in winter-red phenotypes. When redness appears in winter, red phenotypes display lower xanthophyll cycle pools and lower stomatal conductances, but similar water potentials, PSII effective photochemical yields and electron transport rates. Maximum PSII yield is high and similar through out the year. We suggest that subtle intraspecies differences in photosynthetic rates may become critical under low temperatures, leading to the development of an anthocyanic, photoprotective screen in the most sensitive individuals.

P1816. Regulation of Chilling on the Expression of Chloroplast ATP Synthase and its Relation to Photosynthesis in Rice

Z. Guo, Z. Miao, G. Wang, S. Lu;
College of Life Science, South China Agricultural University, Guangzhou, China.

The objective of this study is to investigate the regulation of chilling on chloroplast ATP synthase and its relation to photosynthesis in rice. Photosynthetic rate of rice was significantly reduced under low temperature (8 °C), but chilling-tolerant cultivar remained at higher level than chilling-susceptible cultivar. Chloroplast ATP synthase activity in chilling-tolerant cultivar was not affected, while that in chilling-susceptible cultivar decreased under chilling. *atpI-atpH-atpF-atpA* transcripts were significantly reduced at low temperature after treated for 1 to 5 d. However,*atpB-atpE* transcripts showed different patterns. The large transcripts with strong signal were not affected by chilling, while the small and weak transcripts were reduced by chilling. *rbcL* transcript was not affected by chilling. Western blot analysis revealed that the protein contents of subnuit Ůand III and Rubisco large subunit were not affected under chilling. ABA, sucrose, H_2O_2, paraquat, Ca^{2+}, EGTA, $LaCl_3$ had no influence on the expression. There is no difference of all above genes expression between chilling tolerant cultivar and susceptible one.

P1817. Low-temperature response of two clones of Eucalyptus globulus L.

A. Shvaleva[1], F. Costa e Silva[2], P. Scotti Campos[3], E. Breia[2], M. H. Almeida[2], M. M. Chaves[1], J. S. Pereira[2];
[1]Instituto de Tecnologia Química e Biológica, Oeiras, Portugal, [2]Instituto Superior de Agronomia, Lisboa, Portugal, [3]Estacao Agronomica Nacional, Oeiras, Portugal.

The low cold resistance of Eucalyptus globulus L. is the main factor that affects its growth and restricts the cultivation area. During cold acclimation numerous physiological changes are induced that allow plants to develop efficient tolerant mechanisms needed for winter survival. The main objective of this work was to evaluate cold resistance and capacity for cold acclimation of two highly productive E. globulus clone (ST51 and CN5) in order to understand the strategies that may provide protection at cellular level. Metabolic response to supoptimal temperatures was studied by comparing the effect of cold treatment on membrane integrity and lipid composition, activity of antioxidant enzymes, proteins, pigments (chlorophyll, b-carotene,anteroxanthin) and soluble and insoluble sugars content in leaves and roots of eucalyptus plants in control conditions (22/16ºC, day/night) and after a gradual temperature decrease period to 9/4ºC, day/night.

Cold acclimation of two E. globulus clones was achieved owing to modification in growth, membrane fluidity, activity of antioxidant enzymes, sugars content and correlate with response to water deficit.

P1818. Changes of Carbohydrate Concentration in Cuttings of Deciduous Azalea Cultivar 'Polarzvaigzne'

I. Apine, U. Kondratovics;
University of Latvia, Faculty of Biology, Riga, Latvia.

This study has focused on changes of carbohydrate contents during rooting of cuttings and on stock plant forcing in a greenhouse during the spring as a management of the stock plants.

The concentrations of reducing sugars (RS), sucrose, total soluble sugars (TSS = RS + sucrose), and starch were determined in the leaves and the stem bases of cuttings.

Overall, the patterns of carbohydrate changes were similar in forced and control cuttings. The concentrations of RS, TSS, and starch increased essentially in the leaves and the stem base of cuttings after severance. The concentration of sucrose generally fluctuated over time. In the leaves the sucrose concentration was lower than the RS concentration throughout the rooting process. After root emergence the RS, sucrose, and starch concentrations decreased initially in the stem base and later in the leaves of cuttings.

The results demonstrated that the stock plant forcing did not significantly affect the rooting process and the starch concentration was better related to the rooting of cuttings than the TSS concentration.

This study was supported by the European Social Fund.

P1819. Evidence a new glycoside ester from C*ochlearia* genus.

X. Dauvergne[1], S. Cérantola[1], N. Kervarec[2], S. Salaün[1], E. Deslandes[1], M. Bessières[1];
[1]Institut Universitaire Européen de la Mer, Plouzané, France, [2]UFR Sciences et Technique, Brest, France.

This work reports the procedure for extraction, purification, chemical characterisation and quantification of a new glycoside in halophytic plants**.** This new natural compound, 1-*O*-(2-methylbutyroyl)-ɓ-D-glucopyranoside, was isolated from the aerial parts of *Cochlearia* species, collected along coastal sites of Brittany. An HPLC method for the isolation of this compound is proposed. The crude extract of *Cochlearia* was purified using an Aminex HPX 87C column eluted with deionised water at 85°C. The structure of the product was established mainly on the basis of spectroscopic NMR data (^{1}H, ^{13}C, COSY, TOCSY, HMQC, HMBC, *J*-MOD). A simple, sensitive and selective HPLC method with UV detection (226 nm) was developed for quantification of 1-*O*-(2-methylbutyroyl)-ɓ-D-glucopyranoside. The occurrence and abundance of this glucoconjugate in *Cochlearia* genus and in other halophytic species of Brassicaceae is of interest concerning its chemotaxonomical and ecophysiological potential.

P1820. Sugar components of floral nectar in quince (*Cydonia oblonga* Mill.) cultivars

H. Déri, L. G. Szabó, Z. Orosz-Kovács, P. Bukovics;
University of Pécs, Pécs, Hungary.

The sugar composition of the floral nectar was studied in 22 mainly Hungarian local quince cultivars in 2004. The material for investigation was taken from the quince genebank of the Research and Extension Centre for Fruitgrowing, Újfehértó, Hungary. Sugars were analysed by thin layer chromatography.

The three investigated nectar sugar components were glucose, fructose and sucrose. Sucrose was present in the greatest amount in the nectar of all investigated quince cultivars. Its quantity varied from 47 (cv. 'Váli') to 75 % (cv. 'Késöi Kiskunfélegyházi'). The amount of the total nectar sugars was the lowest (159 mg/ml) in cv. 'Pear-shaped Noszvaji' and the highest (552 mg/ml) in cv. 'Kúti'. The nectar of most cultivars contained more fructose than glucose. According to the Baker-quotient (S/F+G), most of the cultivars were found to have sucrose dominant nectar. However, the nectar of the cultivars 'Mezökövesdi', 'Apple-shaped Dunabogdány' and 'Váli' was sucrose-rich.The above results are important from the viewpoint of pollination biology, apiculture and defence against fire blight.

P1821. Mobilization of raffinose oligosaccharides during seed germination

A. Blöchl, A. Richter;
Department of Chemical Ecology and Ecosystem Research, University of Vienna, Vienna, Austria.

Raffinose family oligosaccharides (RFOs) accumulate during seed maturation and are rapidly mobilized at the early stages of germination by alpha-galactosidases. We investigated the role of RFOs during germination by treating seeds of *Pisum sativum* with a potent alpha-galactosidase inhibitor (DGJ). The germination rate of seed treated with DGJ was about 50% lower than that of controls, providing evidence that RFOs act as an important energy source during the early stages of germination.

During seed maturation alpha-galactosidases are deposited in protein storage vacuoles (PSVs), which merge to greater vacuoles during seed germination. Separation of PSVs from the cytoplasm of imbibed seeds showed that RFOs are mainly stored in the cytoplasm. By using a fluorescent substrate and confocal laser scanning microscopy, we could prove that alpha-galactosidases were active in PSVs during early stages of germination. Thus, the breakdown of RFOs in germinating seeds may involve an import of RFOs into PSVs, while the resulting sucrose and galactose must be transported back to the cytoplasm for further metabolism.

P1822. Effects of water deficit on chlorophyll content, water potential and stomatal properties of Anise(*Pimpinella anisum* L.).

S. Zehtab-Salmasi[1], A. Javanshir[1], R. Omidbaigi[2], H. Alyari[1], K. Gassemi-Golezani[1];
[1]Faculty of agriculture,University of Tabriz, Tabriz, Islamic Republic of Iran, [2]Faculty of agriculture,University of Tarbiat Modarres, Tehran, Islamic Republic of Iran.

For studying the effects of soil available water (SAW) on chlorophyll content, water potential and stomatal properties of Anise (*Pimpinella anisum* L.), a greenhouse experiment with five water supply treatments (20, 40, 60, 80 and 100 % of SAW) was carried out in a randomized complete block design (RCBD) with four replications in the agricultural research of Tabriz University. The results showed that relative water content (RWC) and water potential of Anise in stem elongation and umbel appearance stages were significantly reduced when water supply decreased from 80 % of SAW. Also, there was a linear relationship between water supply and chlorophyll a and b content of leaves. Water deficit in stem elongation stage increased stomatal density, but in such conditions, the length of stomatal pores was reduced. However, water deficit had no significant effect on the width of stomatal pores. It may be concluded that low soil available water (less than 80%) affects the evaluated ecophysiological properties of Anise and therefore the growth, yield and essential oil production of this medicinal plant.

P1823. Stomatal biophysics: What has changed in 400 million years?

P. J. Franks;
James Cook University, Cairns, Australia.

Stomatal guard cells are the most complex biomechanical plant structures, yet, apart from a distinctive modification in grasses, have remained relatively unchanged in form since they appeared in the earliest vascular plants some 400 MY ago. Since the first prototype, plants have never improved on the “bending guard cell pair” as a mechanical solution for regulating the passage of gas molecules across the epidermis. However, within this design constraint there is considerable scope for altering guard cell mechanics such that the motor forces into which environmental signals are translated achieve optimal pore width for any given series of environmental modulations. Innovations in cell microprobe techniques, cell imaging and biochemical manipulation are providing new insights into the dynamic properties of guard cells and how these properties change in different environments. In support of plant diversification throughout an ever changing global climate, the stomate has undergone several key biophysical adaptations.

P1824. Where does the signal for guard cell differentiation come from?

J. Santrucek[1,2], J. Tomsickova[1], M. Simkova[2];
[1]Faculty of Biology, University of South Bohemia, Ceske Budejovice, Czech Republic, [2]Institute of Plant Molecular Biology, Ceske Budejovice, Czech Republic.

Stomata (*st*) are non-randomly distributed on the leaf surface. The underlying mechanism is attributed to two genes/signalling proteins inducing asymmetrical division of meristemoid cell. We show that the diffusion rate (DR) of water can be a factor affecting the epidermal cell fate.
Lepidium sativum and *Zea mays* were grown from seeds in mesocosm atmosphere of (i) helium with additional 21 % O_2 and 350 μ mol mol^{-1} CO_2 (HelOx) or (ii) artificial air (the same mixture with He substituted by N_2, NitOx). DR of H_2O and CO_2 is 2.6 times faster in HelOx than in NitOx. Humidity was controlled. Number and distribution of *st* were evaluated on imprints of cotyledons. Leaf anatomy gas exchange and ^{13}C discrimination ($\varphi\,^{13}$C) were investigated.
St of *L. s.* from HelOx were grouped into clusters of 2-4 while those from NitOx were distributed regularly. Rising humidity enhanced this effect. Distribution of *st* in *Z. m.* was not affected. Leaf anatomy and $\varphi\,^{13}$C indicated faster diffusion in HelOx than in NiOx leaves. The results show different signalling in differentiation of *st* in monocots and dicots and significance of DR of water vapour.
The work was supported by GAAS CR: IAA 601410505.

P1825. Reactive oxygen species (ROS) production during bicarbonate induced stomatal closure in abaxial epidermis of *Pisum sativum*

V. A. Kolla, A. S. Raghavendra;
Department of Plant Sciences, School of Life Sciences, University of Hyderabad, Hyderabad, India.

The guard cells respond strongly to signals, such as light, CO_2 or plant hormones. The presence of 2 mM bicarbonate in the incubation medium induced stomatal closure in abaxial epidermis of *Pisum sativum L* and such stomatal closure was partly prevented by exogenous catalase (CAT) and diphenylene iodonium (DPI). Exposure to 2 mM bicarbonate elevated the levels of reactive oxygen species (ROS) production in guard cells, as indicated by the fluorescent probe dichlorofluorescein diacetate (H_2DCF-DA). The ROS production reached maximum by 5 min on exposure to bicarbonate. The bicarbonate induced increase in ROS production of guard cells was suppressed by the application of CAT or DPI. The results suggest that H_2O_2 is an important secondary messenger during bicarbonate induced stomatal closure in abaxial epidermis of *Pisum sativum.*

P1826. Ionic basis of light signalling in guard cells

M. G. Roelfsema, H. Marten, K. R. Konrad, R. Hedrich;
Julius-von-Sachs Institut, Wuerzburg, Germany.

Stomata of most plants open in the light, thereby enabling uptake of CO_2 for photosynthesis. Two light signalling pathways operate in parallel in guard cells, a blue light specific pathway and one dependent on photosynthetic active radiation (PAR). The blue light pathway is initiated by two phototropin receptors and leads to activation plasma membrane H+-ATPases, while the PAR pathway involves changes in the intercellular CO_2 concentration and inhibits anion channels. In search for a possible interaction of both pathways, we conducted experiments with albino plants. Stomata of albino plants still opened in blue light, but not in red light, showing these stomata lacked the response to PAR. Recordings with intracellular micro-electrodes, on guard cells located in intact plants, revealed that blue light generated outward H+-ATPase currents of 37 pA in albino guard cells and 51 pA control cells. Apparently, this blue light-response is independent of a direct effect of PAR on guard cells.

P1827. Primary production and nutrient accumulation in two saltmarsh species, *Atriplex portulacoides* L. and *Limoniastrum monopetalum* L., in Southern Portugal

J. P. C. Neves, L. F. Ferreira, M. L. Calado, M. P. D. Simões, **L. C. Gazarini**;
Universidade de Évora, Dep.Biologia/ICAM, Évora, Portugal.

Seasonal patterns of above and belowground biomass, net primary production and nutrient accumulation were assessed in *Atriplex portulacoides* and *Limoniastrum monopetalum* in Castro Marim saltmarsh, Portugal. Sampling was conducted in five periods during 2001/2002 (autumn, winter, spring, summer and autumn).
Mean live biomass was 1808 g m^{-2} for *L. monopetalum* and 653 g m^{-2} for *A. portulacoides*. Peak living biomass, in spring for both species, was three times higher in the former, 3500 g m^{-2}, than in the latter, 1076 g m^{-2}. However, while green leaves and stems attained the highest proportion in *A. portulacoides*, woody stems were the main component in *L. monopetalum*. Belowground biomass of *L. monopetalum* was 1,7 times higher than that of *A. portulacoides*. In spite of this *A. portulacoides* showed higher root/shoot ratio along the year. Annual net primary production was 1029 g m^{-2}, for *A. portulacoides* and 4444 g m^{-2}, for *L. monopetalum*.
Nutrient concentrations showed similar patterns throughout the year. *A. portulacoides* showed lower values of N, Mg and Ca, and higher values of K, than *L. monopetalum*, while the values of Mn and P were similar.

P1828. Response of the non-CAM succulent *Augea capensis* (Zygophyllaceae) from the southern Namib Desert, to drought stress

J. W. Swanepoel[1], G. H. J. Krüger[1], H. Krüger[1], W. E. Pretorius[2], P. D. R. van Heerden[1];
[1]School of Environmental Sciences and Development, North-West University, Potchefstroom, South Africa, [2]Electron Microscopy Laboratory, North-West University, Potchefstroom, South Africa.

Plants of *Augea capensis* Thunb. were transferred from their natural habitat in the Namib desert (Namibia) to pots and subjected to drought by withholding water for 20 days. To assess drought stress effects on the physiology of the plants, chlorophyll *a* fluorescence and photosynthetic gas exchange were measured. An anatomical investigation was also conducted and ultra structural changes assessed. Following drought stress, the recovery potential of the plants was monitored.

Chlorophyll *a* fluorescence kinetics indicated a loss in photosystem II electron transport capacity during drought stress. The observed decrease in carboxylation efficiency and CO_2 saturated rate of photosynthesis provides additional support of drought-induced mesophyll limitation of photosynthesis. After 20 days of drought, cell organelles showed typical signs of drought stress, but were still intact. Large numbers of lipids found in leaves of control plants were absent in drought-stressed plants. Following re-watering, a gradual recovery of photosynthetic capacity was observed.

P1829. The study of protein content and gel electrophoresis in mycorrhizal symbiosis *Pisum sativum* L. with *Glomus etunicatum*

S. Saadatmand, F. Fallahyan, H. Fahimy, N. Alimohamadloo;
Azad university , Science and research branch, Tehran, Islamic Republic of Iran.

In this research we studied the effects of mycorrhization on protein content and gel electrophoresis of roots , leaves , and seeds in *Pisum sativum* . After reproduction of *Glomus* with *Sorghum spp.* and *Zea meys* that are susceptibility of mycorrhization , *Pisum sativum* were cultivated in medium contains inoculum of *Glomus* .Results of assay the proteins with Bradford methods show that at the eighth weeks , protein content of roots , leaves and seeds of mycorrhizal plant in compare with the control plants are higher.

Also the separation of electrophoretic bands of leaves , roots and seeds proteins in SDS-PAGE gels have shown the new bands in mycorrhizal samples ; for roots in three main regions , 18.4 to 25 kD_a and second between 35 to 45 kD_a , and the other between 66.2 to 116 kD_a , for leaves in two main regions , the firsth 14.4 to 25 , and the other between 25 to 45kD_a , for seeds in four main region , 14.4 to 18.4kD_a , 18.4 to 25kD_a , 35 to 45 kD_a and 45-66.2kD_a.

P1830. Some Ecophysiological Properties of Tree Seedlings

M. S. Djukic, D. Djunisijevic;
Faculty of Forestry, Belgrade, Serbia and Montenegro.

Drought, extreme temperatures, air pollution and other stress factors, lead to significant modification in ecosystems and affect the reduction of the number of tree species that can be grown.

The investigation was carried out on the seedlings of *Picea abies* Kars*t*., the main species of coniferous forests, *Fagus moesiaca* Domin.Maly.Czeczott., the most widely distributed species in Serbia, *Betula pendula* Roth., a fast growing, pioneer species with very wide ecological adaptability and *Acer heldreichii* Orph., an endemic and relic of Balkan Peninsula.

Physiological parameters, water potential, transpiration intensity and the content of biogenous elements (N, P, K, Ca, Mg) in leaves were measured as well as growth parameters.

Variability of ecophysiological characteristics between individuals of the same species on the same ecological site, show the presence of genetic specifity. The most xeromorphic leaves were those of beech from Mt. Kopaonik and the least of leaves of Balkan maple.

The application of the researched ecophysiological criteria can accelerate and develop the selection procedures tree species for the needs of seedling production.

P1831. Preliminary data about heavy metals accumulation in Xanthoria parietina from Madrid Province

M. T. Solas[1], M. C. Molina[2], C. Vicente[3];
[1]Departamento de Biología Celular, Facultad de Biología, UCM, Madrid, Spain, [2]Departamento de Matemáticas y Física y CC. Naturaleza, ESCET, URJC, Mostoles, Spain, [3]Departamento de Biologia Vegetal I, Facultad de Biologia, UCM, Madrid, Spain.

Numerous studies have documented the ability of lichen to accumulate trace elements from the environment. This characteristic has been used to indicate exposure to trace elements along highways, near smelters, in industrial areas, etc. Thanks to their much higher accumulation factors, related to characteristic thallus structure and longer life, lichens are more advantageous bioindicators than plants.

Several studies have demonstrated the presence of heavy metals in particles trapped in the cell wall, thought the damage in the thallus seems to occur as a consequence of uptake of heavy metals into cells.

Xanthoria parietina is a pollution tolerant lichen, collected of different areas from Madrid Province. These samples were analyzed by conventional scanning electron microscopy (SEM) equipped with a LINK eXL X-ray dispersion detector for microanalysis of the occurrence of heavy metal particles.

The analysis of the samples indicates the presence of Ti, Fe, Si, Cr and Al as main components of the elements retained in the cell wall. It has been discussed if these heavy metals can be contaminants or particles belonging to the substrate in which the lichens live.

P1832. Diversity in functionally important traits of promiscuous group of *Sesbania*-rhizobia and their colonization potential to ecologically diverse habitats of a semi-arid region of India

R. S. Sharma[1], A. Mohmmed[2], V. Mishra[2], C. R. Babu[1,3];
[1]Centre for Environmental Management of Degraded Ecosystesm, University of Delhi, Delhi-110 007, India, Delhi, India, [2]Department of Botany, University of Delhi, Delhi, India, [3]Department of Botany, Delhi, India.

Diversity in functional traits of 28 root- and stem-nodulating bacterial isolates of *Sesbania sesban*, *S. aegyptica* and *S. rostrata* inhabiting 6 ecologically distinct sites of semi-arid Delhi region was analysed. The isolates were highly promiscuous among *Sesbania spp*. and formed morphologically similar nodules differing in symbiotic properties. 16S rDNA sequence analyses revealed that root nodulating isolates belong to *Sinorhizobium saheli*, *S. meliloti* and *Rhizobium huautlense* whereas *Azorhizobium caulinodans* nodulate the stem. *Sinorhizobium spp*. dominate as microsymbiont partner of *Sesbania* in Delhi region. Grouping of isolates into types / clusters based on LPS and NPC-PCR analyses suggest its significance in circumscription of the taxa. However, subtypes and subclusters showed their sorting across the ecological gradients. Enormous diversity in LPS profiles and high specificity of phages might be result of environmental selection pressures operating in ecologically distinct habitats. Effective promiscuity of sesbanias and variations in functionally important traits of rhizobia contribute to wide ecological amplitude of the legume host.

P1833. Effects of vesicular arbascular mycorrhiza (*Glomus etunicatum*) on the chlorophyll content , nodulation and growth parameters in *Pisum sativum* L .

F. Fallahyan, S. Saadatmand, N. Alimohamadloo, H. Fahimy;
Azad university , Science and research branch, Tehran, Islamic Republic of Iran.

Endomycorrhizal symbiosis {vesicular arbascular mycorrhizae) increases the rate of growth and uptake some of elements in plants . In this research , the effects of pea plants mycorrhazation on the growth parameters , chlorophyll content and nodulation investigated .in this purpose , *Glomus etunicatum* seperated of infected soils and pured . Pea plants were cultivated in a medium contains inoculum of *Glomus* .The study of symbiosis and growth parameters performed in sixth , eigth and tenth weeks after inoculum .At this time the number of nodules counted and its size in the control plants roots and mycorrhizal plants roots measured . In compare with the control plants , growth parameters such as leaf numbers , leaf area , pods lenght , flower numbers , number of seeds , dry weigth of roots , leaves and seeds , chlorophyll content in mycorrhizal plants increased . As well as the number of nodules and its size was higher than the control plants .

P1834. Influence of sulphur nutrition on cadmium induced changes in photosynthetic rate and its related variables in moongbean

N. A. Anjum, I. Diva, A. Ahmad, S. Umar, M. Iqbal;
Jamia Hamdard, New Delhi, India.

Mungbean (*Vigna radiata* L. Wilczek) is a potential crop in the Indian sub-continent due to its ready market, nitrogen fixation capability, early maturity and ability to fit well into a crop rotation programme. In the present investigation, an attempt was made to work out the ameliorative effect of sulphur in cadmium toxicity of mungbean. Mungbean was grown in earthen pots at two levels of sulfur (S) viz. 0 and 40 mg S/kg soil and four levels of cadmium (Cd) viz. 0, 25, 50 and 100-mg Cd/kg soil. All the cadmium levels, when applied alone, severely reduced the photosynthetic rate and its related variables; the extent of reduction increased with increase in Cd level. A concomitant supply of sulphur (i.e. S + Cd) significantly ameliorated the toxic effect of cadmium and improved the photosynthetic efficiency and the related variables. These findings demonstrate the nutritional importance of sulphur in plants against the cadmium toxicity.

P1835. Antioxidant response of BY-2 *Nicotiana tabacum* cells to cadmium stress

P. L. Gratão[1], F. R. Capaldi[2], R. F. Fornazier[1], V. A. Vitorello[2], R. A. Azevedo[1];
[1]ESALQ, Piracicaba, Brazil, [2]CENA, Piracicaba, Brazil.

Cadmium can induce the production of reactive oxygen species (ROS) and can cause serious damage to cellular metabolism. Antioxidant enzymes are capable of scavenging heavy metals induced ROS. We have observed alterations in SOD, CAT and peroxidases activities, but a significant increase in GR activity in tobacco BY-2 cells exposed to cadmium (Cd). The results suggest that in BY-2 cells the main defence system to Cd stress is variable during the heavy metal exposure time. The synthesis of GSH, which is used in the synthesis of phytochelatins and substrate for GST is evident during the onset of the stress with CAT and peroxidases taking over the antioxidative responses once the stress becomes severe. The study of such responses may allow the evaluation levels of tolerance, specificity of the response to levels of pollution in the environment. These data may be useful in breeding programs to select tolerant plants and be used in phytoremediation, by reducing the amount of heavy metals in contaminated soils. Financial support by FAPESP, CAPES and CNPq.

P1836. Vegetation studies on a sediment contaminated with chromium (1998-2003)

G. Lakatos, P. Keresztúri, A. Tóth, I. Mészáros;
Debrecen University, Debrecen, Hungary.

In-situ phytostabilization has special significance since it can reduce the dangers associated with the potential toxicity of bioavailable heavy metals. Since vegetation forms a green cover the approach is environmentally attractive and cost-effective.

We present results on the floristic composition, vegetation pattern and the chromium content of the sediment and plants in the units of an abandoned secondary sedimentation pond system of a leather company in Kunszentmárton (Hungary)

In 1998 42 plant species were found in this area, while in 2001 46 ones were determined. Most of these plants found were belonged to the families Compositae and Graminae. In 1998 the 80 % of the area was covered by plants the 80 % of which were five species: Phragmites australis, Bolboschoenus maritimus, Echinochloa crus-galli, Typha angustifolia, Atriplex hastata and Aster sedifolius. Most species found in the area were competitors and native weed species.

P1837. Effects of heavy metal pollution on higher plants, and investigation their availability in the view of phytoremediation

B. Bartha, L. Erdei;
Department of Plant Physiology, University of Szeged, Szeged, Hungary.

Phytoremediation, removal and disposal of environmental pollutants with plants utilizes the natural ability of plants to uptake and accumulate different substances in their tissues during their mineral nutrition. Some species can remove large quantities of heavy metals from their environment.

Different plant species were used in our experiments: Indian mustard (*Brassica juncea* L. Czern.), broadleaf cattail (*Typha latifolia* L.), and sunflower (*Helianthus annuus* L.).

Hydroponically grown plants were treated with 100 µM zinc, cadmium or copper for one week. After the treatment metal ion accumulation in the shoot and the root by atomic absorption spectroscopy and chlorophyll a and b levels were measured. Plants accumulated metal ions preferentially in their roots. Copper treatment had a particularly drastic effect on the root system. Treatments caused a decline in chlorophyll levels and inhibited the growth of plants. The role of antioxidant enzymes, such as catalase, peroxidase, superoxide dismutase, glutathione reductase, and glutathione-S-transferase were also investigated.

P1838. Ecological & biochemical peculiarities of plant resistance to oxide and lead stress

O. I. Kosyk, L. Batsmanova, A. Okanenko, N. Taran;
National Taras Shevchenko University, Kyiv, Ukraine.

The quantity of available heavy metals in soil is increased greatly in industrial areas and being uptaking by plants they induce toxic and adaptive responses. One of the first unspecific reactions in development of the general adaptive syndrome is an activation of lipid peroxidation processes. Therefore experimental plants *Triticum aestivum* L. were sprayed at tillering stage by $Pb(NO_3)_2$ or H_2O_2 solution twice. Data obtained showed that lipid peroxidation was activated in both variant of experiment. Lead treatment caused glycolipid component increase, especially monogalactosyldiacylglycerol, whereas H_2O_2 caused it content decrease accompanied by sulphoquinovosyldiacylglycerol accumulation. We consider their role in adaptation processes to be connected with homeostasis fluidity of photosynthetic membranes and general adaptive reaction of agrophytocenose to anthropogenic pollution.

P1839. Ni, Pb, Zn concentrations, peroxidase activity and chlorophyll content of some trees in Istanbul (Turkey)

H. Ozden[1], G. Baycu Kahyaoglu[1], D. Tolunay[2];
[1]Istanbul University Faculty of Science, Istanbul, Turkey, [2]Istanbul University Faculty of Forestry, Istanbul, Turkey.

In this investigation, concentrations of Ni, Pb and Zn have been measured in soil and in the *Acer, Aesculus, Populus*, and *Robinia* leaves that were collected from the urban sites of Istanbul (Turkey). Peroxidase activity (POD) and chlorophyll content (Chl) were determined to observe some ecophysiological changes in leaves. Concentrations of the elements, POD and Chl showed variations depending on the tree species and sites. Highest Zn (593 mgkg^{-1}dw) was found in *Populus*; highest Ni (5,3 mgkg^{-1}dw) and Pb (29 mgkg^{-1}dw) were found in *Robinia* and *Aesculus*, respectively. In soil samples, highest Ni, Pb and Zn concentrations were determined as 45, 1121 and 529 mgkg^{-1}dw. Lowest Chl (0,68 mgg^{-1}fw) and highest POD (840 φAg^{-1}fwmin) were detected in *Acer.* We have defined a significant positive correlation between Pb-POD in *Populus* (<0,05), and between Pb-Zn in *Acer* and *Aesculus* (<0,01). Significant negative correlations were observed between Pb-Chl and Chl-POD in *Aesculus*. Investigated species are considered to have different tolerance levels to heavy metals. The data obtained shows that, Chl and POD may be used as heavy metal stress biomarkers in the urban trees.

P1840. Regulation of antioxidant activity in lead treatment Soya plants by sulphur compounds

O. Sytar, A. Kosyan, N. Taran;
National Taras Shevchenko University, Kyiv, Ukraine.

Soya plants were grown with or without sulphur in nutrition medium. Oxidative stress was induced by treatment of 14 day Soya shoots with 0,5mM $Pb(NO_3)_2$. MDA content increased in the plants of both variants on the six hour of Pb stressor influence. SOD activity was found to be depressed by 12% in plants grown without sulphur fertilization but it returned back to control in 24 hours. On the contrary, plants grown with sulphur addition had SOD activity increased by 17% in six hours and by 22% in 24 hours. Free thiol content decreased in six hour in treated plants of the two variant. Plants grown without sulphur showed tendency to decrease of free and protein thiol content in 24 and 48 hour. Content of protein thiols in Soya plants grown with sulphur in nutrition medium was much higher than in plants grown without sulphur. Protein thiol content decreased in treated plants in six hour of Pb stressor action, but became stabilized in 24 and 48 hour. The role of sulphur compounds is Soya plants resistance to oxidative stress caused $Pb(NO_3)_2$ treatment discussed.

P1841. Copper mine waste and Cu, Fe, Ni, Pb accumulation in some plant species

G. Baycu Kahyaoglu[1], S. Guran[2], D. Tolunay[3], H. Ozden[1];
[1]Istanbul University Faculty of Science Department of Biology, Istanbul, Turkey, [2]European University of Lefke Faculty of Agricultural Sciences and Technology, Lefke Mersin 10, Turkey, [3]Istanbul University Faculty of Forestry Department of Soil Science and Ecology, Istanbul, Turkey.

CMC (Cyprus Mining Corporation) area is located in the northwest coast of Cyprus (Lefke, Gemikonagi). CMC operated copper mine until 1974, but the spread out nature of the facility left widespread piles of tailing deposits of hazardous waste and heavy metal accumulation caused soil and water pollution. In this study, we aimed to determine tolerant plant species of this area and Cu, Fe, Ni, Pb concentrations in plants and soil samples. *Acacia cyanophylla*, *Asparagus* sp., *Atriplex semibaccata, Juncus* sp., *Phagnalon rupestre, Pistacia terebinthus, Polygonum equisetiforme, Tragopogon sinuatus* were detected as naturally growing plant species around a selected copper flotation tailing pond. Accumulations of Cu (74,9-282,6 mgkg^{-1}dw) and Fe (674,2-767,4 mgkg^{-1}dw) were found high in the above ground parts of *Acacia, Atriplex* and *Juncus.* Highest soil concentrations were determined as 891,1 mgkg^{-1}dw Cu and 1712,5 mgkg^{-1}dw Fe, respectively. Ni and Pb concentrations were found quite low. We assume that *Atriplex, Acacia* and *Juncus* may be thought as tolerant and bioindicator species, which may also be used for phytoremediation to recover the contaminated CMC area.

P1842. The protective effects of gibberellin and ascorbic acid against nickel-induced oxidative damage in soybean plants

H. Fahimi, S. Saeidi Sar, R. A. Khavari-Nejad;
Science and Research Branch ,Islamic Azad University, Tehran,
Islamic Republic of Iran.

The interactive effects of nickel (Ni) and ascorbic acid (AsA) and gibberellin (GA3) on soybean plants (Glycine max L. cv. Union × Elf) were examined. One - week - old hydroponically - grown seedlings were exposed to NiCl2 , 6H2O (0.5 mM),with or without AsA (1 mM) or GA3 (0.05 mM) or AsA (1 mM) + GA3 (0.05 mM), for 5 days. Ni toxicity symptoms, such as formation of reddish - brown mottled spots on the leaf blade, observed in Ni - treated plants. Interestingly, with application of GA3 + AsA, this symptoms did not appear in Ni - streesed plants. Ni suppressed biomass production and reduced chlorophyll content . An enhanced level of malondialdehyde and changes in the activities of catalase (CAT) and guaiacol peroxidase (GPX) indicated that Ni caused oxidative strees. The Ni -treated plants that exposed GA3 + AsA exhibited much better growth. Interaction of AsA and GA3, prevented the decrease in chlorophyll content and lipid peroxidation as well as increasing the activities of CAT and GPX.
This results suggest that GA3 + AsA causes to reduce the negative effects of Ni damage in G. max L. , but more research is needed to elucidate the precise interactive role they played as antioxidants.

P1843. Changes in antioxidant enzyme activities in *Eichhornia crassipes* under heavy metal stress

V. J. Odjegba;
University of Lagos, Akoka - Yaba, Lagos, Nigeria.

Plantlets of *Eichhornia crassipes* were exposed to various concentrations (0, 0.1, 0.3, 0.5, 1.0, 3.0 and 5.0 *mM*) of 8 heavy metals (Ag, Cd, Cr, Cu, Hg, Ni, Pb and Zn) hydroponically for 21 days, and spectrometric assays for total activity of catalase, peroxidase, polyphenol oxidase and superoxide dismutase in the leaves were studied. Plants were harvested at regular intervals of 1 week and prepared for the enzyme assays. At each time-point data referred to metal treated plants were compared to data of untreated ones (control). There was no significant difference in enzyme activity of the control and those treated with 0.1*mM* of the heavy metals studied (except Hg). Generally, the antioxidant activities increased with increase in metal concentration and exposure duration. The authors concluded that heavy metals induced oxidative stress and responses of antioxidant enzymes were proportional to the duration of exposure and metal concentrations.

P1844. Cu,Zn-SOD in *Chlamydomonas gloeogama* and Specific Detection of Its Gene by a PCR-Based Method.

S. Nuchadomrong, G. Saipun;
Faculty of Science, Khon Kaen province, Thailand.

This work demonstrates the first evidence for Cu,Zn-SOD in *Chlamydomonas gloeogama*. The studies were conducted at the protein and DNA levels. With modified native PAGE and activity staining in the presence of H_2O_2 or H_2O_2 plus KCN, two novel Cu,Zn-SOD isozymes were disclosed among Fe-SOD isozymes. Genomic DNA of *C. gloeogama* was amplified by using primers designed from the highly conserved region of tomato Cu,Zn-SOD cDNA. PCR at various Mg^{2+} concentrations showed that the 200-bp fragment should be the specific PCR product. The primers were also used in amplification of Cu,Zn-SOD gene fragments from tomato genomic DNA obtaining 700-bp products. For probe preparation, DIG-labeling on the 700-bp products was achieved by PCR method. The 200-bp amplified fragment of the algal DNA stringently hybridized to the DIG-labeled probe, thus, demonstrating homologous sequences. On the DNA homology rationale, CuZn-SOD gene was figured out in *C. gloeogama*.

P1845. Water Use in Tank and Atmospheric Bromeliads of a Seasonally Dry Forest in Mexico

C. Reyes Garcia, H. Griffiths;
University of Cambridge, Cambridge, United Kingdom.

We analyze traits that allow the coexistence of different epiphytic life forms with contrasting strategies for resource acquisition and morphologies. Epiphytic members of the Bromeliacea have a vast radiation of morphologies that represent two contrasting ecological strategies, tank and atmospherics. These life forms coexist in a wide range of environments, even though physiological differences and morphological differences have been described. We characterized a community from a seasonally dry tropical forest that has a prolonged 8 month drought, during which dew is the only source of water, and measured their seasonal photosynthetic performance. We found that the tank species have most of their photosynthetic activity during the rainy season; our data suggests that these species can intercept dew efficiently to allow their survival during the prolonged drought, counterbalancing their high water loss, compared to the atmospherics. The more drought enduring atmospheric species have most of their activity during the beginning of the dry season, when the dew constitutes their main water source.

P1846. Vertical distribution, composition and diversity of vascular epiphytes along a spatial gradient in Bogotá city, Colombia

C. Gil Sáenz, M. Diazgranados;
Herbarium Pontificia Universidad Javeriana, Bogotá, Colombia.

Studies about epiphytes diversity and distribution have been made in forests, but there are just a few made in cities. We analyzed how vertical distribution, composition and diversity of vascular epiphytes change along an East-West spatial gradient of 4 Km in Bogotá, between two mountain chains. The gradient was divided into 10 transects of 400 m long, with 3 replications (total: 40 transects). The phorophytes were subdivided in 5 vertical zones. We found 633 epiphytes individuals of 4 families (Bromeliaceae, Polypodiaceae, Acanthaceae and Araliaceae) and 9 species, growing on 175 phorophytes of 10 species. The most abundant species were *Pleopeltis macrocarpa* (55.45%) followed by *Tillandsia incarnata* (36.33%). There were differences in the vertical distribution between families. Bromeliaceae prefers the medium and high zones of the canopies (2nd, 3rd and 4th zone), whereas the other families grow below those (1st, 2nd and just a few in the 3rd zone). There is a notable increase of diversity and richness towards the East. We explain this because the mountains in the East could represent a continent for dispersion of seeds.

P1847. Strongly and weakly expressed crassulacean acid metabolism in orchids of Panama

K. Silvera[1], L. S. Santiago[2], K. Winter[1];
[1]Smithsonian Tropical Research Institute, Panama, Panama,
[2]University of California, Berkeley, CA, United States.

We investigated the occurrence of crassulacean acid metabolism (CAM) in 200 native orchid species from Panama and 14 non-native species using carbon isotopic composition (ŭ^{13}C) and compared these values with nocturnal acid accumulation measured by titration in 173 species. Foliar ŭ^{13}C showed a bimodal distribution with the majority of species exhibiting values around -28‰ (typically associated with the C_3 pathway), or around -15‰ (strong CAM). Even though thick leaves were related to ŭ^{13}C values in the CAM range, some thin-leaved orchids were capable of CAM photosynthesis when titratable acidity measurements were performed. With the majority of species in this study being epiphytes, we found that many species within the C_3 isotopic range were capable of significant acid accumulation at night. Of 128 species with ŭ^{13}C more negative than -22‰, 42 species showed nocturnal acid accumulation per unit fresh mass characteristic of weakly expressed CAM. These data suggest that among CAM orchids, there may be preferential selection for species to exhibit strong CAM or weak CAM, rather than intermediate metabolism.

P1848. Hydraulic vulnerability of Norway spruce trunkwood assessed by the hydraulic and the acoustic method

S. Rosner[1], A. Klein[2], R. Wimmer[2];
[1]Institue of Botany, BOKU, Vienna, Austria, [2]Institue of Wood Science and Technology, BOKU, Vienna, Austria.

Juvenile wood is not much appreciated by the wood industry because of its poor mechanical properties and its shrinkage behavior, but it may fulfill important physiological functions within the living tree stem. Two different methods to asses the hydraulic vulnerability of juvenile and mature Norway spruce (*Picea abies* (L.) Karst.) trunk wood were compared. Vulnerability curves were either based on the percent loss of conductivity *versus* pressure application using a pressure collar (hydraulic method) or on the cumulated acoustic emissions *versus* the relative loss of water (acoustic method). Acoustic emissions were detected in the high-frequency range of 100 kHz to 1 MHz during drying of sapwood samples at defined temperatures. Concerning the hydraulic method, juvenile wood showed lower hydraulic capacity but was less sensitive to dehydration than mature wood. Acoustic emission testing provided additional information about anatomical characteristics of the sapwood samples. The number of acoustic emissions detected in juvenile wood was much higher than in mature wood, indicating a higher number of tracheids per wood volume.

P1849. Synchronization and asynchronization of stem diameter changes during night transpiration in quercus crispula

E. Kato[1], k. yoda[2];
[1]Hokkaido University, Sapporo, Japan, [2]Ishinomaki Senshu Univeristy, Ishinomaki, Japan.

To evaluate water movement in tree stem, we setup eight opto-electronic dendrometers on the different parts of the stem from breast height to the peripheral region of crown of Quercus tree (6m height). We examined the changes of stem diameter during night time to avoid the effect of photosynthesis on water movement driven by the transpiration of leaves, and then described whether these diameter changes are synchronized or not among the eight measuring parts of stem.

In addition to the diurnal change of stem diameter (shrinkage in the day and swelling in the night), each stem showed short time diameter changes in the scale of 5 to 10 minutes, and the changes along time sequence are summarized with several types of synchronization levels among stems. Parallel directional changes, reciprocal directional changes, and independent directional changes were found depending of time periods, and these patterns indicate time dependent movement of internal water content of tree stems and its locality within tree parts.

P1850. Effects of low vigour-rootstocks on water relations and hydraulic architecture of seedlings of Olea europaea L.

F. Raimondo[1], M. Lo Gullo[1], A. Nardini[2], S. Salleo[2];
[1]Dipartimento di Scienze Botaniche, Messina, Italy, [2]Dipartimento di Biologia, Trieste, Italy.

The research was aimed at studying water transport and the role of rootstock in the hydraulic architecture and water relations of young olive plants either self-rooted or obtained by grafting two cultivars i.e. Leccino"Dwarf" (LD) and Leccino Minerva (LM). The former, is characterized by low vigour and tolerance to low temperatures. Water relations parameters like diurnal time course of leaf conductance to water vapour (gL), water potential (YL) and leaf osmotic potential at full turgor (Ypo), were measured during the summer period as well as the vulnerability to cavitation of 1-year-old stems and xylem conduit dimensions. Ypo measured in LD plant was about -2.5 ± 0.06 MPa in July and nearly the same in September. LM plants showed significantly less negative Ypo (Ypo = -2.07 ± 0.11 MPa). The water potential triggering stem cavitation (YCAV) was -1.7 MPa for LD plants but only -1.1 MPa in LM ones. Our conclusion is that dwarf olive clones (LD) seemed to be more resistant to drought than LM. These results are discussed in terms of water management of olive orchards and of mechanisms adopted by dwarf plants to resist seasonal water stress.

P1851. Xylem transport in stands of the common reed (*Phragmites australis* TRIN ex Steudel) growing in brackish water

I. Erichsen, S. Stiller, M. Fritz, R. Ehwald;
Humboldt-University, Berlin, Germany.

Water transport studies were carried out at Hiddensee (baltic sea) on a stand growing in brackish water. When intensively transpiring shoots were excised, stomata closed within 10 min. Xylem sap was collected using a hand-driven air pump. After excision the xylem sap rised from the sectioned internode vessels into the intact ones of the next internode within 1-2 min. Intact vessels above the sectioned internode remained sap-filled even after wilting of the leaves (osmotic pressure about 2 MPa), thus proving a strong cavitation barrier. Only a few culms of a dense stand were found to import acid fuchsin via the rhizome, after a culm was detopped under the dye solution and its xylem was connected with a reservoir of this solution. Some of the stained shoots were distant by more than 3 m from the dye infusion site. Obviously most shoots kept their water balance by own water uptake using adventive roots at the basal nodes. No dye entered the xylem at the root basis of the transfused culms, although the water potential of the brackish substrate was < -0.6 MPa. Results show, that sap flow can proceed against a strong osmotic force in the absence of a cohesion tension.

P1852. Cavitation events or artefacts? Ultrasonic signals emitted from conifer sapwood sections

S. B. Kikuta, B. Kartusch;
Institute of Botany, University of Natural Resources and Applied Life Sciences, Vienna, Austria.

During dehydration, radial sapwood sections of *Juniperus virginiana* L. (Cupressaceae) produced ultrasonic acoustic emissions (UAE). Such signals are commonly considered to result from cavitation events in water-conducting elements. Varying settings of selected parameters, e.g. contact force between acoustic emission sensor and sample, gain of the monitor amplifier, and event-time-out, influenced the number of emissions detected.

With the total gain of the ultrasound counter set at 72 to 80 dB, an amplification range usually used in UAE measurements, and the contact force at 30 N, the numbers of intact tracheids present in a section (as calculated from section thickness, tracheid length, lumen diameter, cell wall thickness) were always higher than the numbers of emissions recorded. One possible reason is sound attenuation by living parenchyma cells. With gains over 80 dB, signal production increased continuously but results are no more considered reliable due to background noise.

Problems in acquisition and interpretation of UAE data are discussed and the acoustic technique is critically evaluated.

P1853. Xylem embolism and repair: what do we really know for sure?

M. A. Lo Gullo[1], S. Salleo[2], P. Trifilò[1], F. Raimondo[1];
[1]Dipartimento di Scienze Botaniche, Messina, Italy, [2]Dipartimento di Biologia, Trieste, Italy.

Xylem cavitation and consequent embolism is a common event in the plant's life and has been recorded in stems, roots and leaves of several species. Xylem embolism has been shown to be fully or partly reversed in plants of *Laurus nobilis* L. under low transpiration, even when pressures were still substantially negative. The loss of hydraulic conductance of stems was recovered by about 50% within 20 min after cavitation had been induced. The mechanism for such a rapid refilling is largely unknown. The present study reports measurements of sucrose, glucose and fructose concentration in the cortex, secondary xylem and sap as well as of the osmotic pressure of sap in precavitated stems of *L. nobilis* prior to and during xylem refilling. Our data show that all the three sugars increased in concentration, significantly only 2 min after embolism and increased further during the 15 more minutes required for the refilling to occur. Sugars were the product of starch depolymerization. The "osmotic" hypothesis for xylem refilling is, on this basis, confirmed in terms of active solute inflow into xylem conduits from vasicentric cells, as possibly driven through a sugar/proton antiport.

P1854. Hydraulic redundancy in shrubs along aridity gradients in North and South America

C. Goedhart[1], G. Pongetti[1], M. Nordenstahl[2], S. Espino[1], H. Schenk[1];
[1]California State University Fullerton, Fullerton, CA, United States,
[2]University of Buenos Aires, Buenos Aires, Argentina.

Arid regions around the globe are dominated by shrubs with strongly segmented woody roots and stems, which often physically split apart as the shrubs mature, resulting in complete axial segmentation of the plants' hydraulic system. We postulate that axial hydraulic segmentation is a form of hydraulic redundancy, which increases the chances for survival of the whole genetic individual under water-limited conditions, but at the cost of loosing parts of the plants to drought-induced mortality. Based on this premise we hypothesized that the degree of hydraulic redundancy in shrubs will decrease along aridity gradients from arid to mesic conditions. To test this hypothesis, we documented the prevalence of morphological axis segmentation in shrubs from a variety of genera along North and South American aridity gradients located between 30° and 35° latitude. Along the same gradients we also measured axial hydraulic segmentation at the anatomical level by mapping pathways of water transport in the xylem using injected dye tracers. The results support our hypothesis that the degree of hydraulic redundancy in shrubs decreases from arid to mesic environments.

P1855. Are emboli any good? - The importance of gas in stems for oxygen diffusion and supply

J. Sorz, P. Hietz;
Institute of Botany, BOKU, Vienna, Austria.

The presence of gas in xylem conduits is known to impede water transport, but could affect sapwood oxygen supply. In times of zero sapflow or flooded soils, when oxygen can not be transported upwards with the sapflow, the only source is the oxygen stored or diffusing radially through bark and xylem. We measured radial and axial diffusion of oxygen in wood of coniferous, ring-porous and diffuse-porous trees at different water and gas contents in the laboratory. The diffusion coefficient (D) in radial direction was between 10^{-11} and 10^{-7} m^2s^{-1} and was significantly increasing with decreasing water content. Axial diffusion was one or two orders of magnitude higher. D was lowest in conifers, highest in diffuse-porous and intermediate in ring-porous hardwoods, where large vessels were mostly blocked by tyloses. Model calculations showed that at very high water content radial diffusion can be too low to assure an adequate supply of sapwood with oxygen. Also, due to the low solubility in water, ca. 150 times more oxygen can be stored in the same volume of air than in water. Thus a prime importance of gas in stems appears to be the supply of oxygen through storage and diffusion.

P1856. Rainfall absorption by the shoot of three Amazonian trees

R. S. Oliveira[1,2], T. E. Dawson[2], D. C. Nepstad[3], S. S. O. Burgess[4];
[1]Instituto Nacional de Pesquisas Espaciais, Cachoeira Paulista- SP, Brazil, [2]University of California, Berkeley, Berkeley, CA, United States, [3]Woods Hole Research Center, Woods Hole, MA, United States, [4]University of Western Australia, Crawley, Australia.

Water uptake by aerial organs is a potentially important mechanism of water acquisition by terrestrial plants in environments prone to soil water deficits. Here, we present patterns of sap flow in branches and trunks of 3 tree species in the Tapajós Forest, Amazônia (Brazil), that demonstrate direct foliar absorption of rainfall. We measured sap flow in branches and trunks of the 3 study species over a 2-year period using the heat ratio method, a sap flow technique that allows bi-directional measurement of water flow. During the first heavy rains of 2002, which occurred after a three-month dry period, reverse or acropetal flow in stems and branches of *Protium robustum* (breu), *Coussarea racemosa* (caferana) and *Manilkara huberi* (maçaranduba) were observed, a pattern that indicates absorption of water by the crown. The uptake of water by aerial parts may be advantageous for Amazonian species, because it may help reduce water stress at the sites of absorption, also supplementing soil water uptake, which in turn, can influence the performance, survival and persistence of these plants when exposed to extreme water deficits.

P1857. Refilling in Conifers at the Alpine Timberline

P. Schmid, S. Mayr;
University of Innsbruck, Innsbruck, Austria.

Refilling processes enable the removal of embolism in plant water transport systems. We studied refilling in conifers growing at the alpine timberline, which are known to exhibit excessive embolism rates during winter.

Based on conductivity and water potential measurements as well as on dye perfusions, we analysed the dynamics of refilling in Picea abies trees at the timberline. Furthermore, we studied refilling of dehydrated young trees which were re-hydrated under various conditions.

At the alpine timberline, refilling was observed between late February and the end of May. During this period, loss of conductivity decreased from about 60% to 8% and water potentials increased from -2.4 to -0.2 MPa. In experiments, trees submersed in water showed some refilling within four weeks.

Results demonstrate that refilling does occur in conifers at the alpine timberline. As soil and stem base are frozen during the refilling period, an uptake of water by needles or over the bark seems likely. This hypothesis is also supported by our refilling experiments.

P1858. The preliminary study of drought stress on sorghum collection genebank of iran

M. Narouirad[1], M. Farzanju[1], R. Abbassi[2];
[1]agriculture and natural resources research center, zabol, Islamic Republic of Iran, [2]seed and plant improvement institute karaj, karaj, Islamic Republic of Iran.

In order to study of low irrigation effect on iran sorghum collection gene bank, this germplasms with four check local planted in augment design in agriculture research station zahak - zabol . Total of germplasm derived from iran national plant genebank and number of germplasms were 128 . in this study all germplasm before panicle initiation , irrigation interrupted to harvest stage. Descreptive statistic results showed ,yield , stem diameter , panicle length and 100 seed weight had the most coefficient variation . Correlation coefficient between yield and stem diameter , panicle length and day number to flowering was significant and positive . Regression analysis by method backward indicated only stem diameter and panicle length remained in final model .Factor analysis showed three factors determined 72% from total variance among traits . Cluster analysis showed collection divided to four groups.

P1859. Effect of $CaCl_2$ on growth performance, photosynthetic efficiency and nitrogen assimilation of C*ichorium intybus* L. grown under NaCl stress

A. Arshi, M. Z. Abdin, M. Iqbal;
Jamia Hamdard, New Delhi, India.

Pot culture experiments were conducted to assess the extent of growth, photosynthetic efficiency and nitrogen assimilation of Kasni (*Cichorium intybus*) as affected by NaCl and $CaCl_2$ alone as well as in combination. Six treatments, i.e., 80 mM and 160 mM NaCl, 5 mM and 10 mM CaCl2 and 80 mM + 10 mM and 160 mM + 10 mM of NaCl + CaCl2 were given to the growing plants separately at three developmental stages, viz., the pre-flowering (30 DAS), flowering (120 DAS) and post-flowering (150 DAS) stages. Each NaCl treatment caused a significant reduction in total plant biomass, photosynthetic rate, stomatal conductance, total chlorophyll content, soluble protein content, NR activity and nitrogen content, although nitrate content increased. On the contrary CaCl2 treatment gave a favorable effect, compared to the control. The effect of combined treatments was similar to that of NaCl but less in magnitude. The combined treatments thus mitigated the adverse effect caused by NaCl.

P1860. Influence of calcium on seed germination of *Arthrocnemum indicum* under chloride and sulphate salinities

B. Gul, S. Saeed;
University of Karachi, Karachi, Pakistan.

Arthrocnemum macrostachyum **(Chenopodiaceae)** is a stem succulent perennial halophyte commonly found in the subtropical salt marshes which are frequently inundated with seawater. Seeds were collected from a coastal tidal salt march located on the Arabian sea coast, Karachi, Pakistan.

Seeds were incubated in NaCl, Na_2SO_4, KCl, K_2SO_4, $MgCl_2$, and $MgSO_4$ (0, to 1000 mM) with various concentrations of Ca^{++} (0, to 100 mM $CaCO_3$) at alternating temperature regime of 20-30 °C. Maximum germination occurred in distilled water. Low concentrations of different salts (200 mM) had little effect on germination and a further increase in salinity substantially inhibited germination. High concentrations of different salts (1000 mM) reduced seed germination substantially in *A. macrostachyum* however, application of Ca^{++} alleviated the salinity effects. Rate of germination was low at high concentrations in the absence of Ca^{++} however; the presence of Ca^{++} increased the rate of germination under saline conditions. All Ca^{++} concentrations alleviated the effect of salinity enforced dormancy in *A. macrostachyum*.

P1861. The effect of osmotic stress on lectin activity in bean (*Phaseolus vulgaris L.*) embryonic axis

N. V. Kovalchuk, L. I. Musatenko;
M.G. Kholodny Institute of Botany NAS of Ukraine, Kyiv, Ukraine.

Many studies describe the accumulation of lectins under the influence of stress factors of various origins. The lectin activity dynamic during osmotic stress caused by draught were studied. Draught lead to increasing lectin activity in twice after 1 hour and in 11 times after 4 hours in isolated embryonic axis compared to normal conditions. Several lines of evidence implicate abscisic acid (ABA) in the control of lectin synthesis. The exogenous ABA influence on lectin activity was investigated as well. The effect of exogenous ABA (0,5 mg/l) during 3 hours before draught was similar to effect of osmotic stress leading to increase of lectin activity. In control exogenous ABA caused faster and briefer increase of activity in embryonic axis. At the same time combined action of exogenous ABA and draught caused weaker and more prolonged increase of lectin activity. Exogenous ABA in these conditions (before stress) can be the way of increase osmotic stress tolerance by accumulating defense proteins such as lectins.

P1862. The effect of Ca^{2+} on growth, accumulation of nutrient elements and electrophoretic patterns in *Descurainia sophia* salt stressed

K. Kalantari, **H. Mozafari**;
International Center of Science, High Technology & Enviromental Sciences, Mahan, Islamic Republic of Iran.

Calcium plays an important role in the resistance of plants to the salt stress. The effects of calcium salts at two concentrations on *Descurainia Sophia* which were under salt stress were studied. The chemical parameters was determined by using AA method.To assess the effect of salinity and Calcium treatments on electrophoretic polypeptide pattern, plant proteins were seprated on SDS-PAGE gels. The results indicated that solutions containing 5 mM Ca^{2+} with 50mM NaCl have best effect on plant tolerance. Comparison between Polypeptide patterns showed that the Ca^{2+} effected proteins synthesis in plants. With the plants treated with 25 and 50mM NaCl, polypeptide bands (56 KDa) were more condensed than with the control. Bands of polypeptide with the MW of 66-170KDa were observed in plants treated with 25, 50 and 75 mM NaCl. These bands were not observed in plants pretreated with Ca^{2+}.

P1863. The study of some physiological responses of *Atriplex canescens* to salinity

M. Farzami Sepehr[1], M. Ghorbanli[2];
[1]Department of Biology, Faculty of Agriculture,, Saveh, Islamic Republic of Iran, [2]Department of Biology, Faculty of Science,, Gorgan, Islamic Republic of Iran.

The effect of salt stress on growth and some osmolytes production of xerohalophyte *Atriplex canescens* (Pursh.) Nutt in liquid culture solution was studied. Four weeks-old solutions grown *Atriplex canescens* plants were treated with NaCl of 0(control), 42.73, 85.47, 170.94, 256.41 and 341.88 mM in Humes nutrient solutions. The plants were grown under controlled environment . The plants were harvested after 5 weeks treatment for measurements of growth and biochemical analysis. Different growth parameters and the accumulation of different osmolytes in shoot and root were measured .

Growth not only did not decrease but also in some cases increased at salinity treatments. Treated plants tolerated at high concentrations of NaCl. At 170.94 mM NaCl different growth parameters were more than control. Root and stem proline contents increased with increasing of salinity but root protein contents were lower than control. The contents of shoot protein increased with increasing of NaCl in medium and received to high concentration at 256.41mM NaCl. Root and shoot total soluble sugar contents significantly increased with increasing of salinity.

P1864. Influence of water availability and soil acidity on free proline levels in pigeon pea.

D. M. M. Santos, A. Marin;
Universidade Estadual Paulista,UNESP, Jaboticabal, SP., Brazil.

Proline accumulation is not only associated to plants under water stress but also to the aluminium toxicity from soil acidity. Therefore, the physiological mechanisms involved in this response are possibly similar. The aim of this work to evaluate the influence of water availability and soil acidity on the levels of free proline in shoots of the pigeon pea cultivars ‘IAPAR 43-Aratã’ and ‘IAC Fava Larga’. Four days after planting in sand with no water restriction plants were transferred to pots with the soil acidity treatments (pH in $CaCl_2$ = 5.9; 5.3; 4.8 and 4.1), and then submitted to 60%, 40% and 20% of water availability. The experiment was a 2x3x4 factorial with four replications arranged in completely randomized design, with cultivars, water availability and soil acidity as factors. Under severe water restriction the cultivar ‘IAC Fava Larga’ can be considered more tolerant because of its higher accumulation of free proline. The presence of aluminium associated to severe water restriction showed a synergistic effect on the levels of free proline. (Fapesp 01/03597-0)

P1865. Screening for drought resistance in Chickpea genotypes (C*icer arietinum* L.).

A. Ganjali, M. Kafi, A. Bagheri;
Ferdowsi University of Mashhad, Mashhad, Islamic Republic of Iran.

In order to evaluate drought resistance of chickpea genotypes , an experiment was conducted during 2003 in Mashhad and Nishabour regions .34 enotypes were tested . Quantitive drought resistance indeces such as Stress Tolerance Index (STI), Stress Susceptibility Index (SSI), Mean Productivity (MP), Harmonic Mean (HM), Tolerance Index (TOL) and Geometric Mean Productivity (GMP) base on yield in stress and non stress conditions were calculated. . Results of regression analysis showed that MP,GMP,STI and HM indices have positive and high significance correlation with yield in stress and non stress conditions . Theses results indicate that MP,GMP,STI and HM are the most suitable criteria for screening drought resistance genotypes. Base on these criteria , genotype numbers of 4,16 and 19 that have the Highest yield in stress and non stress condition and resting near to vectors of drought resistance indeces like MP,GMP,STI and HM in multivariate biplot space, therefore these genotypes may recommended as drought resistance genotypes in this study.

P1866. PP2C type Phosphatase Regulates Stress-activated MAP Kinases

A. Schweighofer, V. Kazanaviciute, E. Scheikl, M. Teige, H. Hirt, I. Meskiene;
Max Perutz Laboratories, Vienna, Austria.

Protein phosphorylation is mediated by action of protein kinases and protein phosphatases in eukaryotic signal transduction. Arabidopsis has 76 different PP2C genes. We isolated and characterized PP2C-type phosphatase from Arabidopsis and identified its substrate protein kinases. The data on MAPK (mitogen activated protein kinase) specific inactivation by cluster B member of PP2C family AP2C will be presented. We provide evidence that PP2Cs display exquisite substrate specificity for precise down-regulation of stress activated MAPKs. It demonstrates the mechanism for direct MAPK inactivation through dephosphorylation of specific phospho-threonine. Mutant analysis indicate that inactivation of MAPKs depends on the catalytic activity of AP2C. Comparative analysis was performed of this phosphatase and two other Arabidopsis PP2Cs, from cluster A, ABI2 and HAB1 in their ability to inactivate MAPKs. Yeast two-hybrid screen of cDNA library with AP2C and analysis of knock out and transgenic plants lines over expressing AP2C supports AP2C function on MAPK and propose a model of AP2C action in plant cells.

P1867. Allelopathic potential of *Sorghum bicolor* L. (Moench) genotypes against weeds

I. S. Alsaadawi[1], M. H. S. Al-Ekelle[2], M. K. Al-Hamzawi[2];
[1]Office of Agricultural Researches, Ministry of Science and Technology, Baghdad, Iraq, [2]College of Education, Al-Kadysiah University, Al-Kadysiah, Iraq.

abstract

Ten sorghum genotypes were screened for their allelopathic potential against weeds. The mechanisms by which it affects weeds, the persistence of the residues phytotoxins in soil and identification of phytotoxins in sorghum residues were conducted.

All sorghum genotypes significantly inhibited emergence and growth of *Lolium tennlintum* seedlings. Giza, 15, Giza 115 and Enkath were found to be the highest allelopathic cultivars while cultivar Rabeh was the lowest. Residues of these cultivars when added to the soil at a rate of 3 and 6 g/kg soil significantly reduced seedlings emergence and growth of several weeds.

Field experiment showed that the allelopathic cultivars (Giza 15, Giza 115 and Enkath) exhibited a great ability to reduce weeds growth. The toxicity of sorghum residues persisted in soil for 10 weeks and reached its maximum at 4, 5 and 6 weeks of decomposition. Six phytotoxins (phenolic acids) were identified in the residues. The total phenolic acids were found to be higher in high allelopathic cultivars than in the low allelopathic cultivar (Rabeh).

P1868. Importance of Fertigation in new reclaimed lands in Egypt

M. T. El-Saidi;
National Research Centre,, Dokki, Cairo, Egypt.

Fertigation (ferti-irrigation) is the frequent application of appropriate amount of designed fertilizers in irrigation water or through irrigation systems. Fertilizer is added in time when the crop needs it. Sprinkler and drip irrigation has increased during the last two decades in newly reclaimed areas. With increasing usage of these systems of irrigation a corresponding increase in fertigation has taken place. Such systems result in less water usage and better uniformity than in the cases of non-uniform furrow and flood systems.

Effective fertigation requires knowledge of certain soil characteristics such as pH, EC, soil texture, type of clay, plant characteristics e.g. optimum daily water usage, nutrient consumption rate and root distance in the soil. Irrigation water quality e.g. pH, mineral content, salinity and nutrient solubility is considered. Compared to the traditional method of fertilizer application, fertigation indicates more availability of nutrients to be absorbed by active root system, greater plant growth, high dry matter production, better crop uniformity and fruit quality, lower requirements of fertilizers.

P1869. Environmental gradients expressed in San Andrés Island mangroves, Colombian Caribbean

M. F. Buitrago, L. F. Cuartas, A. Lema, L. E. Urrego, J. H. Polania;
National University of Colombia, Medellín, Colombia.

We studied the relationship between the mangrove species in San Andrés Island, Colombia, and some environmental variables such as flooding level, salinity, pH, soil depth and texture. Those variables were measured through 74 plots of 500 m^2 each one, across 20 transects with length according to the extension of the six mangrove zones in the island. In order to establish species-environment relation we used Canonical Correspondence Analysis (CCA). We found a strong correlation between *Avicennia germinans* (L.)L., and soils with higher salinity values. *Conocarpus erecta* L. and *Cocos nucifera* L. were found in the soils with higher sand percentage, the species *Phyllanthus* sp, *Annona glabra* L.*, Terminalia catappa* L. and *Ficus trigonata* L., were present in higher flooding levels environments, and a group of dry forests species was related to a coralline substrate in the mangrove of Hooker Bay. The island mangroves are dominated by *Rhizophora mangle* L.*, A. germinans, Laguncularia racemosa* (L.)C.F.Gaertn and *C. erecta*, all of them widely distributed among Caribbean mangroves. Moreover other 17 species were registered associated to these ecosystems.

P1870. Cadmium Transport in *Salsola kali* tissues

G. de la Rosa[1], H. Pelayo[2], A. Martinez[2,1], J. Peralta-Videa[1], H. Castillo-Michel[1], **J. Gardea-Torresdey**[1];
[1]University of Texas at El Paso, Texas, TX, United States, [2]Universidad Autonoma de Ciudad Juarez, Ciudad Juarez, Mexico.

Salsola kali is a desert plant worldwide distributed. This plant is a potential Cd hyperaccumulator as it concentrated about 2000 ppm Cd in leaves. X-ray data showed that thiol related compounds are involved in Cd sequestration within the plant. In order to determine the mechanism involved, Cd content in phloem/xylem was evaluated and the response at the protein level. Plants were treated with 0, 20, 200, and 400 ppm Cd for 48 h in hydroponics media. The stem was used to separate the epidermis/phloem from the xylem/pith. Samples were lyophilized and Cd was evaluated in the two portions. Cd concentration was higher in phloem than that in xylem (7600 and 3000 ppm Cd, respectively) in 200 ppm Cd treatments. The protein profile in SDS-PAGE showed that in the presence of Cd, two peptides (of 29 and 14 kDa) were expressed. These protein bands were confirmed after G25 gel filtration protein and Cd codetermination. The nature of these peptides is currently being characterized.

P1871. The influence of water deficit on pigment and chlorophyll fluorescence of olive plants

I. Arji[1], K. Arzani[2], S. Sasani[3];
[1]1- Agricultural and Natural Resource Research center of Kermanshah, Kermanshah, Islamic Republic of Iran, [2]University of Tarbiat Modarres, Tehran, Islamic Republic of Iran, [3]University of Tehran, Karaj, Islamic Republic of Iran.

One-year-old rooted cutting Olive (*Olea europaea* L.) trees were grown in 14-liter pots containing a mixture of sandy loam soil, were subjected to various levels of water stress during two growing seasons in 2001 and 2002. Irrigation treatments were control (soil water at field capacity, Ꝗ$_{soil}$ = -0.03 MPa), medium stress (Ꝗ$_{soil}$ = -0.5 MPa) and severe stress (Ꝗ$_{soil}$ = -1.5 MPa). A factorial experiment based on randomized complete block design was used. Some characters like chlorophyll a, chlorophyll b, total chlorophyll and carotenoid and chlorophyll fluorescence were measured. Results showed that the degree of water stress had significant effect on the pigment degradation. The amount of chlorophyll a, chlorophyll b, total chlorophyll and carotenoid showed a decrease under drought stress and this decrease under severe drought stress was significant in compare with other treatments. In present research initial chlorophyll fluorescence (Fo), maximum chlorophyll fluorescence (Fm), variable chlorophyll fluorescence (Fv) and chlorophyll fluorescence ratio (Fv/Fm) were increased, decreased, decreased and decreased respectively under drought stress.

P1872. The taxonomy and biology of mangrove swamp plant species in Nigeria

O. T. Ogundipe, J. D. Olowokudejo;
University of Lagos, Lagos, Nigeria.

Mangroves are a taxonomically-diverse group of plants which posses a common ability to survice and perpetuate themselves along sheltered tropical

coastlines in saline environments under tidal influence.

The mangrove vegetation in Nigeria can be found throughout the south western region of the country, in contact with sea in places like Ikorodu, Forcados in Delta State, Akassa in River State, Opobo in Akwa Ibom and Calabar in Cross Rive State, interrupted by fresh water swamp forest in Niger Delta.

About twenty six (26) species ina bout firteen families have been identified to thrive very well in Nigeria mangrove swamp, examples are Rhizophora racemosa (Rhizophoraceae), Avicenia germinans (Avicnniaceae) while associated species include Conocarpu erectus (Combretaceae), Pasplaum vaginatum (Poaceae) etc.

The various species are able to seurvice in the harsh environment because they possess a wide range of morphological, anatomicl and physiological adaptations which have eliaed much scientific interest.

P1873. The Protective Function of Calcium, Cholesterol and Brassinosteroid on the Membrane of Rice Plant under Temperature Stresses

S. Wang;
College of Agronomy & Life Science,Southwest Agricultural University, Chongqing, China.

In Southwestern China, rice (*Oryza sativa* L.) is often subjected to temperature stresses, the function of cell membrane and the ultrastructure of membrane of chloroplast and mitochondria were damaged gravely. A induced stress resistance of plant was observed when chilled rice seedling or high temperature and water stresses rice plant were treated with Ca, cholesterol and brassinosteroid (BR). It was found that electrolyte leakage and malondialdehyde contents decreased, the activities of superoxide dismutase , catalase and peroxidase increased and the structure of membrane of chloroplast and mitochondria were better. Chlorpromazine , a specific inhibitor of calmodulin (CaM), would inhibit Ca^{2+} function to protect cell membrane under temperature stresses. The result suggests that there is a relationship between Ca^{2+} function and CaM. Cholesterol and BR also raised heat stable protein and ATP contents, induced stress proteins. A wide range of influence of Ca, cholesterol and BR on rice physiological and biochemical characteristics, grain yield and yield components at the different rice growth stage was also studied under temperature stresses.

P1874. Environmental stress, altitudinal distribution and ecophysiology of Andean Plants from the Mediterranean Region of Central Chile.

H. M. Cabrera[1,2], T. Rioseco[3], M. T. Kalin-Arroyo[4];
[1]Instituto de Biología - Pontificia Universidad Católica de Valparaíso, Valparaiso hcabrera@ucv.cl, Chile, [2]Grupo de Fisiologia Vegetal - Depto. de Biologia, Universidad de las Islas Baleares, Spain, [3]Instituto Biología - Pontificia Universidad Católica de Valparaíso, Valparaiso hcabrera@ucv.cl, Chile, [4]Depto. de Biología, Universidad de Chile. CMEB, Santiago. Casilla 653. southern@uchile.cl, Chile.

In Mediterranean ecosystems, species distribution and vegetation types are determine by several stress. We studied the combined effect of water, thermic and light factors on the photosynthesis, water balance and cold tolerance of evergreen trees (*Kageneckia oblonga*), semideciduos trees (*K. angustifolia*), shrubs (*Anartrophyllum cummingii*) and cushion plants (*A. gayanum*) in an gradient (1000-3100 m) in the Mediterrenean Andes of Chile (33°). We hypothesized that the limiting factors would be dryness for trees, cold at the higher altitudes and the synergistic effect of light stress. For 3 years (2000-2002) we characterized the climate and soils and measure photosynthesis, transpiration, photoinhinition, pigments (xantophylls), water potentials and tolerance or supercooling (temperature of damage by freezing) for the four species studied. The stress factors considered affect the plants differentially. We will discuss effects on plants distribution of conditions of climate changes.

P1875. The production and characterization of salt tolerant substituted tritipyrum lines by genomic fluorescent *in situ* hybridisation (FISH)

H. S. Hassani;
ICST, Kerman, Islamic Republic of Iran.

Soil salinity is a serious problem in the world. Wheat, although moderately is tolerant to salt, but can not be cultivated in many areas, however, some of the wild wheat relatives are highly tolerant, e.g. *Thinopyrum bessarabicum*. Eight hexaploid tritipyrum lines have been produced which can set seed in at least 250 mM NaCl. These tritipyrums (2n=6x=42, $AABBE^bE^b$) due to a variety of reasons such as brittle rachis, late maturity, and meiotic instability will not fulfil the requirements of a successful commercial salt tolerant crop. To overcome these problems substituted tritipyrum, in which selected E^b chromosomes are replaced by D genome chromosomes of 6x wheat, was produced from 6x tritipyrum x 6x wheat hybrids (F1: 2n=6x=42, $AABBDE^b$). The fertile plants were screened by the genomic fluorescent *in situ* hybridisation technique to identify their E^b and D chromosome constitution. This study showed that the potential of producing tritiprum with variable numbers of E^b and D genome chromosomes is feasible and that FISH is a useful technique for determining the number of E^b chromosomes present.

Keywords: Tritipyrum, Fluorescent *In Situ* Hybridization, salinity

P1876. Functional responses to salinity of *Cochlearia* living along the coast of Brittany

X. Dauvergne, M. Bessières, S. Salaün, E. Deslandes;
Institut Universitaire Européen de la Mer, Brest, France.

The genus *Cochlearia* grows in salt marshes and cliff, thus these plants must face to different levels of salt stress. This work reports the procedure for extraction, purification, chemical characterisation and quantification of organic solutes accumulated as stress response. In this study, twenty five populations from Brittany were investigated. These populations belonged to three well-known species, namely *C. aestuaria*, *C. anglica* and *C. officinalis*. Discriminant characteristics between these species were investigated through ecophysiological approaches. Organics solutes were extracted using methanol-water. When required extracts were partially purified, by treating with ion exchange resins or using a HPLC. The structures of these solutes were established by NMR spectroscopy. Solutes such as Proline, Glucose, Fructose, Sucrose and one glucoconjugate were identified. Solutes levels were quantified by HPLC with ultra violet detection or refractive index. A possible correlation between these contents and the environmental conditions investigated.

P1877. Polyamines, development and stress response in plants : outcomes from the research on the subantarctic “Kerguelen cabbage”

F. Hennion;
UMR CNRS 6553 ECOBIO - Université de Rennes 1, Rennes, France.

The subantarctic Brassicaceae *Pringlea antiscorbutica* or “Kerguelen cabbage” can tolerate adverse conditions from saline to freeze-thaw. However, *P. antiscorbutica* is sensitive to water stress under present climate warming and drying. We investigated growth regulators polyamines, which respond to abiotic stresses in plants. *P. antiscorbutica* displays high diversity for these metabolites. Amine metabolism in *P. antiscorbutica* showed a high responsiveness to temperature conditions, but some amines appeared sensitive to combinations of environmental factors. We showed that, in this plant, the response of polyamine metabolism to abiotic stress was effective in the field. Part of the polyamine pools could be allocated to the plant protection against adverse conditions. *N*-acetylputrescine, *N*-acetylspermidine and *N*-acetylspermine, which are characteristic of animals and bacteria, were detected at high levels in plants growing in low-altitude herbfields and this was possibly related to conditions of low water availability. Tyramine and dopamine were responsive to temperature conditions and a high tyramine level may be related to a slow plant growth.

P1878. High apoplastic solute concentrations in leaves alter water relations of the halophytic shrub, Sarcobatus vermiculatus

J. H. Richards[1], J. J. James[1], N. N. Alder[1,2], L. A. Donovan[3], K. A. Shackel[4], K. H. Muehling[5], A. E. Laeuchli[1];
[1]Land, Air & Water Resources, University of California, Davis, CA, United States, [2]Medical Biochemistry & Genetics, Texas A & M University, College Station, TX, United States, [3]Plant Biology, University of Georgia, Athens, GA, United States, [4]Plant Sciences, University of California, Davis, CA, United States, [5]Institute of Plant Nutrition, Justus-Liebig University, Giessen, Germany.

It has long been known that many plants, particularly stress tolerant species, fail to equilibrate with soil water potential by dawn. While recent studies show that both nighttime shoot and root water loss can contribute to predawn disequilibrium (PDD), even when these are prevented PDD can be large. We predict that a major mechanism of PDD is high solute concentration in the leaf apoplast. We quantified leaf apoplastic solutes of the desert halophytic shrub, *Sarcobatus vermiculatus*, which has both large PDD and large discrepancies between predawn leaf and xylem water potentials. Pressure probe and nanoliter osmometer measurements confirmed leaf cell water relations consistent with psychrometric data. Analyses of apoplastic fluid collected by centrifugation showed 80±11 to 229±36 mM Na^+, depending on salinity treatment, plus ~50 mM K^+ in leaves at dawn. This demonstrates that leaf apoplastic solute concentration can be very high, explaining discrepancies between leaf and xylem water potentials at dawn, as well as contributing to PDD. High apoplastic solute concentrations affect water relations and mineral nutrition of stress tolerant species with high PDD.

P1879. Selection of Rice (*Oryza sativa* L.)for Drought Tolerance under Field and *in Vitro* condition

S. Bunnag[1,2];
[1]Faculty of Science, Khon kaen, Thailand, [2]Department of Biology, Khon kaen, Thailand.

Seven rice cultivars, namely Khao Dok Mali 105, IR58821-23-B-1-2-1, CT9993-5-10-1-M, IR62266-42-6-2, IR57514-PMI-5-B-1-2, IR52561-UBN-1-1-2 and Jaw Hom Nin were screened under water stress condition in the field. These rice cultivars were divided into three groups. The first group which showed the highest tolerance to water stress was rice cv. CT9993-5-10-1-M. The second group which was moderately tolerance to water stress included rice cv. Khao Dok Mali 105. The last group which was most sensitive to water stress comprised rice cv. IR62266-42-6-2. In the second experiment, fresh weight, dry weight, percent survival, percent regeneration, osmotic potential, proline content, DNA bands and protein patterns of three rice cultivars namely Khao Dok Mali 105, CT9993-5-10-1-M and IR 62266-42-6-2 were investigated. These rice cultivars were cultured on MS medium supplemented with various concentrations of polyethylene glycol or mannitol. It was found that fresh weight, dry weight, % survival, % regeneration, osmotic potential in all three rice cultivars decreased whereas proline content increased.

P1880. Productivity and water relations of corn plants grown under different conditions of water supply and potash fertilization

A. A. El-Noemani[1], A. A. El-Ganayni[2], A. A. Abdel-Hafiz[2], M. T. El-Saidi[1], M. A. A. Abdou[1];
[1]National Research Centre, Giza, Egypt, [2]Fac.Agric.,Cairo Univ., Giza, Egypt.

Two field experiments were conducted in Shalakan, Egypt, during 2000 and 2001 seasons, to study the effect of four irrigation treatments, i.e. 80, 60, 40 and 20% of available soil moisture (ASM) and four potassium levels, viz. 57,86,115,144 kg K2O/ha on corn. A split plot design with four replicates was used , where irrigation levels were run at the main plots and potassium in the sub ones. The study included 16 traits in addition to some water relationships. The obtained data showed that irrigation gradually increased products of most traits, including grain yield. No. of rows/ear did not respond to irrigation varying, meanwhile shelling % increased as irrigation level was reduced. Potassium addition up to 86 kg/ha reflected in positive effect on most studied aspects, including grain yield. It was concluded that 80% ASM in combination with 57 or 86 kg K2O/ha produced the highest grain yields. Water consumptive use (WCU) increased by increasing irrigation and through hot seasons. The value of (WCU) was ranged between 3663 to 6123 m^3 /ha. The treatments 80% ASM, 57 kg K2O/ha and their combination produced the highest values of water use efficiency (WUE) in both seasons.

P1881. Transcripts expression of two groundnut (*Arachis hypogaea* L.) varieties tolerant and sensitive to drought

N. Kadi Dramé[1], D. Clavel[2], C. Passaquet[1], A. T. Pham Thi[1], Y. Zuily-Fodil[1];
[1]Laboratoire d'Ecophysiologie Moléculaire, UMR-IRD 137, FST, Université Paris 12, Créteil, France, [2]CIRAD - Centre de Coopération Internationale en Recherche Agronomique pour le Développement, TA 70/01, Montpellier, France.

Groundnut (*Arachis hypogaea* L.) is an important crop in the semi-arid Tropics. It is often exposed to extremely severe climatic conditions. Little is known about its molecular responses to drought although water deficit-induced genes have been described in other plant species.

Using RT-PCR on a system including a drought-sensitive and a drought-tolerant variety, expression of genes involved in protein turnover, phospholipid degradation and membrane protection was studied under water limiting conditions. Results showed that genes encoding a cysteine protease and phospholipase D were over-expressed while a serine protease gene was repressed and that of a LEA protein induced by drought. For all but the LEA gene, expression patterns in response to progressive drought-stress differed between the tolerant and sensitive variety. Therefore, studying genes with known functions allowed us to identify genes controlled by drought in groundnut and to better understand how this species copes with drought-stress.

P1882. Multicystatins are induced by drought-stress in Cowpea (*Vigna unguiculata* (L.) Walp) leaves

N. N. Diop[1], M. Kidriļ [2], A. Repellin[1], M. Gareil[1], Y. Zuily-Fodil[1];
[1]Laboratoire d'Ecophysiologie Moléculaire, UMR-IRD 137, FST, Université Paris 12, Créteil, France, [2]Department of Biochemistry and Molecular Biology, Jo ef Stefan Institute, Ljubljana, Slovenia.

Phytocystatins are proteinaceous inhibitors of cysteine proteinases (CP). CP can be induced by abiotic stresses resulting in cell protein autophagy. To study involvement of phytocystatins in plant response to abiotic stresses, we isolated a full-length cDNA encoding a two-domain cystatin from cowpea (*Vigna unguiculata* (L.) Walp.) leaves and studied cystatin expression pattern in response to drought-stress in two cowpea cultivars with different capacity to resist drought (EPACE-1, resistant and IT83, sensitive). Our results showed that both cultivars developed an inhibition-based control strategy towards cysteine proteinase activities, involving at least two cystatin messengers and proteins as revealed by Northern and Western analyses, respectively. Furthermore, in the resistant cultivar, this inhibitory strategy appeared to be carried out further, in terms of water deficit intensity. This could minimize protein loss and allow leaf cells to adapt to drier environments and/or to recover more easily at the end of the drought.

P1883. Diluted Seawater and Benzyl Adenine Effects on Macro and Micro Nutrients States in Barley Shoots

M. M. Hussein, A. A. Abd El-Kadier, M. S. Abo El-khier, O. M. Kassab;
National Research Center, Dokki, Cairo, Egypt.

A pot experiment was conducted in the greenhouse of the National Research Centre, Dokki, Cairo, Egypt during 2000/2001 winter season to study the effect of Benzyl adenine (spraying 50 ppm and without) and salt stress [tap water (250 ppm), 2000, 4000 ,6000 and 8000 ppm from mixed diluted seawater by fresh water] on macro and micro nutrients concentration and contents in shoots of barley plants. All micro-nutrients contents i.e. N,P, K, Ca and Na lowered by salinity. Mn and Zn values showed approximately the same response. Fe content was increased by salt stress up to 2000 ppm and tended to decrease by increasing salt concentration up to the highest level used. Spraying BA in the rate of 50 ppm led to significant decreases in N and Ca content but P and K contents were reversely responded. Zn content was lowered, however, Fe and Mn contents seemed to be without effect by BA treatment compare to the control. The interaction effects of BA and salt stress in the nutrient concentration and contents were discussed.

P1884. Polyamine Metabolism in Response to Drought and Cold stresses

J. C. Cuevas[1], R. Alcazar Hernandez[1], R. Lopez Cobollo[2], M. Patron Jovellar[1], J. Salinas[2], T. Altabella Artigas[1], A. Ferrando Monleon[3], A. Fernandez Tiburcio[1];
[1]Facultat de Farmacia, Universitat de Barcelona - Barcelona, Spain, [2]Departamento de Biotecnología, INIA - Madrid, Spain, [3]Dto. Bioquimica y Biologia Molecular, Universitat de Valencia - Valencia, Spain.

The oldest known and perhaps the most dramatic changes in polyamine (PA) metabolism are those obtained when plants are challenged with different abiotic stresses. For many years, the nature and physiological meaning of the massive PA accumulation under these challenging conditions have remained ill-defined. The relevance of such metabolic pathway in the plant response to abiotic stress has just been recently approached with the use of Arabidopsis as a model plant, since it allows global approaches to study the function of PA metabolism. In our lab we started a multidisciplinary approach based in transcriptomics, metabolomics and functional genomics in order to gain insight into the role of PA metabolism in plant abiotic stress responses. Gene expression analyses by real-time RT-PCR of *Arabidopsis* thaliana plants subjected to cold and dehydration stresses have identified the key PA metabolic genes which expression is differentially regulated by these environmental insults. Metabolomic data have also identified specific PA profile for each type of stress. The function of key genes in such stress responses has been analyzed by using gene-disruption mutants

P1885. Photosynthetic activity of *Vaccinium vitis-idaea* during winter

T. Saarinen, R. Lundell, H. Hänninen;
Plant Biology, University of Helsinki, Helsinki, Finland.

The photosynthetic activity of lingonberry (*Vaccinium vitis-idaea*), a common evergreen dwarf shrub in boreal forests, was studied during winter. The leaves of lingonberry maintained substantial photosynthetic capacity throughout winter, the lowest light-saturated rates of gross photosynthesis measured being approximately 1 µmol CO_2 m^{-2} s^{-1}. High values of the Fv/Fm ratio of chlorophyll fluorescence induction (ca 0.73) and stable low electrolyte leakage percentage of the leaves suggested that shoots covered by snow did not suffer from winter stress. Immediately after snow melt, however, Fv/Fm ratios decreased to approximately 0.3. The decrease was accompanied by a clear reduction in CO_2 uptake, probably due to photoinhibition of leaves exposed to high light at relatively low temperatures. The recovery of both photosynthesis and chlorophyll fluorescence required several weeks. The results suggest that a protecting snow cover is a key factor affecting the wintertime photosynthetic activity of *Vaccinium.*

P1886. Ecophisiological Strategies of Desiccation-Tolerant Crustaceous Cryptogamic layer on Tropical Inselbergs

L. Nie[1,2], P. Evelin[3], Z. Tuba[2,3];
[1]Foshan University, Foshan, China, [2]Department of Botany and Plant Physiology, Faculty of Agricultural and Environmental Sciences, Szent Istvan University, Gödöllõ, Hungary, [3]“Plant Ecology” Departmental Research Group of the Hungarian Acedemy of Sciences, Gödöllõ, Hungary.

The bare calcareous and quartzitic rock surfaces of inselbergs are generally pioneering inhabited by a complex community of cyanobacteria, algae, fungi and lichens. Although these cryptogamic plants constitute a prominent part of the biofilm of exposed rocks in the tropics and subtropics, and show a luxuriant growth in the extremely conditions, their diversity and ecophisiological strategies to withstand long periods of drought in a dehydrated state are poorly investigated. The degrees of water availability in different habitats establish the different growth forms of cryptogamic plants, and the growth forms of the biofilms influence the photosynthetic behavior including the carbon gain under different water regimes, and finally determine the different distribution patterns and the color of inselbergs. The time-scale ecophisiological responses, especially the photosynthetic changes of the biofilm on the rocks to the rehydration are still need further studied.

P1887. Proteolytic activities in response to water deficit in desiccation-tolerant and desiccation non-tolerant species of the family *Gesneriaceae*

M. Kidric[1], B. Stevanovic[2];
[1]Jozef Stefan Institute, Department of Biochemistry and Molecular Biology, Ljubljana, Slovenia, [2]Faculty of Biology, Institute of Botany, Belgrade, Serbia and Montenegro.

In the response of plant to drought, the control of protein breakdown and cellular proteolytic activity is held to be very important. We have studied protease activities in the desiccation tolerant flowering plant *Ramonda serbica* Panc. Severe water deficit led to desiccation (3% relative water content) and induced a marked increase of aminopeptidase and serine protease activities in *Ramonda* leaves. These increases were fully reversed within 24 hours on rehydration. The increase of both endo- and exopeptidase activities strongly suggests a requirement to remove proteins that accumulate on water removal and to provide a source of recycled amino acids for resythesis of proteins on rehydration. *Saintpaulia ionantha* is a membre of the same family but it is not tolerant to desiccation. In watered plants it exhibits a similar prifile of protease activities to that measured in *Ramonda*. A comparison of the influence of the first stages of dehydration will be reported.

P1888. Changes in spectral reflectance of some foliar lichens during dessication

J. Gloser;
Department of Plant Physiology, Faculty of Science, Masaryk University, Brno, Czech Republic.

Remote detection of water status and photosynthetic or photoprotective pigments using analysis of spectral reflectance in visible and near infrared spectral regions would be very helpful in ecophysiological study of lichens. Specific surface morphology, anatomy and deposition of secondary metabolites in lichen thalli may complicate applicability of reflectometric approaches well elaborated for leaves of seed plants. We have investigated validity of several reflectance indices for detection of water status in some foliar lichens (*Umbilicaria hirsuta, U. antarctica, Lasallia pustulata*). In spite of extremely high increase in total reflectance during dessication, caused mainly by structural changes in the upper cortex, it was possible to derive useful information by a narrow-band analysis. The depression in reflectance around 970 nm and its derivative characteristics were the most reliable predictors of water status. They were in close correlation with both the water content and the water potential of the thalli within a broad range of hydration from full saturation to critical water shortage at which photosynthetic processes were inactivated.

P1889. Leaf structure and soluble carbohydrate composition of pteridophytes from rock outcrops of Rio Janeiro State, Brazil.

M. G. Moraes[1], M. G. Santos[2], A. A. Q. Oliveira[1], M. R. C. Ribeiro[1];
[1]Universidade Federal Fluminense, Niteroi, Brazil, [2]Universidade do Estado do Rio de Janeiro, São Gonçalo, Brazil.

Rock outcrops are prominent sites for desiccation tolerance research. Studies concerning this topic in pteridophytes have been focusing mainly northern *Selaginella* species, and little is known about desiccation tolerance processes in other pteridophyte groups. *Anemia tomentosa* (Sav.) Sw. var. *anthriscifolia* (Schrad.) Mickel and *Anemia villosa* Humb. et Bonpl. ex Willd. are desiccation tolerant ferns commonly associated to vegetation islands on rock outcrops located in Rio de Janeiro. In this work, leaf anatomy and sugar composition of these species was analyzed. Despite the environmental restrictions imposed in rock outcrops, both species have leaf blades with mesomorphic characteristics, that could be important on structural integrity maintenance during dehydration curling, contrasting to xeromorphic petiole, which cortical cells store protective substances. Glucose, fructose and sucrose, are the main sugars present in whole leaf water extracts of both species. The results show how structure and biochemical features may be contributing for the establishment of these species in habitats with water shortage.

P1890. Ecophysiological investigation of tropical desiccation-tolerant vascular plants

J. Balogh[1], S. Czóbel[2], E. Péli[1], S. Porembski[3], Z. Tuba[1,2];
[1]Plant Ecological Research Group of Hungarian Academy of Sciences, Szent István University, GödöllŖ, Hungary, [2]Department of Botany and Plant Physiology, Szent István University, GödöllŖ, Hungary, [3]Department of Botany, University of Rostock, Rostock, Germany.

The main goals of the project were to describe the main ecophysiological processes of some poikilohydric desiccation-tolerant (DT) vascular inselberg plants. It is extremely important to examine DT plants on the whole Globe to gain better knowledge on the drought tolerance. Morphological and ecophysiological processes of selected tropical flowering plant species were carried out on widely distributed tropical poikilohydric species, like *Afrotrilepis pilosa, Coleochloa microcephala and Xerophyta scabrida* under *in situ* natural habitat like greenhouse conditions. The selected taxa are suitable objects for ecophysiological screening, as well as representative for characteristic tropical region. Desiccation and revival afterwards very drastically influence the whole photosynthetic system of these plants, hence the present study mainly focused on the photosynthetic processes. The *in situ*-like greenhouse examinations included gas exchange and fluorescence measurements during desiccation and revival processes as well as metabolically active stage.

P1891. Ecophysiological differences between the desiccation-tolerant species *Ramonda serbica* and *R. nathaliae*

T. Zivkovic[1], M. Quartacci[2], C. Sgherri[2], V. Stevanovic[1], B. Stevanovic[1], F. Navari-Izzo[2];
[1]Faculty of Biology, Institute of Botany, Belgrade, Serbia and Montenegro, [2]Dipartimento di Chimica e Biotecnologie Agrarie, Università di Pisa, Pisa, Italy.

The presence in the Balkan peninsula of several poikilohydric flowering plants belonging to the *Gesneriaceae* family provides the possibility to investigate comparatively the unique phenomenon of desiccation tolerance and to establish the specificity, degree and pattern of their resistance. This is also important for protecting these Balkan endemo-relict plants.

We studied the species *Ramonda serbica* and *R. nathaliae*, pointing out their chorological differentiation in the Balkans, ecoanatomical differences, electrolyte leakage of leaves subjected to dehydration. The pattern of chlorophyll metabolism of these homoiochlorophyllous species during dehydration and rehydration was also studied. Special attention has been paid to *R. serbica*, with respect to its photosynthetic activity, defence systems against oxidative stress, plasma membrane lipids and low-molecular weight substances during dehydration and rehydration. Similar investigations on *R. nathaliae* are in progress.

P1892. Photosynthetic features of desiccation tolerant moss species native of CO$_2$ spring

A. Juhász[1], M. Kaligaric[2], Z. Csintalan[1], M. C. F. Proctor[3], Z. Tuba[1];
[1]Department of Botany and Plant Physiology, Szent István University, Gödöllő, Hungary, [2]Department of Biology, Faculty of Education, University of Maribor, Maribor, Slovenia, [3]Department of Biological Science, University of Exeter, Exeter, United Kingdom.

So far many long and short term high-CO$_2$ experiments were run in growth cabinets however none of these studies could answer the basic question of how plants would respond to chronic atmospheric CO$_2$ enrichment. The natural CO$_2$ springs permit studying the real long-term effects on plants or plant communities. Since long-term effect on adaptation of photosynthetic system of poikilohydric species are less known our aim was to investigate desiccation tolerant forest-floor moss species growing around a CO$_2$ vent as well as a nearby control site in the vicinity of Gornja Radgona in Slovenia. The study was carried out on five indigenous species. The CO$_2$ assimilation showed upward acclimation in every CO$_2$ spring samples. There was no noticeable difference in Fv/Fm values while RFd was higher in four vent samples. The photosynthetic pigment content differed considerable only in two species, but it increased at the majority of the species at the vent. The carbon content and C/N ratio were also higher in the high-CO$_2$ moss samples. The results suggest that long-term adjustment of photosynthetic features to elevated atmospheric CO$_2$ may be diverse and definitely species dependent.

P1893. Desiccation Survival Times in Different Desiccation-Tolerant Plants

Z. Tuba;
Faculty of Agricultural and Environmental Sciences, Department of Botany and Plant Physiology, Szent István University, Gödöllő, Hungary.

There is no exact information about the longevity of the desiccated period after what the desiccation tolerant plants can recover their photosynthetic structure and function. Generally, longer the period spent in a desiccated state lesser the potential to full metabolic recovery. We know just vascular DT-s can survive longer desiccated periods than cryptogams. Therefore, in the case of three cryptogam DT species: the moss *Tortula ruralis*, and the lichens *Cladonia convoluta*, and *C. furcata*, and two vascular monocotyledonous DT species: *Xerophyta scabrida*, and *Coleochloa microcephala* were examined for the recovery of their net CO$_2$ assimilation during rehydration (following stored in dry stage for different lengths). According to our results the cryptogams were able to recover their photosynthetic activity just after 4 months or less, while the leaves of *X. scabrida* and *C. microcephala* remained able to revive after 2-11 years of desiccation.

P1894. The role of growth regulators in formation of plants adaptive potential to unfavorable environmental conditions

O. Terek, O. Velychko, N. Yavorska;
Ivan Franko National University of Lviv, Lviv, Ukraine.

The mechanisms of plant adaptive reactions induced by such adverse factors as high (+42^{0}C) and low (+8^{0}C) positive temperatures and ions of heavy metals (Cd^{2+}, Pb^{2+}) under influence of Ukrainian growth regulators were investigated. The action of extreme factors resulted in changes of endogenous phytohormone balance, lipid peroxidation process (LP) intensity and antioxydation enzyme systems activity (peroxidases, catalases). Inducing of the protein polymorphism under different stress conditions was established. Growth regulators (ivin, emistym C and agrostimulin) influence on physiological and biochemical functions and promote plant adaptation on stress.

P1895. The role of growth regulators in formation of plants adaptive potential to unfavorable environmental conditions

O. I. Terek, O. Velychko, N. Yavorska;
Ivan Franko National University of Lviv, Lviv, Ukraine.

The mechanisms of plant adaptive reactions induced by such adverse factors as high (+42^{0}C) and low (+8^{0}C) positive temperatures and ions of heavy metals (Cd^{2+}, Pb^{2+}) under influence of Ukrainian growth regulators were investigated. The action of extreme factors resulted in changes of endogenous phytohormone balance, lipid peroxidation process (LP) intensity and antioxydation enzyme systems activity (peroxidases, catalases). Inducing of the protein polymorphism under different stress conditions was established. Growth regulators (ivin, emistym C and agrostimulin) influence on physiological and biochemical functions and promote plant adaptation on stress.

P1896. Reconsidering leaf structure vs. physiological traits relationships: a comparison between species with heterobaric or homobaric leaves, growing in Mediterranean environment

V. Liakoura[1], M. N. Fotelli[1], G. Liakopoulos[1], H. Rennenberg[2], G. Karabourniotis[1];
[1]Laboratory of Plant Physiology, Agricultural University of Athens, Athens, Greece, [2]Institute of Forest Botany and Tree Physiology, Albert-Ludwig University of Freiburg, Freiburg, Germany.

Heterobaric leaves (HEL), contrary to homobaric (HOL), are characterized by bundle sheath extensions forming a transparent area network on their lamina. Although photosynthetically inactive, this network enhances photosynthesis by transferring light in deep internal mesophyll layers.

Here, the leaf structural strategies of more than 40 species belonging to either HEL or HOL groups were compared in respect to physiological traits. HEL, contrary to HOL, showed a positive correlation between LMA and thickness. Furthermore, HEL had significantly higher N concentration, as well as greater investment of nitrogen per leaf area with increasing LMA, than HOL. Moreover, both the negative PNUE to thickness and the positive thickness to transparent-area volume correlations indicate a high structural N-cost of the latter. Still, the photosynthetic capacity of HEL, expressed per unit (projected) area, increased and did not differ significantly from that of HOL. Given the significantly ^{13}C-enriched HEL, compared to HOL, corresponding to higher WUE, it is implied that although N-demanding, transparent areas formation is a response for improving leaf water status.

P1897. The influence of the photoperiod on redox regulation and stress responses

B. Becker[1], **S. Holtgrefe**[1], C. Wunrau[1], A. Kandlbinder[2], K. Dietz[2], J. Backhausen[1], R. Scheibe[1];
[1]Pflanzenphysiologie, Osnabrück, Germany, [2]Biochemie und Physiologie der Pflanzen, Bielefeld, Germany.

Under natural conditions plants are subjected to a changing environment. Plants possess a large set of mechanisms, e. g. the malate valve, to prevent damages in the short term while persisting alterations in the redox state induce a long-term response on the transcriptional level. To investigate the different acclimation responses, Arabidopsis plants grown in low light either in short days (SD) or long days (LD) were transferred into high light at 12°C. In SD plants, the NADP-MDH activation state increased, and its protein level was up-regulated a few hours after the onset of stress. Array analysis showed an increase of glutathione metabolism and some photosynthesis-related genes. The cellular glutathione content increased at a constant redox state. In LD plants, only the expression of several antioxidative enzymes increased strongly. We conclude that the endogenous systems that measure the day length interact with redox regulation, and override the interpretation of the signals, i. e. they redirect redox-mediated acclimation signals from a more efficient light usage and from redox poising in SD towards the avoidance of oxidative damage under LD conditions.

P1898. Isolation and characterization *of yellow stripe1-like* gene family in rice

S. Lee, G. An;
Pohang University of Science and Technology, Pohang, Republic of Korea.

Plants release ferric chelating phytosiderophores and then transport ferric-phytosiderophores complexes across the plasma membrane by the yellow stripe1 (YS1). We report the isolation and characterization of the rice *YSL* (*yellow stripe1-like,* designated *OsYSL*) genes. There are 18 members in rice. Their expression patterns under the micronutrient deficiency were analyzed by RT-PCR. From the pool of rice T-DNA insertional lines transformed with pGA2715, we have identified an activation tagged mutant of *OsYSL16*. To analyze the phenotype of *OsYSL16* activation line, we tested the iron deficiency tolerance by germinating and growing the plants on a solid medium without iron. Visual differences were reflected by the chlorophyll contents, indicating that the *OsYSL16* activated line is more tolerant to iron deficiency than wild type. Iron content of the *OsYSL16* activated line is similar to that of wild type. RT-PCR analysis indicated that *OsYSL16* gene is preferentially expressed in leaves. Our results suggested that the function of OsYSL16 in iron homeostasis is more related to the distribution of iron through the tissues than the uptake from the soils.

P1899. PS 2 thermotolerance in relation to ice nucleation, frost and heat damage in evergreen subalpine plants during winter

M. Pramsohler, **G. Neuner**;
Institute of Botany, Innsbruck, Austria.

PS 2 thermotolerance was compared to ice formation, frost and heat damage of evergreen subalpine plants (*Picea abies, Pinus cembra, Rhododendron ferrugineum, Saxifraga paniculata)* under naturally low (winter) and high (summer) PS 2 efficiencies.

Basic chlorophyll fluorescence (F_0) was recorded during freezing (+2°C - -10°C at 2°C/h). On extracellular ice formation (-4 to -7°C) a significant, sudden increase in F_0 was observed. This was not caused by frost damage that occurred below <-21°C at least in winter. Also surface ice had no effect on F_0. F_0 measurements are hence a useful tool to distinguish between surface ice and extracellular ice inside the leaf tissue which cannot be differentiated by freezing exotherms.

PS 2 heat tolerance was determined by T-F_0 curves (20-65°C at 1°C/min). With F_V/F_M>0.8 two F_0 maxima were recorded. The first corresponded with tissue heat damage (46.9-54.3°C), the second occurred above 60°C. With F_V/F_M<0.3 only the second F_0 maximum was detectable leading to an overestimation of heat tolerance by >10°C. Under conditions with low F_V/F_M PS 2 heat tolerance cannot be determined via T-F_0 curves.

P1900. The effect of gamma irradiation on cytological and physiological function of two cultivar of barley

S. Karbalaii G.[1], F. Majd[2], H. Fahimii[3];
[1]Nuclear Research Center for Agriculture and Medicne, Tehran, Islamic Republic of Iran, [2]Nuclear Research Center for Agriculture and Medicne, Karaj, Islamic Republic of Iran, [3]Tehran University, Tehran, Islamic Republic of Iran.

An investigation was performed in cytogenetic lab. of Nuclear Agriculture- Atomic Energy Organization of Iran in 2004-5.In this research the effect of gamma irradiation on cytological and physiological function of two cultivars of barley were examined. For this aim cytological and physiological sensitivity of two cultivars (30109, 30130) were assessed by different gamma radiation doses (50,150,250,350,450 Gy).By cytological studies in addition to defining the karyotype, the rate of chromosomal aberrations due to the effect of irradiation was studied and it was observed that the chromosomal aberrations increased by increasing the rate of irradiation.In 350 and 450 Gy were observed more different forms of chromosomal damage such as ring & dicentric chromosome, deletion and Translocation than the other dose. The results showed that by increasing gamma ray dose, the growth rate, root and shoot length of two cultivars were decreased, and germination percentage had no significant difference.This work suggested that the increasing of chromosomal aberrations, so decrease mean value of growth rate.

P1901. ABA signal transduction in guard cells: systems biology and key players.

S. M. Assmann, S. Li, S. Pandey, L. Perfus-Barbeoch, Z. Zhao, R. Kawaguchi, T. E. Gookin, L. Wilson, R. Albert;
Penn State University, University Park, PA, United States.

Guard cells regulate stomatal apertures by responding dynamically to many environmental and endogenous signals, including the stress hormone abscisic acid (ABA). ABA-induced stomatal closure is one of the best characterized signal transduction processes in plants, but a predictive model is still not available for this complex multistep process. We have synthesized over 140 experimental observations into a consistent guard cell signaling network for ABA-induced stomatal closure, and have modeled this process using Boolean methods. Our dynamic model captures several essential features of this biological system, such as the existence of complementary signaling pathways. We are combining genetic, biochemical and cell biological assays to probe one key aspect of this signaling network, consisting of the signal transducing heterotrimeric G protein and its interaction partners (Curr Opin Plant Biol. 7: 719-731). We have found that plants harboring T-DNA mutations in genes encoding proteins of the G protein complex exhibit altered stomatal sensitivity to ABA.

Supported by NSF MCB-0209694 & MCB-03-45251 (S.M.A.), and by a Sloan Research Fellowship (R.A.).

P1902. Gene Expression Patterns of Stress-induced PP2C Phosphatases

J. Umbrasaite, V. Kazanaviciute, A. Schweighofer, I. Meskiene;
Vienna Biocenter, Vienna, Austria.

Cells are communicating by signals generated at cell membranes, transmitting/processing the information and responding selectively to diverse inputs. Strategy exercised in these transmissions is based on reversible protein phosphorylation that is mediated by concerted action of protein kinases and protein phosphatases. The phosphoprotein phosphatases of PP2C-type are involved in signalling pathways, including abiotic stress conditions. They were found to regulate stress-activated MAPKs in plants by displaying exquisite substrate specificity. We isolated, characterised and addressed the developmental regulation of two Arabidopsis PP2C phosphatases by promoter-reporter gene approach. Promoter activity associated to stomata suggests that PP2C may regulate MAPK pathways in these cells.

To characterize further these phosphatases we produced transgenic plants overexpressing epitope tagged proteins and analysed T-DNA insertion lines.

P1903. Cadmium Toxicity Is Associated with Oxidative Metabolism Dysfunction and the Production of Oxyradicals in *Zea mays* L. Seedlings

M. M. I. Mohamed;
Faculty of Science-Alexandria University, Alexandria, Egypt.

The aim of the study is to test the hypothesis that Cd^{2+} induces maize defense pathways against abiotic stresses. Different physiological and developmental changes were studied in roots of hydroponically grown maize seedlings. Antioxidant enzymes were studied to know the possible involvement of Cd^{2+} in oxidative stress. Cd^{2+} produced a significant inhibition of growth as well as reduction in pigments. An alteration in the activated oxygen metabolism were detected and evidenced by reduction in sulfhydryl group as well as a decrease in total glutathione .Moreover, the accumulation of H_2O_2 due to imbalance of redox and inhibition of antioxidant system. CAT, APx and POX were enhanced up to 50 µM Cd^{2+} supply. Roots challenged by Cd^{2+} at concentrations exceeding the detoxification capacity exhibit an increase in the rate of cell death and accumulation of soluble phenolics, and a decrease in dry weights as well as leaf area. Cd^{2+} induced oxidative stress indicated by the accumulation of MDA result from lipid peroxidation and significant increase in the SOD activity. Cd^{2+} did not cause injury in root but expedite differentiation, accelerating aging.

P1904. Efeect of Phosphorus on soluble sugars,Phenolic compounds and Lipids of *Brassica napus .L*

E. Faghani[1], H. Fahimi[2], A. Nourinia[3], M. Niakan[1];
[1]Islamic Azad Unversity Science and Researches Branch, Gorgan, Islamic Republic of Iran, [2]Islamic Azad University Science and Researches Branch, Tehran, Islamic Republic of Iran, [3]Agricultural and Natural Resources Research Center of Golestan Province, Gorgan, Islamic Republic of Iran.

Brassica napus knows a very important oil seed plant specially for its edible oil. An attempt was made to study the effects of P on sugar, phenolic compounds and lipids of Brassica napus seeds were germinated in the soil in pot.

Treatments of employed when seedlings were three leafleted . Different concentrations of P in the form of NaH_2Po_4 as 0, 0.02, 0.2 and 2M were added to the soil once.

After 5 weeks leaves and 8 weeks seeds samples were collected from plants.soluble ,sugar, phenolic compounds of leaves and lipids of leaves and seeds were measured.

The data analyized with MSTATC program.DMRT showed that soluble, sugar, phenolic compounds ,unsaturated /saturated ratio of fatty acids and also total lipids of leaves and seeds significantly (except sugar) increased by addition of P .The amount of fatty acids of seeds of plants grown in 0.02 M P significant(p<0.05)increased.

It cant be discussed that increasing of sugars and phenolic compounds which synthesized in photosynthesize are involved P synthesize of lipids is also related to sugars and phenolic compounds protect lipids against oxidation.

Generally addition of P in brassica napus increased secondary metabolite.

P1905. Hepatoprotective effect and antioxidant role of Methanol extract of *mucuna pruriens* seeds on Paracetamol intoxicated rats

Y. Rajeshwar, U. K. Mazumder, M. Gupta;
Department of Pharmaceutical Technology, Kolkata, India.

The methanol extract of the seeds of *Mucuna pruriens* (Family: Fabaceae) was evaluated for hepatoprotective activity against paracetamol induced liver toxicity in rats. The levels of serum glutamate oxaloacetate transaminase (SGOT), pyruvate transaminase (SGPT), alkaline phosphate (SALP), bilirubin, total protein, creatinine and blood urea were determined. The paracetamol induction at the dose of 500mg/kg/day resulted a significant elevation in the levels of serum enzymes, bilirubin, total protein with decreased blood urea. An intraperitoneal administration of methanol extract of *Mucuna pruriens* (MEMP) seeds at the dose of 125mg and 250mg/kg body weight for 9 days exhibited significant (P < 0.01) protective effect by decreasing SGOT, SGPT, SALP, bilirubin, total protein, and creatinine. The results were found to be in a dose dependent manner. Further, the study was extended to estimate the effect of MEMP on the levels of lipid peroxidation (LPO), reduced glutathione (GSH), catalase (CAT) and total protein *in vivo*. The MEMP significantly (P < 0.05) decreased the levels of thiobarbituric acid reactive substances (TBARS) and increased levels of reduced glutathione (GSH), and the activities of Catalase (CAT) and total protein resulted in reducing the free radical formation in liver. The effects of MEMP were compared with a standard drug Silymarin at the dose of 25mg/kg. body weight.

P1906. Study on the germination of BELLA-DONNA L.seeds in West Mazandaran, Iran.

A. Rahnavard, G. Asadian, K. Ghorchibeigy;
poster, Tonekabon, Islamic Republic of Iran.

From ancient times Atropa bella-donna L. is well known medicinal plant with roots, leaves and stem used as herbal drugs.The whole plant contains tropan alkaloids mainly atropine and a small hyosciamine, scopolamine and apoatropine.Banewort row material has been collected from habitats for the need of pharmacenetic industry.This plant is one of the most important medicinal plant which are growing wild in west of Iran in Gorgan, Ramsar, tonekabon, Gilevan, Roudbar,Tavalesh and Asalem. In this study sampels were collected from Kandovan.

The seed germination was studied with effect of scarification, variable temperature and treatments Giberllic Acid(GA3). The present study showed effect of scarification is insignification but variable temperature (6 hour at 30 °c and 18 hour at 15°c)simulated significantly seed germination(82.5%)and with Giberellic Acid (GA3)1mg/l H2O (89.5%).

P1907. Effects of different rates of nitrogen on yieid,protein and nitrate accumulation in forage of two varieties CORN(Zea mays L.)hybrids.

A. Rahnavard, G. Asadian, K. Ghorchibeigi;
poster, Tonekabon, Islamic Republic of Iran.

The objective of this study was to examine plant morphological characters and the forage yield,protein and nitrate accumulation on responses of two corn hybrids under effects of four different rates of nitrogen fertilizer.Two single-cross hybrids maize varieties,KSC 604(mid-season)and KSC 704(late-season)were planted at plant density(70000 plant/ha)and four nitrogen fertilizer rates(0,300,450 and 600/ha)as urea(0,175,225 and 300 kg N/ha).A split plot design was used with four replications which,hybrids as main plot and nitrogen levels as sub plot.In this expriment forage yield and its components and some attributed characters such as total number of leaves,number of ear,plant height,number of tassel,leaf as compared with stem,total dry matter,harvest index,nitrate accumulation in plant,soil and protein were evaluated.The analysis of variance shows that main effects and their intractions were observed significantly.Some of main results are:with increasing nitrogen fertilizer, forage yield and nitrate accumulation increased. highest forage yield with lowermost nitrate in both varieties were obtained at 450 kg urea/ha.

P1908. Influence of environmental factors on seed germination of Salvia sclarea under laboratory comditions(collected from Roudbar,IRAN).

G. Asadian, A. Rahnavard, K. Ghorchibeigy;
Poster, tonkabon, Islamic Republic of Iran.

Evaluation of temperature, resistance to salinity and water stress was study on germination of Salvia sclarea seeds under laboratory conditions. seed sample was gathered from Roudbar ecotype. Start of germination was in 0 °c . max percentage was in 4 and 8 °c. from 12 to 24 °c percentage of germination was reduced. Rate of germination increased from 0 to 12 °c and in the latter temperature, it was maximum and in temperature higher than 12 °c. rate of germination was reduced. Percentage of germination was maximum in control and with increasing of osmotic potential (NaCl),it was reduced. In this case, there was not statistically significant differences from -6 to -3 bar from -12 to -9 bar, with increasing osmotic potential, rate of germination was reduced. In this case, control treatment had significant difference with other treatments but there was not significant difference between other salinity levels but the trend was decreasing.

P1909. Interacting effects of climate change on sagebrush (Artemesia tridentata) seedlings

S. Lambrecht;
San Jose State University, San Jose, CA, United States.

Seedling response to climate change has often been ignored. Sagebrush (Artemesia tridentata) is common in the Western United States, where variability in climate is expected to increase. I grew two subspecies of sagebrush, one native to mountains (Mountain sagebrush) and the other to the desert (Basin sagebrush). I studied growth and photosynthesis of seedlings exposed to two levels of soil moisture in combination with freezing. Under high moisture, photosynthesis of Mountain sagebrush was twice that of Basin sagebrush. Drought reduced photosynthesis of Basin sagebrush by 75% and Mountain sagebrush by 60%. In contrast, freezing reduced photosynthesis of Mountain sagebrush by 78% while Basin sagebrush was unaffected. However, droughted Basin sagebrush was more sensitive to freezing, which reduced photosynthesis by 50%. In contrast, drought did not affect the susceptibility of Mountain sagebrush to freezing. Subspecies native to contrasting environments may have dissimilar responses to various aspects of climate change. Furthermore, the susceptibility of plants to an aspect of climate change may be modified by other simultaneously occurring factors.

P1910. Dependence of soil microorganisms on recent photosynthates from trees

S. G. Göttlicher[1], K. Steinmann[2], N. R. Betson[1], P. Högberg[1];
[1]Section of Soil Science, Department of Forest Ecology, Swedish University of Agricultural Sciences (SLU), Umeå, Sweden, [2]Department of Landscape Dynamics, Swiss Federal Research Institute, WSL, Birmensdorf, Switzerland.

We studied the dependence of the carbon status of soil microorganisms on the supply of current photosynthates from the tree canopy in a boreal forest. We used the method SIR (Substrate Induced Respiration) in a girdling experiment, using sucrose from a C_4 plant which had a c.16‰ more positive ŭ^{13}C value than the boreal “C_3-soil”. The respiration rate after sucrose application was on average c. 1.7 times higher in both girdled and non-girdled plots than the basal respiration during the course of three days. In non-girdled plots, respiration of added C_4-sucrose accounted for 25% only of total respiration after sucrose application, whereas it accounted for 50% in girdled plots. The increased release of C_3-carbon after amendment with C_4-sucrose is viewed as increased respiration of C already present in the microbial biomass. Our data thus show that less C is available to the microorganisms in girdled plots and heightens the importance of recent plant photosynthates for soil processes.

P1911. An investigation of the allelopathic effects of Cressa cretica on the germination and growth of purslane, goosefoot and oat seedlings

G. H. Zarei;
Islamic Azad University of maybod, Maybod, Islamic Republic of Iran.

Cressa cretica belongs to *Convulvulaceae*. This plant is annual herb, which grows on salty soils. Plant collected from Yazd province in Iran. For this the root and shoot of the plant dried and powdered separately. The extract

of 2%, 5% and 10% was prepared from the root and shoot powder. Then 3 kinds of seed of weeds including *Portulaca oleracea*, *Chenopodium album* and *Avena sativa* planted in the prepared extracts in petridish on watman paper. This project is done in a completely randomized design

with 3 replication (for every replication 20 seeds). Also 20 seeds from every weed planted in distilled water as a control group. After 72 hours the number of germination seeds counted and after a week seedling high measured.

According to the results and statistical analysis, *Cressa cretica* is an allelopathic plant. 10% extract of shoot showed the strongest allelopathic effect and 2% extract of root showed the weakest. In the following the strongest to the weakest allelopathic parts of *Cressa cretica* in related to seeds germination is shown: 10%shoot>5%shoot>10%root>5%root>2%shoot>2%root>distilled water

P1912. Effect of Substituents of Some Synthetic Monoethanolamine Salts of *para*-Substituted Benzoic Acids (MEASPBA) during Cucumber (*Cucumis sativus* L.) Germination

M. E. Crisan[1], C. M. Bertea[2], M. Grozav[1], L. Kurunczi[1], M. Maffei[2];
[1]Institute of Chemistry Timisoara-Romanian Academy, Timisoara, Romania, [2]Department of Plant Biology and Centre Excellence CEBIOVEM, University of Turin, Turin, Italy.

Studies were conducted in order to test a series of the monoethanolamine salts of *para*-substituted benzoic acids (MEASPBA), new compounds with biological activity as plant growth regulators and to evaluate the correspondence between the effects of different substituents on germination rate, root and shoot size, fresh and dry biomass, protein content, isocitrate lyase and catalase activity. The higher concentrations of the compounds inhibited the *Cucumis sativus* L. seed germination (exceptions were nitro- and amino- substituents), but lower concentrations had no effect or were stimulatory. The data showed that fresh biomass and root size decreased dramatically in seedlings incubated with compounds containing a halogen- (in order of its increasing atomic size) and nitro-substituents. The activity levels of isocitrate lyase (ICL, EC 4.1.3.1) and catalase (CAT, EC 1.11.1.6) in cucumber seedlings and their correlation with the above mentioned parameters are also discussed.

P1913. Phytochemical and Biological Investigation of Dendrosicyos socotranus

N. A. Ali Awadh[1,2], U. Lindequist[3], M. A. Al-fatemi[1], S. Hammod[4];
[1]Pharmacognosy Department, Faculty of Medicine and Health Sciences , Aden University1, Aden, Yemen, [2]Pharmacognosy Department, Faculty of Pharmacy, Sana'a University,, Sana'a, Yemen, [3]Department of Pharmaceutical Biology, Institute of Pharmacy, Ernst-Moritz-Arndt- University, Greifswald, Germany, [4]Pharmacology Department, Faculty of Medicine and Health Sciences , Aden University1, Aden, Yemen.

D. socotranus grows on the coastal plains and hills in Socotra island. It is the only tree in the Curbitaceae family. Dried powdered leaves were extracted in a Soxhlet apparatus successively with petroleum ether, dichlormethane, methanol, and cold water. Evaporation of the solvents was followed by drying in vacuo to provide crude extracts. The dried crude extracts were tested for antibacterial activity by using the modified disc diffusion method1; for their cytotoxic effects on FL-cells by using the neutral red assay2, and for their effects in the isolated rabbit ileum assay3. Phytochemical evaluation of plant extracts was performed using TLC. No antibacterial activity against (S. aureus1 (ATCC 29213), E. faecalis (ATCC 29212), E. coli (ATCC 25922) and P. aeruginosa (ATCC 27853) has been shown for the extracts till now. DM- and PE- extracts showed IC50 of 110 and 500 µg.

P1914. Facilitation can be mediated by allelopathy in communities of arid-land plants

M. Tavakoli, M. Jankju - Borzelabad;
Yazd University, Yazd, Islamic Republic of Iran.

In arid areas, plant coexistence is affected by different types of plant-plant interaction. In a field experiment, we found that facilitation by perennial *Artemisia aucheri* increased establishment for annual grass *Bromus tectrum*. Interaction was switched to competition and led to eventual death of *Artemisia*. Here we are arguing that facilitation can also be mediated by allelopathic effects. In a glasshouse experiment, *Bromus* seeds were grown in Petri dishes and irrigated with a solution containing 8 levels of *Artemisia* extracts. Furthermore *Bromus* seedlings were grown in pots containing 4 levels of *Artemisia* tissue powder plus field soil. Results indicate significant allelopathic effects of *Artemisia* on germination and seedling growth of *Bromus*, only at high concentration of extract and powder. Interestingly, under the same concentration of *Artemisia* powder, we found higher performance for *Bromus* in soils originated from *Artemisia* understory than bare field.

P1915. Study of Allelopathic potential of job's tear plant (*Coix lacryma-jobi* L.)

A. Rezaeinodehi, S. Khangholi, M. Amini Dehaghi, Y. Filizadeh;
Faculty of Agricultural Sciences, University of Shahed, Tehran, Islamic Republic of Iran.

Job's tear native perhaps to southeast Asia is a perennial grass and common weed in paddy fields in north of Iran. Because of the no information about allelopathic potential of the species, the experiment was conducted to determine the effect of the plant extract concentrations on germination, radicle and hypocotyle growth of test plants including; garden cress, lettuce and redroot pigweed. The collected seeds were cultivated in greenhouse and after four months growing the plants harvested. Vegetative plants body was dried and then ground. Concentrations with 2, 4 and 8% were prepared from extract and distilled water was used as control. The results showed that job's tear has high negative allelopathic potential. Test plants germination was reduced by increasing the concentrations with the exception of pigweed at 2%. Radicle and hypocotyle growth of the test plants were significantly reduced by increasing the concentrations with the exception of lettuce and pigweed hypocotyles at 2% in compare with control. In general radicle growth was more affected in compare with hypocotyle. Test plants had different sensitivity to job's tear allelopathic potential.

P1916. Restoration of riparian areas dominated by Eucalyptus globulus: allelopathic constraints

C. Canhoto, P. Cruz, J. Canhoto;
University of Coimbra, 3004-517 Coimbra, Portugal.

Large areas of Portugal are covered by monocultures of the exotic E. globulus. The impact caused, in lotic systems, by eucalypt plantations may be minimized by the restoration of native riparian corridors. Herein we assess the allelopathic potential of eucalypt leaves and seeds against the deciduous Alnus glutinosa L.. Increasing concentrations of leaves leachates, obtained from artificial washing of leaves, were bioassayed for their phytotoxic effects on germination and seedling growth of alder. Low concentrations of eucalypt leachates significantly reduced radicle and aerial growth of the germinated seedlings. Eucalypt seeds incubation in agar culture medium significantly depressed alder but stimulated eucalypt germination. Germination rate and radicle growth seems to be negatively correlated with distance from the exudates origin.

We suggest that deciduous plantations in eucalypt streams riparian areas should be made in colder months to avoid high contents of leachates in the soil (due to the high summer input and impregnation with leachate rich stream water). Alder trees should be planted as saplings and at a distance from the eucalypt plantation.

P1917. Determination of selected phenolic compounds in common buckwheat (*Fagopyrum esculethum* Moench)

J. Kalinova[1], N. Vrchotova[2], J. Triska[2];
[1]University of South Bohemia, Faculty of Agriculture, Ceske Budejovice, Czech Republic, [2]Laboratory of Analytical Chemistry, Institute of Landscape Ecology, Academy of Sciences of the Czech Republic, Ceske Budejovice, Czech Republic.

Buckwheat (*Fagopyrum esculentum* Moench) is known as good weed competitors. The phenolic compounds have wide biological activities and they are propably responsible for allelopathy potential of buckwheat.

The aim of this work was to identify and determine of selected the phenolic compounds in different parts of plant and their change during vegetation.

Common buckwheat (vyriety Emka) was grown in Ceske Budejovice (sand-loam brown soil) in year 2004. Lyophilized parts of plant (sampled three times during vegetation) were extracted by 90% methanol. Supernatants were analyzed by HPLC (DAD detector).

The highest content of quercetin, catechin and chlorogenic acid was determined in inflorescence. The highest content of derivates of quercetin was in stems at the end of vegetation. Rutin culminated in leaves in flowerage period. Myricetin was identifed only in stem.

The allelopathic activity of described compounds will be tested. This work was supported by grant GACR 521/03/D076 and AV0Z60870520.

P1918. Allelopathic potential of tea (*Camellia sinensis* (L.) Kuntze) on germination and growth of some plants species

A. Rezaeinodehi, S. Khangholi;
Faculty of Agricultural Sciences, University of Shahed, Tehran, Islamic Republic of Iran.

Effect of tea organs extract concentrations on germination, radicle and hypocotyle growth of garden cress, lettuce and redroot pigweed and golden foxtail weeds and effect of rates of their dried residues on leaf area, root, shoot and leaf dry weight of the weeds were studied. Concentrations and dried residue rates were consisting of 0, 2.5, 5 and 10% of organs extract and 0, 8, 16, 24 and 32g.kg^{-1} respectively. The results showed that garden cress and redroot pigweed germination was reduced by all extracts of tea organs with the exception of leaf extract at 2.5%. Lettuce germination was inhibited by all extracts with the exception of leaf and fruit extracts at 2.5 and 5% concentrations respectively. Golden foxtail germination was also inhibited by all extracts with the exception of leaf and fruit extracts at 2.5% concentrations. Radicle and hypocotyle growth of studied palnts were significantly reduced by all extracts of tea organs with the exception of lettuce hypocotyle at 2.5% concentration of leaf and fruit extracts. Weeds leaf area, root, shoot and leaf dry weight were significantly lower with tea organs residues especially at rates of 24 and 32 g.kg^{-1} incorporation.

P1919. Effects of coffeine a toxic(allelopathic compound) on germination and growth of three wheat cultivars

L. Ziaebrhimi[1,2], R. Khavarinejad[2], H. Fahimi[2];
[1]Azad University, Kerman, Islamic Republic of Iran, [2]Tehran Azad University Science and Research branch, Tehran, Islamic Republic of Iran.

In this study concentrations of 0, 50, 100, 200, 300 400 mg/l 0f caffeine used for germination and growth of 3 wheat cultivars.(higher concentrations inhibited germination). Timeof first germination, germination percentage ,wet and dry weight of roots and shoots (1st leaves) , average length of roots and shoots and number of lateral roots estimated. Chlorophyll,protein and sugar content of both roots and shoots measured and finally activity of peroxydases measured in roots and shoots. Statistical analysis showed that caffeine caused delay in germination and germination percentage decreased. Dry and wet weight also showed deduction in root and shoot parts. Root and shoot length decreased more reduction in roots. Total amount of chlorophylls decreased,chla reduced more than chlb.in concentration of 400mg/l amount of two chlorophylls are nearly equal. While starch content of seedlings not affected ,soluble sugars slightly increased. Protein content of roots and shoots showed a slight decrease in high concentrations. Activity of antioxidant enzymes (peroxidases) in response to toxic situations strongly increased in roots more than shoots.

P1920. Impact of the waterweeds *Elodea* spp. on the performance of an aquatic herbivorous lepidopteran

D. Erhard, E. M. Gross;
Limnological Institute, University of Konstanz, Konstanz, Germany.

The submersed neophytes *Elodea canadensis* and *E. nuttallii* invaded many water bodies in Europe. Both species are well adapted to various environmental conditions and are allelopathically active against competing primary producers. Here we show that at least *E. nuttallii* is also chemically defended against important invertebrate herbivores; a trait that might further enhance the success of this plant. In our bioassays, waterweeds affected feeding, growth and survival of larvae of the lepidopteran *Acentria ephemerella*. These larvae preferably feed on various aquatic plants but only seldom on *E. canadensis* and never on *E. nuttallii*. Live plants influenced the larvae on different stages of their life cycle. Whereas newly hatched larvae mainly suffered from increased mortality, larvae after hibernation primarily faced growth inhibition. Extracts from *E. nuttallii* exhibited antifeedant properties, reduced growth and increased mortality of the larvae. Flavonoids present in *Elodea* might have accounted for the feeding deterrence, but did not affect survival of the larvae, indicating that chemical defence in *Elodea* is based on multiple compounds.

P1921. Two novel uses for *Arabidopsis thaliana* (L.) Heynh seeds.

M. Pennacchio, L. V. Jefferson, K. Havens;
Institute for Plant Conservation, Chicago Botanic Garden, Glencoe, IL, United States.

We report on two novel uses for the seeds of the cruciferous weed species, *Arabidopsis thaliana* (L.) Heynh. The first focuses on using the seeds as part of a set of standard target species in phytotoxic bioassays. Lettuce and other crop species have traditionally been used in that role. There is concern that they may not be sensitive enough and may not reflect what is actually occurring in the field. We tested seven known allelochemicals on *A. thaliana* seeds and compared them to lettuce seeds. Our study revealed that *A. thaliana* seeds were significantly more sensitive and useful in phytotoxic bioassays.

In a second study, we evaluated the effects of aerosol smoke on *A. thaliana* seeds. The results showed that smoke treatments ranging from 1-8 min significantly promoted rate of germination while 32-64 min inhibited it.

A. thaliana seeds appear to be ideal for phytotoxic studies and for those that focus on the response of germination to smoke treatments. The large body of knowledge already amassed for this species is an excellent resource for determining the effects of natural chemicals on seed germination and growth.

P1922. Study on the Allelopathic potential of bur parsly [Tungenia latifolia (L.)HOFF.]seed extracts collected from Roudbar, Iran.

A. Rahnavard, G. Asadian, K. Ghorchibeigi;
poster, Tonekabon, Islamic Republic of Iran.

Experiments were conducted to determine the effect of different concentrations of seed extructs of bur parsley on germination and growth of two aryland wheat(Triticum aestivum L.)cultivars(Rashid and Khalij)and bur parsleyseeds.Poliethylen glycol(PEG)was used todetermine the influence of osmotic potential on the bioassay materials.Burparsley sees extruct concentrations of 60,80 and 100% of original strength reduced the germination of two wheat cultivars after three days.After seven days,germination of Rashid wheat seeds was significantly reduced by using seed extract concentrations of 40,60,80 and 100% and germination of Khalij wheat seeds was significantly reduced by usingseed extract concentration of 80 and 100% seed extract concentration also reduced coleoptile and radicle lengths in the two wheat cultivars.Bur parsley seeds were not sensitive to the lower concentration of their own extruct.The results of this study show the allelopathic potential of bur parsley seed extructs on the two dryland wheat cultivars.

P1923. The alkaloid liriodenine during germination of *Annona diversifolia* Saff.

A. R. González-Esquinca, L. M. Luna-Cazáres, I. De la Cruz-Chacón;
Universidad de Ciencias y Artes de Chiapas, Tuxtla Gutiérrez, Chiapas, Mexico.

Annonaceae plants produce a series alkaloids, like liriodenine an oxoaporphine alkaloid that plays an important role in the plants that produce it. This research was made in *Annona diversifolia* Saff for know the first stages of liriodenine production during the development. The quantification was done by HPLC in the organs and tissues from the newly collected seed, with two and ten days of imbibition, when the radicle emerged in the stage of seedling. According with the results the liriodenine is not imported from the mother plant and is not a product of the embryogenesis, because it appears for the first time in the endosperm at the tenth day of imbibition, remaining exclusively in this place in spite of the development of one cm radicle. Once the seedling stage has initiated it the liriodenine can be found in roots and stems and it is absent from the cotyledon leaves and from the true leaves. Due to this, its biosynthesis is organ specific and seems to be controlled by early development programs in the plant that represent an important biological function, perhaps in the defense mechanism of the plant.

P1924. Presence of lichen compounds in the butterfly *Talicada nyseus* (Lycaenidae)

V. Karunaratne[1], S. Kathirgamanathar[1], A. Wijesekera[2], S. Wijesundara[3];
[1]University of Peradeniya, Peradeniya, Sri Lanka, [2]Horticulture Research and Development Institute, Gannoruwa, Sri Lanka, [3]Royal Botanic Gardens, Peradeniya, Sri Lanka.

During our studies on Sri Lankan lichens, we discovered the sequestration of aromatic lichen products such as usnic acid and atranorin the triterpenoid zeorin and a long chain fatty acid ester belonging to the crustaceous lichen *Leproloma sipmanianum* Kummerl & Leukert by the butterfly *Talicada nyseus* Guerin (red pierrot) in Beragala, Uva province, Sri Lanka. *T. nyseus* was found flying close to the extensive lichen thallus, growing on road side proterozoic rocks of gneiss and quartz schist which are exposed at road edges, and roosting on it periodically. The presence of these compounds in the butterfly was confirmed by comparative TLC and HPLC studies with authentic lichen substances isolated from the lichen *L. sipmanianum*. The presence of lichen compounds in both the larvae and larval waste collected from Beragala suggests that the adult butterfly was accumulating the lichen compounds through the larvae and was using the lichen as an alternative food source, probably when the natural food source *Bryophyllum calycinum* is not plentiful.

P1925. Comparison of defences induced by piercing-sucking and chewing herbivores in *Medicago truncatula*

M. Leitner, W. Boland, A. Mithöfer;
MPI für chemische Ökologie, Jena, Germany.

The modes of chemical defence in plants can basically be divided in induced and constitutive ones. The former can further be classified in indirect and direct defensive mechanisms.

Induced phytochemicals in *Medicago truncatula* were investigated using the defence against two arthropod pests (*Spodoptera littoralis* and *Tetranychus urticae*) with different feeding manners as example.

As component of indirect defence a sizeable variety of volatiles is released, particularly of sesquiterpenoids. Regarding direct defence, the deposition of phenolics at the wounding sites was observed with a similar pattern as described for pathogen attack. Moreover, the accumulation of reactive oxygen species was detected adjacent to the wounds.

These reactions are at least in part mediated by the phytohormones salicylate and jasmonate. Both, the pattern and the time course of their accumulation clearly differs depending on the inducing herbivores.

P1926. Cyanogenesis of Lima Bean (*Phaseolus lunatus* L.): Intraspecific and Ontogenetic Variability

D. J. Ballhorn, R. Lieberei;
Biocenter Klein Flottbek and Botanical Garden, University of Hamburg, Germany.

Cyanogenesis is a process by which hydrogen cyanide (HCN) is released from endogenous cyanide-containing compounds as reaction to cell or tissue disintegration.

We found substantial variation of the cyanogenic potential (HCNp; the total amount of HCN which can be released from a given plant tissue), specific ß-glucosidase activity and the resulting cyanogenic capacity (HCNc; the relase of HCN per time unit) by screening for cyanogenic properties of 14 lines of *P. lunatus.* In addition to this intraspecific variability a distinct ontogenetic variability of cyanogenic properties in leaf material occurred.

Plant cyanogenesis is considered to act as a constitutive plant defence but our studies on the obligate cyanogenic Lima bean let assume a plastic character of cyanogenic features in quantitative aspects. Analysis of Lima bean plants infested with two-spotted spider mites (*Tetranychus urticae* Koch) and Mexican bean beetles (*Epilachna varivestis* Mulsant) revealed an increase of specific ß-glucosidase activity within the damaged leaf tissue.

P1927. Unprecedented oxylipin pathways in the moss *Physcomitrella patens*: Isolation and characterization of a new multifunctional lipoxygenase with lyase cleaving activity.

T. Wichard[1], T. Senger[2], G. Cornelia[3], K. Susan[3], G. Pohnert[1], I. Feussner[3];
[1]Max-Planck-Institut für chemische Ökologie, Jena, Germany, [2]Institut für Pflanzengenetik und Kulturpflanzenforschung, Gatersleben, Germany, [3]Georg-August-Universität Göttingen, Göttingen, Germany.

The moss *Physcomitrella patens* was chosen as model system to study plant lipid metabolism since it harbors a wide range of different polyunsaturated fatty acids. Here oxylipin pathways responsible for volatile formation in this moss were investigated. Upon cell damage (*R*)-1-octen-3-ol, 2-octen-1-ol and (5*Z*,8*Z*,10*E*)-12-oxo-dodecatrienoic acid (12-ODTE) as well as (2*E*)-nonenal and 11-oxoundeca-5,9-dienoic acid (11-OUDE) were identified as major oxylipins. Most interestingly all volatile oxylipins turned out to be cleavage products of arachidonic acid.

We isolated a lipoxygenase (LOX) with yet unknown catalytic properties. The enzyme shows high sequence homology to linoleate 13-LOX from plants. In addition, it was characterized as an arachidonate 12-LOX with preferences against C20 polyunsaturated fatty acids. This enzyme exhibits a high hydroperoxidase- and a yet not known fatty acid cleavage activity. Thus the action of this multifunctional LOX directly led to formation of the identified unsaturated alcohols and 12-ODTE when arachidonic acid was used as substrate. Interestingly, (2*E*)-nonenal and 11-OUDE do not belong to its product spectrum.

P1928. Activity of Acetylcholinesterase in larvae an adult of the fall armyworm *Spodoptera frugiperda* (Lepidoptera: Noctuidae) using diets containing Burseraceae plants

B. Zúñiga[1], B. Rodarte[1], J. L. Contreras[2], P. Guevara[1];
[1]Facultad de Ciencias, Universidad Nacional Autónoma de México, Mexico, [2]Benemérita Universidad Autónoma de Puebla, Puebla, Mexico.

Acetylcholinesterase, a serine hydrolase, catalyzes the breackdown of the neurotransmitter acetylcholine into acetate and choline.The enzymatic inhibition of the acetylcholinesterase has been used in order to test the effects of diverse compounds upon insect physiology. In the present work, we evaluated separately whether an artificial diet containing dry plants or methanolics extracts at different concentrations of *Bursera lancifolia, B. aleoxyllon*, *B. grandifolia, B. aptera and B. longipes* widely distributed in Mexico, has an effect in acetylcholinesterase inhibition of larvae and adult of *Spodoptera frugiperda*. Results obtained indicate that Acetylcholinesterase inhibition was about 70-90 % in larvae and 5-30% in adults with all Burseraceae species. *B. lancifolia* was the one with main effect (98% in larvae and 30% in adults). These data suggest that some compounds of these plants, possibly terpenics, have anticholinesterase activity in this insect-plague which represent a devasting higly cost crops damages for our country.

P1929. Neoplasmic formations on trees: host plant tissues are affected

G. Ievinsh;
Faculty of Biology, University of Latvia, Riga, Latvia.

In order to test a hypothesis that neoplasmic formation on trees induced by arthropods affects biochemical characteristics of both newly formed galls as well as host plant tissues, biochemical characteristics with a possible adaptive role were determined in nine gall former - host tree combinations. Photosynthetic pigments, extractable protein content, and oxidative enzyme activities were determined in gall tissues, leaf tissues of galled leaves, and leaves on ungalled tree branches. Neoplasmic tissues were characterized by a low content of pigments, decreased chlorophyll a/b ratio, lower extractable protein content, and decreased activities of peroxidase and polyphenol oxidase as compared with ungalled host leaf tissues. In galled leaves or in leaves adjacent to galls increased level of peroxidase activity was found. In several gall inducer - host plant combinations, galled host plant tissues contained increased activity of polyphenol oxidase as well. The presented data reflect long-term systemic effects of neoplasmic formation on host-tree physiology suggesting that gall inducers affect potential adaptive responses of host plants.

P1930. Cytokinins in the gall forming wasp Diplolepis rosae and its galls on Rosa canina

V. Krystof, M. Mistrik, O. Novak, P. Tarkowski, M. Strnad;
Palacky University & Institute of Experimental Botany, Olomouc, Czech Republic.

Attempts to determine the chemical signals of the gall-inducing insect, that initiate the gall formation on host plant and its development, resulted up to date in an identification of a number of different compounds that appear to be involved in cecidogenesis. Among them, elevated amounts of naturally occuring plant hormones were found in galls, including auxins and cytokinins. In the present work the levels of 39 cytokinins in galls induced by wasp *Diplolepis rosae* on *Rosa canina* were quantified and identified, with iP, iPR and BAP to be the most abundant. In larvae of *D. rosae*, 11 of the present cytokinins showed significant variations in time course during the wasp lifecycle. The most dramatic changes were found in iP and iPR levels. Significant cytokinin levels were found in quiescent larvae and surprisingly also in adult wasps. Physiological explanation for that finding evokes speculations on the actual origin of cytokinins in gall-forming insect and their physiological role.

P1931. Distribution and quality of chemical cues for a herbivores' host plant recognition

K. Reifenrath, C. Müller;
Julius-von-Sachs Institute for Biosciences, Wuerzburg, Germany.

The first contact zone between an insect and its host plant is the plant surface. However, epicuticular leaf waxes of *Nasturtium officinale* (Brassicaceae) were shown to lack feeding stimulatory activity for the mustard leaf beetle *Phaedon cochleariae*. Only by damaging the wax layer, the beetles might receive information on the host plant quality. Thus, in these plants, the leaf wax coverage can be regarded as defensive shield against specialist herbivores. Nevertheless, extracts of *N. officinale* leaves evoked strong feeding activity. In bioassays, the most characteristic secondary plant compounds of Brassicaceae, glucosinolates, did not stimulate feeding. Therefore, analyses of fractionated host plant extracts and corresponding bioassays led to the isolation of further stimulating plant compounds. Potential additive or synergistic effects of these plant metabolites from inner leaf tissue on the feeding behaviour of *P. cochleariae* were investigated.

P1932. Insecticidal activity of deoxypodophyllotoxin, isolated from *Juniperus sabina* L, and related lignans against larvae of *Pieris rapae* L

R. Gao[1], X. Yu[2], X. Zhang[3];
[1]Applied Institute of Toxicology, Nanjing, China, [2]Food safety research center, Jiangsu Academy of Agriculture Science, Nanjing, China, [3]Research and Development Center of Biorational Pesticide, Northwest Science and Technology University of Agriculture and Forestry, Yangling, China.

A petroleum ether extract of *Juniperus sabina* L was found to show insecticidal activity against larvae of *Pieris rapae* L. From the extract, an insecticidal compound was isolated by bioassay-guided fractionation. The compound was identified as deoxypodophyllotoxin (1). In bioassays, 1 showed antifeedant activity against larvae of *P rapae* at 0.05-1.00 g litre^{-1} and its AFC$_{50}$ (concentration for 50% antifeedant activity) values at 12 and 48 h were 0.170 and 0.060 g litre^{-1}, respectively. In that concentration range, all treated insects died within 48 h after treatment and compound 1 showed delayed insecticidal activity. At 0.015-0.100 g litre^{-1}, 1 showed insecticidal activity, with an LC$_{50}$ of 0.020 g litre^{-1}. The related compound deoxypicropodophyllotoxin (2), showed lower antifeedant and insecticidal activities than 1 in bioassay. This indicated that the *trans*-lactone ring is an important moiety for enhancing activity in these compounds. Comparison of the insecticidal activities of 1 and another related compound, podophyllotoxin (3), suggested that varying the substituent at C-4 is an exciting possibility for synthesizing more potent analogues.

P1933. The effect of root exudates on plant-fungus-interactions in the tomato rhizosphere

R. Mammerler, M. Nell, M. Permann, F. Stabauer, H. Vierheilig, S. Steinkellner;
Institute of Plant Protection, Vienna, Austria.

The stimulation of plant pathogens by root exudates is an integral part of the concept of inoculum potential. Propagules of several plant pathogenic fungi have been shown to germinate in the presence of root exudates, but as reviewed by Nelson (1991) little is known about the nature of specific exudate molecules initiating fungal growth. In our study we assessed spore germination and mycelial development of the tomato pathogens Fusarium oxysporum f. sp. lycopersici and Fusarium oxysporum f. sp. radicis-lycopersici in the presence of root exudates and several flavonoids. We could show that tomato root exudates contained a major amount of phenolic compounds which affect the development of F. oxysporum in the course of plant development. The possible involvement of flavonoids in the fungal development will be discussed.

Nelson, E.B. 1991: Exudate molecules initiating fungal response to seed and roots. pp 197-209 in: The rhizosphere and plant growth. D. L. Keister & P. B Cregan, eds. Kluwer, Dortrecht.

P1934. Evaluation *of Balanites aegyptiaca* Del. (Zygophyllaceae) kernel cake saponins and their larvicidal effect against *Culex pipiens* mosquito larvae

B. Chapagain, Z. Wiesman;
Phyto-Lipid Biotechnology Lab (PLBL), The Institutes for Applied Research, Ben-Gurion University of the Negev, Beer-Sheva, Israel.

Balanites aegyptiaca Del. is a drought-tolerant desert tree native to Africa, the Middle East and South Asia. Although various plant parts are widely used in folk remedies (whose activities may be attributed to the saponin constituents), this plant remains one of the world's most neglected species. To widen the uses of this plant - and hence to aid in its domestication - a methanolic extract of *B. aegyptiaca* kernel cake after oil extraction was analyzed phytochemically (LC-MS, NMR and colorimetry) for saponin constituents and tested for its larvicidal effect on *Culex pipiens* mosquito larvae. The kernel cake contained a large amount of saponins, having the sugar moiety attached in positions C-3 and C-26 and diosgenin as the aglycone. The main steroid saponin was 26-(*O*-ɓ-D-glucopyranosyl)-22- *O* -methylfurost-5-ene-3ɓ, 26 diol 3- *O* -ɓ-D-xylopyranosyl-(1Ÿ 3)- ɓ-D-glucopyranosyl-(1Ÿ 4) [Ŭ-L-rhamnopyranosyl-(1Ÿ 2)]-ɓ-D-glucopyranoside. The high larvicidal activity of the extract against *C. pipiens* larvae (LC$_{50}$ 76 ppm and LC$_{90}$ 545 ppm in 24 h) indicates that the kernel cake can be used as an effective larvicide (the saponins being the main active agents).

P1935. The effects of herbivore damage and elevated ozone concentration on the volatile terpenoids produced by two hybrid aspen (*Populus tremula x tremuloides*) clones

J. D. Blande[1], P. Tiiva[1], V. Freiwald[1], E. Oksanen[2], J. K. Holopainen[1];
[1]University of Kuopio, Kuopio, Finland, [2]University of Joensuu, Joensuu, Finland.

The terpenoids produced by two clones of hybrid aspen in response to herbivory by leaf weevils (*Phyllobius argentatus*), and larvae of the autumnal moth (*Epirrita autumnata*), have been studied in field plots running for two years under ambient and enhanced ozone levels. The volatile organic compounds produced by the differentially treated aspen clones were collected from either intact tree material in the field, or from cut twigs transported to the laboratory. Data was collected during the summer of 2004, and it is planned to increase the data set in 2005 using the field collection protocol. Tentative analysis of the data collected in 2004 suggests that isoprene emissions are not influenced by herbivore damage, but that there is some induction of monoterpenes, sesquiterpenes and homoterpenes, with particular induction of the monoterpene (cis)-beta-ocimene. A doubling of the ambient ozone concentration did not appear to induce terpenoid emission, but there was some clonal variation in the emission quantities of the homoterpene (*E*)-4,8-dimethyl-1,3,7-nonatriene (DMNT). The relative importance of ozone and herbivore damage on VOC induction will be discussed.

P1936. Future ozone-enriched environments: Can they affect plant-insect interactions?

D. Pinto[1], P. Tiiva[1], P. Miettinen[2], J. Joutsensaari[2], A. M. Nerg[1], A. Laaksonen[2], J. K. Holopainen[1];

[1]University of Kuopio, Department of Ecology and Environmental Science, Kuopio, Finland, [2]University of Kuopio, Department of Applied Physics, Kuopio, Finland.

Terpenes play an important role in chemical communication between plants and insects. They react with ozone (O_3), tropospheric levels of which are predicted to rise. This is likely to affect herbivore induced plant volatile blends and influence plant insect interactions. We addressed 1) how O_3 alters the blend of terpenes emitted by cabbage plants, 2) how O_3 concentrations are influenced by reaction with phytogenic terpenes and 3) if secondary organic aerosols -SOA are detectable in the oxidation of phytogenic terpenes. White cabbage (*Brassica oleracea* cv Lennox) plants were treated with methyl jasmonate or infested with *Plutella xylostella* and placed in a 22-liter glass desiccator. O_3 was conducted onto plants at various levels. The headspace volatiles were collected. In a second experiment, to avoid loss of O_3 on plant surfaces, volatiles were conducted into a FEP Teflon tube chamber where O_3 flow was adjusted and monitored at the inlet and exit. Plant volatiles were collected before and after the reaction chamber and analyzed by GC-MS. Particle size distributions were measured at the end of the reaction chamber to analyze SOA. Preliminary results are presented.

P1937. Anatomy and histochemistry of leaves from *Omphalea oleifera* (Euphorbiaceae) and its relationships with the herbivore *Urania fulgens* (Uranidae).

E. M. Silvia[1], S. T. Fabiola[1], D. M. Rodolfo[2], G. F. Patricia[1,3];
[1]Facultad de Ciencias, México, Mexico, [2]Instituto de Ecologia, México, Mexico, [3]Universidad Nacional Autónoma de México, Mexico, Mexico.

Herbivore feeding by rainforest insects includes underground parts and plant fluids. The *Omphalea oleifera* (Euphorbiaceae), present in Los Tuxtlas Mexico; is subject of intense herbivory. In the present work, we studied anatomy and qualitative and quantitative aspects their histochemistry leaves. The calcium oxalate crystals (druses and prismatic) are abundant in leave's adaxial and abaxial epidermis. Laticiferous containing insoluble polysaccharides, phenols and lipids, are associated to vascular tissue and are present in all venation. Lignin deposits were detected around harmed areas by herbivore activity, which suggest a healing to avoid infections. Calcium oxalate crystals and the percentage of lignification found in leaves tissue were 8-10%; as well as lactiferous components, could participate reducing herbivory. Ecological studies, have shown that *Urania fulgens* feed adult plants, juvenile and seedlings being totally defoliated by this diurnal moth larvae. Thereafter it is of interest to study *U. fulgens* in order to know the physiological mechanisms by means this insect digest this plant, being considered as a specialist for *O. oleifera*.

P1938. Possible role of secondary metabolites in the host choice by codling moth larvae (Cydia pomonella)

W. Harand, H. Greger, **F. Hadacek**;
Department of Chemical Ecology and Ecosystem Research, Faculty of Life Sciences, University of Vienna, Vienna, Austria.

The question how fruit miners select the appropriate host is central in understanding the biology of codling moth, Cydia pomonella L, the most important insect pest in pome fruit production. In this study, methanolic extracts of leaves of Tanacetum vulgare and of inflorescences of Erigeron annuus were found to be feeding deterrent against newly hatched larvae. Bioassay-guided fractionation with dual choice tests on artificial substrate indicated that the most lipophilic fractions of both extracts contained the active compounds. Gas chromatography/mass spectrometry analyses revealed a group of sesquiterpenes as main constituents of the active fraction of the E. annuus extract. One of these, identified tentatively as a sesquiterpene with an aromadendrane skeleton by library comparison, deserves special attention, since a compound with identical spectrum is also present in the active fraction of T. vulgare. These findings suggest that secondary metabolites may interfere with host plant acceptance of codling moth larvae besides that of adults.

P1939. Biological activities of *Stemona* species

B. Brem[1], B. Rinner[2], R. Pfragner[2], H. Greger[1];
[1]Section of Comparative and Ecological Phytochemistry, University of Vienna, Vienna, Austria, [2]Institute of Pathophysiology, Centre for Molecular Medicine, Medical University of Graz, Graz, Austria.

Stemonaceae represent a rather isolated family within the Monocotyledons consisting of 3 genera and about 32 species. *Stemona* is the largest genus with about 25 species occurring as subshrubs or twining herbs mostly with perennial tuberous roots. Since the roots of several species are widely used as insecticides and for medicinal purposes, they are offered for sale on local markets in Thailand, China and Japan. However, because of the similar shape of the fleshy tuberous roots, quality control clearly showed that confusions with different species and even with representatives from other plant families are common. This uncertainty in purchasing appropriate plant material and unsolved taxonomic problems at the species level have led to confusions in chemical and pharmaceutical literature.
Stemona is characterized by family-specific alkaloids, showing an unusual molecular architecture with a pyrrolo[1,2-a]azepine nucleus or a pyrido[1,2-a]azepine nucleus. Moreover, the accumulation of stilbenoids is a typical chemical trend of many *Stemona* species. To contribute to a better understanding of the bioactive capacities of *Stemona* chemicals, we present antioxidative, insecticidal and cytotoxic activities from selected species and geographical provenances.

P1940. The importance of being red when young: field evidence that anthocyanins in juvenile leaves of *Quercus coccifera* afford camouflage against insect consumers but no protection against excess light

P. Karageorgou, Y. Manetas;
University of Patras, Patras, Greece.

We have tested two hypotheses for the function of red anthocyanins transiently appearing in young leaves i.e. the photoprotective hypothesis against excess light and the handicap signal against herbivory. We took advantage of the intraspecies variation in anthocyanin levels in young leaves of *Quercus coccifera*. PSII photochemical efficiencies measured in the field under white or red light (which by-passes anthocyanins) were not indicative of a photoprotective role. Yet, red phenotypes suffered considerably lower insect attacks and contained higher levels of deterring phenolics. We suggest that an anthocyanic screen may not be photosynthetically important in young, thin low chlorophyll leaves, where the attenuated green light may not be important for chlorophyll excitation. Yet, the leveling of reflectance in the 400-570 nm band makes red leaves less discernible to insect herbivores. Even after accidental approach, overconsumption is discouraged by high phenolic levels.

P1941. Infection process in sclerotial dieback of *Cryptomeria japonica* - competitive fungi in needle insect galls-

T. Kubono, Y. Ichihara;
Tohoku Res. Ctr. For. For. Prod. Res. Inst., Morioka, Japan.

Scolicosporium sp., the causal pathogen of sclerotial dieback of Japanese cedar (*Cryptomeria japonica*), was frequently isolated from needle galls associated with the gall midge insect *Contarinia inouyei* Mani. It was hypothesized that the pathogen establishes in needle tissue by taking advantage of the microenvironment conferred by the galls. The purpose of this study was to identify the gall ENDOPHYTES and relate these to the presence of *Scolicosporium*. Isolation tissues were separated into four categories:(1) needle tissue before gall formation; (2) incipient gall with larva; (3) necrotic gall with larva; and (4) necrotic gall post larval exit. *Pestalotiopsis* sp., *Rhinocladiella* sp. and *Cladosporium* sp. were frequently isolated from (1) whereas *Scolicosporium* sp. was absent. However, *Scolicosporium* sp. was isolated from (2), (3) and (4) together with *Pestalotiopsis* sp., *Rhinocladiella* sp. and *Cladosporium* sp. This investigation strongly suggested that *Scolicosporium* sp. first establishes at the incipient gall with included larva stage and that *Pestalotiopsis* sp., *Rhinocladiella* sp. and *Cladosporium* sp. were the predominant ENDOPHYTES.

P1942. Carboxylesterase-like proteins dehydratate 2-hydroxyisoflavanone in leguminous isoflavone biosynthesis: implication for the recruitment of enzymes from primary to secondary metabolism

T. Akashi, T. Aoki, S. Ayabe;
Dept. Appl. Biol. Sci., Nihon University, Fujisawa, Kanagawa 252-8510, Japan.

Isoflavonoids are ecophysiologically-active natural products of the leguminous plants. Isoflavones are early products of the pathway and synthesized by the dehydration of 2-hydroxyisoflavanones, the products of the P450 isoflavonoid synthase. cDNAs of 2-hydroxyisoflavanone dehydratases (HIDs) producing 4'-methoxy- and 4'-hydroxy-isoflavones were cloned from leguminous plants *Glycyrrhiza echinata* and soybean, respectively. The substrate specificity of HIDs agreed with the profiles of isoflavonoids produced by each plant species. Surprisingly, HIDs were found to be the members of carboxylesterase family to which many plant proteins involved in defense responses but with unknown catalytic activity belong. The amino acid residues composing the oxyanion hole and catalytic triad are important for both HID and a faint ester hydrolysis activity. HIDs must have been recruited form enzymes of the primary metabolism during evolution. Homology modeling and site-directed mutagenesis of HIDs are in progress to elucidate the structural requirements for the different activities.

P1943. Identification of *anthocyanidin synthase* gene promoters in apples

C. Honda[1], B. E. Ubi[2], H. Bessho[3], M. Wada[3], S. Kobayashi[4], T. Moriguchi[1];
[1]Natl Inst Fruit Tree Science, Tsukuba, Japan, [2]University of Calabar, Calabar, Nigeria, [3]Natl Inst Fruit Tree Science, Morioka, Japan, [4]Natl Inst Fruit Tree Science, Akitsu, Japan.

The accumulation of anthocyanins in apple fruit skin is genetically determined and influenced by environmental factors including temperature and light. We have shown that the expression level of the anthocyanin biosynthetic genes in the fruit skin of ‘Akane’ (a well-colored cultivar) at the stage of ripening was higher than that in ‘Tsugaru’ (a poorly-colored cultivar), and that the expression increased under low temperature and UV-B conditions in both cultivars (submitted). In particular, the expression of *anthocyanidin synthase* (*ANS*) gene was remarkably induced under these conditions. Southern blot analysis indicated the polymorphism in the genomic structure of *ANS* genes in ‘Akane’ and ‘Tsugaru’. We isolated the five clones containing *ANS* gene from the ‘Tsugaru’ genomic library. The nucleotide sequences of the coding region of the five clones were almost identical, while those of the promoter region of the five clones were different from each other. Isolation of *ANS* genes from the ‘Akane’ genomic library is currently being conducted to compare the nucleotide sequences of the promoter region that is responsible for regulation of the gene expression.

P1944. Evolution of benzoic acid-specific type III polyketide synthases

L. Beerhues[1], B. Liu[1], T. Raeth[1], T. Klundt[1], M. Bocola[2];
[1]Institut für Pharmazeutische Biologie, Braunschweig, Germany, [2]Max-Planck-Institut für Kohlenforschung, Mülheim a.d. Ruhr, Germany.

Type III polyketide synthases (PKSs) catalyze the iterative condensation of a starter substrate with malonyl-CoAs and the subsequent cyclization of the intermediate polyketide. Variation of either the starter substrate or the number of condensations and the type of cyclization leads to an impressive array of secondary products. Benzophenone synthase (BPS) and biphenyl synthase (BIS) are PKSs which prefer benzoyl-CoA to form identical linear tetraketides. While this intermediate is cyclized by BPS via an intramolecular Claisen condensation, BIS catalyzes an intramolecular aldol condensation and decarboxylative elimination of the terminal carboxyl group. The enzymes share 54% amino acid sequence identity. In a phylogenetic tree, BPS and BIS group together with PKSs which functionally differ from the ubiquitous PKS, chalcone synthase (CHS). CHSs form an individual cluster. CHS-derived BPS and BIS homology models guided the generation of site-directed mutants.

P1945. 4-Coumarate:CoA Ligase in the Moss Physcomitrella patens

M. V. Silber, J. Ebel;
Botanisches Institut, München, Germany.

4-Coumarate:CoA Ligase is a central enzyme of general phenylpropanoid metabolism and provides CoA thioesters of ring-substituted cinnamic acids as precursors for a large variety of important plant secondary products such as lignin, flavonoids, or phytoalexins. The existence of 4CL isoforms with different substrate specificities and their phylogenetic reconstructions indicate, that higher plant 4CLs can be classified into two large, evolutionary ancient classes. To clarify the evolutionary origin, we analyzed 4CL in the moss, *Physcomitrella patens*. Two structurally different 4CL genes, *Pp4CL1* and *Pp4CL2*, were identified. The proteins show an identity of about 62% when compared with higher plant 4CLs. However, the substrate specificity of *Pp*4CL1 is distinctly different from that of higher plant 4CLs. The recombinant enzyme, produced in *E. coli*, efficiently converted cinnamate to the corresponding thioester, while cinnamate is a very poor substrate for higher plant 4CLs. This suggests an important role for cinnamate as a physiological substrate in *P. patens*.

P1946. Polymorphisms of cannabinoid synthase gene in Cannabis sativa.

M. Kojoma[1], S. Yoshida[2], T. Muranaka[2];
[1]The University of Tokyo, Minami-izu, Japan, [2]RIKEN, Yokohama, Japan.

Cannabis (*Cannabis sativa* L.), one of the oldest cultivated plants, has been grown worldwide for thousands of years for its fiber and seed oil. In addition, the dried flowering tops and leaves are used as the narcotics marijuana and hashish. In the present study, cannabinoid (narcotic chemical substances) contents and DNA polymorphisms of eight different strains of *C. sativa* were analyzed. There were two chemotypes; “chemotype I” with high delta-9-tetrahydrocannabinolic acid (THCA) content and low cannabidiolic acid (CBDA) content, and “chemotype II” with equal content of THCA and CBDA. Genomic DNA sequence polymorphisms in the THCA synthase gene were studied. The defined sequences of the THCA synthase gene in eight strains were classified into three types as “[T][G][T]-type”, “[T][A][T]-type”, and “[A][A][A]-type”. All genomic polymorphisms observed in the present study seemed to be synonymous substitution, not affected amino acid sequences, and also the enzymatic activity of THCA synthase.

P1947. Polyphyletic origin of pyrrolizidine alkaloids. Differential tissue expression of homospermidine synthase.

S. Anke, D. Niemüller, **D. Ober**;
Institut für Pharmazeutische Biologie, Braunschweig, Germany.

The evolution of pathways within plant secondary metabolism has been studied by using the pyrrolizidine alkaloids (PAs) as a model system. PAs are constitutively produced by plants as a defense against herbivores. The occurrence of PAs is restricted to certain unrelated families within the angiosperms. Homospermidine synthase (HSS), the first specific enzyme in the biosynthesis of the necine base moiety of PAs, was originally recruited from deoxyhypusine synthase (DHS), an enzyme involved in the posttranslational activation of the eukaryotic initiation factor 5A. Recently, this gene recruitment has been shown to have occurred several times independently within the angiosperms and even twice within the Asteraceae. Immunolocalization experiments have shown that, within these two PA-producing tribes of the Asteraceae, viz. Senecioneae and Eupatorieae, HSS is expressed differently, despite catalyzing the same step in PA biosynthesis.

P1948. Caffeine biosynthetic enzymes are closely homologous each other in coffee.

K. Mizuno[1], M. Kato[2], H. Ashihara[2], T. Fujimura[3];
[1]Akita Prefectural University, Akita city, Akita, Japan, [2]Ochyanomizu University, Bunkyo-ku, Tokyo, Japan, [3]University of Tsukuba, Tsukuba city, Ibaraki, Japan.

In coffee plant, caffeine is synthesized from xanthosine via a pathway that has three S-adenosylmethionine-dependent methylation steps. We identified and characterized respectively genes encoding enzymes for these three methylation steps of caffeine biosynthesis. Although these genes, named CmXRS1, CTS1, CTS2 and CCS1, are closely homologous each other, these enzyme specificities are strictly divided. Caffeine biosynthesis is presumed to begin with CmXRS1 converting xanthosine to 7-methylxanthosine. CmXRS1 can catalyze only the first methylation step. CTS1 and CTS2 only catalyze the second methylation step that is the conversion from 7-methylxanthine to theobromine, and do not have 1-N-methylation activity that is third methylation step. CCS1, like tea TCS1, can catalyze the second and the third methylation steps. The structure/function relationships of these N-methyltransferases that are involved in caffeine synthesis are discussed with YOU!

P1949. Isolation and functional analysis of caffeine synthase and related methyltransferases in plants

M. Kato[1], N. Yoneyama[1], K. Mizuno[2], H. Ashihara[1];
[1]Ochanomizu University, Bunkyo-ku, Tokyo, Japan, [2]Akita Prefectural University, Akita city, Akita, Japan.

Caffeine synthase(CS) in tea(Camellia sinensis) leaves is an S-adenosylmethionine(SAM) dependent N-methyltransferase that catalyzes the last two methylation steps in the caffeine biosynthetic pathway. CS methylate N-3 and N-1 positions of purine ring and work as a key enzyme in caffeine biosynthesis. We purified CS and isolated cDNA, named TCS1. High levels of transcripts of TCS1 were detected in developing leaves and much lower amounts were present in old leaves. These expression patterns mirror the distribution of caffeine synthase in tea leaves. Furthermore, we isolated TCS homologous gene from theobromine (3,7-dimethylxanthine)-accumulating plants, Camellia irrawadiensis and Theobroma cacao, in order to compare the function of TCS homologous gene. Recombinant enzymes from these TCS homologous genes possess 3-N- but not 1-N-methylation activity. The accumulation of purine alkaloids is therefore, depend on N-methyltransferase substrtate specificity.

P1950. Growth and production optimization of tropane alkaloids in *Datura stramonium* cell suspension culture

A. R. Iranbakhsh[1], M. A. Oshaghi[2], A. Majd[3];
[1]Garmsar university of Islamic Azad, Garmsar, Islamic Republic of Iran, [2]Damghan university of Islamic Azad, Damghan, Islamic Republic of Iran, [3]Sadra University, Tehran, Islamic Republic of Iran.

Tropane alkaloids play vital roles in pharmaceutical industries. This work is conducted to optimize the physicochemical factors affecting the growth and production of tropane alkaloids in *Datura stramonium* (Solanaceae). Cell suspension was prepared from semiclear calli of leave explants in MS medium. Results showed that at 30 and 40 g/lit glucose and 20 and 40 g/lit sucrose concentrations the highest production of alkaloid and biomass will be obtained respectively. High concentration of nitrate led to reduction of the alkaloids production. The best concentration of potassium nitrate was 9.4mM for alkaloids and 37.6mM for biomass. Also it was evidenced that the optimized concentration of ammonium nitrate for alkaloids production was 10.3mM, and for the biomass was 41.22mM. The study of calcium chloride indicated that the best concentration for the growth and production of alkaloids was 7.92mM. Study on the effects of different temperature revealed that the best condition for the highest production of alkaloids was at 20^0C and that of the most biomass production was at 25^0C.

.

P1951. Molecular analyses of a glucosinolate polymorphism in Barbarea vulgaris (Brassicaceae).

H. van Leur[1], U. Wittstock[2], J. Gershenzon[2], N. M. van Dam[1];
[1]NIOO-CTE, Heteren, The Netherlands, [2]Max Planck Institute of Chemical Ecology, Jena, Germany.

The capacity of plants to defend themselves against phytophages heavily depends on the quantity and quality of secondary metabolites. For crucifers the most well-known defense compounds are glucosinolates. In Dutch *Barbarea vulgaris* populations, we have found different frequencies of two naturally occurring chemotypes: one produces mainly 2-phenylethylglucosinolate (gluconasturtiin) whereas the other produces mainly the hydroxylated form, S-2-OH-2- phenylethyl-glucosinolate (glucobarbarin). Due to this single 2-hydroxyaltion, the glucosinolates and their hydrolysis products may have a different toxicity.

We found that the heritability of this polymorphism is determined by a single gene with a dominant allele for glucobarbarin and a recessive allele for gluconasturtiin. Based on a similar 2-hydroxylation enzyme found in *A. thaliana*, we hypothesize that the hydroxylation of gluconasturtiin is performed by a 2-oxoacid dependent dioxygenase (2ODD). We use degenerate primers based on that 2ODD in *A. thaliana,* and homologues of that gene in other plants, to identify the enzyme responsible for differences in glucosinolates in *B. vulgaris*.

P1952. Characterization of dihydrodipicolinate synthase in opaque and floury maize endosperm mutants

V. A. Varisi[1], P. J. Lea[2], M. J. S. Carpes[3], R. A. Azevedo[1];
[1]ESALQ/USP, Piracicaba, Brazil, [2]University of Lancaster, Lancaster, United Kingdom, [3]UNICAMP, Campinas, Brazil.

Maize is an important source of protein for human and livestock. However, the nutritional quality is not adequate, due to the lack of the essential amino acids lysine and tryptophan in the seed. Dihydrodipicolinate synthase (DHDPS) is the key regulatory enzyme which controls the rate of lysine synthesis in the aspartate pathway, catalyzing the condensation of pyruvate and aspartate ɓ - semialdehyde. We have studied DHDPS activity in the endosperms of four different lines of maize with single opaque and floury mutations, which have been shown to contain higher concentrations of lysine: Oh43 (WT), *o1*, *o2, fl1* and *fl2*; W22 (WT) *o10, o11* and *o13*; B37 (WT) and *o7*; B77/79 (WT) and *o5*. The developing endosperms were harvested at 16, 20 and 24 days after pollination (DAP). DHDPS activity increased 20 and 24 DAP and was shown to vary considerably in the mutants. The *fl2* and *o13* mutants exhibited the highest and lowest activities at 20 DAP, respectively. Lysine inhibited DHDPS activity at low concentrations, but the amount varied depending on the mutation, indicating an altered regulation of DHDPS activity. Financial support by FAPESP and CNPq.

P1953. Both steroidal sapogenin and steroidal alkaloid are glycosylated by a single glycosyltransferase

T. Muranaka[1], A. Kohara[1], C. Nakajima[1], T. Ikenaga[2], H. Tanaka[3], Y. Shoyama[3], S. Yoshida[1];
[1]Plant Science Center, RIKEN, Yokohama, Japan, [2]Nagasaki University, Nagasaki, Japan, [3]Kyushu University, Fukuoka, Japan.

We succeeded in cloning a cDNA for steroid glycosyltransferase from Solanum aculeatissimum, for the first time. The Solanaceae contain steroid saponins with diverse biological and pharmacological activities. Glycosylation is the final step in the biosynthesis of saponins, and their sugar chain structure is considered important for their activities. After screening gene fragments for putative glycosyltransferases (GTs) from several Solanum sp., three candidates for full-length cDNAs were obtained from S. aculeatissimum. Recombinant GTs were expressed in E. coli as GST fusion proteins. One of the GTs, named SaG4A, showed sugar acceptor specificity for some steroidal sapogenins, as well as spirosolane-type alkaloids. Gene expression analysis revealed that the accumulation of SaGT4A transcripts showed a unique response to wounding stress indicating the involvement of SaGT4A in plant defense.

P1954. The root organogenesis and indole alkaloid production in Leaf _ stalk of *catharanthus roseus*

A. Ataei Azimi, B. Delnavaz Hashemloian;
Azad Islamic University, Saveh, Islamic Republic of Iran.

Periwinkle(Catharanthus roseus G .Don) is a unique species containing dimeric indole alkaloids of vinblastine and vincristine that have become highly valued drugs in cancer chemotherapy due to their potent antitumor activity against various leukemias, Hodgkin's disease and solid tumors. Tissue cultures originating from leaf_stalk.C.roseus were initiated under various concentration of NAA with Kin treatments and subcultured to give the callus, root or shoot regeneration. The different calli and the regenerated roots were analyzed by TLC and HPLC with respect to the indole alkaloids producing capacity.The root_calli cultures were induced from leaf_ stalk of C.roseus in the presence of 0.1mg/l NAA with 0.1,5,10 and20mg/l Kin.Of the16 groups cultured, the MS with NAA=Kin=0.1mg/l of group had the highest vindoline, catharanthine, vincristine and root organogenesis capacity.In this roots were produced the highest vincristine(6fold),catharanthine(10fold),serpentine(125fold),vinblastin(20fold),vindoline(0.5fold) and ajmalicine(0.34fold) compared to that in the leaf_stalk of intact plants.

P1955. Composition of the Essential Oil within Summer Savory (*Satureja hortensis* L., Lamiaceae) from Syria Based on SPME Single Gland Analysis

J. Novak, L. Merza-Bahoo, U. Mitteregger, C. Franz;
Institute for Applied Botany, Wien, Austria.

The essential oil of Lamiaceae is produced in oil glands on the leaf epidermis and stored in the glands subcuticular space. An interesting approach to better understand the variability of the essential oil composition within a plant is the analysis of single oil glands.

Oil glands from summer savory (*Satureja hortensis*) (petals, calyces, young, medium and old leaves) were analysed by sampling the content of each oil gland with a SPME-fibre.

The main compound carvacrol was highest in the petals (85%). The calyx showed intermediate values of 75% while carvacrol was equal in all three leaf positions (young, medium and old leaf) with

58%. ɔ-Terpinen increased from 9% in the calyx to 30% in the leaves.
The lanceolate leaves were divided into four sections starting from the leaf base (no. 1) to the leaf top (no. 4). The content of carvacrol increased from 56% on sector no. 1 to 66% in sector no. 2 and decreased then steadily down to 53% in sector no. 4. ɔ-Terpinene showed the opposite trend with a decrease from 32% (sector no. 1) to 25% (sector no. 2) and a steady increase to 36% in sector no. 4.

P1956. Biosynthesis of Isoprenoids in Tobacco BY-2 Cells

T. J. Bach[1], A. Hemmerlin[1,2], E. Gerber[1], L. Wentzinger[1], M. Hartmann[1], D. Tritsch[1], M. Rohmer[1];
[1]Institut de Biologie MolÃ©culaire des Plantes, CNRS-UPR 2357, Strasbourg, France, [2]Institut Le Bel, UniversitÃ© Louis Pasteur, Strasbourg, France.

For our studies we have chosen tobacco Bright Yellow-2 (TBY-2) cells, which are characterized by high metabolic flux rates. The MVA pathway, mainly leading to the formation of sterols, but also of the side chain of mitochondrial ubiquinone, occurs in the cytoplasm and can be affected by mevinolin, but also by compounds that block reactions upstream or downstream of the rate-limiting HMG-CoA reductase (HMGR) step. Some of those compounds act as cell cycle inhibitors. It seems that the de novo synthesis of a product downstream from MVA and possibly close to some end product (sterol or intermediate) is essential for feedback suppression of HMGR. We can visualize in TBY-2 cells the isoprenylation of GFP, fused with a protein domain bearing a CaaX prenylation motif. Absence of isoprenylation leads to migration of modified GFP mainly into the nuclei instead of targeting to the plasma membrane. The system recognizes effects exerted by inhibitors, also of the alternative plastid isoprenoid (methylerythritose phosphate = MEP) pathway, or by intermediates potentially piling up. It also provides a means for the study of metabolic cross-talk between the MVA and the MEP pathway.

P1957. Quantitative study of epithelial cells in *Carum carvi* fruit secretory canals

A. N. Ivanova, **M. R. Kolalite**;
Komarov Botanical Institute, St.-Petersburg, Russian Federation.

C. carvi fruits contain 3-7% of essential oil with carvone and limonene as main compounds. The essential oil is synthesized in fruit secretory canals of two types: flat and rounded. Area of epithelial cells in flat canals (FCC) is 47 µm^{2}and that of epithelial cells in round canals (RCC) is 25 µm^2. Endoplasmic reticulum (ER) in FCC is scanty, cisternal, in RCC - abundant, tubular. Mitochondria in FCC are numerous (12, number per cell cross section is given), small (average area is 0.2 µm^2), their partial volume (portion of cell cross section that is occupied by organelles, v/v) is 4.7%; in RCC they are rare (1.3), large (3.4 µm^2), v/v is 1.7%. In RCC leucoplasts are large (1.3 µm^2) but few (4.2), v/v is 20%, they have contacts with ER at about 7% of their surface. They contain solitary thylacoids and few plastoglobuli. In RCC leucoplasts are small (0.5 µm^2), few (2.3), v/v is 7%, but they have contacts with ER at about 32% of their surface. They contain dilated thylacoids filled with opaque substance and protein bodies surrounded by plastoglobuli. Ultrastructural data shows that the canals may differ by their exudation composition. The study was supported by RSCI (N 04-04-49417).

P1958. Ultrastructure of terpenoid-secreting trichomes on leaves of *Plectranthus ornatus* (Lamiaceae)

L. Mota, L. Ascensão;
Centro de Biotecnologia Vegetal, Faculdade de Ciências da Universidade de Lisboa, Lisboa, Portugal.

In a previous work we characterized five morphological types of secretory trichomes on leaves and flowers of *Plectranthus ornatus*. Here we present the ultrastructure of peltate and long-stalked capitate trichomes, where the bulk of essential oils from the leaves is produced. In both trichomes, at onset of secretion, the lateral stalk walls undergo cutinisation. During the active secretory phase, the most striking ultrastructural features of glandular cells are the hypertrophy of leucoplastidome and the extensive proliferation of tubular SER. The high development of these two cell compartments is related to the biosynthesis and transport of terpenoids. A granulocrine secretion mechanism may operate alone or concurrently with an eccrine process. Secretory products accumulate in a large subcuticular space. Whereas in peltate trichomes the secretion (an oleoresin) remains trapped in the subcuticular space, in long-stalked capitate trichomes the secretory products (a gumresin) are released by cuticular rupture. During the postsecretory phase a progressive degeneration of the glandular cells is observed. Secretion may be considered mero-holoccrine.

P1959. Cytological development, metabolite secretion and molecular identification of terpenoid cyclases in sunflower glandular trichomes

J. C. Göpfert, O. Spring;
Institute of Botany, Stuttgart, Germany.

Secretion of sesquiterpene lactones (STL) in capitate glandular trichomes from the anther appendages of Helianthus annuus was observed during development of the florets within the sunflower capitulum. All stages of forming the cuticular globe, from the presecretory to the postsecretory phase, were studied microscopically. The secretory activity was simultaneously monitored using 6 STL for quantitative HPLC analysis. Thereby, beginning and termination of the STL biosynthesis was defined in relation to floret ontogenesis, particularly the pollen formation. Part of the secreted material showed autofluorescence due to the presence of a 5-deoxygenated hydroxy-trimethoxy-flavone.
cDNA from anther trichomes in their biosynthetic activ stage was used for homology-based PCR. This resulted in 2 DNA fragments of putative germacrene synthases with approximately 550bp and 600bp in length and nucleotide identity of 83% and 67%, respectively, to corresponding germacrene synthases from Lactuca sativa.

P1960. *Ent*-Kaurene Diterpenes from *Rabdosia excisa* and Their Chemical Conversion

K. Takeya, Y. Aoyagi, M. Gui, T. Hasuda;
Tokyo University of Pharmacy & Life Science, Hachioji, Tokyo, Japan.

Rabdosia excisa Hara (Labiatae), which has been used as a folk medicine for treatment of fever and arthralgia in north China. A number of diterpenes from *Rabdosia* plants are *ent*-kaurene diterpenes having cytotoxic, antibacterial, NF-əB activation-inhibiting, and apoptosis-inducing activities. In our present chemical investigation of this plant, collected in Jing Yu County, Jinlin Province of China, we isolated four novel *ent*-kaurene diterpenoids and eight known ones. Furthermore, facile transformation of 7,14-dihydroxy-*ent*-kaurenes such as excisanin A, kamebanin, and kamebakaurin, which are abundant in the plants, to *ent*-abietanes was accomplished under the Mitsunobu reaction conditions. The ŭ, Ůunsaturated *cis*-fused Ŭ-methylene ɔ-lactones thus prepared and the isolated diterpenes were applied to cytotoxic activity on P388 murine leukemia cells. In this congress, we report the isolation, structural elucidation, chemical conversion, and cytotoxic activity of these *ent*-kaurenoids.

P1961. Cloning and expression of a farnesyl diphosphate synthase cDNA from *Centella asiatica* (L.) Urban

O. Kim[1], J. Ahn[2], H. Park[3], B. Hwang[4], **N. Seong**[1];
[1]National Institute of Crop Science, RDA, Suwon 441-857, Republic of Korea, [2]Department of Life Sciences, Seonam University, Namwon 590-170, Republic of Korea, [3]Department of Chemistry, Chonnam National University, Gwangju 500-757, Republic of Korea, [4]Department of Biology, Chonnam National University, Gwangju 500-757, Republic of Korea.

A cDNA encoding farnesyl diphosphate synthase (FPS; EC2.5.1.1/EC2.5.1.10) was isolated from *Centella asiacita* (L.) Urban, using degenerate primers designed from two highly conserved domains. A full-length cDNA clone was subsequently isolated by rapid amplification of cDNA ends PCR. The sequence of *CaFPS* (*C. asiatica* farnesyl diphosphate synthase) contains an open reading frame of 1029 nucleotides which codes for 343 amino acids with a molecular mass of 39.6 kDa. The deduced amino acid sequence of CaFPS exhibits 84%, 79%, and 72%, identity to those of the *Artemisia annua*, *Arabidopsis thaliana*, and *Oryza stavia* farnesyl diphosphate synthase, respectively. Southern blot analysis showed that the *C. asiatica* genome might contain only one gene for FPS. The artificially expressed soluble form of the CaFPS enzyme was identified by SDS-PAGE and CaFPS exhibits high specific activity that produces farnesyl diphosphate as the major isoprenoid.

P1962. 3beta-Hydroxysteroid dehydrogenase (3beta-HSD) from *Erysimum crepidifolium* Rchb.

J. Frankenstein, V. Herl, F. Müller-Uri, W. Kreis;
LS Pharmazeutische Biologie, Erlangen, Germany.

In order to extent our knowledge on the evolution of the cardenolide trait in angiosperms we studied cardenolide biosynthesis in the genus *Erysimum* (Brassicaceae). *E. crepidifolium* Rchb. and *E. allionii* hort., used in this study, accumulate strophantidin-type cardenolides to considerable levels. We focussed on two of the early biosynthetic steps, namely the conversion of pregnenolone to progesterone and the conversion of progesterone to 5β-pregnane-3,20-dione, catalyzed by 3β-hydroxysteroid dehydrogenase (3β-HSD) and 5β-progesterone reductase (5β-POR), respectively. Several starting materials, such as leaves, callus and cell-suspension cultures were checked and we found *E. crepidifolium* and its *in vitro* cultures to be more suitable than *E. allionii.* The activities of the two target enzymes was detected by TLC and HPLC and the conditions for isolating and characterizing 3β-HSD were optimized. Since oligonucleotide primers generated on the basis of the 3β-HSD cDNA isolated from *Digitalis lanata* were not suitable to isolate the gene directly, the protein is to be purified and sequenced.

P1963. Cloning of a cDNA encoding putative β-amyrin synthase associated with asiaticoside biosynthesis from *Centella asiatica* (L.) Urban

O. Kim[1], J. Ahn[2], N. Seong[1], **B. Hwang**[3];
[1]National Institute of Crop Science, RDA, Suwon 441-857, Republic of Korea, [2]Department of Life Sciences, Seonam University, Namwon 590-170, Republic of Korea, [3]Department of Biology, Chonnam National University, Gwangju 500-757, Republic of Korea.

A homology-based PCR method was used to clone a cDNA for oxidosqualene cyclase from *Centella asiatica,* which produces a large quantity of triterpene saponins such as asiaticoside and madecassoside. Sequence analysis of one clone found sequences related to beta-amyrin synthase. ORFs of the full-length clones were named *CabAS* (*Centella asiatica* putative beta-amyrin synthase). On the basis of amino acid sequences, CabAS appears to be an enzyme (beta-amyrin synthase), which synthesizes beta-amyrin. Southern analysis showed that the *C. asiatica* genome contains one copy of the putative beta-amyrin synthase gene. Northern blot analysis demonstrated that the *CabAS* gene is expressed in leaves with no detectable transcript in other plant tissues, consistent with the organ-specific accumulation of the asiaticoside. Also, up-regulation of expression of *CabAS* by methyl jasmonate in leaves was demonstrated. This suggests that beta-amyrin synthase may play an important role in enhancement of saponin production, including asiaticoside.

P1964. Genetic Transformation of *Ajuga multiflora* Bunge with *Agrobacterium rhizogenes* and 20-Hydroxyecdysone Production in Hairy Roots

O. Kim[1], J. Ahn[2], N. Seong[1], **B. Hwang**[3];
[1]National Institute of Crop Science, RDA, Suwon 441-857, Republic of Korea, [2]Department of Life Sciences, Seonam University, Namwon 590-170, Republic of Korea, [3]Department of Biology, Chonnam National University, Gwangju 500-757, Republic of Korea.

An efficient transformation system for *Ajuga multiflora* Bunge was established by using *Agrobacterium rhizogenes* A4 strain. A number of hairy-root clones were obtained from micro-calli of leaf petioles and leaf explants after inoculation with the bacteria. One of the various lines was revealed to be a fast-growing line. This line also showed the highest production of 20-hydroxyecdysone (20-HE). The polymerase chain reaction amplification of rooting locus genes showed that left-hand transferred DNA of the root inducing plasmid of *A. rhizogenes* was inserted into the genome of transformed *A. multiflora* hairy roots. Integration of rooting locus genes into genome of transgenic plants was further confirmed by Southern hybridization. The content of 20-HE in hairy root was 10 times higher than that in wild-type roots. These results indicate that hairy roots of *A. multiflora* are able to produce higher 20-HE than wild-type roots and considered as the high efficient culture system for 20-HE production.

P1965. Studies on *Thymus teucrioides* subsp. *candilicus*: Chemical composition of the essential oil content of the glandular trichomes, using a novel isolation method.

A. Markantonatou[1], **D. Daferera**[2], V. Liakoura[3], P. Tarantilis[2], G. Karabourniotis[3], M. Polissiou[2], C. Fasseas[1];
[1]Agricultural University of Athens, Department of Agricultural Biotechnology, Laboratory of Electron Microscopy, Athens, Greece, [2]Agricultural University of Athens, Department of Science, Laboratory of Chemistry, Athens, Greece, [3]Agricultural University of Athens, Department of Agricultural Biotechnology, Laboratory of Plant Physiology, Athens, Greece.

Thymus teucrioides Boiss. & Spruner subsp. *candilicus* (Beauverd) Hartvig (Lamiaceae) is a subspecies of the genus *Thymus* growing wild in Greece. Micromorphological studies in *Thymus* showed that this taxon is characterized by the presence of abundant glandular trichomes on the vegetative and reproductive organs surface secreting mixtures of secondary metabolites of biotechnological and pharmacological interest in high quantities. We tested a novel method to obtain the content of glandular hairs directly, using a micropipette. The mixture was further analyzed using GC/MS and found to be rich in p-cymene (46.1-58.3%), p-cymene-2,3-diol (10.4-12.2%) and 3-hydroxy-2methyl-5isopropyl-p-benzoquinone (7.2-12.1%). The proposed method gives a different composition of the essential oil compared to the Micro-Steam Distillation Extraction Method (MSDE). The high essential oil's yield was determined using the Hydrodistillation method. Micromorphological and chemical results showed that the proposed isolation procedure might become a useful tool to obtain the content of glandular trichomes without significant changes on their *in vivo* composition.

P1966. cDNA isolation and functional expression of Linalool Synthase from *Nicotiana alata*

C. Ganz, B. Piechulla;
University of Rostock; Dept. of Biological Sciences, 18059 Rostock, Germany.

Flowers of *Nicotiana alata* (Solanaceae) emit a broad range of volatile organic compounds (VOCs), comprising primarily mono- and sesquiterpenes and aromatic esters. Linalool, an acyclic monoterpene, is a major component emitted from *N.alata* flowers during the night. A cDNA encoding a monoterpene synthase was isolated via RT-PCR from petals. The nucleotid sequence of this terpene synthase consists of 1629 bp encoding a protein of 542 amino acids. The protein sequence is similar to other monoterpene synthases from different plant families. The heterologous expression of the tps clone allowed purification and characterization of this enzyme. It converts geranyl diphosphat into linalool and is therefor designated Linalool Synthase (LIS), although the protein shows highest identity at the amino acid level to an Ů-terpineol synthase from *Vitis vinifera*. The *lis* gene is only expressed in petals and anthers, not in other flower and plant tissues. High transcript levels during night correlate with the nocturnal emission.

P1967. Unraveling the wizardry of terpene biosynthetic enzymes

B. T. Greenhagen[1], S. Takahashi[1], Y. Zhao[2], P. O'Maille[3], J. Noel[3], R. M. Coates[2], J. Chappell[1];
[1]University of Kentucky, Lexington, KY, United States, [2]University of Illinois, Urbana, IL, United States, [3]Salk Institute, La Jolla, CA, United States.

Many plants respond to pathogen attack by the synthesis and secretion of anti-microbial compounds. For example solanaceous plants produce anti-microbial terpenes that inhibit germination and growth of several fungal species. The production of these chemicals has therefore been interpreted as an important defense response. We have also hypothesized that an understanding of the mechanisms responsible for the biosynthesis of the anti-microbial terpenes should provide a means for engineering the generation of novel and more efficacious compounds. Towards that goal, we have elucidated a 2-step biosynthetic pathway for capsidiol, an anti-microbial sesquiterpene di-alcohol. The pathway consists of a terpene synthase that catalyzes the cyclization of farnesyl diphosphate to a bi-cyclic hydrocarbon structure, followed by the action of a P450 hydroxylase that introduces 2 hydroxyl functions with stereo- and regio- specificity. Using a combination of methods, we have mapped functional features of the respective enzymes, and more recently have used this information to evolve novel catalytic activities for the generation of unique chemical entities.

P1968. Phenolic constituents from Juniperus plants

Y. Inatomi[1], N. Iida[2], H. Murata[1], A. Inada[1], T. Nakanishi[1], J. Murata[3], F. A. Lang[4];
[1]Setsunan University, Hirakata, Japan, [2]San-Ei Gen F. F. I., Inc., Toyonaka, Japan, [3]University of Tokyo, Tokyo, Japan, [4]Southern Oregon University, Ashland, OR, United States.

In our study of the chemical constituents in *Juniperus* plants, we investigated the structures and biological activities of phenolic components of *Juniperus communis* L. var. *depressa* Pursh and *J. occidentalis* Hook. collected in Oregon, U.S.A. The genus *Juniperus* belongs to family Cupressaceae and comprises about seventy species distributed in the Northern Hemisphere. From the methanolic extracts of the two *Juniperus* plants, 22 flavonoids, 15 neolignan (lignan) glycosides and 17 phenylpropanoids (phenylethanoids) were isolated and their structures were established on the basis of spectral and chemical evidence. Among them, 14 isolates were new compounds. The inhibitory activities of some isolated compounds on the Maillard reaction and lipid peroxide formation were examined. Some flavonoids showed inhibitory activities. In addition, thin-layer chromatograms of some *Juniperus* species distributed in Japan are reported for comparisons in chemical components. Flavonoid components are also discussed from chemotaxonomical viewpoints.

P1969. Studies on color change of blue morning glory and pH increase during flower opening

K. Yoshida[1], M. Kawachi[1], M. Mori[2], M. Maeshima[3], T. Kondo[3], M. Kondo[4], M. Nishimura[4];
[1]Graduate School of Information Science, Nagoya Univesity, Nagoya, Japan, [2]Graduate School of Human Informatics, Nagoya Univesity, Nagoya, Japan, [3]Graduate School of Bioagricultural Sciences, Nagoya Univesity, Nagoya, Japan, [4]National Institute for Basic Biology, Okazaki, Japan.

Petals color of morning glory, *Ipomoea tricolor* cv. Heavenly blue, changes from reddish-purple to blue during flower opening. The color change is caused by an unusual vacuolar pH increase from 6.6 to 7.7 of the adaxicial and abaxicial colored cells. To clarify the alkalization of epidermal vacuoles we focused on vacuolar membrane proteins. We isolated colored protoplasts from buds and full-opened petals and purified vacuolar membranes. The membranes contained V-ATPase, V-PPase and NHX1, which were immunochemically detected, with relatively high transport activity. NHX1 could be detected only in the vacuolar membranes of full-opened petals. These results suggest that the vacuolar pH increase of morning glory petals is due to an active transport of Na$^+$ and/or K$^+$ from cytosol into vacuoles through a sodium driven NXH1, which is supported by V-PPase and V-ATPase. This systematic ion transport brought alkalization of vacuolar pH to resulted sky-blue flower petals.

P1970. Studies on blue sepal color development of Hydrangea macrophylla

T. Kondo[1], Y. Toyama-Kato[2], D. Ito[3], Y. Shinkai[4], K. Yoshida[3];
[1]Graduate School of Bioagricultural Sciences, Nagoya University, Nagoya, Japan, [2]School of Life Studies, Sugiyama Jogakuen University, Nagoya, Japan, [3]Graduate School of Information Science, Nagoya University, Nagoya, Japan, [4]Graduate School of Human Informatics, Nagoya University, Nagoya, Japan.

The sepal color of *Hydrangea macrophylla* is very famous for ready change of hues. All colored sepals, red through purple to blue, contain the same anthocyanin, delphinidin 3-glucoside and the same co-pigments, quinic acid derivatives. It is well known that acidity of the soil influences sepal color; the higher the Al^{3+} content of hydrangea growing in the acidic soil is, the bluer the sepals become. Thus, there must be some interesting system for developing the wide variety of colors. Furthermore, the structure of blue color pigment is still obscure. To clarify the blue color development of hydrangea we reconstructed blue solution by mixing the sepal components. When Al^{3+} was added to delphinidin 3-glucoside in buffered solution blue-black colored mass was quickly precipitated indicating that aluminum complex of the anthocyanin is insoluble in an aqueous solution. However, the mixture of the anthocyanin, Al^{3+}, and 5-*O*-caffeoylqunic acid gave a stable blue colored solution the same color as hydrangea sepals. Therefore, the quinic acid derivative have a strong co-pigment effect on Al-complex of the anthocyanin.

P1971. Pinoresinol-Lariciresinol Reductases from Justicidin B producing cell cultures of *Linum perenne*

S. Hemmati[1], T. Schmidt[2], W. Alfermann[1], E. Fuss[1];
[1]Institut für Entwicklungs Und Molekularbiologie der Pflanzen, Duesseldorf, Germany, [2]Institut für Pharmazeutische Biologie, Duesseldorf, Germany.

Lignans are dimers of phenylpropanoid units. For the first time we have isolated the arylnaphthalene lignans justicidin B and isojusticidin B and glycosides of diphyllin from suspension cultures of *Linum perenne* Himmelszelt. Pinoresinol-lariciresinol reductase (PLR) is discussed as an early general step in the biosynthesis of lignans [Davin and Lewis (2003) Phytochem. Rev. 2, 257-288]. Therefore, to get first insights in the biosynthetic pathway of arylnaphthalene lignans we isolated a partial cDNA sequence probably encoding PLR from *L. perenne* Himmelszelt. We will isolate a full length clone and express the protein in *E. coli* to prove its functionality. To show wether the PLR is involved in the biosynthesis of arylnaphthalene lignans in *L. perenne* we will transform a RNAi construct into *L. perenne* Himmelszelt with the help of *Agrobacterium rhizogenes*. We could already set up a transformation protocol for this plant species. The resulting hairy roots contain the same lignans like the suspension cultures.

P1972. Phenylpropanoid- and apigenin-glucoside derivatives in the course of development of *Matricaria chamomilla* ligulate flowers

M. Repcak, T. Krausova;
Institute of Biology and Ecology, P. J. Safarik University, Kosice, Slovakia.

Matricaria chamomilla synthesize (*Z*)- and (*E*)-2-*b*-D-glucopyranosyloxy-4-methoxy cinnamic acids as one of the main phenolic secondary metabolites of shoot and flower. Apigenin-7-*O*-glucoside and its acylated derivatives are accumulated exclusively in ligulate flowers. Quantity of the compounds was estimated in six phases of development of ligulate flowers of diploid and tetraploid chamomile cultivars. (*E*)-2-*b*-D-glucopyranosyloxy-4-methoxy cinnamic acid, the precursor of phytoanticipin herniarin, is accumulated in higher concentrations in young growing ligulate flower, during flowering and post-flowering phases its content decreases. Tetraploid plants of chamomile with higher content of defence compounds probably raise power of resistance in comparison with diploid plants. The content of apigenin glucoside derivatives in ligulate flowers of diploid plants was found significantly higher before start of flowering. The study was supported by the Grant Agency VEGA (no. 1/0444/03).

P1973. Structure analyses of polyacylated anthocyanins and other polyphenols in the leaves of Gynura bicolor DC. and estimations of their radical scavenging activities

K. Yoshitama[1], H. Numajiri[2], C. Nagai[2], S. Yahara[3];
[1]Department of Biological Science, Faculty of Science, Kumamoto University, Kumamoto 860-8555, Japan, [2]Kumamoto University, Kumamoto, Japan, [3]Department of natural medicine, Faculty of Pharmacy, Kumamoto University, Kumamoto, Japan.

Gynura bicolor belonging Compositae is vegitables cultivated in Southeast Asia and Japan. The under surface of the leaves is colored in purple by anthocyanins. We isolated the pigments and analyzed their structures by UV, NMR and Mass spectra. One of the two major anthocyanins was identified as 3-O-(6-O-malonyl-D-glucopyranosyl)-7-O-(6-O-(4-O-(6-O-caffeyl-D-glucopyranosyl)caffeyl)-D-glucopyranosyl)-3'-O-(6-O-caffeyl-D-glucopyranosyl)cyanidin, which was identical with the polyacylanthocyanin isolated previously by us from purple petals of Senecio cruentus belonging Compositae and named as rubrocinerarin. The other anthocyanin was characterized as malonylrubrocinerarin, the analysis of the bond position of a malonyl residue being in progress now. The vegetables contained some flavonoids and chlorogenic acid in addition to anthocyanins, the flavonoids being identified as 3-0-glucoside and 3-0-galactoside of quercetin / kaempferol. Rubrocinerarin and the other flavonoids showed high scavenging activities of DPPH radical.

P1974. Color variations and flavonoids in the flowers of *Clematis patens* (Ranunculaceae)

M. Hashimoto[1], S. Matsumoto[2], W. Marubashi[1], T. Iwashina[2];
[1]School of Agriculture, Ibaraki University, Ibaraki, Japan, [2]Tsukuba Botanical Garden, National Science Museum, Tsukuba, Japan.

The flower colors of *Clematis patens*, which is listed in “Threatened Wildlife of Japan”, varied from white, pink to purple. In this survey, the anthocyanin and other flavonoid composition in various flower colors of the species was compared by HPLC characterized. Major anthocyanin of purple flowers was characterized as delphinidin caffeoylglucoside with minor cyanidin glycoside. Though both the anthocyanins were contained in pink flowers, they were small in quantity as compared with those of purple flowers. In white flowers, some flavonols but not anthocyanins were present and seven were estimated as kaempferol 3-caffeoylglucoside, 3-glucoside, 3-rutinoside, 3-gentiobioside, 3-alloside and two 3-glycoside.In pink flowers, the former two glycosides were detected as major compounds and other ones as minor. However, their flavonols were apparently absent in purple flowers on HPLC chromatogram.

P1975. Flavonoid diversity of *Saussurea* species in the Tien Sian Mountains

T. Iwashina[1], K. Kusano[2];
[1]Tsukuba Botanical Garden, National Science Museum, Tsukuba, Japan, [2]School of Agriculture, Ibaraki University, Ibaraki, Japan.

The genus *Saussurea* (Compositae) is widely distributed from alpine region to low land of eastern Asia, and is morphologically varied. In this survey, the flavonoids were isolated from seven *Saussurea* species, *S. sordida*, *S. schanginiana*, *S. elegans*, *S. involucrata*, *S. leucophylla*, *S. gnaphalodes* and *S. setaraphifolia*, in the Tien Sian Mountains of central Asia. They were identified as quercetin 5-glucoside, quercetin 7-glucoside, isorhamnetin 5-glucoside, kaempferol 5-glucoside, luteolin 7-glucoside from *S. sordida*, isoorientin, isovitexin, quercetin 3-rutinoside from *S. schanginiana*, velutin, luteolin 7-methyl ether from *S. leucophylla*, luteolin 7-glucuronide, selagin, selagin 7-methyl ether from *S. gnaphalodes*, nepetin, hispidulin, hispidulin 7-glucoside from *S. involucrate* and so on, by UV, NMR, MS manners. From the results described above, the flavonoids of *Saussurea* species are complex, and chemical diversification of the genus is chemotaxonomically interested.

P1976. Peroxynitrite attacks prenylhydroquinone glucoside: A NMR analysis.

S. Mañez, A. Olmos, R. Giner;
Departament de Farmacologia, Universitat de Valencia, Burjassot, Spain.

Some plant phenolics are recognised as scavengers of peroxynitrite ($ONOO^-$), an anion formed as a result of the combination of nitrogen monoxide and superoxide (O_2^-). At neutral or acidic pH, $ONOO^-$ is converted into peroxynitrous acid, which decomposes to nitrogen dioxide, a free radical able to nitrate aromatic aminoacid residues. The mechanism underlying the effect of phenols is their susceptibility to undergo either oxidation to benzoquinone or nitration of the activated aromatic ring [1].

In the present study we report on the chemical modifications involved in the reaction of $ONOO^-$ and 2-dimetylallylhydroquinone-1-glucoside (DHG), one of the active principles of *Phagnalon rupestre* (Asteraceae). Examination of the ^{1}H- and ^{13}C-nuclear magnetic resonance spectra of the products formed indicated that DHG undergoes mono- and dinitration, depending on the molar ratio of the reagents. High $ONOO^-$ concentration causes degradation.

P1977. Comparison of anthocyanin and flavone pigments between blue and other flower colors of *Centaurea cyanus*

T. Mishio[1], K. Takeda[2], T. Iwashina[2];
[1]School of Agriculture, Ibaraki University, Ibaraki, Japan, [2]Tsukuba Botanical Garden, National Science Museum, Tsukuba, Japan.

It has been reported that the blue flower of *Centaurea cyanus* is due to coexistence of an anthocyanin, cyanidin 3-*O*-(6nj succinylglucoside)-5-*O*-glucoside and a flavone, apigenin 7-*O*-glucuronide-4Nj*O*-(6njmalonylglucoside). However, the pigments of other flower colors are not reported, except pink flower. In this survey, the pigments were isolated from various flower color cultivars and identified, and compared with that of the blue flower. White, pink, red, reddish purple and purple flowers of *C. cyanus* were used as materials. Purple flower of *C. cyanus* contained the same flavone with blue, but major anthocyanin was different. In reddish purple, though the anthocyanin was the same with blue, flavone was different. In pink and red flowers, anthocyanin was pelargonidin. Moreover, the flavone of latter was also different from blue. Consequently, it was presumed that various flower colors of *C. cyanus* are revealed by the combination of quantitatively different anthocyanins and flavones.

P1978. Aloe arborescens. Plant chemistry and chemical defense systems.

E. Chauser-Volfson (Wolfson), Y. Gutterman;
Jacob Blaustein Institution For Desert Research, Ben Gurion University of the Negev, Sede Boker Capmus, Midreshet Ben-Gurion, Israel.

Aloe arborescens Miller (Liliaceae) is a dense, shrubby plant. It is widely used as a hedge to protect agricultural fields. It is possible the most widely cultivated aloe in the world and can be seen grown in gardens in many cities around the world.

Aloe arborescens has attracted public attention as a plant which can be used as a natural health food and also in cosmetics and medicinal drug applications.

According to some studies A. arborescens is richer than A. Vera in respect to medicinal properties.

During the last 14 years screening of A. arborescens and other A. species have been carried out. The secondary phenolic metabolites (SPhMs), bioactive compounds, such as barbaloin, aloeresin and aloenin have been found in the A. arborescens leaves. The distribution of the SPhMs in Aloe arborescens leaves depends on the leaf part, age, position of the leaf, after prunning leaves, as well as on seasonal influences. Perhaps most are involved in chemical defense systems, which protect plants from herbivory and from other destructions.

P1979. Formation of UV-honey guides in Rudbeckia hirta

K. Schlangen, **H. Halbwirth**, K. Freudmann, K. Stich;
Institute of Technical BioScience, Vienna, Austria.

Honey guides are part of the flower pigmentation pattern, which serves to attrack the pollinator to the sex organs and nectar of the particular blossom. In Rudbeckia hirta, honey guides are formed by the accumulation of higher hydroxylated, UV-absorbing flavonol glycosides, which are invisible to the human eye but detectable by insects. In this studies, biochemical investigations were performed on the flavonoid enzymes, which are involved in the formation of the higher hydroxylated flavonol glycosides in Rudbeckia hirta: flavonol-6-hydroxylase, flavonol-7-O-glucosyltransferase and flavonol-6-methyltransferase. Enzymatic formation of quercetagetin-7-O-glucoside, 6-methoxyquercetin-7-O-glucoside and 6,7-dimethoxy-quercetin-3-O-glucoside was demonstrated for the first time in Rudbeckia hirta (cultivars ‘Goldilocks’ and ‘Indian Summer’). In addition, the distribution pattern of this flavonols were investigated spectrometrically.

P1980. Anthocyanins in the flowers of *Gladiolus* cultivars

T. Takemura[1], Y. Takatsu[2], M. Kasumi[2], W. Marubashi[1], T. Iwashina[3];
[1]School of Agriculture, Ibaraki University, Ibaraki, Japan, [2]Plant Biotechnology Institute, Ibaraki Agricultural Center, Iwama, Japan, [3]Tsukuba Botanical Garden, National Science Museum, Tsukuba, Japan.

The *Gladiolus* is largest genus in the family Iridaceae and consists of ca. 250 species. In addition, many cultivars were made by crossing among numerous species. So far, some anthocyanins have been identified as flower pigments from some cultivars.

In this survey, the anthocyanins of six cultivars, *G.* × *grandiflora* ‘Ariake’, ‘Beijing’, ‘Jyuku-gaki’, ‘Fado’, ‘Ben Venuto’, ‘Marches’ and ‘Vioretta’ were analysed. Eleven anthocyanins were isolated from the flowers and identified as 3,5-di-*O*-glucosides of pelargonidin, cyanidin, peonidin and malvidin, two pelargonidin and malvidin glycosides, and each one cyanidin, peonidin and petunidin glycosides.The anthocyanin composition of 89 cultivars, which are representative red, purple, reddish purple and pink, were surveyd by HPLC. The distribution patterns of anthocyanins were divided into some groups, i.e., red, purple, reddish purple and pink into 3, 2, 2 and 5 groups, respectively.

P1981. Red Leaf Flushing in Tropical Plants

S. Y. Heung, H. Y. Cheng, **L. Ramsden**;
University of Hong Kong, Hong Kong, China.

Red-leaf flushing is a conspicuous phenomenon in tropical woody plants due to the production of anthocyanins in developing leaves and shoots. It has been suggested that the red colouration can provide protection against photodamage or by making the leaves cryptic to herbivores. This project investigated red-flushing by comparing the herbivory rate of 12 red-flushing species with 8 normal-greening species. Red young leaves were grazed more rapidly than both normal greening young leaves and mature leaves of red-flushing species. Red young leaves showed no increased resistance, or were even more susceptible, to herbivory than controls. Measurement of the rate of photosynthesis revealed that young red leaves showed smaller inhibition at high light intensity when compared to green young leaves. For dark recovery following photoinhibition, anthocyanin-pigmented young leaves were able to recover 69% of fluorescence yield while non-anthocyanin-pigmented young leaves only recovered 58%. Red young leaves were more resistant to photo damage supporting the photoprotection hypothesis.

P1982. On the relationships between isoprene emission and light and dark respiration in hybrid poplars under free-air CO_2 enrichment

M. Centritto[1], C. Calfapietra[2], G. Alessio[3], F. Loreto[3];
[1]CNR-IIA, Monterotondo Scalo (Roma), Italy, [2]Universita' della Tuscia - DISAFRI, Viterbo, Italy, [3]CNR-IBAF, Monterotondo Scalo (Roma), Italy.

Climate change may have contrasting effects on isoprene emitted by forest. While elevated CO_2 may reduce isoprene emission, rising temperature is expected to increase this rate. Rosenstiel *et al*. (2003) data suggested that isoprene emission competes with mitochondrial respiration for cytosolic phospho-enolpyruvate. Increasing rates of mitochondrial respiration driven by rising CO_2 and temperature may therefore by responsible for the decrease of isoprene emission observed in laboratory and field experiments under high CO_2. We tested this in a *Populus* × *euramericana* plantation grown in free air CO_2 enrichment (FACE). Isoprene emission and light and dark respiration were measured on-line in developing and developed leaves at the temperatures of 25 and 35 °C. For isoprene emissions lower than 30 nmol $m^{-2}s^{-1}$, an inverse relationship was observed with light and dark respiration, in both CO_2 treatments. However, when isoprene emissions are enhanced, principally by exposure to elevated temperature, this relationship is reversed, and light and dark respiration increase concurrently with isoprene emission.

Supported by ESF-VOCBAS scientific programme.

P1983. Changing the none-isoprene emitting model plant *Arabidopsis thaliana* into an isoprene emitter by genetic transformation

M. Loivamäki, A. Bachl, R. Fischbach, J. Schnitzler;
Research Center Karlsruhe GmbH, Garmisch-Partenkirchen, Germany.

There has been growing research focusing on the volatile hemiterpene isoprene. It is known that volatile isoprenoids emitted by vegetation have various meanings, i.e. in plant defence, but also in atmospheric chemistry. However, the physiological function of isoprene for plants itself is still unknown. Actual studies indicate that isoprene can enhance thermotolerance or quench oxidative stress; however the underlying mechanisms are widely unknown.

Aim of the presented work is to study the proposed biological function of isoprene formation in transgenic *Arabidopsis thaliana*. Plants have been transformed with different constructs of an isoprene synthase gene (*ispS*) from grey poplar as well as with the deoxyxylulose 5-phosphate reductoisomerase (*dxr*) gene from poplar catalysing one possible committed step of the MEP-pathway in order to enhance the metabolite flux within the pathway. The presented data show our selection of transgenic lines and their ability to produce and emit isoprene.

P1984. Chemical and Morphological Investigations And Habitat Specificity of Endemic *Salvia plifera* Montbret & Aucher ex Bentham from Turkey

S. Karaman, N. Comlekcioglu, A. Ilcim;
Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey.

The genus Salvia comprises 89 species which are found in Turkey and ratio of endemism in the genus in % 50. *Salvia plifera* is known in Central, South and West Anatolia (300 between 1320 m altitude). *S. plifera* plants were collected from South East Mediterranean Region of Turkey Kahramanmaras Ahirdag provinces at different altitudes among bushes and macchies in June. Morphological characteristics were determined both macroscopically and steriomicroscopically. Some morphological differences were established according to altitudes and Flora of Turkey.

The air dried flowering parts of the plants were hydrodistilled with clevenger type apparatus and the essential oil content was found as 0.1%. The chemical composition of the essential oils was determined with GC/MS and nineteen components identified in the oil representing 96.4% of the total oil. *S. Plifera* oil had high levels of 1.8 cineol (12.4 %), ɓ-pinene (10.2 %) and Ŭ-pinene (10 %), Ŭ-thujone (8.7%) and ɓ-caryophyllene (8%).

P1985. Isoprene interaction with nitric oxide and reactive oxygen species in leaves exposed to high ozone.

V. Velikova[1], P. Pinelli[2], S. Pasqualini[3], L. Reale[3], F. Ferranti[3], **F. Loreto**[2];
[1]Bulgarian Academy of Sciences, Sofia, Bulgaria, [2]CNR-IBAF, Monterotondo Scalo (Roma), Italy, [3]Universita' di Perugia- Dipartimento di Biologia Vegetale e Biotecnologie Agroambientali, Perugia, Italy.

Isoprene reduces ozone damage to leaves by an unknown mechanism. Fumigation with high doses of ozone stimulated isoprene emission from *Phragmites* leaves, bringing further, indirect, evidence of its antioxidant role. The photosynthetic apparatus of leaves in which isoprene emission was inhibited by fosmidomycin was more damaged by ozone than in isoprene-emitting leaves. Three days after ozone fumigation, the necrotic leaf area was higher in isoprene-inhibited leaves than in isoprene-emitting leaves. Isoprene-inhibited leaves exposed to ozone accumulated antioxidant enzymes, reactive oxygen species (ROS, namely H_2O_2), products of lipid peroxidation, and nitric oxide (NO). It is speculated that isoprene may react with peroxynitrites formed by NO in presence of ROS, draining NO. In nature, the simultaneous quenching of NO and ROS by isoprene may be an effective mechanism to control dangerous compounds formed under stress conditions, while attenuating the induction of hypersensitive responses leading to cellular damage. *Supported by ESF-VOCBAS and EC-MCRTN (ISONET).*

P1986. The role of exogenous isoprene in protecting Arabidopsis mutants deficient in the xanthophylls cycle (NPQ1) from high light

C. Barta[1], I. Nogues[1], V. Velikova[2], F. Brilli[1], F. Loreto[1];
[1]CNR-IBAF, Monterotondo Scalo (Roma), Italy, [2]Bulgarian Academy of Sciences, Sofia, Bulgaria.

Isoprene was proven to have a thermo-protective role and to decrease ozone damage. In order to expand our understanding of isoprene functions in leaves, we investigated whether exogenous isoprene could replace the photoprotective role of other isoprenoids, namely xanthophylls. Leaves of transgenic *Arabidopsis* NPQ1 plants, defective in the xanthophylls cycle, being unable to convert violaxanthin to zeaxanthin in the light, were used. NPQ1 mutants were compared to wild types (cv. Columbia) for photosynthesis, fluorescence properties, electron transport rate, antioxidant status and reactive oxygen species (ROS) production, when exposed to excessive light in presence or absence of exogenous isoprene. Preliminary results indicate that, when exposed to exogenous isoprene, NPQ1 leaves became less sensitive to photoinhibition and produced less ROS. This suggests that isoprene might in fact alleviate photodamage although it remains to be studied whether this effect be due to a biochemical mechanism related to the xanthophylls cycle.(Supported by MCRTN-CT-2003-504720, ISONET)

P1987. Development of a transient expression system in poplar protoplasts: A tool for the study of volatile terpenoids physiological role.

S. Louis, R. J. Fischbach, J. Schnitzler;
Forschungszentrum Karlsruhe, Garmisch-Partenkirchen, Germany.

Many plant species emit volatile terpenoids whose functions are diverse and not always well characterized. To understand their physiological role and to better predict their release into the atmosphere where they are highly reactive, studies are conducted on different species, including poplars which are strong emitters of isoprene. It has been shown that in poplars isoprene emission and its synthesizing enzyme (isoprene synthase) gene expression follow seasonal and diurnal variations. Aim of the presented work was to develop a transient expression assay system with mesophyll poplar protoplasts (*Populus x canescens*). The presented work shows that these protoplasts emit isoprene after incubation under light. To better characterize the regulatory factors of isoprene emission and its possible physiological function at the cellular level, constructs aimed at over-expressing or repressing isoprene synthase as well as other terpene synthase genes will be introduced into these protoplasts.

P1988. Monitoring terpene emissions by high elevation terrestrial ecosystems in response to global changes - REMOTE

R. Mabilia[1], G. Scarascia Mugnozza[2], F. Loreto[2], G. Matteucci[3], P. Ciccioli[4], A. Ciaschi[5];
[1]CNR - IIA, Monterotondo, Italy, [2]CNR - IBAF, Monterotondo, Italy, [3]CNR - ISAFOM, Cosenza, Italy, [4]CNR - IMC, Monterotondo, Italy, [5]Istituto Nazionale di Ricerca sulla Montagna, Roma, Italy.

The impact of anthropogenic pollution and global change on terrestrial ecosystems is investigated worldwide. Remote ecosystems at high altitudes are exposed to background levels of on-site anthropogenic pollutants and greenhouse gases, but may be subjected to regional and global trends of air composition changes, and to transboundary pollution. The REMOTE project will assess impacts of increased pollution and climate changes on forest ecosystems of high altitudes in the Himalayan, Alpine and Andine regions. Supported by the Istituto Nazionale Ricerca sulla Montagna (INRM), REMOTE will focus on ecosystem functional and structural features. A large effort is planned to screen forest emissions of Volatile Organic Compounds (VOC), studying the relations between VOC and assimilated carbon, and focussing on VOC (terpenes) of importance in atmospheric chemistry. An environmental and ecophysiological database will be created. The project outputs will be useful to parametererize the impact of the environment and long-range pollution on remote forest of mountain areas, and to develop models predicting the role of these ecosystems in atmospheric chemistry.

P1989. Reasons of chemotypic variation in *Thymus pulegioides* L.

K. Lo ienā[1], P. R. Venskutonis[2];
[1]Institute of Botany, Vilnius, Lithuania, [2]Kaunas University of Technology, Kaunas, Lithuania.

The influence of change of environmental conditions on chemical composition of essential oils in five different chemotypes of *Thymus pulegioides* L. was examined. The plants collected in various natural habitats were planted into a cultivated field under even soil conditions and propagated clonally every year for 5 years. The essential oil composition was monitored by capillary GC and GC/MS. It was found that according to the stability of essential oil composition after the change of environmental conditions two groups of *T. pulegioides* can be distinguished: 1) plants which preserve their chemical composition of the essential oils; 2) plants which considerably change their chemical composition of the essential oils. This may be explained by the dependence of the interaction of genes on the environmental factors. Some alleles, which determine the chemotype of plants, may condition a wider reaction range or their interaction with certain genes depends more on the environmental factors.

P1990. Effect of high phosphorous on isoprene emission from Phragmites australis in reconstructed wetlands.

S. Fares[1], F. Brilli[1], D. Serafini[1], S. Dagli[2];
[1]Istituto di Biologia Agroambientale e Forestale, Monterotondo Scalo, Italy, [2]The Scientific and Technical Research Council of Turkey, Marmara, Turkey.

Phragmites australis is a strong isoprene emitter. Isoprene can contribute to air pollution when reacting with anthropogenic compounds but *Phragmites* is used to phytoremediate polluted wastewater in urban environments. Isoprene emission requires phosphorilated compounds and may be controlled by inorganic phosphorous level (Pi). We are determining whether excess of Pi, normally occurring in reconstructed wetlands used for phytoremediation, can regulate isoprene emission, possibly increasing its load in the urban atmosphere. Three groups of plants are growing under three different levels of KH_2PO_4 and controlling all other environmental variables. Preliminary results indicate that basal levels of isoprene emission from *Phragmites* are less sensitive than photosynthesis to Pi and are not stimulated by high Pi. Plants growing in reconstructed wetlands may remove high levels of Pi from water without increasing the load of isoprene in the atmosphere. *Research supported by ESF-VOCBAS.*

P1991. Stress induced emission of biogenic VOC: Induced sesquiterpene emissions from ozone exposed tobacco

M. Miebach[1], U. Schurr[1], J. Wildt[1], E. Kleist[1], R. Lawrenz[1], J. Beauchamp[2], A. Wisthaler[2], A. Hansel[2], Ü. Niinemets[3];
[1]Research Centre Juelich, Juelich, Germany, [2]Institute of Ion Physics, Leopold-Franzens-University, Innsbruck, Austria, [3]Department of Plant Physiology, University of Tartu, Tartu, Estonia.

The kinetics of stress induced VOC emissions were studied after ozone (O_3) exposures of tobacco Bel W3. After O_3 exposures we observed increased emissions of methanol, LOX products, methyl salicylate (MeSA), and sesquiterpenes (SQT) starting with lag times of 0.5 - 16 h. These lag times were dependent on O_3 uptake and VOC species. Methanol emissions increased first, followed by those of MeSA and LOX products.

SQT emissions increased in some cases before in other cases simultaneously to those of LOX products and MeSA. SQT emissions often showed two peaks and their emission pattern was not constant implying at least two different plant internal signals leading to increased SQT emissions. Exposures with methyl jasmonate or with MeSA led to increased SQT emissions but with patterns significantly differing from those observed after O_3 exposures. Exposing the plants to ethene led to increased SQT emissions with a pattern very similar to that during the first peaking SQT emissions after O_3 exposure. Hence, we believe that in case of ozone exposed tobacco neither accumulation of jasmonic acid nor of salicylic acid is responsible for increased SQT emissions.

P1992. Terpene content and headspace of in vitro cultures of Myrtus communis L.

F. Rapparini, A. Soldo, S. Predieri, E. Gatti, R. Baraldi;
Institute of Biometeorology, Bologna, Italy.

Micropropagation of myrtle has been reported for genotypes of various sources and could allow rapid clonal propagation, germplasm conservation and is a basic prerequisite for the exploitation of biotechnological techniques. Terpene headspace and tissue content of in vitro cultures of different clones of myrtle characterized by different morphological features and geographic origin have been investigated. Headspace technique combined with adsorption on solid materials and to GC-MS analysis was applied for the determination of volatiles emitted by plants in vitro cultured. The terpene content was evaluated after extraction with solvent and analysis by GC-MS. Several terpenes were detected in both headspace and tissue content of Myrtus communis cultures. The main terpene components of in vitro plant headspace were isoprene, a-pinene, p-cymene and other compounds in smaller quantities such as 1,8-cineole. The main terpene components of microcutting content were a-pinene, linalool, limonene and 1,8-cineole. Each clone was characterized by a unique profile of headspace and tissue content of terpene. A limonene chemiotype was detected.

P1993. BVOCs produced by Pyrus communis in response to fire blight infection

F. Spinelli[1], **F. Rapparini**[2], M. Noferini[1], E. Rondelli[1], R. Baraldi[1], G. Costa[1];
[1]Department of Arboriculture, University of Bologna, Bologna, Italy, [2]Institute of Biometeorology, CNR, Bologna, Italy.

Few studies have been carried out on volatiles specifically aging between the bacteria and plants. Fire blight, caused by the bacterium Erwinia amylovora (Burrill), is the most destructive bacterial diseases of pomaceous plants such as apple (Malus domestica) and pear (Pyrus communis). Fire blight is characterized by a long asymptomatic phase, therefore an effective diagnosis is very important to avoid further spread of the disease. The present contribution reports preliminary results on the possible role of volatiles produced during the interaction Erwinia amylovora/pear plants using the bag-enclosure system combined with adsorption on solid materials and to GC-MS analysis and the electronic nose. Specific volatiles were detected in the plant/bacterium system, while electronic nose was able to distinguish between the infected plants and the control ones, showing the possibility to perform an early diagnosis of the disease in asymptomatic plant via the use of this system.

P1994. Isoprenoid emissions from three Nothofagus species in Patagonia Argentina

M. Centritto[1], C. Di Bella[2], R. Baraldi[3], F. Rapparini[3], M. E. Beget[2], A. Kemerer[2], F. Loreto[4], C. Rebella[2];
[1]Istituto Inquinamento Atmosferico, CNR, Monterotondo Scalo (Roma), Italy, [2]Instituto de Clima y Agua, INTA-Castelar, Castelar (Buenos Aires), Argentina, [3]Institute of Biometeorology, CNR, Bologna, Italy, [4]Istituto di Biologia Agroambientale e Forestale-CNR, Monterotondo Scalo (Roma), Italy.

Earlier studies, concerning the occurrence of isoprenoid production within the plant kingdom, showed that none of the measured species of the Fagaceae family (i.e. Fagus, Nothofagus, Chrysolepis, Castanea, and Lithocarpus) exhibited isoprene emission. However, a recent study showed that Fagus sylvatica (European beech) was an emitter of monoterpenes. The Nothofagus (southern beech) species is a woody plant native of the southern Hemisphere. Three Nothofagus (N. Antarctica, N. pumilio, and N. dombeyi) species, growing in natural forests in Bariloche (Argentina), were screened for emissions of biogenic volatile organic compounds (BVOCs). N. Antarctica and N. pumilio are deciduous species, whereas N. dombeyi is an evergreen species. Basal emissions of isoprenoids measured at photosynthetic photon flux density of 1000 mmol m-2s-1 and at a leaf temperature of 30 °C in fully expanded leaves of adult trees, indicated that all the tested Nothofagus were monoterpene emitters but at different emission rates.

P1995. Changes in the cuticular waxes during tomato fruit development and their importance as a transpiration barrier

J. Leide, K. Reußing, G. Vogg, M. Riederer;
Lehrstuhl für Botanik II, Würzburg, Germany.

During ripening of tomato (Lycopersicon esculentum MILL.) fruits, cuticular waxes undergo significant changes. From the onset of fruit development (immature green fruits) up to mature red fruits total soluble wax load increases by a factor of 3.5. This quantitative effect of surface waxes changes in a characteristic way, involving compositional alterations in cyclic as well as aliphatic components. Along with these chemical alterations the cuticular transpiration decreases dramatically.

The aim of the present project is to elucidate the direct correlation between the cuticular wax composition and its transpiration barrier properties as it is possible due to the astomatous surface of intact tomato fruits.

In addition, a tomato ɓ-ketoacyl-CoA synthase deficient wax mutant (lecer6) is analysed in these two parameters during fruit ripening. The comparison of mutant and wild-type fruits leads to a more detailed understanding on the importance of the cuticular waxes, especially of their chemical composition, on cuticular transpiration. The developmental changes in the composition of cuticular wax are discussed with regard to their biosynthesis.

P1996. Relevance of cuticular wax properties for the interspecific interaction of powdery mildew with its host plant barley

V. Gartmann, G. Vogg, M. Riederer;
Lehrstuhl für Botanik II, Würzburg, Germany.

As an obligate biotrophic fungi Erysiphe graminis depends on Hordeum vulgare host cells to obtain products of plant metabolism for nutrition and reproduction. The plant cuticular waxes are the first contact site and are therefore discussed to influence primary processes of the infection.

Appressoria formation during the pre-penetration process can be rated as a reaction to successful host recognition. Therefore a decrease in number of appressoria points to modified surface parameters that act as interactive mediators in this parasitic system.

In biotests different leaf surfaces from wild-type and various cuticular cer-mutants of barley are inoculated with fungal conidiospores. Distinct features such as chemistry, crystal structure and hydrophobicity of H. vulgare epi- and intracuticular leaf waxes are analysed and combined with germination rates of the conidiospores. Data are discussed in how far surface features of cuticular plant waxes are affecting the pre-penetration processes.

P1997. Supplement potassium to enhace foliar uptake of micronutrients

T. Durstberger, M. Meister, H. Bolhar-Nordenkampf;
University of Vienna, Vienna, Austria.

Content of minerals in green leafy vegetables is essential for the nutritional and health status of the human body. To increase nutrients foliar application is an important and effective way. Burkhardt and Eichert 2001 showed that stomatal uptake of solutes increased with humidity, stomatal aperture and stomatal density. To determine the effect of potassium (2500g ha^{-1}) and two concentrations of B, Mn, Zn (M1: 150/250/210 and M2: 300/500/420g ha^{-1}) on the nutritional status of *Spinacia oleraceae* the plants were sprayed 44 days after sowing in a field experiment with seven treatments and three replicates.

To study if a potassium application increases the stomatal width and consequently leads to an enhancement of mineral uptake stomatal conductance was measured.

The expected influence of potassium on stomatal conductance could not be proved.

The foliar application of M1 as well as the combined application of potassium and M1 did not affect the leaf concentration of micronutrients significantly whereas the doubled concentration, M2, increased the B content in leaves significantly and lead to a slight rise of Mn, Zn content of spinach leaves was not affected.

P1998. The water permeability of cuticular membranes

J. Karbulková[1], J. antrŢļ ek[1,2], M. imková[2], E. imáŔová[3], L. Schreiber[3];
[1]Faculty of Biology, University of South Bohemia, Ļeské BudŊjovice, Czech Republic, [2]Institute of Plant Molecular Biology, AS CR, Ļeské BudŊjovice, Czech Republic, [3]Institute of Cellular and Molecular Botany, University of Bonn, Bonn, Germany.

The water permeability of cuticular membranes (CM) isolated from the upper astomatous and lower stomatous surface of ivy (*Hedera helix*) leaves was measured by using a new method which allowed separation of total water flux through cuticle into its parts: the flux through pores and the flux through solid membrane. The principle of this method is based on fact that the diffusivity of water vapour in the gas phase can be manipulated by using gases with various molecular mass (e.g. helium, nitrogen, xenon) while diffusivity of water vapour in the solid phase is not affected. This approach allowed to calculate the flux of water across stomatal pores (stomatal transpiration) separately from the flux of water across the cuticle solid phase (cuticular transpiration) on stomatal CM.As we expected, water flux across the cuticle isolated from upper astomatous leaf surface was not affected by the gas composition. The water permeability of astomatous cuticles was about 7 times lower than water permeability of stomatous cuticles. Surprisingly about 80% of water flux was facilitated through solid (non-porous) phase of stomatous cuticle.

P1999. Leaf wax structures in selected Central European *Salix* species

D. Tomaszewski;
Institute of Dendrology, Kórnik, Poland.

The morphology of the wax layer on the abaxial leaf surface was studied in 23 species of the genus *Salix*. A SEM analysis revealed that the lower part of the leaf blade can be covered by a nearly uniform wax film (*S. alpina*, *S. herbacea*, *S. pentandra*, *S. retusa* and *S. viminalis*) or specific wax structures (*S. acutifolia*, *S. alba*, *S. aurita*, *S. caprea*, *S. cinerea*, *S. daphnoides*, *S. elaeagnos*, *S. fragilis*, *S. helvetica*, *S. lapponum*, *S. myrtilloides*, *S. nigricans*, *S. purpurea*, *S. repens*, *S. reticulata*, *S. silesiaca*, *S. starkeana* and *S. triandra*). The above-mentioned structures (named here ‘conicoids’) are composed of apically convergent wax filaments. They did not appear on leaf margins and major veins. Size differences were found between some groups of species. Conicoids are formed by accumulation of new material at the base and simultaneous horizontal expansion due to leaf development. This causes the splitting of the originally continuous wax layer into patches. The observed differences between species can be used as additional features in classification of *Salix* species.

P2000. On the chemistry of *Selaginella*: Biflavonoids and unusual C_{28}-spirostene glycosides from Indian *Selaginella* species.

O. I. Nandi[1], R. Chidananda Swamy[2], O. Kunert[3], A. V. N. Appa Rao[2], **W. Schühly**[4];
[1]Institute of Systematic Botany, Zurich, Switzerland, [2]University College of Pharmaceutical Sciences, Warangal, India, [3]Institute of Pharmaceutical Sciences, Graz, Austria, [4]Insitute of Pharmaceutical Sciences, Graz, Austria.

Many aspects of the chemistry and the chemotaxonomy among the Lycopodiophyta (including Lycopodiales, Selaginellales and Isoetales) are still weakly elucidated. The lack of knowledge regarding secondary metabolites that could be used as markers in these groups makes a chemosystematic approach difficult.

During a survey of two Indian species, *Selaginella bryopteris* (L.) BAK. and *S. chrysocaulos* (HOOK. & GREV.) SPRING were investigated for their chemistry for the first time. We present herein data on biflavonoids of the amentoflavone- and hinokiflavone-type from these species, as well as the finding of steroids with C_{21}-carboxylation and unusual C_{28}-spirostene glycosides, which have not yet been described from any plant species. The classes of biflavonoids and steroids could, therefore, be useful chemotaxonomically among members of this taxonomic group. The chemotaxonomic relevance of the compounds within the Lycopodiophyta and related groups will be discussed.

P2001. Comparison of leaf flavonoids in *Crocus* species (Iridaceae) from Iran

A. Saboora[1], H. Ebrahimzadeh[2], T. Radjabian[3], P. Abrishamchi[4];
[1]biology department, azzahra university, Thehran, Islamic Republic of Iran, [2]biology department, tehran university, Thehran, Islamic Republic of Iran, [3]biology department, shahed university, Thehran, Islamic Republic of Iran, [4]biology department, ferdosi university, Mashed, Islamic Republic of Iran.

Crocus includes nine species in Iran. Intra- and inter-specific variation of population investigated among 38 populations. Flavonoids extracted from leaves, 2D-TLC and HPLC were used to separate those. Spots were observed using NP and four reagents. Data from HPLC scored by standardized peak area. Cluster analysis was carried out using squared Euclidean Distance and ward's methods. Grouping of the populations were interpreted comparing with geographical locality and altitudes. Some constituent were purified and identified at the level of classes of flavonoids by spectrophotometry and application of shift reagents.

The main compounds were: flavon, flavonol, isoflavon and dihydroflavonols. Most of the flavonoids were flavon C-glycosides and some of flavonol O- glycosides. Luteolin, apigenin, methylated and hydroxylated of these observed repeatedly. Type of the flavonoids was similar at the level of intraspecies of *C. caspius* but their concentration was variable. Also, *C. cancellatus* populations were different with respect of type and concentration. Results show that *C. almehensis* and *C. caspius* were diverse from other by their flavonoid patterns.

P2002. Paralogy and homology in polyketide genes of lichen fungi

L. Muggia, J. Rankl, J. Blaha, M. Grube;
Institute of Plant Sciences, Karl-Franzens-University, Graz, Austria.

Lichens are outstandingly rich in extrolites of polyketide origin, both with regard to amounts produced and their structural diversity. While this has traditionally been used in the chemical classification of lichens, the analysis of natural thalli may still underestimate the chemical potential of the mycobionts. In axenic cultures, the fungi may produce a shifted spectrum of polyketides, and frequently also compounds that are unknown from the intact lichen. The goal of our investigation is to explore the genetic diversity of polyketide synthase genes in lichen mycobionts and to analyse these in a phylogenetic framework. The analysis of paralogous sequences will be used to assess which genes evolved prior or after the diversification of lichen lineages. The functional assignment of genes to particular compounds is nevertheless complicate, for this needs to consider incomplete sampling of paralogs and possible post-PKS modifications of compounds. The correlation of transcribed genes with produced compounds may result in a better estimate of gene functions. First results from these experiments are presented.

P2003. Characterization of different ecotypes of *Salvia officinalis* grown in Albania

F. Babani, A. Bacu, E. Kongjika;
Biological Research Institute, Tirana, Albania.

The study of reflectance signature of leaves, composition of essential oils and genetic polymorphism are applied to characterize some ecotypes of the species *Salvia officinalis* L. grown in Albania. Indicators like reflection values in some characteristic wavelengths (550 nm, 700 nm, 750 nm and 800 nm) and reflection ratios in these wavelengths have been determined via reflection spectra of leaves. The composition of the essential oil extracted from leaves by steam distillation, in two different vegetative phases, was determined via gas-chromatography and the identification of the peaks was based on their retention times. Genomic DNA isolated from young fresh leaves of individual plants were evaluated via RAPD analysis. The ecotypes collected in four different areas of Albania exhibited changes on the reflectance spectra and reflection ratios, differences on essential oil components especially in the quantity of thujons and camphor as well as showed a clear genetic variability. Based on the obtained results we conclude that these ecotypes can be grouped into clusters of similarity.

P2004. Flavonoids as characters in cladistic analysis of Lythraceae s.l.: use of biosynthetic pathway

C. Rocini[1], R. Mello Silva[1], S. Graham[2], D. Y. A. C. Santos[1];
[1]Institute of Biosciences, University of São Paulo, São Paulo, Brazil, [2]Missouri Botanical Garden, Saint Louis, MO, United States.

A coding method for using the steps of flavonoid biosynthesis as characters in cladistic analysis is presented. Eriodictyol intermediates the synthesis of flavones (luteolin) and flavonols (quercetin), while dihydrokaempferol intermediates only flavonol synthesis (kaempferol and quercetin). A cladistic analysis using all precursors as binary characters for flavonoid patterns observed in some genera of Lythraceae s.l. lead to the following relationship: ((((((Heimia montana, Galpinia transvaalica) Punica granatum) Pleurophora anomala) Capuronia madagascariensis) ((Lythrum salicaria, Lagerstroemia tomentosa) Rotala ramosior) Woodfordia uniflora, Koehneria madagascariensis, Ginoria rohrii) G. nudiflora, G. glabra, G. americana, Adenaria floribunda). Species bearing quercetin derivatives, but no kaempferol, form a clade with luteolin bearing species. It suggests that those species produce quercetin via eriodictyol instead of via dihydrokaempferol. The results could suggest a new interpretation of flavonoid evolution. FAPESP, CAPES.

P2005. Two examples of correlation between alkaloid biosynthesis and phylogeny

S. Larsson[1], A. Backlund[1], H. El-Seedi[2], A. Vinnersten[3];
[1]Division of Pharmacognosy, Department of Medicinal Chemistry, Uppsala University, Uppsala, Sweden, [2]Department of Chemistry, Faculty of Science, El-Menoufia University, Shebin El-Kom, Egypt, [3]Department of Systematic Botany, Uppsala University, Uppsala, Sweden.

The biosynthetics involved in the production of plant metabolites are under evolutionary constraints. This means that they do not appear out of nowhere, and secondary metabolites are only retained if they give the organism that final edge of survival of the fittest. In systematics certain compounds has thus been used as taxonomic markers. Due to the hereditary nature of biosynthetic machinery a chemical can be regarded as a synapomorphy if it truly has arisen only once, thus defining a monophyletic group. The biosynthetic machinery necessary to produce colchicine and analogues appears to be a synapomorphy for the family Colchicaceae, eventhough the class of phenethylisoquinoline alkaloids are not. How unique a compound is may be due to only minor mutations in the machinery. Tracing the enzymatic paths might thus be necessary to ensure a synapomorphic status, as for the cyclopeptide alkaloids having different substructures in different systematical groups of eudicots.

P2006. Characterization of some *Thymus* taxa using molecular markers

G. Horváth, L. G. Szabó;
Biological Institute, Pécs, Hungary.

The similarity of *Thymus* species morphological and anatomical features posses a problem for adequate identification. The aim of our study is to be detect genetic diversity of some Thymus taxa, based on their individual RAPD pattern. In the study RAPD markers have been used to provide more objective analysis of genotype and genetic relationships.

Materials and Methods: DNA from 8 Thyme taxa was isolated with Dneasy Plant Mini Kit (Quiagen) and analysed by randomly amplified polymorhic DNA (RAPD) with decamer primers (OPA, OPB, OPI, OPN, OPO, OPP, OPW) obtained from Operon Technologies (Alameda, CA.). Dendogram was constructed based on the similarity matrix data by applying the unweighted pair-group method with arithmetic averages (UPGMA) cluster analysis using the SYN-TAX 5.0 program package.

Results: among the examined 86 primers 54 showed polymorphic pattern. The most polymorphic pattern were shown by the following primers: OPA-3, OPI-7, OPI-12, OPN-(3-6), OPO-4, OPO-20, OPP-8. The number of bands obtained by primers varied from 11 (OPN-6) to 21 (OPN-4). On the basis of the observed bands it was possible to differentiate the taxa studied.

P2007. Comparative molecular and phytochemical investigation of Central European populations from *Leontodon autumnalis* (Lactuceae, Asteraceae)

S. Grass[1], C. H. Zidorn[1], F. R. Blattner[2], H. Stuppner[1];
[1]Institut für Pharmazie, Innsbruck, Austria, [2]Institut für Pflanzengenetik und Kulturpflanzenforschung, Gatersleben, Germany.

Previous analyses of *Leontodon autumnalis* L. revealed the existence of two chemotypes. In the current study, molecular and phytochemical methods were combined to investigate 24 Central European populations of *L. autumnalis.* DNA fingerprint profiles of 183 individuals were established by randomly amplified polymorphic DNA (RAPD) providing 77 molecular markers. Contents of phenolics and sesquiterpenoids of flowering heads and subaerial parts were determined by HPLC-DAD quantification. Evaluation of results by Principal Component Analysis (PCA) showed that geographic distribution of the two detected chemotypes partially overlapped. Phylogenetic groupings displayed in an unrooted Neighbour Joining (NJ) tree calculated from the RAPD data matrix correlated with the geographical origin of the plant material. However, genetic profiles were not consistent with the two chemotypes nor with the morphologically based subspecies of *L. autumnalis* recognized by some authors. In conclusion, morphotypes seem to be of multiple origin and chemical differences might be due to different ecological growing condition rather than genetically determined.

P2008. Chemodiversity of exudate flavonoids from the farina of Dionysia spp. (Primulaceae)

K. M. Valant-Vetschera[1], E. Wollenweber[2];
[1]Department of Systematic and Evolutionary Botany, Institute of Botany, Vienna, Austria, [2]Institute of Botany, TU Darmstadt, Darmstadt, Germany.

Dionysia Fenzl comprises approx. 50 species, occurring mainly in mountain regions of Iran and neighbouring countries. Relationships to *Primula* subgen. *Sphondylia* are so close that *Dionysia* is likely to be incorporated in the genus *Primula* once the taxonomy is satisfactorily resolved. This relationship is also reflected by the production of farinose exudates in 9 studied *Dionysia* species. Their flavonoid composition corresponds largely to that known from farinose *Primula* species. The exudate is an almost pure mixture of several flavonoid aglycones. Chemodiversity features include a low degree of *O*-substitution and partly unusual substitution patterns. Unsubstituted flavone is an ubiquitous component of the flavonoid mixture, very often accompanied by 2´-hydroxy- and 2´,5´-hydroxyflavones and their derivatives. Chalcones with corresponding substitution patterns are rather rare (*D. mira* only), whereas flavanones with different substitution patterns occur on most of the studied species. Chemosystematic aspects at the infrageneric and intrageneric level as well as ecological significance are briefly addressed.

P2009. Phytochemical studies of genus Consolida (DC.)S.F.Gray

S. Poor Habibian, M. Pakravan, K. Kia Rostami;
Azzahra University, Tehran, Islamic Republic of Iran.

The Genus Consolida comprises 18 species in Iran.It has various from diterpens group. They divided in to two groups, C20-diterpen and C19 (Nourditepen).In this research we compare alkaloids in 3 species. Reproductive organs used for extraction. TLC on GF254 silicagel plates with solution system ethylacetate, Isopropanol, Amonic 20% (45:35:15) used for alkaloid isolation. The spots observed under UV .In the TLC of flowers many similarity in C. leptocarpa spots and C. leptocarpa var. khorasanica were similar to C.camptocarpa morphologically. This results proved by TLC investigation. This method also confirmed the differences between C. rugulosa and C. leptocarpa .The chromatogram of seed exracts of three species were studied. C. leptocarpa ,C. leptocarpavar khorasanic and C. rugulosa showed similar pattern in TLC. They showed difference in flower alkaloids. TLC patterns in C. persica were completely different from other species. That shows the isolation of this species.

P2010. Comparison of essential oils and alkaloids in three species of *Annona* from Chiapas.

L. M. Luna-Cazáres[1], A. R. González-Esquinca[1], M. C. Pérez-Amador[2];
[1]Universidad de Ciencias y Artes de Chiapas, Tuxtla Gutiérrez, Chiapas, Mexico, [2]Universidad Nacional Autónoma de México, México, D.F., Mexico.

The alkaloids and essential oils are a constant in the Annonaceae. However, few are the studies that integrate the chemical data with the plants physiology. In this research was compared the presence and distribution of alkaloids in *Annona lutescens*, *A. diversifolia* and *A. purpurea*, as well as the essential oils of their seeds. The plants were collected in the same locality of the state of Chiapas. The essential oils were analyzed by gas chromatography; the alkaloids were obtained by selective extractions of root, bark, leaves and seeds and the profiles was compared intra and inter specifically for TLC, the two major alkaloids were identified by spectroscopy as liriodenine and oxopurpureine. Were identified 22 similar essential oils in the endosperms of *A. diversifolia* and *A. purpurea* and 15 in *A. lutescens*. Were detected in *A. diversifolia* and *A. purpurea* 23 alkaloids and 11 in *A. lutescens*. For the presence of essential oils and alkaloids *A. diversifolia* and *A. purpurea*, had a chemical relationship, in agree with the physiologic likeness exists when fructification time and to present seeds with latency.

P2011. Allelopathic effects of Artemisia on seed germination and growth of Hordeum vulgare L. and Agropyron.

A. Rahnavard, G. Asadian, K. Ghorchibeigy;
poster, Tonekabon, Islamic Republic of Iran.

The allelopathic potential of Artemisia herba-alba on germination and growth of Hordeum vulgare L.and Agropyron tauri was investigated.barly as a crop plant and Agropyron as a rangland plant were selected.

Effect of root,stem,leaf and flower of Artemisia was investigated seperately.

These experiments were carried out using completely randomise block design.From the first aqueus extract(10%W/V)solution with 5,10,20,and 40 percent were obtained.Then the effects of these solution on germination and growth ofbarly and agropyron were studied. Also the effects synthetized santonin with concentration of 20,40,80 and 160 ppm and Artemisia flower powder
with amounts of 0.2,0.4 and 0.8 g were investigated.

The observation showed that extracts of leaf and flower statistically reduced the seed germination and growth of barly and Agropyron.however the extracts of root and stem did'nt showed significant reduction.Also the santonin with concentration of 80 and 160 ppm and flwer powder reduced seed germination and growth of barly and Agropyron.

P2012. Dynamics of peroxidase complex activity in pathogen system *Claviceps purpurea - Secale cereale*

Z. Olteanu[1], S. Surdu[2], M. M. Zamfirache[1];
[1]University Al. I. Cuza Iasi, Faculty of Bioloy, Iasi, Romania, [2]Research Biological Institute, Iasi, Romania.

The strains of fungus have different biosynthetic alkaloid capabilities and predominantly produce a certain peptide alkaloid. In submerged cultures enzyme activity is lower at ergocristine strains and higher at cultures obtained from ergotamine and ergocryptine sclerotia. Peroxidase activity of sclerotia is strong at beginning of ontogenetic development, and decrease to the end of sclerotia development. The parasite influences peroxidase activity in host plants. The alkaloid accumulation in sclerotia and intensity of peroxidase activity there are in relation of inverse proportionality. The alkaloid complex influences the peroxidase activity in plant. Comparatively with control, enzyme activity level is lower in parasitized plants by ergotamine sclerotia and higher in parasitized plants by ergotoxine sclerotia. Peroxidase isoforms number in host plants varies depending on age and predominant alkaloid in sclerotia which growth on *Secale cereale.*

P2013. Use of repellent plants in malaria vector control

A. A. Gbolade;
Department of Pharmacognosy, Faculty of Pharmacy, Obafemi Awolowo University, Ile-Ife, Nigeria.

A review of literature indicated that 32 plants which belonged to 13 genera in 20 families have been investigated for repellent properties against the malaria vector mosquitoes. Owing to the prevalence of malaria in tropical Africa and other tropical regions of the world, repellent plants have found extensive usage in various forms for mosquito control, and thereby complement other methods of managing the malaria burden. Direct burning, placing whole potted plants in houses and local application of plant juices on the skin are common traditional methods employed especially by the rural dwellers in exploiting the repellent properties of promising plants. Protection periods of repellent products are usually short, but methods for improvement have been developed. Base properties of formulated essential oil repellents have been modified to improve efficacy and reduce side effects on human subjects. Bioactive repellent compounds have been isolated and notable ones identified.

P2014. Comparative research involving macro- and microelements in pathogen system *Claviceps purpurea - Secale cereale*

S. Surdu[1], Z. Olteanu[2], I. Burzo[3], M. M. Zamfirache[4];
[1]Biological Research Institute, Iasi, Romania, [2]University Al.I.Cuza Faculty of Biology, Iasi, Romania, [3]Nicolae Balcescu University Faculty of Horticulture, Bucuresti, Romania, [4]Al.I.Cuza University Faculty of Biology, Iasi, Romania.

In the pathogen system *Claviceps purpurea* - rye, the parasite produces profound modifications. In order to study the alkaloids' influence upon the mineral metabolism we have investigated the some macro- and microelements in whole rye plants parasitized by *Claviceps purpurea*, as well as from sclerotia formed on these plants. These elements are found in different amounts, depending on the alkaloids which act upon the plant. There is a convergence of the manifestations for the calcium ions, depending on the predominant alkaloid which acts upon the plants. In this pathogen system, mineral metabolism is strong influenced by bioproductive proprieties of different alkaloid strains of parasite both in the host plants and in ergotamine, ergocristine or ergocryptine sclerotia. The ergot alkaloids influence rye plants' metabolism, by their concentration and alkaloid type produce modifications of some ions concentration.

P2015. Specific impact of changed microgravitation upon pigment composition reaction against viral infection.

L. Mishchenko, I. Mishchenko, N. Taran;
Kyiv National Taras Shevchenko University, Kyiv, Ukraine.

Comparison of two abiotic factors - viral infection (virus of wheat strip mosaic) and changed microgravitation (by clinostat rotation) showed their antagonistic impact upon pigment composition of Apogej wheat variety (created for the space flight specially). Virus of wheat strip mosaic in conditions close to natural (unmoving plants without containers) caused total chlorophyll and carotenoid content in Apogej wheat variety decrease approximately by 20-30 %, chlorophyll/carotenoid ratio decreased by 10 %. In microgravitation conditions infected plants showed opposite to control pigment complex specific reaction. Main pigment content increase in viral infected plants compared with those treated by microgravitation only was observed. Pigment content in wheat leafs correlate with crop productivity of microgravity variants. Mechanism of mikrogravity adaptive reaction with/without virus infection discussed.

P2016. The Essential Oil Composition of Some Salvia Species from Bosnia

D. Vidic[1], M. MaksimoviĹ [1], S. Ĺavar[1], M. Miloš[2];
[1]Faculty of Science, Sarajevo, Bosnia and Herzegovina, [2]Faculty of Chemical Technology, Split, Croatia.

The genus Salvia L. (Lamiaceae) comprises about 900 herbs and shrubs widespread throughout the world, and is represented by 14 species in Bosnia and Herzegovina, some of them being endemic.

Air-dried plant material of S. officinalis, S. glutinosa, S. verticillata and S. pratensis was subjected to different methods of extraction. The essential oils were analysed by GC-MS.

alpha-Thujone and beta-thujone constituted up to 65.04% and 7.65%, respectively, of total headspace extractives of S. officinalis essential oil, while in steam distilled oil dominant constituents were manool (48.10%) and viridiflorol (31.14%).

Ethylhexadecanoate (10.8 %) and tricosane (10.7%) were main components of S. glutinosa oil.

Content of germacrene D (4.1 - 20.3%), beta-caryophyllene (9.4 - 20.0%) and spathulenol (7.0 - 20.0 %) varied for different plant parts of S. verticillata.

S. pratensis essential oil was characterised by spathulenol (32.9 %) and caryophyllene oxide (12.5%), while its endemic variety S. varbossania K. Malý contained caryophyllene oxide (19.4 %) and beta-caryophyllene (9.6 %) as the major components that permit the differentiation between these species.

P2017. Early Flowering Response of *Dendrobium* Sonia 'Eiskul' and Expression of Some cDNA Induced by Chitosan

P. Limpanavech[1,2], S. Jayasuta[1], R. Pichyangkura[3,2], C. Khunwasi[1], S. Chadchawan[1,2], P. Lotrakul[1,2], R. Bunjongrat[1], A. Chaidee[1], T. Akaraeakpanya[1];
[1]Department of Botany,Faculty of Science, Chulalongkorn University, Bangkok, Thailand, [2]Center for Chitin-Chitosan Biomaterials, Chulalongkorn University, Bangkok, Thailand, [3]Department of Biochemistry, Faculty of Science, Chulalongkorn University, Bangkok, Thailand.

Six types of chitosan molecules, polymer form with 70% degree of deacetylation (DD)-P70, 80% DD-P80, and 90% DD-P90, together with oligomer form with the similar %DD-O70, O80 and O90, were tested for the effects on growth of *Dendrobium* Sonia 'Eiskul'. The various concentrations of chitosan at 0, 1, 10, 50 and 100 ppm were added to the fertilizer solution and applied once a week during the experiment. No significant effects of chitosan on vegetative growth of 1 year-old after exflasking orchid plants were detected during three months of application. However, early flowering response was found best induced by O80. The differential display of gene expression of O80 chitosan-treated orchid shoot and non-treated control showed the total of 145 different cDNA bands. Some of the cDNAs were cloned. Sequence analysis of these cDNA clones indicated their possible roles in calcium signaling and floral development. The data supported the high potential use of chitosan as plant growth stimulator.

P2018. Oil and fatty acid composition of species with potential use pharmacology of semi-arid northeastern

S. I. Silva, S. M. Rejane;
Universidade Federal Rural de Pernambuco, Recife, Brazil.

Oil obtained from seeds at seven species with potential use pharmacology, for will be tested in the etiological agents of several endemic disease were analyzed for total lipids as well as fatty acids. The oil was extracted by *n*-hexan, saponified with metanolic NaOH and methylated with metanolic Boro trifluoride. The fatty acids were analysed in a Shimadzu 5017-A gas cromatography (GC) and MS-Mass Spectometry. Total oil content ranged from 8,0% in *Ipomoea incarnata* Meisner in Martius to 21,0% in *Leonotis nepetaefolia* (L) R. Br. Palmitic was the main acid in *Sapium glandulatum* Pax (42,5%) and *Leonotis nepetaefolia* (47.9%), while oleic acid was found in high quantity in *Mansoa hirsuta* DC. (62,4%). *Myracrodruon urundeuva* Fr. All..showed highest amount (67,2%) of fatty acids not identified, followed of the *L. nepetaefolia* (10,4%), *S. glandulatum* (8,35%) and *M. hirsuta* (3,3%), probably a unusual fatty acids. The ocorrency of the unusual fatty acids to wear a expectation to find bioactives.

P2019. A new sequiterpene from *Centaurea cadmea* Boiss.

C. Karamenderes[1], E. Bedir[2], H. Abou-Gazar[3], I. A. Khan[3,4];
[1]Department of Pharmaceutical Botany, Faculty of Pharmacy, Ege University, Izmir, Turkey, [2]Department of Bioengineering, Faculty of Engineering, Ege University, Izmir, Turkey, [3]National Center for Natural Products Research, Institute of Pharmaceutical Sciences, University of Mississippi, Oxford, MS, United States, [4]Department of Pharmacognosy, School of Pharmacy, University of Mississippi, Oxford, MS, United States.

The large genus *Centaurea* L. (Asteraceae) comprises about five hundred species which are predominantly distributed around the Mediterranean area and West Asia. *Centaurea* species are used for many purposes such as stimulant, tonic, anti-diabetic, diuretic, cholagog and anti-inflammatory agent in traditional medicine. The phytochemical studies on this genus deal mainly with sesquiterpene lactones. *Centaurea cadmea* Boiss. is an endemic species for Western Anatolia. The plant is not used in Turkish folk medicine; however, other species of the same genus (*C. pulchella C. drabifolia* and *C. solstitialis* subsp. *solstitialis*) are used for treatment of abscess, in hemorrhoid and for colds. Our ongoing study resulted in the isolation of a new sesquiterpene (Eudesma-4(14), 11(13)-dien-12-oic acid, 2Ŭ, 6Ŭ-dihydroxy-,ɔ-lactone) from the chloroform extract of aerial parts of *C. cadmea*. The structure elucidation of the new compound was achieved by a combination of one- (^1H, and ^{13}C) and two dimensional (G-HMQC, G-HMBC, COSY and NOESY) NMR techniques.

P2020. The dynamics of some biochemical and physiological parameters at some *Pelargonium* species producing of essential oils with microbiological effects

R. I. Apetrei[1], M. M. Zamfirache[1], I. Burzo[2], D. Mihaiescu[2], S. Surdu[3], Z. Olteanu[1];
[1]University Al. I. Cuza Iasi, Faculty of Bioloy, Iasi, Romania, [2]Nicolae Balcescu University Faculty of Horticulture, Bucuresti, Romania, [3]Biological Research Institute, Iasi, Romania.

We have been studied three *Pelargonium* species (*P. zonale*, *P. radens* and *P. odoratissimum*) and have investigated assimilating pigments, fat, respiration, sugars from leaves and essential oils content from herba. The fat content is in inverse ratio to the essential oils extraction efficiency and to the number of components, for all species. At *P. zonale* there is a very big difference between the number of components before the flowering period (49) and during the flowering period (161). The physiological and biochemical parameters investigated have been found to have various values and there is a correlation between physiological parameters and essential oil content; the dynamics of these parameters was found to be various from one period to another, as well as from one species to another.Microbiological tests for essential oils produced by *P. radens* evidence a higher inhibition effect upon *Staphilococcus aureus* then *Esherichia coli.*

P2021. Phytochemical investigation of *Rotala ramosior* (L.) Koehne and *Ammannia coccinea* Rottb. (Lythraceae) from the Southeastern United States

W. Schühly[1], N. H. Fischer[2], R. Bauer[1];
[1]Institute of Pharmaceutical Sciences, Graz, Austria, [2]Department of Pharmacognosy, University, MS, United States.

The landmark work by Robert Hegnauer, *Chemotaxonomie der Pflanzen*, promoted interest in the fields of phytochemistry and chemosystematics. The family of Lythraceae has been widely neglected in phytochemical research, partially because only few species of Lythraceae have records of ethnomedicinal use.

As part of our research on the phytochemistry of plants of the Southeastern United States, we examined the chemistry of two herbaceous species of Lythraceae. These species, native to large parts of North America, *Rotala ramosior* (L.) KOEHNE and *Ammannia coccinea* ROTTB., are commonly found in ditches and moist agricultural land, where they have a potential to be weedy as with *Rotala indica* KOEHNE, which is a noxious weed in rice fields in Southeastern Asia.

Results from the examination of the non-polar extracts of aerial flowering plant material are presented and implications in relation to known chemistry of the family are discussed.

P2022. Effects of flavonoid-rich methanolic extract of *Cnestis ferruginea* DC. (Connaraceae) on permeability transition of isolated rat liver mitochondria

K. O. Ogunwenmo[1], **O. H. Unigbe**[1], O. O. Olorunsogo[2];
[1]Babcock University, Lagos, Nigeria, [2]University of Ibadan, Ibadan, Nigeria.

Changes in mitochondria matrix volume resulting from opening of the mitochondria transition pore triggered by 300nM $Ca^{2+}mg^{-1}$ protein was quantified by decrease in absorbance at 540nM.

There was little or no change in matrix volume of mitochondria (0.000 - 0.002) in the absence of a triggering agent. However, triggering agent (Ca^{2+}) opened the mitochondrial permeability transition pore making the inner membrane non-selectively permeable to small solutes resulting in a profound increase in matrix volume (0.000 - 0.400). 0.1mM spermine caused inhibition of permeability transition (0.000 - 0.050). 10µg, 20µg and 30µg of methanolic extract of *Cnestis ferruginea* inhibited the permeability transition to a larger extent, 0.013 (1min), 0.035 (12min), 0.008 (11min) respectively. 20µg was anomalous in its effect, as it did not generate the maximum likelihood inhibition compared to 10µg and 30µg. *Cnestis ferruginea* may delay apoptotic cell death.

P2023. Bioprospection of Brazilian semi-arid land flora

A. M. Lucchese[1], J. M. Barbosa Filho[2], T. M. Sarmento[3], J. P. L. David[4], J. M. David[4], L. M. Conserva[5], R. R. Santos[6], M. B. P. Soares[7], A. M. Giulietti[1], L. P. de Queiroz[1];
[1]Universidade Estadual de Feira de Santana, Feira de Santana, Brazil, [2]Universidade Federal da Paraiba, João Pessoa, Brazil, [3]Universidade Federal da Paraíba, João Pessoa, Brazil, [4]Universidade Federal da Bahia, Salvador, Brazil, [5]Universidade Federal de Alagoas, Maceió, Brazil, [6]CPGM-Fiocruz, Salvador, Brazil, [7]CPMG-Fiocruz, Salvador, Brazil.

The semi-arid region of NE Brazil, covering 975,000 km^2, supports a population of c. two million inhabitants. The region is characterized by its low socio-economic index, high level of environmental degradation and low level of knowledge of its biodiversity. The Project on the Semi-arid, of the Instituto de Milênio, aims to trace the chemical profile of species with biologically active compounds, which occur in the semi-arid and with this in view, collections of over 2000 species of native plant were assembled. 90 of these, principally species of Leguminosae, Solanaceae, Euphorbiaceae and Labiatae were pharmacologically evaluated in terms of nitric oxid production inhibitory activity, linfoproliferation inhibition, and imunomodulation. From a total of 536 extracts, 103 pure compounds were isolated, of which 14 were previously unknown, and 20 semi-synthetic derivatives were obtained and pharmacologically evaluated. These compounds are new potential medicines for diseases typical of the semi-arid region. The species are also been studied with a view to their propagation, molecular and genetic characterization and conservation.

P2024. Essential oil from the flowers of *Edgeworthia chrysantha* Lindl

S. Chen, L. Yin, F. Yiting, F. Chengxin;
Lab of Systematic & Evolutionary Botany and Biodiversity, Hangzhou, China.

Edgeworthia chrysantha (family Thymelaeaceae),native to China, is a deciduous small shrub. It has strongly aromatic flowers. It is used as folk medicine to cure eye disease in China. The flowers are reputed to cure wet dream and abnormity of leucorrhea. Ethanolic and enhydrous extracts of E. chrysantha also showed antibacterial and antifungal activities. Some chemical components such as coumarin and glucoside have been studied.

The flowers of E. chrysantha afforded 0.13% (of fresh wt.) essential oil, characterized by a special odour. A total of 45 compounds were identified by GC-MS, about 75.75% of the composition of the oils. Chemical structures of compounds are given by NIST(2004) database. The oil is rich in ester (41.4%) and ketones (16.57%). The remaining portions of the oils consist of long chain alkane (6.07%), alkyl aromatics (4.76%) and other trace amounts components.

P2025. The effects of hydro alcolic extract of soya in the histological structure and the level of estradiol and testosterone in male sorie

M. Rahnama, S. Nassiri, H. ghassempour;
Azad university Zanjan, Zanjan, Islamic Republic of Iran.

Soja is a rich source of phytoestrogen. soja extract can change the structure of male reproductive tissue and it can influence on the level of sex hormon. For this purpose, 50male sories were selected and divided into 4 groups.3experimental groups were fed with 150,100 and 75 mg/kg of hydro alcoholic extraction of soja and control group were fed with the solevent (water) for 50 days.Blood samples were taken in zero and fiftieth day of experment and the level of sex hormon were measured. Histological of servtions were revealed some changein testis. In the testis many spermatcytes at the metaphase stage in 150 and 100 mg/kg treated groups and some of these mitotic figures, most of the spermatocytes is denaturing of DNA strands. In conclusion, it seems that soja extract can change the spermatocyte cyto architecture, in low concentration,it may induce proliferation and high concentration, it may lead to cell deat and nucleus fragmentation.The result indicated that level of testosterone and estradiol was also decreased significantly in the groups, which treated with 150mg/kg and 100mg/kg.

P2026. Hepato Protective and Antioxidant Role of *Berberis Tinctoria* Lesch on Paracetamol Induced Hepatic Damage in Rats

T. K. Maity;
Dept of Pharmaceutical Technology, Jadavpur University, Kolkata, India.

The scientific evaluation of medicinal plants used in the preparation of folk remedies has provided modern medicine with effective pharmaceuticals for the treatment of diseases. This prompted us to the investigation of Hepatoprotective activity of *Berberis tinctoria* Lesch leaves. The methanol extract of the leaves of *Berberis Tinctoria* Lesch (Berberidaceae) was evaluated for Hepatoprotective activity in rats by including acute damage by paracetamol(750mg/kg).Hepatoprotective activity was measured by using biochemical parameters such as serum transaminase (SGOT and SGPT),alkaline phosphatase(ALP),bilirubin and total protein. The methanol extract of *Berberis Tinctoria* (MEBT) (150mg/kg and 300mg/Kg) produced significant hepatoprotective effect by decreasing the activity of serum enzymes, bilirubin and lipid peroxidation while it significantly increased the levels of GSH, CAT and Protein in a dose dependant manner. The effects of MEBT were comparable to that of standard drug Silymarin. These results suggest that Berberis Tinctoria may be potential therapeutic value in some liver disorders.

P2027. Fatty acid composition from cypsela of some *Centaurea* species (subgenus Jacea)

P. Janackovic[1], V. Tesevic[2], P. D. Marin[1], S. M. Milosavljevic[2];
[1]Faculty of Biology, Belgrade, Serbia and Montenegro, [2]Faculty of Chemistry, Belgrade, Serbia and Montenegro.

In this work fatty acid composition from mature cypsela lipids of *Centaurea jacea* L., *C. phrygia* L., *C. nervosa* Willd., *C. triumfetti* All., *C. cyanus* L. and *C. montana* L., belonging to subgenus Jacea, were investigated. The specimens were collected at natural habitats in Serbia and Montenegro. The fatty acids were extracted and prepared by standard procedure. They are analyzed by means of GC and identified comparing to authentic standards. Four different fatty acids were determined: palmitic, stearic, linoleic and linolenic. All of investigated species were characterized by presence of all identified acids. Results showed that the linolenic was predominant acid in all investigated species. The obtained amounts of linolenic fatty acid were following: 66.9 % *C. jacea* L., 73.1 % *C. phrygia* L., 35.8 % *C. nervosa* Willd., 60.6 % *C. triumfetti* All., 70.7 % *C. cyanus* L. and 59.2 % *C. montana* L. Stearic acid was present in traces in *C. jacea* and *C. nervosa* seeds. Given results revealed some differences in fatty acid somposition of the analyzed species. Taxonomic significance of fatty acid composition of this group and other *Centaurea* spp. from previous works is discussed.

P2028. Pentacyclic triterpenoid from the leaves of *Ficus racemosa* and its anti- inflammatory activity

S. C. Mandal[1], B. P. Saha[2];
[1]Pharmacognosy and Phytotherapy Research Laboratory, Department of Pharmaceutical Technology, Faculty of Engineering and Technology, Jadavpur University, Kolkata-700 032, India, [2]Division of Pharmaceutical Chemistry, Department of Pharmaceutical Technology, Faculty of Engineering and Technology, Jadavpur University, Kolkata-700 032, India.

Traditional medicines, with a very long history and remarkable features, are very popular in Asian countries. Phytochemicals in leaves, fruits, vegetables and traditional herbal medicinal plants have been found to play protective roles against many human chronic diseases including cancer, cardiovascular and inflammatory disorders. Among the thousands of phytochemicals found in the traditional medicines, steroids and triterpenoids stand out as two most important compounds. A single plant could contain highly complex profiles of these compounds. This makes the separation and detection of these phytochemicals a challenging task. The present review focuses on the detailed study of isolation and characterization of lupeol acetate, a pentacyclic triterpenoid from the petroleum ether extract of the leaves of *Ficus racemosa* L. Syn. *Ficus glomerata* Roxb. (Moraceae). The anti-inflammatory activity of this compound has been evaluated and found to be effective in both acute and the chronic models in rats.

P2029. Fruit maturation effect on hesperidin content in some local *Citrus* varieties in north of Iran

H. Kazemi[1], A. Rezaeinodehi[2], S. Khangholi[2];
[1]Educational center of Agricultur,Agricultural research organization, Rasht, Islamic Republic of Iran, [2]Faculty of Agricultural Sciences, University of Shahed, Tehran, Islamic Republic of Iran.

Hesperidin is a flavonoid compound that found in *Citrus* fruit peel. In view of the fact that, hesperidin content depends on fruit growth and development process, it is necessary to determine the best time of fruit harvesting for optimal hesperidin content. In order to determine the best time of fruit harvest from hesperidin content point of view in four varieties of *Citrus* including, local sweet orange, bloody orange, sour orange and local tangerine this study was carried in north of Iran. Harvest times of fruit were consist of 45, 50, 55 and 60 days after full bloom and a comparison also was performed between fruits that were fallen bellow trees and those on trees. Results showed that hesperidin content was increased in the varieties with progress of growth and development process of fruit. Best profitable time of harvest was 55 to 60 days after full bloom. There wasn't significant difference between fallen fruits and those on trees from hesperidin content point of view. *Citrus* varieties had different hesperidin content.

P2030. Some Lichens of Ethnic Value from Darjeeling Himalayas of India as Antimicrobial Agents.

S. Bhattacharyya;
Maulana Azad College, Calcutta, India.

Darjeeling hills are located on the Singalila range of Eastern Himalayas bordering Nepal and Sikkim. The tribes here traditionally use extracts of various lichens for curing several ailments ranging from cuts and burns to gastro-enteric disorders. For this study, ethanol extracts of three species of lichens namely *Usnea* sp., *Ramalina* sp. and *Parmelia* sp. were fractionated with water and methanolic ethyl acetate respectively, for obtaining non-polar and polar compounds like glycosides and flavonoids . The methanol fraction of *Usnea* sp. revealed three bands, of which the major band showed significant presence

of reducing sugar. When tested for antimicrobial activity against a range of pathogenic organisms, this fraction appeared to be highly potent. Effects on population growth as well as inhibition of protein synthesis and growth were studied. The gram-positive *Staphylococcus aureus* proved to be most sensitive. Comparable results were observed when the cells were treated with the broad-spectrum antibiotic ampicillin. Gram negatives like *E.coli* were more resistant to fractions of *Ramalina* sp. and *Parmelia* sp. had no significant effect.

P2031. Terpenoids from Juniperus plants

T. Nakanishi[1], N. Iida[2], Y. Inatomi[1], H. Murata[1], A. Inada[1], J. Murata[3], F. A. Lang[4], Y. Sakagami[5], H. Iwabuchi[2];
[1]Setsunan University, Hirakata, Japan, [2]San-Ei Gen F. F. I., Inc., Toyonaka, Japan, [3]University of Tokyo, Tokyo, Japan, [4]Southern Oregon University, Ashland, OR, United States, [5]Osaka Prefectural Institute of Public Health, Osaka, Japan.

In a survey of chemical components from useful plants grown in western North America, we have identified a number of various types of phenolic compounds (phenylpropanoids, neolignans, and flavonoids) in their glycosides from *Juniperus communis* L. var. *depressa* Pursh and *J. occidentalis* Hook. (Cupressaceae) collected in Oregon, USA and these chemical results have been reported already. Upon continued chemical investigation of these *Juniperus* plants, two new monoterpene glucosides and three new natural megastigmane glycosides were isolated along with a known megastigmane glucoside, (6*S*, 9*S*)-roseoside A. Their whole structures were determined on the basis of spectral (MS, ^{1}H- and ^{13}C-NMR by using 2D-techniques, and CD) and chemical evidence. Essential oil compositions of both *Juniperus* plants were also examined. In addition, antibacterial activities of the isolated components against *Helicobacter pylori* were also investigated. As a result, one of the components showed a potent inhibition comparable to that of a positive control.

P2032. Preliminary screening of *Leucosidea sericea* (Rosaceae) for biological activity and the isolation of anthelmintic and antiplasmodial compounds.

A. A. Bosman, S. Combrinck, B. M. Botha, R. I. Mc Crindle;
Department of Chemistry and Physics, Tshwane University of Technology, Pretoria, South Africa.

Leaves of *L. sericea*, an aggressive invader of disturbed areas, are used medicinally by indigenous South African tribes as a vermifuge and astringent. Extracts of the dried leaves, prepared using solvents of different polarities, were screened for bioactivity. Antibacterial activity was investigated by serial dilution to determine the Minimum Inhibitory Concentration (MIC). Ethyl acetate and methanol extracts exhibited the highest inhibitory effect against *Staphylococcus aureus*, *Escherichia coli, Pseudomonas aeruginosa* and *Enterococcus faecalis* with MIC values between 0.31 - 0.63 mg/ml and 0.078 - 0.31 mg/ml respectively. Bioautography of the more non-polar extracts indicated zones with antibacterial activity. Bioassay guided fractionation of these extracts and subsequent chromatographic purification procedures yielded pure compounds, identified as phloroglucinol derivatives using GC-MS and NMR techniques. According to literature these compounds have anthelmintic and anti-plasmodial properties.

P2033. Antifungal activities from tropical sawdust hardwoods

P. Sumthong, Y. H. Choi, H. K. Kim, R. A. Damveld, M. Arentshorst, A. F. J. RAM, C. A. J. van den Hondel, R. Verpoorte;
Institute of Biology, Leiden University, Leiden, The Netherlands.

Tropical sawdust hardwoods of *Hopea odorata* Roxb., *Shorea albida*, *S. obtusa* Wall ex Blume, *Tectona grandis* L.f. and *Xylia xylocarpa* Roxb. were extracted by $CHCl_3$-MeOH. Thirteen strains of wood rot fungi were tested with these extracts. We found that *T. grandis* inhibit growth of brown rot fungi, *Gloeophyllum trabeum* and *Gloeophyllum sepiarium*, as well as white rot fungi, *Phlebia brevispora* and *Merulius tremellosus*. In order to learn more about the possible mode of action, the effect of *T. grandis* extract on an *Aspergilus niger* was studied. This particular cell wall damage model will show induction of 1,3 *Ŭ*-D glucan synthase by coupling a green fluorescent protein (GFP) marker encoding sequence to the glucan synthase gene. Induction will be detected as fluorescence in the fungal cells. The results showed that *T. grandis* extract induced fluorescence in the transgenic *A. niger* cells which indicated that the plant extract contains compounds that damage the fungal cell wall.

P2035. Trichome morphology and chemical aspects of the essential oil of *Lippia scaberrima* Sond. (Verbenaceae)

S. Combrinck, A. A. Bosman, W. Du Plooy, B. M. Botha, R. I. McCrindle;
Department of Chemistry and Physics, Tshwane University of Technology, Pretoria, South Africa.

Lippia (Verbenaceae) comprises about 200 species occuring mainly in tropical and temperate regions of America and Africa. Six species are found in savanna and grassland areas of southern Africa. *L. scaberrima* is a medicinal, aromatic shrub, invasive in overgrazed land.

Trichome morphology, distribution and density, and oil localization was investigated using light microscopy and SEM. Essential oil, extracted from a bulk sample by steam distillation, was characterised by GC-FID and GC-MS. The effect of post-harvest drying on trichome structure, as well as on essential oil yield and composition was determined. In a consecutive study, the chemical profiles of individual specimens, harvested within a single and different localities, were compared.

The major oil components were identified and include limonene and R-carvone. Post-harvest drying was found to increase the quantities of extractable oils. Combined with SEM results, it was proved that glandular trichomes are not as susceptible to oil loss through desiccation, as previously suggested.

P2036. Essential oil composition from the different parts of Eryngium glaciale Boiss. from Spain

J. Palá-Paúl[1], M. J. Pérez-Alonso[1], A. Velasco-Negueruela[1], J. Varadé[1], A. M. Villa[1], J. Sanz[2], J. J. Brophy[3];
[1]Universidad Complutense de Madrid, Madrid, Spain, [2]Instituto de Química Orgánica, Madrid, Spain, [3]New South Wales University, Australia, Australia.

The Eryngium L. genus belongs to the Apiaceae family and, with about 250 species, has a cosmopolitan distribution. In the Iberian Peninsula grow 14 of the 26 species described in Flora Europaea. The essential oil from the different parts (stems + leaves, inflorescences and roots) of E. glaciale Boiss. gathered in Sierra Nevada (Spain) have been extracted by steam distillation and analysed by Gas Chromatography (GC) and Gas Chromatography coupled to Mass Spectrometry (GC-MS). Quantitative but not qualitative differences have been found between the analysed parts. The principal compounds from the inflorescences oil were found to be phyllocladene isomer (43.5%), (E)-Caryophyllene (15.2%) and Valencene (11.5%), while the oil from stems and leaves only showed phyllocladene isomer (41.3%) as main one. The oil from the roots presented phyllocladene isomer (49.4%) and linalool (19.1%) as major constituents. As far as we know this is the first report about the essential oil composition of E. glaciale. It is worth mentioning the presence of a diterpenes as main compounds of the essential oil.

P2037. Antifungal activity of *Achillea millefolium* L. essential oil

A. M. Simic[1], M. Sokovic[2], M. Ristic[3], S. Grujic-Jovanovic[1], J. Vukojevic[1], P. Marin[1];
[1]Fac. Biology Inst. Botany and Botanical Garden, Belgrade, Serbia and Montenegro, [2]Insttute for Biological Research Sinisa Stankovic, Belgrade, Serbia and Montenegro, [3]Institute for Medicinal Plant Research Dr Josif Pancic, Belgrade, Serbia and Montenegro.

The essential oil of *Achillea millefolium* L. as potential antifungal agent was analyzed. The main compounds in the oil were 1.8-cineole (28.08%), camphor (10.57%), p-cymene (8.29%), ɔ-terpinene (6.60%) and Ŭ-thujone (5.73%). Following micromycetes as test organisms were used: *Alternaria alternata*, *Aspergillus* spp., *Aureobasidium pullulans*, *Cladosporium cladosporioides*, *C. fulvium, Fusarium tricinctum*, *F. sporotrichioides, Mucor mucedo, Penicillium funiculosum, P. ochrochloron*, *Phomopsis helianthi, Phoma macdonaldii, Trichoderma viride*, *Trichophyton menthagrophytes* and yeast *Candida albicans*. Using the microdilution method, minimum inhibition concentrations (MIC) and minimum fungicidal concentrations (MFC) were recorded. Commercial antimicotic bifonazol was used as a control. The concentrations of 15 µl/ml of essential oil showed fungicidal activity against *Aspergillus*, *Penicillium* and *T. viride*. For *Mucor mucedo* MFC was 10 µl/ml, and for *A. pullulans* 5 µl/ml. Fungistatic and fungicidal activity of the oil for the other tested micromicetes were 1-2.5 µl/ml.

P2038. One new triterpenoid saponin from Meyna laxiflora, a less known medicinal plant species used for antifertility

J. G. Handique, D. Saikia;
Dibrugarh University, Dibrugarh, India.

Meyna laxiflora Robyns (family Rubiaceae) is a small tree and found wild in North East India. Seeds of *M. laxiflora* are reported to induce termination of pregnancy and in some cases permanent sterility in women. Fruit pulp is also used as contraceptive. Leaves are considered to be good for diphtheria and used as antidandruff agent. In continuation of our search for plant based antifertility agents we have carried out a preliminary screening of various extracts of seed, fruit pulp and leaf of *M. laxiflora*. The alcoholic extract of the defatted seeds responded to the characteristic colour test for triterpenoid saponin. As potential antifertility agents from plants include triterpenoid saponin, it has prompted us to isolate and characterize the triterpenoid saponin of this plant. The crude saponin was precipitated from the concentrated ethanolic extract using a standardized procedure. Column chromatographic separation of this mixture yielded 3ɓ,19Ŭ-dihydroxy-urs-12-en-24,28-dioic acid-28ɓ-D-glucopyranoside (I) along with other compound which are still under investigation. Saponin (I) has been characterized by both chemical and spectroscopic methods.

P2039. Alkaloids in calyx and corolla of *Erythrina coralloides* A.DC. and *Erythrina americana* Miller (Fabaceae).

S. Sanchez-Herrera[1], M. Soto-Hernández[1], G. Kite[2];
[1]Colegio de Postgraduados, Texcoco. Mexico, Mexico, [2]Royal Botanic Gardens Kew, London, United Kingdom.

In Mexico the flowers of *Erythrina* species are used to cook, but their use is limited because the toxicity. The objective was to determine the alkaloid content in calyx and petals in *E. coralloides* and *E. americana* using liquid chromatography coupled with mass spectrometry (LC/MS). Crude alkaloid fractions were prepared. Identification of the alkaloidal extracts was done by LC/MS. Was observed differences between calyx and corolla in *E. americana.* In the calyx Ŭ-erythroidine, ɓ-erythroidine, 8-oxo-Ŭ-erythroidine, erythrinine, erythraline and crystamidine was observed, whereas in corolla Ŭ-erythroidine, ɓ-erythroidine, 8-oxo-Ŭ-erythroidine, erythrinine and erysodine. In *E. coralloides* calyx was found the same alkaloids than *E. americana* calyx and also erysodine and 8-oxo-erythraline. In corolla the same pattern than in the calyx was observed but less 8-oxo-Ŭ-erythroidine. The method of LC/MS allowed the detection of alkaloidal structures in calyx and corolla of *E. americana* and *E. coralloides* that had not been identified in previous studies.

P2040. Antimicrobial evaluation of extracts of *Tillandsia imperialis* (Bromeliaceae).

A. Vite Posadas[1], M. Rojas Bribiesca[2], R. Osuna Fernández[1], **A. Brechú Franco**[1], G. Laguna Hernández[1];
[1]Facultad de Ciencias, México, D. F., Mexico, [2]Centro de Investigación Biomédica del Sur, IMSS, Xochitepec, Morelos, Mexico.

Tillandsia imperialis is used in Mexican folk medicine mixed with other plants and animals for respiratory ailments. Six crude extracts: hexane (H), Methylene Dichoride (MD) and methanol (M) from leaves and inflorescence were evaluated for antimicrobial activity against bacteria and one yeast. The minimal inhibitory concentration (MIC) was determined for each extract using a two-fold dilution assay.

Five extracts exhibited antimicrobial activity against at least one of the microorganisms tested at concentrations of 8 mg/ml or below. Three extracts inhibited *Staphylococcus aureus*: the H extract from the leaves (MIC 4mg/ml); the (H) and (MD) extracts from inflorescence (MIC 0.5mg/ml). *Streptococcus faecalis* was inhibited by (H) inflorescence extract (MIC 8mg/ml). *Klebsiella pneumoniae* and *Salmonella typhi* were inhibited by (M) extracts from leaves and inflorescence (MIC 8mg/ml). Neither one of the extracts showed antimicrobial activity against *Candida albicans* and *Escherichia coli.*

This indicates the existence of antimicrobial compounds in the extracts and show a correlation between the traditional uses of this plant and the experimental data.

P2041. Alkaloid composition of *Erythrina americana* Miller and *Erythrina coralloides* A.DC seeds

M. Soto-Hernandez[1], S. Sánchez-Herrera[1], G. Kite[2];
[1]Colegio de Postgraduados, Texcoco, Mexico, [2]Royal Botanic Gardens Kew, London, United Kingdom.

In Mexico an important number of Erythrina species is found. Many of them are used in agro forestry systems. As typical legumes improve the soil and provide animal fodder, medicines and wood products. These attributes are diminished by the toxicity of the plants because they accumulate alkaloids particularly in the seeds. This work is an investigation of *E. americana* and *E. coralloides* seeds about their alkaloid composition using liquid chromatography-mass spectrometry as analytical tool. The crude methanolic extracts of both species showed some differences related with the alkaloid profile. In the seeds of E americana some dienoid alkaloids such as erythraline, erythrinine, crystamidine, 8-Oxo-erythraline and the lactonic alkaloids Ŭ-erythroidine and ɓ-erythroidine dominate. In contrast, the alkaloid content of *E. coralloides* is observed to be mainly erythrinine, crystamidine and 8-Oxo-erythraline in lesser amount. According to these data erythrinine was found regularly in the seeds of *E. coralloides* whereas in *E. americana* it was scarce. However, the presence of the lactonic alkaloids were dominant in *E. americana* and scarce in *E. coralloides*.

P2042. Phytochemistry and biological activity of root and leaf extracts of *Aspidosperma polyneuron* from Londrina, Brazil

D. Trevisan Ferreira[1], J. P. Pinto[1], J. F. S. Daniel[1], T. A. Santos[1], A. M. Barbosa[1], L. Yassumoto[1], R. Braz-Filho[2];
[1]Universidade Estadual de Londrina, Londrina, Brazil, [2]Universidade Estadual do Norte Fluminense, Campos, Rio de Janeiro, Brazil.

The genus *Aspidosperma* (Apocynaceae) has been well studied but there has been little investigation on the roots of *A. polyneuron*. This paper shows this species as a pharmacologiacal potential using both roots and leaves extractives, which were subjected to bioassay with *Artemia salina,* using a modified Meyer method. The LD_{50} were 69 and 36 ppm for the roots and leaves, respectively (extracts were considered active at LD_{50} <1000 ppm). The extracts were also tested against eight yeast and fungal species by the diffusion test, and did not inhibit their growth. The compounds were identified by chromatographic and NMR, GC-MS, IV techniques. From the roots were isolated: aspidospermine, lupeol, aliphatic alcohols and hydrocarbons of long chains, ß-sitosterol, stigmasterol, and one quebrachamine derivative, whose structure is being investigated. From the leaf extracts were isolated: lupeol, ursolic acid, oleic acid, linoleic acid, carboxylic esters of long chains and a cyclitol. Some of these compounds quoted above have been described to possess pharmacological properties in laboratory animals, such as antiinflammatory, antiplasmodial, and others.

P2043. Evaluation of essential oil composition of Pterospartum tridentatum grown in Portugal

A. C. Grosso[1], M. M. Costa[2], L. Ganço[1], A. L. Pereira[3], G. Teixeira[4], J. M. G. Lavado[5], **A. C. S. Figueiredo**[2], J. G. Barroso[2], L. G. Pedro[2];
[1]Universidade de Lisboa, Faculdade de Ciências de Lisboa, DBV, C2, 1749-016 Lisboa, Portugal, [2]Universidade de Lisboa, Faculdade de Ciências de Lisboa, DBV, Centro de Biotecnologia Vegetal, C2, 1749-016 Lisboa, Portugal, [3]Universidade de Lisboa, Faculdade de Ciências de Lisboa, DBV, Centro de Biologia Ambiental, C2, 1749-016 Lisboa, Portugal, [4]Universidade de Lisboa, Faculdade de Farmácia de Lisboa, Centro de Biologia Ambiental, 1649-019 Lisboa, Portugal, [5]Direcção Regional de Agricultura da Beira Interior, Rua Amato Lusitano, 6000-150 Castelo Branco, Portugal.

Pterospartum tridentatum L. Willk. [= Chamaespartium tridentatum (L.) P. Gibbs.; Genistella tridentata (L.) Samp.] is an European endemic Fabaceae (= Leguminosae) species. This small shrub, up to 100cm, is very common in the mountains of the north-centre of Portugal showing yellow flowers, alternate branches and coriaceous winged stems. The flowers are traditionally harvested in spring and either used as condiment or in traditional medicine. The infusion of the dried flowering tops is used as an excellent bechic and emollient.

The essential oils, isolated by hydrodistillation and distillation-extraction, from the aerial parts of different populations from P. tridentatum collected during the flowering and vegetative phases, were analysed by GC and GM-MS.

All the P. tridentatum populations studied afforded a yellowish oil in a yield of <0.05% (v/w).

cis-Theaspirane, trans-theaspirane and octen-3-ol were, in variable amounts, the dominant components of the oils. Theaspiranes are common flavouring agents responsible for the tea, herbal, green and slightly spicy odour of the plant.

This study was partially funded by IFADAP under research contract AGRO 800.

P2044. Novel ribosome inactivating proteins (RIPs) from Himalayan *Viscum album* (L.)- potential biomolecules for bioprospecting

V. Mishra[1,2], R. S. Sharma[3], S. Bilgrami[2], M. Paramasivam[2], S. Yadav[2], C. R. Babu[1,3], T. P. Singh[2];
[1]Department of Botany, University of Delhi, Delhi-110 007, India, [2]Department of Biophysics, All India Institute of Medical Sciences, New Delhi-110 029, India, [3]Centre for Environmental Management of Degraded Ecosystems, University of Delhi, Delhi-110 007, India.

Ribosome inactivating proteins (RIPs) of *Viscum album* constitute the active principle of traditional tumor therapy in Europe. Himalayan *V. album* populations showed high morphological diversity. To assess the prospecting potential of this wild resource, 4 novel isoforms of its RIP (HmRIP) were purified and characterized. HmRIP was stable to a broad range of temperature (0-65 °C) and pH (3-9). Unlike all other type II RIPs, HmRIP1, 2 and 4 showed unique sugar affinity for L-rhamnose, meso-inositol and L-arabinose besides the galactose. Amino acid sequence of HmRIP determined by cDNA cloning showed deletions at one of the two sugar-binding sites. Crystal structure of HmRIP-sugar complex determined by X-ray crystallography revealed a significantly different conformation of the 2ɔ sugar-binding pocket. Due to deletion of two critical residues forming wall of the pocket, the site has become much broadened. Therefore the sugar binds in a significantly different manner. The recognition of the sugar chains present on the cell surface is the first step in biological activity therefore HmRIP with distinct sugar specificity has pharmacological significance.

P2045. Phytochemistry of Riccia nigerica jones

O. A. Ariyo;
Centre for Alternative Medicine, Banjul, Gambia.

The Phytochemical composition of Riccia nigerica Jones have been studied. Fresh plants of Riccia nigerica were extrated using acetone. Fractions were obtained through column chromotography. The absorbance spectra of the five fractions of the extracts showed a fluctuation from 0 to 1.18 at 400 to 950 wavelength. The anti-microbial activities of the crude extracts were tested against some selected species of bacteria and fungi, thus the test extract was found to have significant inhibitory effect (>17mm) as indicated by zones of inhibition on Bacillus substilis, Pseudomonas aeruginosa, Staphylococus aureus, Shigella dysenterae, Aspergillus niger, Aspergillus flavus and Rhizopus sp. The results of the phytochemical study outlined in this work has shown that the extract of Riccia nigerica exhibited a remarkable inhibitory effect on test organisms both bacteria and fungi.

P2046. The Needle Volatile Composition of Trispecies Hybrids (*Pinus nigra* J. F. Arnold x *P. sylvestris* L.) x *P. densiflora* Siebold et Zucc. and (*P. nigra* J. F. Arnold x *P. sylvestris* L.) x *P. thunbergiana* Franco

M. Idzojtic[1], H. W. Pfeifhofer[2], M. Zebec[1];
[1]University of Zagreb, Faculty of Forestry, Zagreb, Croatia, [2]University of Graz, Institute of Plant Physiology, Graz, Austria.

The needle volatile composition of two trispecies hard pine hybrids produced by the controlled hybridization and their parents was researched with gas chromatography and gas chromatography/mass spectrometry in order to explore the utility of terpenes in hybrid identification as well as confirmation of hybridity. The analysed trispecies hybrids were: (*Pinus nigra* J. F. Arnold × *P*. *sylvestris* L.) × *P*. *densiflora* Siebold et Zucc. (= *nisyde*) and (*P*. *nigra* × *P*. *sylvestris*) × *P*. *thunbergiana* Franco (= *nisyth*). The female parent was F_1 hybrid *P*. *nigra* × *P*. *sylvestris* (= *nisy*). The male parents were *P*. *densiflora* (= *de*) and *P*. *thunbergiana* (= *th*). A total of 58 compounds was identified.

Trispecies hybrids showed the same qualitative pattern of the needle volatile composition as their parents. However, there were quantitative differences in several major terpenes between them. The hybrids *nisyde* were more similar to the female parent (F_1 hybrid *nisy*), whereas the hybrids *nisyth* were more similar to the male parent (*P. thunbergiana*). The intermediary quality of the trispecies hybrids for most components in relation to their parents, confirms their hybrid character.

P2047. Anti-Trypanosomal secondary metabolites from two Cameroonian medicinal plants

D. NGAMGA, P. Tane;
Department of chemistry, Faculty of Science, University of Dschang, Dschang, Cameroon.

In the search of our course for antitrypanosomal compounds from natural source, two plants used in central and western part of Cameroon to treat several diseases were investigated : *Xymalos monospora* Baill (Monimiaceae) and *Millettia griffoniana* Bail (Leguminosae). From the stem bark of *Xymalos monospora,* five alkaloids including the new *Epi*-temuconine were isolated. From the seeds of *Millettia griffoniana*, twelve isoflavonoids with five new namely 7-methoxyebenosin, griffonianone (E-H) were isolated. The structure of compounds were established by MS, 1D and 2D spectroscopy including DEPT, COSY, HMQC and HMBC experiments. Crude extracts as well as pure compounds have been tested for growth inhibitory activity in vitro vs. Bloodstream forms of African trypanosomes. IC50 values in the range of 1-3µg/ml were found for many of pure compounds isolated.

Acknowledgements Authors gratefully acknowledge financial support from the international program in the chemical Sciences (IPICS), Uppsala

P2048. Modulation of GABAergic Neurotransmission by a New Component from Cyperus Rotundus

D. U. Lee[1], B. S. Koo[2], S. I. Lee[3];
[1]Department of Biotechnology, Dongguk University at Gyeongju, Gyeongju, Republic of Korea, [2]Department of Oriental Neuropsychiatry, Dongguk University, Seoul, Republic of Korea, [3]School of Life and Health, Sorabol College, Gyeongju, Republic of Korea.

We report the isolation of some components, including new sesquiterpenes, from the active fraction of Cyperi Rhizoma and the agonistic property of a newly identified constituent from this plant on the rat cerebrocortical benzodiazepine receptor. Four sesquiterpenes, ɓ-selinene, isocurcumenol, nootkatone and aristolone and one triterpene, oleanolic acid were isolated from the ethylacetate fraction of the rhizomes of *Cyperus rotundus* and tested for their ability to modulate ɔ-aminobutyric acid ($GABA_A$)-benzodiazepine receptor function by radioligand binding assays using rat cerebrocortical membranes. Among these compounds, only isocurcumenol, one of the newly identified constituents of this plant, was found to inhibit [^{3}H]Ro15-1788 binding and enhance [^{3}H]flunitrazepam binding in the presence of GABA. These results suggest that isocurcumenol may serve as a benzodiazepine receptor agonist and allosterically modulate GABAergic neurotransmission via enhancement of endogenous receptor ligand binding.

P2049. Isolation and Identification of the Major Terpene Components of the Essential Oil of *Salvia officinalis L.* (Sage) Grown in Egypt

A. E. Edris;
National Research Center, Cairo, Egypt.

This paper deals with the isolation and identification of the major terpene constituents of the essential oil of *Salvia Officinalis* (commonly known as Sage), a herb that long been used to impart aroma and flavor to food. The essential oil extracted from the leaves is important due to its application in traditional medicine and its properties as antibacterial, antiviral and cytotoxic properties. The essential oil was isolated from the leaves of *Salvia officinalis* by steam distillation using a Clevenger-type apparatus. Identification of the terpenes constitution of the essential oil was carried out using gas chromatography equipped with flam ionization detector, as well as gas chromatography-mass spectroscopy. From the analysis data it was clear that the major terpene components constituting the essential oil are: Ǔ-thujone 30.21%; camphor 20.5%; ɓ-thujone 11.34% and 1,8-cineol 9.21%. These values were compared with a previous reported data observed from *Salvia offinicalis* essential oils grown in other different environments around the globe.

P2050. X-ray structure of a blue complex pigment from the blue flowers of *Centaurea cyanus*

M. Shiono[1], N. Matsugaki[2], **K. Takeda**[3];
[1]Department of Physics, Graduate School of Science, Kyusyu University, Hakozaki 6-10-1, Fukuoka 812-8581, Japan, [2]Photon Factory, High Energy Accelerator Research Organization, Oho 1-1, Tsukuba 305-0801, Japan, [3]Department of Biology, Tokyo Gakugei University, Koganei, Tokyo 184-8501, Japan.

The blue pigment of the cornflower, named protocyanin, has long been investigated, but its precise structure has remained unclear. Our recent research demonstrated the components of protocyanin to be anthocyanin (AN), flavone glycoside (FL), Fe^{3+}, Mg^{2+} and Ca^{2+} ions and we succeeded in the reconstruction of protocyanin. In this study, we revealed the X-ray structure of protocyanin. The crystal structure of the reconstructed protocyanin was determined at a resolution of 1.05Å. The refined molecule has pseudo three-fold symmetry and four metal ions, Fe^{3+}, Mg^{2+} and two Ca^{2+}, align along the pseudo three-fold axis. The four metals are coordinated to six AN molecules and six FL molecules. The inner Fe^{3+} and Mg^{2+} ions are each coordinated to three AN molecules respectively, while the outer two Ca^{2+} ions are each coordinated to three FL molecules . Both AN and FL molecules are self-associated with each other as AN-AN and FL-FL in pair and this hydrophobic association also exists between AN and FL molecules. Protocyanin is a tetra-metal (Fe^{3+}, Mg^{2+}, $2Ca^{2+}$) nuclear complex of twelve molecules of anthocyanin and flavone glycoside, a new type of supramolecular pigment.

P2051. Curcuminoid Fingerprint of *Curcuma longa* Linn.

L. Sriphong[1], P. Yaipakdee[1], U. Sotanaphun[2];
[1]Department of Pharmaceutical Chemistry, Faculty of Pharmacy, Silpakorn University, Nakorn Prathom, Thailand, [2]Department of Pharmacognosy, Faculty of Pharmacy, Silpakorn University, Nakorn Prathom, Thailand.

Curcuma longa Linn. (family Zingiberaceae), known as turmeric has been widely used as a natural food coloring agent and major component of curry powder as well as an anti-inflammatory agent and the treatment of flatulence, dyspepsia, hepatitis, jaundice, menstrual difficulties and many other disorders. In Thailand this medicinal plant has been used as herbal drug and herbal drug preparations. Since chemical fingerprint shows an important mean for quality control of herbal medicines. Curcuminoid fingerprint was established using thin layer chromatographic method for determination of three major curcuminoids; curcumin, desmethoxycurcumin and bisdesmethoxycurcumin. The chromatographic chemical profiling method demonstrated successful applications to identify and assess the consistency of turmeric from different sources. This curcuminoid fingerprint represented the characteristic components that would be useful for the quality control and chemotaxonomic determination of turmeric.

P2052. Qualitative and Quantitative Radiation Protection Analysis of Mucosa of ICR Strained Mice Using Selected Herbal Extracts such as GC-2112 from Garlic (*Allium sativum*) and GX-2137 from Ginseng (*Panax sp.*)

J. B. Bunagan[1,2];
[1]University of Perpetual Help Rizal, Las Pinas, Philippines, [2]Kester Grant College, Quezon City, Philippines.

Earlier reports showed that ginseng has significant radioprotective and stimulatory effect on the recovery of the lymphocytes and leukocytes

Using graded absorbed doses of radiation (1.5, 5, 20, 50 Gy) applied in ICR strain male white mice which was injected with GX-2137 from ginseng (*Panax sp*.) and GC-2112 from garlic (*Allium sativum*) was tested to prove some radioprotective efficiency. The herbal extracts were injected intraperitoneally and the experimental mice were sacrificed 2 and 48 hrs. post-irradiation. Factors such as analyzing kinetics of critical tissue parameters (length of villi, the number of crypt and villi cells and cell density) and determining the Relative Protection Efficiencies (RPE) using quantitative histopathological techniques were used to quantify the radiation protection assay in the duodenum of ICR strain mice.

Results showed that GC-2112 and GX-2137 protected the villi structures. After 2 hrs. post irradiation, tissue degeneration was evident. RPE values of significant radioprotection of the crypts is demonstrated at absorbed dose. It was found that some villi cells are even viable at non-physiologic dose of 50 Gy.

P2053. Chemical composition and antibacterial activity of essential oil of *prangos ferulacea L.*

H. Amiri[1], A. Rustaiyan[2], M. H. Meshkat[3];
[1]Department of Biology,Lorestan University, Khoramabad, Islamic Republic of Iran, [2]Department of Chemistry , Science and Research Campus, I. A. University, Tehran, Islamic Republic of Iran, [3]Department of Chemistry,Lorestan University, Khoramabad, Islamic Republic of Iran.

South-West of Iran which is mainly used as rich herb in animal feeding. This plant was collected from Broujerd mountains of Lorestan province in Iran. The air-dried epigeous parts were subjected to *hydrodestillation* method (in a yieid 0.45% W/W).Identification of essential oil costitiuents was made by GC and GC/MS.The antibacterial tests were carried out by drilling well and measuring diameter of inhibition zone.

A large proportion of the oil was composed of hydrocarbon monoterpens.The major component is Ŭ-pinene(36.6%) and ɓ-pinene(31.1%). The results of the antibacterial activity showed that the oil was active aginest of most the positive and negative bacteria specialy Staphyllococcus aureus.

P2054. Isolation of curcumin from curcuma amada rhizome and studing the effects of penteration enhancer and vehicle type on the percutaneous permeation of curcumin and its total extract rhizom

A. Zarghi, H. R. Moghimi, B. Shahmir;
School of Pharmacy, Shaheed Beheshti University of Medical Sciences, Tehran, Islamic Republic of Iran.

Curcumin is the principle pigment and active component present within the rhizome of various species of curcuma genus. It has several pharmacological effects, such as: anticancer, antioxidant, antihepatotoxicity and antinflammatory activities. In this study attempts were made to evaluate the extent of percutaneous permeation of curcumin for topical application as well as its isolation from curcuma amada rhizome.To perform this study, curcumin was isolated from C. amada rhizome. Then four semisolid topical formulations of curcumin in the form of gel, cream and ointment were prepared and the effects of these vehicles on the permeation of curcumin through rat skin, using the static diffusion cells, were studied. Results of these studies showed that gel is the best vehicle for topical formulation of curcumin. Finally, the permeation of hydroalcoholic mixtures of curcumin and C. amada rhizome total extract, through rat skin was also studied in the presence or absence of penetration enhancers, such as aqueous mixture of lecithin (1 mg/mL), aqueous solution of sodium lauryl sulfate and mixture of ethyl acetate: n-hexane (1:1, V/V). Results showed that the absorption rate of curcumin and C. amada total extract through rat skin were increased by ethyl acetate: n-hexane about 2.23 and 1.50 times, respectively.

P2055. Distribution and Accumulation of Ginsenosides in *Panax quinquefolium* during Plant Growth

X. Du, J. Zhou, Y. Liu;
College of Pharmaceutical, Heilongjiang University of Chinese Medicine, Harbin, China.

Ginsenosides are the secondary metabolic products and active components in *Panax quinquefolium* that exert medicinal and nutritional effects on human beings. The research work determined the concentrations of ten ginsenosides in the leaves, stems, root cortex, phloem and xylem in four-year-old American ginseng at nine growing stages of sprout, separation of leaf and stem, flowering, green fruit, red fruit, fruit abscised, yellow leaf, leaf abscised and plant dormancy from early spring to late autumn. The results demonstrated that the highest concentrations of ginsenosides in stems, leaves, root cortex, phloem and xylem showed at the growing stages of flowering, red fruit, flowering and fruit abscised, fruit abscised and leaves abscised, respectively. The sequence of the accumulation of ginsenosides in American ginseng seems from the stem and leaves to root cortex, phloem and xylem. The main individual ginsenosides in the leaf and stem were Re and mRd, while in root were Re, mRb_1 and Rb_1. From the root cortex to phloem and xylem, the percentage of Re in total ginsenosides showed decrease, while the percentages of mRb_1 and Rb_1 in total ginsenosides were increase.

P2056. Flow cytometric investigations with an arabinogalactan-protein (AGP) from *Echinacea purpurea* and human leucocytes

S. Thude[1], **B. Classen**[1], W. Blaschek[1], D. Barz[2], H. Thude[2];
[1]Pharmaceutical Institute, Department of Pharmaceutical Biology, University of Kiel, Kiel, Germany, [2]Institute of Transfusion Medicine, University of Jena, Jena, Germany.

An AGP from pressed juice of the aerial parts of *Echinacea purpurea* is a high molecular weight glycoprotein ($1.2x10^6$ Da) with a highly branched carbohydrate moiety of >90% (w/w), mainly consisting of 3-, 6- and 3,6-linked ß-D-Gal*p* residues, substituted with terminal Ŭ-L-Ara*f* residues and terminal GlcA and has been shown to have complement-stimulating activities *in vitro* (1, 2). In order to get information about possible interactions of AGP with the immune system on a cellular level, we generated polyclonal antibodies against this AGP. Ara*f* residues form a key part of the antigen epitope for these polyclonal antibodies (3). Flow cytometric investigations show binding of the AGP to the cell surface of human leucocytes (lymphocytes, monocytes and granulocytes). Competition assays with two antibodies directed against CD4 and CD8 revealed no interaction of AGP with these receptors, leading to the conclusion that binding of AGP is mediated via different structures (4).

P2057. Volatile Composition and in Vitro Antimicrobial and Antioxidant Activities of the Essential Oil of *Laurus nobilis* L. Leaves from Turkey

K. Cemil;
KSU, Kahramanmaras, Turkey.

In the present study, essential oil from the leaves of laurel (*Laurus nobilis* L., Lauraceae) grown at 1100 m altitude in Turkish state forests (Andirin district), was obtained by steam distillation. The volatile composition of essential oil was analysed by GC and GC-MS. It contains 54,7 % 1,8-cineol, 25,1 % monoterpene hydrocarbones, 7,8 % monoterpene alcohols and carbonyls, 9.3 % monoterpenyl acetates and 0,95 % sesquiterpene hydrocarbones as well as 0,27 % sesquiterpene alcohols and oxides and 0,33 % eugenol derivates. The reducing power, antioxidant and 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical-scavenging activities of the essential oil were found to be low, compared to ascorbic acid, and BHT, respectively. Antimicrobial activities of the essential oil of the leaves of *L. nobilis* were determined using agar-disc diffusion method. Laurel essential oil shows good antimicrobial activities against *Escherichia coli,* compared to control antibiotics. No activity could be measured with *Yersinia enterocolitica, Micrococcus luteus* and the yeast *Kluvyeromyces fragilis.*

P2058. Utilization of *Wolffia Arrhiza* extracts for protein rich husk and seeds yield of lentil and its socio-economic value

R. Shrivastava;
PSPT College,Ramaipur, Kanpur, India.

Wolffia arrhiza is known as noxious weed and rated as one of the ten major weeds growing in South-East Asia, commonly infesting natural impounded waters in India. Studies on effect of *W. arrhiza* extract on protein rich husk and seeds yield of lentil (*Lens culinaris,* variety D.P.L.-15) were made. Pre-soaking seed treatments for 12 and 24 hrs. were given with 1, 2 and 5 percent ether and water extracts of *W. arrhiza*. Synthesis of protein and consequently protein contents were increased in husk and seeds yield of lentil produced to the maximum extent in treatments 12 and 24 hrs. with 5 per cent ether and water extracts. Results are statistically significance at 5 percent error probability.

The NSSO reports showed that 42 percent of the rural and 49 percent of the urban population receive less than accepted norms of daily calorie intake (2200K Cal). The average intake of pulses is around 37 g. per capita per day as against the recommended dietary allowance of 50g. Too little energy and too little protein in the diet of about 80 million children have caused several disorders associated with protein energy malnutrition (PEM).

Present finding are of both social and economical significance of malnutrition in children, human beings, cattle and need practical adoption in agriculture of lentil by growers of commercial crop.

P2059. Volalite Composition and In Vitro Antimicrobial and Antioxidant Activities of the Essential Oil of *Laurus nobilis* L. Leaves from Turkey

D. Metin;
KSU, Kahramanmaraк, Turkey.

In the present study, essential oil from the leaves of laurel (*Laurus nobilis* L., Lauraceae) grown at 1100 m altitude in Turkish state forests (Andirin district), was obtained by steam distillation. The volatile composition of essential oil was analysed by GC and GC-MS. It contains 54,7 % 1,8-cineol, 25,1 % monoterpene hydrocarbones, 7,8 % monoterpene alcohols and carbonyls, 9.3 % monoterpenyl acetates and 0,95 % sesquiterpene hydrocarbones as well as 0,27 % sesquiterpene alcohols and oxides and 0,33 % eugenol derivates. The reducing power, antioxidant and 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical-scavenging activities of the essential oil were found to be low, compared to ascorbic acid, and BHT, respectively. Antimicrobial activities of the essential oil of the leaves of *L. nobilis* were determined using agar-disc diffusion method. Laurel essential oil shows good antimicrobial activities against *Escherichia coli,* compared to control antibiotics. No activity could be measured with *Yersinia enterocolitica, Micrococcus luteus* and the yeast *Kluvyeromyces fragilis.*

P2060. A data bank of terpene species of Italian Flora

P. M. Bianco;
Università del Molise, Campobasso, Italy.

Occurrence and distribution of plant volatiles has been significantly known in the last 15 and permits preliminary overviews. We taken into account Italian flora for the availability of a detailed flora and occurrence of different biomes. We put in databank and analysed relation between contents and emissions of terpenes and ecological characteristic of species; we taken in consideration isoprenoids and sesquiterpenes, constituents of essential oils and particularly active from the metabolic point of view. Futhermore isoprenoids are the principal constituents of bVOCs, important in pollution problems. We cross data relative to presence in plants with information related to taxonomy, corological type, biological forms, habitat, syntaxonomy to verify corrispondence between emission and storing of terpenes and ecological characteristic of plants and to identify trends in relation to taxonomical or ecological groups. Our statistical analysises can help the comprehension of their function in relation to environment and climatic condition.

P2061. Taiwan Biological Database and Its Use in Vegetation Classification

H. Liu;
National Sun Yat-sen University, Kaohsiung, Taiwan Republic of China.

Taiwan Biological Database was established in 1999 to hold data from Taiwan biological survey project. The project recorded sample site, species name, and other data the individual researcher needed, such as sample area size. The locality accuracy is required to be within 100 m, but in most cases the data are recorded within 10 m in accuracy. In the current Taiwan vegetation inventory and mapping program, because steep topography and more time required to record species in the releves from tropical and subtropical areas, the program time would not able to survey every polygons delineated. As the result, the vegetation samples are taken from the delineated polygons with greater dissimilarity, and the polygons with Biological Database data in will not be surveyed to have more different-class polygons sampled. Data from Biological Database are combined with current and historic vegetation samples to construct a vegetation classification system. The classification systems with and without Biological Database are compared.

P2062. Vaccinio - Piceetea Br.-Bl. in Br.-Bl. et al. 1939 Class in Moldova (Romania)

C. Manzu, T. Chifu, O. Zamfirescu;
Faculty of Biology, Iasi, Romania.

Moldova is one of the historical provinces of Romania, situated in the E-NE part of the country. The western limit of this province is represented by one branch of the Carpathian Mountains, namely the Oriental Carpathians. Forest phytocoenosis - made of coniferous forests - coveres a large area in the Romanian Mountains. In Moldova there were identified 8 associations: *Hieracio transsilvanici - Piceetum* Pawl. et Br.-Bl. 1939; *Soldanello montanae - Piceetum* Volk in Br.-Bl. et al. 1939; *Dicrano - Pinetum* Preissing et Knapp in Knapp ex Oberd. 1957; *Pino cembrae - Piceetum* Chifu et al. 1984; *Piceeto - Juniperetum sibiricae* Br.-Bl. 1930; *Rhododendro - Pinetum mugi* Borza 1959 em. Coldea 1985; *Leucanthemo waldsteinii - Piceetum* Krajina 1933; *Hieracio transsilvanici - Abietetum* (Borhidi 1971) Coldea 1991. These associations are included in 5 alliances (*Piceion excelsae, Dicrano - Pinion, Pinion mugi, Chrysanthemo rotundifolii - Piceion, Abieti - Piceion*) and 2 orders (*Piceetalia excelsae, Athyrio - Piceetalia*).

P2063. Spatial patterns of plant communities in a protected semiarid region in tropical Mexico.

E. Sandoval-Palacios, **G. Hernández-Cárdenas**, J. Zavala-Hurtado;
Universidad Autónoma Metropolitana-Iztapalapa, Mexico City, Mexico.

Although the debate on communities as natural or artificial units is a matter of the past, the identification of plant associations is still of great practical relevance for the management of protected areas and for attempts to predict possible plant community shifts with anticipated climate or other environmental changes. We explored vegetation-environment relationships in the semiarid Zapotitlán Valley, a local basin in the heart of the Tehuacán-Cuicatlán Biosphere Reserve in tropical Mexico. We analyzed spatial patterns of plant communities from 27 sampling sites in 2003. Environmental variables were obtained from field surveys, remote sensing and cartographic sources. Ordination (Canonical Correlation) and classification (Cluster and Discriminant) analyses allowed the definition of six plant associations and the detection of major environmental gradients. These groups differ in absolute abundance and abundance ranking, but showed only slight differences in species composition. Discriminant functions were incorporated in a Geographic Information System to generate a cartographic model which, in turn, was used to produce a vegetation map.

P2064. Evaluation of classical and numerical approach in syntaxonomy

S. Barudanovic, S. Redzic;
Center for Ecology and Natural Resources, Sarajevo, Bosnia and Herzegovina.

Striving to establish generally acceptable principles in syntaxonomic researches, methods of numerical ecology are today often used.

In contrast to classical approach bringing along high level of subjectivity, methods of numerical ecology having an opportunities for needed sciences objectivity.

However, methods of numerical ecology could not play the basic and only way in establishing of syntaxonomical units, as well as characteristic species of particular communities.

Traying to accomplish the higher level of objectivity, methods of numerical ecology are using a numbers of releves with different origin. It is not possible to avoid the fact of different authors subjectivity level. Using releves with different origin is establishing of assemly, but not a system as suitable base.

No one computer program is not able to assess importance of particular species. Programs are registering presence, absence and quantitative aspects of all species equally.

Next step in progress of objectivization could be combining classical and numerical syntaxonomy through previous ranging of species by its phytocoenological belonging.

P2065. The Diversity of Vegetation of Serbia and their Relationship to European Habitat Classification

D. V. Laku iĺ [1], J. Bla enļ iĺ [1], V. RanĽeloviĺ [2], B. Butorac[3], S. Vukojiļ iĺ [1], B. Zlatkoviĺ [2], S. Jovanoviĺ [1], G. Tomoviĺ [1], J. in ar-Sekuliĺ [1], V. Stevanoviĺ [1];
[1]Institute of Botany and Botanical Garden «Jevremovac», Faculty of Biology, Belgrade, Serbia and Montenegro, [2]Faculty of Sciences, University of Niš, Niš, Serbia and Montenegro, [3]Institute for Nature Protection, Novi Sad, Serbia and Montenegro.

In co-production with Ministry for Sciences and Nature Protection of Republic of Serbia and Faculty of Biology University of Belgrade, group of scientists have compiled a list of phytocoenological names (from classes to subassociations and facies) in their overview covering the whole of Serbia.

Initial Vegetation of Serbia Data Base was made. Position of territory of Serbia between several phyto-geographical regions ī C. European, Pontic-S. Siberian, Mediterranean and Alpine generates great floristic and vegetation diversity. Based on checking of 1.580 phytocoenological references, 2.160 names of associations, subassociations and facies was classified into 40 classes, 85 orders, 184 alliances and 21 suballiances.

The all associations and subassociations with their facies are cross-referenced with correspodnig EUNIS, PALEARCTIC, CORINE, RAMSAR, EMERALD and NATURA habitat types.

P2066. Classifying the main plant communities in the reserve “Kamenshtitsa”, Central Stara planina mountain

K. Pachedzhieva;
Sofia University, Sofia, Bulgaria.

The aim of the present investigation is classifying the vegetation in the reserve “Kamenshtitsa”, Central Stara planina mountain.

The research was worked out during the vegetation periods in 2002 and 2003 year. For implementation of the aim the following tasks have been set: identification of the main plant communities in the reserve and an attempt of composing a geobotanical map of the vegetation. For solving these tasks the principles of the two phytocoenological schools are used - the Braun-Blanquet and the Russian school.During the terrain work over 45 phytocoenological descriptions were made. The described associations are of mixed origin and belong to several main vegetation formations: that of *Fagus sylvatica, Quercus daleschampi, Festuca dalmatica* and others. A map of the plant associations is created. Some comparisons with similar investigations are made. The results are used for making conclusions for the succession changes in the reserve.

P2067. Leaf physiognomic communities: A new approach for vegetation classification

C. Traiser, V. Mosbrugger;
IFG Institute of Geosciences, Tuebingen, Germany.

A new approach of vegetation classification is presented which is based on leaf physiognomic characteristics of vegetation. Contrary to many existing vegetation classifications leaf physiognomic traits of vegetation are regarded as chronological independent classification units. This circumstance allows the application of the concept of “leaf physiognomic communities” to extant as well fossil vegetation types. For definition of the syn-physiognomic units 25 leaf physiognomic characters of 108 European hardwoods are recorded and scored. Based on synthetic chorologic floras a grid data set comprising the leaf physiognomic character composition of the vegetation was compiled. A hierarchical classification of the grid data using cluster analysis reveals 5 principal leaf physiognomic vegetation units in Europe (Mediterranean, oceanic, Scandinavian, sub-continental and continental class). Ordination methods (PCA, RDA) allow a further analysis of these classes in the leaf physiognomic character space. As an example two fossil leaf assemblages from the Paleogene of Spitsbergen and Switzerland demonstrate the application of the classification.

P2068. Classification of vegetation on exposed pond bottoms of the Czech Republic

K. Šumberová[1,2];
[1]Institute of Botany, Academy of Sciences, Brno, Czech Republic,
[2]Department of Botany, Faculty of Science, Masaryk University, Brno, Czech Republic.

A classification of vegetation of the classes Isoëto-Nanojuncetea and Bidentetea by Cocktail method was performed. The method is based on the creation of the specific groups of species under a supervision of an expert; the process is statistically controlled. An individual community is characterised by the presence of the specific species group or by the combination of more species groups, appropriately by their absence. The communities which are lacking such a group of species, can be defined by dominants in some cases. The “dominant approach” had to be used in most Bidentetea communities, because using the “species group approach” the Bidentetea are not clearly defined versus Isoëto-Nanojuncetea communities. The results of the Cocktail method were compared with the results of cluster analysis and with the definition of individual associations of Isoëto-Nanojuncetea and Bidentetea, traditionally accepted in Czech phytosociological literature and based on methods of "classical" phytosociology. The Cocktail classification lead to the broadly-defined plant communities and to the reduction of a number of described association.

P2069. Formalized classification of ombrotrophic bog vegetation of the Czech Republic

J. Navratilova[1,2], M. Hajek[1,3], P. Hajkova[1,3], M. Chytry[1], L. Tichy[1], I. Knollova[1];
[1]Department of Botany, Masaryk University, Faculty of Science, Brno, Czech Republic, [2]Department of Plant Ecology, Institute of Botany, Academy of Sciences, Trebon, Czech Republic, [3]Department of Ecology, Institute of Botany, Academy of Sciences, Brno, Czech Republic.

The vegetation of Czech ombrotrophic bogs and allied bog woodlands has been traditionally classified into 11 associations of the class *Oxycocco-Sphagnetea*, 6 as. of the class *Vaccinio-Picetea* and 3 as. of the class *Scheuchzerio-Caricetea fuscae.* Particular associations are conventionally defined in the different ways, mostly by species composition and dominance, but also by habitat and geographical characteristics. We used the procedure of formalized reproduction of an expert-based vegetation classification to define the associations in a formal way. Applying the Coctail method to a geographically stratified data set of 21,795 relevés of all Czech vegetation types, we defined groups of species with the statistical tendency of joint occurrences in vegetation. Combinations of these species groups by logical operators and dominance of some species yielded formal definitions of associations. We rejected the associations that could not be reproduced by any combination of species groups or species dominance and the associations lacking diagnostic species that could be derived from entire data set by calculating fidelity of species to the associations.

P2070. Determination of plant ecological groups in the beech(Fagus orientalis Lipsky)forests,Siyahkle,eastern Guilan,Iran

H. Pourbabaei[1], M. Beygom Faghir[2], A. Pourrostam[1];
[1]Department of Forestry, Faculty of Natural Resources, Someasara, Islamic Republic of Iran, [2]Department of Biology, Faculty Sciences, Rasht, Islamic Republic of Iran.

The aim of this research was to determine plant ecological groups and their relations with topographical factors in the beech forests of Shenrood,district No.6, Siyahkle. The systematic random method and nested plot sampling procedure were used for data collection. Within each sampling plot tree, shrub, herb and tree seedling layers were collected and identified, in spring and summer. Their abundance- dominance was estimated based on Braun-Blanquet criterion. Ecological groups were diagnosed by means of TWINSPAN classification method. The results showed that three ecological groups were found in the tree and shrub layer. In the herbal and tree seedling layer of spring collection, four ecological groups and in the herbal and tree seedling layer of summer collection, three groups were found. Comparing distribution of plant ecological groups with aspect, slope and elevation revealed that between them and aspect, and also some ecological groups there were significance relationships between them and aspect and slop, while remarkable relationships were not observed between ecological groups and elevation.

P2071. Can plant community ordinations be affected by various sample plot sizes in grasslands?

Z. Otýpková;
Masaryk University, Brno, Czech Republic.

Vegetation samples from plots that are stored in phytosociological databases often differ by one or two orders of magnitude in size, even within a single vegetation type. This fact may influence vegetation analysis, but the extent of this possible influence has not been investigated so far. The effect of sample plot size on ordination results was investigated in grassland vegetation in southern Moravia (Czech Republic), using data from nested plots of 1, 4, 16, 25 and 49 m^2, placed along two ecological gradients: long gradient (including different vegetation types and various climatic condition in a larger area) and short gradient (small area with a floristically homogeneous vegetation type). In both gradients the smallest plot sizes showed the most deviating patterns in ordinations, while samples of larger sizes gave similar results. The transformation of percentage cover also affected the results, more so when samples were collected along short ecological gradient. Samples differing in size by one order (1 and 49 m^2) seem to be inappropriate to combine together in ordination analysis, especially when they were sampled along a short ecological gradient.

P2072. A comparison of unsupervised and supervised classification of meadow vegetation of the Czech Republic

M. Havlová[1], P. Hájková[1], M. Hájek[1], M. Chytrý[1], L. Tichý[1], D.
Bla ková[2], K. Šumberová[3], T. Ļ erný[2], J. Novák[4], T. Kuļ era[5];
[1]Masaryk University, Brno, Czech Republic, [2]Institute of Botany,
Academy of Sciences, Praha, Czech Republic, [3]Institute of Botany,
Academy of Sciences, Brno, Czech Republic, [4]University of South
Bohemia, Ļ eské BudŊovice, Czech Republic, [5]Institute of Landscape
Ecology, Academy of Sciences, Ļ eské BudŊovice, Czech Republic.

A comparison of two different classifications of a large phytosociological data set of meadow vegetation of Molinio-Arrhenatheretea class from the Czech Republic is presented. The first classification was performed using cluster analysis and in the second classification vegetation units were defined by combination of species groups created by Cocktail method. While in cluster analysis vegetation plots are classified by an unsupervised algorithm of a computer program, Cocktail classification is basically created by expert knowledge. In cluster analysis, a resemblance measure and a group linkage method are chosen and then we cannot influence the process of classification and assignment of relevés to the groups. By contrast, in Cocktail classification an expert makes subjective choices during the classification process while the program suggests possible solutions and ensures that particular steps in the classification process are applied consistently throughout the data set.

P2073. Can be plant species groups transferred across scales?

P. Petrik[1], H. Bruelheide[2];
[1]Institute of Botany, Czech Academy of Sciences, Pruhonice, Czech
Republic, [2]Institute of Geobotany and Botanical Garden, Martin Luther
University Halle-Wittenberg, Halle an der Saale, Germany.

Three datasets were sampled: a floristic one on a 0.5 km^2 grid, another floristic one on a 0.13 km^2 grid, and a vegetation dataset at the plot scale (∴200 m^2). Species groups (SG) were extracted from all the datasets using the method Cocktail and the SG were assigned crosswise from one dataset to the other two ones. Correlation between GIS-variables and species distribution at each scale was calculated by multivariate analysis. The SG that were common to all datasets (across all scales) represented the main ecological gradients of the area. SG derived from broader scale data had generally a lower correspondence when applied to fine-scale data than *vice versa*. Some SG were less scale-dependent (i.e. spatially stable) than others. The most important variables for the spatial distribution of species was the size of forest area, whilst most variability of data explained the fine-scale. A possible application is to predict the potential occurrence of missing species in areas with incomplete floristic or vegetation surveys.

P2074. Classification of boreal forest vegetation in the Middle and Eastern Europe: a comparison

V. I. Vasilevich;
Komarov Botanical Institute, St.Petersburg, Russian Federation.

Boreal forests in European Russia are divided in four zones: north, middle, south and hemiboreal. Zonal associations differentiate every zone. Besides there are plant associations that occupy different habitats in every zone. Boreal forests in Eastern Europe are very homogeneous from west to east and it is impossible to distinguish any geographical vicariants on the level of association or subassociation.

Comparison of classification in Middle and Eastern Europe is very difficult task. Common classifications of boreal forests are absent in these regions. Diagnoses of associations are not formulate explicit. Characteristic and differential species are not constant and have geographical and ecological ranges that do not coincide completely with range of association. Only Calamagrostio arundinaceae-Piceetum and Sphagno girgensohnii-Piceetum from north-eastern Poland correspond partly to associations of spruce forests in Russia.

P2075. The "total cover value ratio" - an alternative fidelity measure for the determination of diagnostic species

W. Willner;
VINCA, Vienna, Austria.

The fact that species differ in their diagnostic value is reflected by the concept of fidelity. Recently, several fidelity measures have been proposed, based solely on constancy. BERGMEIER et al. and DENGLER proposed a threshold for diagnostic species which seems rather weak for a sharp delimitation of associations. Moreover, constancy is strongly dependent on the size of the relevés used, making it impossible to compare e.g. forests with herb vegetation. An alternative solution was presented by BARKMAN who proposed the "total cover value" (TC), defined as the average cover value of a species in a syntaxon, also taking into account the relevés where it is absent. Here, a more general definition is presented which takes into account also the size of each relevé. In this form, the TC is no longer dependent on size or shape of the relevés used. Fidelity can be defined by the TC ratio which is the TC of a species in a given syntaxon divided by its TC in the compared syntaxon. Threshold values for diagnostic species are suggested, based on the assumption that a good diagnostic species should (almost) be restricted to the syntaxon for which it is diagnostic.

P2076. Stratified resampling of vegetation plot databases as a bias reduction technique in classification studies

I. Knollová, M. Chytrý, L. Tichý;
Department of Botany, Masaryk University, Kotlarska 2, CZ-611 37
Brno, Czech Republic, Brno, Czech Republic.

Large vegetation plot databases are increasingly used for description of vegetation patterns over large areas and testing various ecological hypotheses. The analyses, however, may be seriously biased due to heterogeneous origin of the data in such databases, where many records are based on opportunistic sampling. We propose some resampling strategies that may reduce such bias and compare classifications of the data sets that were prepared with these resampling strategies. As a demonstration database we used 6050 plot records of meadows and mesic pastures from the Czech Republic. We used the following resampling strategies: (1) Geographical stratification; Three types of habitat stratification: (2) by phytosociological associations; (3) by numerical classification; (4) by Ellenberg indicator values; (5) selection of plots with potential diagnostic species. We also used four combinations of the geographical stratification with the other methods. The results indicate that stratified resampling may strongly influence the results of classification and possibly reduce the bias inherent to large databases.

P2077. Intrapopulational variability of *Abies alba* from the Tisovik Reserve expressed in needle traits

E. Pawlaczyk[1], M. A. Bobowicz[1], A. F. Korczyk[2];
[1]Department of Genetics, Adam Mickiewicz University, Poznan, Poland, [2]Natural Forest Department, Forest Research Institute, Bialowieza, Poland.

European silver fir (*Abies alba* Mill.) is a mountain tree, but sometimes it may occupy lowlands, especially in northern parts of its distribution. The geographical distribution of silver fir is limited mainly to the Central-European mountains and in Central Poland reaches the northern border. However, 120 km on the north from the border of range silver fir occurs in small, natural and isolated populations in Bialowieza Primeval Forest - the Tisovik Reserve (Byelorussia).
The human activities caused the severe losses in this stand thus the preservation of gene pool should be entered upon at an urgent mode. Bearing this in mind, our investigation aimed at describing the intrapopulational structure and genetic variability of silver fir from the Tisovik Reserve.
One-year old needles were collected from silver fir trees and characterised in respect to 12 morphological and anatomical traits and next were subjected to multivariate statistical analyses. Studied trees within the population showed a homogeneous character so it may be concluded that individuals from the Tisovik Reserve showed the uniform character and this population is weakly differentiated.

P2078. Tree diversity and regeneration dynamics of a montane forest in Ecuador and factors affecting it

J. Homeier[1], S. W. Breckle[2];
[1]Albrecht-von-Haller-Institute for Plant Science, Göttingen, Germany, [2]Department of Ecology, Bielefeld University, Bielefeld, Germany.

Field research for this study was carried out on the eastern slope of the Cordillera El Consuelo in Southern Ecuador. On permanent plots of 400 m^2 situated in altitudes between 1850 and 2450 m above sea level all trees with a DBH (diameter at breast height) of 5 cm or more were inventoried. Woody plant regeneration was investigated. With ordination methods based on tree species composition in the plots forest types could be distinguished. These types are not only distinct in species composition, but also in diversity, structural features like tree basal area and radial growth rates. Structure, species composition and regeneration dynamics are closely related to topography. Highest species diversity was found on lower slopes and in ravines, together with highest basal area and highest growth rates. Nutrient supply seems to be one controlling factor for tree diversity and growth. Specific site conditions influence growth and mortality of the woody regeneration.

P2079. Tall herb spruce-fir forests as a refuge for boreal forest plant diversity

M. V. Bobrovsky[1], L. G. Khanina[2], O. V. Smirnova[3];
[1]Institute of PhysicoChemical and Biological Problems in Soil Science of RAS, Pushchino Moscow region, Russian Federation, [2]Institute of Mathematical Problems in Biology of RAS, Pushchino Moscow region, Russian Federation, [3]Center of Problems of Ecology and Productivity of Forests of RAS, Moscow, Russian Federation.

We studied vegetation and soil in old-growth spruce-fir forests in North-East of European Russia (average age of spruce about 150 yrs, max. age - 380 yrs). According to ground vegetation composition we revealed 7 different forest types, and for each of them we estimated plant and soil diversity. The highest plant diversity (more than 40 vascular plants per 100 m^2, and 261 species from total 280 that we registered) correlated with the richest soil and was observed in tall herb spruce-fir communities (TH). The last were found in river valleys as well as at watersheds. Indicator species calculated by the IndVal method were: *Filipendula ulmaria, Cacalia hastata, Urtica dioica* etc. and *Aconitum septentrionale, Geranium albiflorum, Cirsium heterophyllum* etc. respectively. Then we noticed: tree fire scorches were absent in TH, and carbons in soil were met very rarely and deeply, while in other forests fire traces were met everywhere. We concluded: i) the appearance of tall herbs in spruce-fir forests is possible only under long-term fire absence**;** ii) TH are boreal forest refugium where the most of boreal species are stored; iii) TH are the most close to climax boreal forests.

P2080. Variation of Composition, Diversity and Structure of Vegetation along an altitudinal gradient in a Tropical Mountain Forest (SFF Guanentá - Alto del Río Fonce, Colombia)

D. Del Pino, M. Diazgranados, J. Ríos;
Herbarium Pontificia Universidad Javeriana, Bogotá, Colombia.

There are two main hypotheses about how change the composition of vegetation in altitudinal gradients: the monotonic and the hump models. We studied the vegetation of a tropical mountain forest at the Guanentá - Alto del Río Fonce natural park, on a gradient between 2000 and 3000 m of altitude. We established 5 stations for sampling, separated one another 250 m of altitude. Each station had 4 transects (50x5m), in which we sampled woody plants with dbh Ó2.5 cm. We found 250 species. The richest families were Melastomataceae (21), Rubiaceae (19) and Araliaceae (10). Richness and diversity show significant differences between stations (Ŭ=0.05, p=0.014 and 0.025) and they decrease with altitude. Regarding structure, we got significant differences in the total height and competition factor (Ŭ=0.05, p=0.004 and 0.0025), but they did not follow any predictable pattern. Density, evenness, mixture coefficient and basal area did not vary significantly. The higher values of IVI increase conspicuously with altitude. We conclude that composition and diversity follow monotonic model. In contrast, we think changes in structure do not respond to altitude but to disturbances.

P2081. The fragmented Brazilian *Mata Atlântica* and Edge Effects: the case of *Reserva Biológica União* (Rio de Janeiro, Brazil)

P. Pena Rodrigues[1,2], M. T. Nascimento[2], J. A. Braga[1], M. A. Iguatemy[1], R. C. R. Abreu[1];
[1]Jardim Botânico do Rio de Janeiro, Rio de Janeiro, Brazil,
[2]Universidade Estadual do Norte Fluminense, Campos dos Goytacazes, Brazil.

The *Mata Atlântica* is severely threatened by habitat loss and fragmentation and remnants are still subjects to edge effects. Functional and structural alterations can degrade the fragments and leading this biome, still largely unknown, to extinction. This long-term multidisciplinary study initially aimed to investigate arboreal structure, floristic and local edge effects on trees and seedlings communities at *Reserva Biológica União*. Permanent plots nearly two deforested corridors, *Rede Elétrica* and *Gasoduto* and preserved *Interiors* were used since 1999. Trees communities were very rich (208 sp/ha) and diverse (H'=4,9 *nits*). Local structural patterns were altered by edge effects. Edges heterogeneity was observed in practically all analyzed parameters. Typically pioneers and the alien jack-fruit were edges exclusives. Seedlings showed low density and high mortality mainly on edges. The heterogeneity observed suggests that, if cease the anthropogenic impacts, as the edge effects observed, ecosystem can recovery natural patterns and process.

P2082. Edge Effects on *Mata Atlântica* seedlings

M. A. Iguatemy[1], **P. Pena Rodrigues**[1,2], M. T. Nascimento[2];
[1]Jardim Botânico do Rio de Janeiro, Rio de Janeiro, Brazil,
[2]Universidade Estadual do Norte Fluminense, Campos dos Goytacazes, Brazil.

Among the impacts that *Mata Atlântica* biome remnants are subject we highlight the processes generated by edge effects that potentially may lead to a complete degradation. This study includes a long-term perspective that aimed to investigate aspects of edge effects on seedlings communities' dynamics at *Reserva Biológica União* (Rio de Janeiro, Brazil), one of the newest Brazilian protected areas. Inside a multidisciplinary project permanent plot near two deforested corridors, *Rede Elétrica* and *Gasoduto* and preserved *Interiors* were used since 2000 to 2004 year. Comparisons were made and we found that smaller individuals were more susceptible to edge effects. Size structures and densities vary among the years, but clearly edges always were more heterogeneous (based on coefficients of variation) than interiors. Patterns observed indicate that edge effects are altered seedlings communities' properties and artificial limits maintenance may degrade the forest remnant. Otherwise buffer zones probably may avoid direct edge effects on seedlings.

P2083. Modelling of ground vegetation dynamics in forest ecosystems

L. G. Khanina[1], M. V. Bobrovsky[2], A. S. Komarov[2], A. V. Mikhajlov[2];
[1]Institute of Mathematical Problems in Biology of RAS, Pushchino

Moscow region, Russian Federation, [2]Institute of PhysicoChemical and Biological Problems in Soil Science of RAS, Pushchino Moscow region, Russian Federation.

The method of predicting forest ground vegetation dynamics on a base of standard forest inventory data is proposed. We use the functional plant species groups, which have been described earlier. We found a distribution of the functional groups accordingly to tree dominant, soil fertility and moisture for Central Russian forests. The table allows for prediction of the dominant group in ground vegetation using forest inventory data. We applied model of forest growth EFIMOD to simulate dynamics of 'trees-soil' system at the stand level and proposed rules for predicting the group modifications at the simulated changes of tree species composition, dead wood biomass, soil organic matter and nitrogen dynamics. We estimated level of plant species richness for the forest type on the base of combining of dominant group in ground vegetation with tree dominant using database FORUS, which contains 9000 releves from European Russia. The method was applied for a forest area under different forest management strategies.

P2084. Tree invasions into Seychelles tropical forests: ecophysiology of native vs. invasive species.

E. Schumacher, P. J. Edwards, M. Tobler, C. Kueffer, H. Dietz;
Geobotanical Institute, Zuerich, Switzerland.

For oceanic islands it is hypothesized that invasive plants possess new functional attributes that were not previously present in the native flora. The forests on the Seychelles granitic islands harbor one of the oldest and most isolated floras of the world that are ideal for comparing functional traits of native vs. introduced and invasive trees.
Growth characteristics of juveniles were studied in five native and five invasive woody plant species in field and common garden experiments. Light and nutrient availability were varied as main factors. In a water stress experiment seedlings were grown under different light and water availability.
Overall, the invasives showed higher growth rates and higher phenotypic plasticity than the natives by better exploiting high resource levels (light, nutrient). However, the two groups did not differ in their response to water stress. Generally, among-species variation in the responses to different resource levels and water stress were large.
In Seychelles, natural gap dynamics may provide sufficient opportunity for plastic invaders to spread because they survive in shade and rapidly exploit high resource levels in gaps.

P2085. Tree Diversity Patterns in Los Cedros de Pampa Hermosa, Chanchamayo,Junín, Perú.

M. La Torre-Cuadros;
Herbario Forestal MOL (UNALM), Lima 18, Peru.

Tree abundance and species richness (dbh^{3}10cm) was quantified in 1 hectare from the Cedros de Pampa Hermosa montane (CP) forest, one of the eight Pleistocenic refuges in the Eastern Andean rain forests. A total of 140 species, 72 genera and 36 families were recorded (~400 individuals), though species-area curves suggested that sample size underestimated local diversity. Lauraceae, Meliaceae and Moraceae were the dominant families, while tree species mostly contributing to total basal area were also of economical interest (Cedrela lilloi, Guarea sp. and Guarea guidonia). Indicator species showed that the study forest is little fragmented and locates in an ecotonal area between tropical rain and premontane forest. Tree community structure shown by multivariate ordination of 7 montane forest types in the Chanchamayo area (485 taxa), revealed the uniqueness of the CP forest. >50% of the taxa pool could not be keyed out to species level, so the effect of including/excluding morphospecies on community structure analysis was discussed. The features of the CP forest highlights the global importance of this site in conservation strategies focusing on montane forests.

P2086. Diversity and composition of dead wood inhabiting fungal and bryophyte assemblages in semi-natural beech forests in Europe

P. Ódor[1], J. Heilmann-Clausen[2], M. Christensen[2], E. Aude[3], K. W. van Dort[4], A. Piltaver[5], I. Siller[6], M. T. Veerkamp[4], R. Walleyn[7];
[1]Department of Plant Taxonomy and Ecology, Loránd Eötvös University, Budapest, Hungary, [2]Royal Veterinary and Agricultural University, Frederiksberg C, Denmark, [3]National Environmental Research Institute, Ronde, Denmark, [4]ALTERRA, Wageningen, The Netherlands, [5]Institute for the Systematics of Higher Fungi, Ljubljana, Slovenia, [6]Department of Botany, Faculty of Veterinary Science, Szent István University, Budapest, Hungary, [7]Institute for Forestry and Game Management, Geraardsbergen, Belgium.

Species composition and diversity of fungi and bryophyte assemblages occurring on dead beech trees were analysed in five European countries.
In the composition of fungi the effect of decay stage exceeded the effect of geographical difference, whereas for bryophytes it was the opposite. In the case of bryophytes in Slovenia hepatics, in Hungary and Denmark pleurocarpic mosses, and in The Netherlands and Belgium acrocarpic mosses were the most important.
The species richness of both groups differed among countries but their diversity patterns deviated. Slovenian sites were a biodiversity hotspot of bryophyte diversity (high species richness, presence of threatened species), Hungarian sites had and intermediate position while the Atlantic region had deteriorate assemblages. For fungi species richness was very high in Denmark, but the Hungarian and Slovenian sites were richer in threatened species. For both organism groups the most important factor in tree level species richness was the size of trees. For the diversity of both organism groups forest history, dead wood availability and continuity were more important than climatic conditions.

P2087. Dominant woody species near human disturbed landscapes on Mt. Makiling, Philippines

I. E. Buot Jr[1], K. Osumi[2], E. Abraham[1], A. Luna[1];
[1]University of the Philippines Los Baños, College, Laguna, Philippines,
[2]Forestry and Forest Products Research Institute, Kyoto, Japan.

Forty plots were set up near disturbed landscapes on Mt. Makiling, Philippines to know the woody species composition. A total of 92 species in 76 genera and 42 families were recorded. The agricultural farm and the residential had the lowest number of woody species (17-19). The forest edge had 25 species. The buffer zone and undisturbed forest had the highest number (45). Cluster analysis showed two distinct groups, the vulnerable and the more stable landscapes. At a lower dissimilarity level, the five land uses are distinct.
Basal area values indicate *Brassaia actinophylla , Cocos nucifera, Ficus spp., Gmelina arborea, Spathodea campanulata* and *Sweitenia macrophylla*, as dominant in vulnerable landscapes. *Alangium longiflorum*, *Chisocheton cumingianus, Litsea garciae, Ludekia bernardoi* and *Pisonia umbellifera* dominate the more stable landscapes while *Arenga pinnata, Celtis luzonica and Diplodiscus paniculatus* are the most dominant in both the vulnerable and the more stable landscapes.

P2088. Study on structure and plant species diversity in the box tree (Buxus hyrcana pojark) sites, eastern Guilan, Iran

H. Pourbabaei[1], M. Fakhari Rad[1], A. Meraji[2];
[1]Faculty of Natural Resources, Someasara, Islamic Republic of Iran,
[2]Bioenvironmental Research institute, Jahade Daneshgahi, Guilan, Rasht, Islamic Republic of Iran.

The aim of this study was to characterize structure and plant diversity in the box tree sites, Anjilbon and Radarposhteh, eastern Guilan. The tree, tree regeneration and herbaceous species were sampled by using random-systematic method.To study structure, number per hectare and height curves, and mean of diameter, number, and basal area per hectare of box tree were obtained. Plant diversity in three layers was calculated by using diversity indices. Results revealed that mean of number per hectare of box tree in Anjilbon was higher than Radarposhteh, while mean of diameter, height and basal area per hectare in Anjilbon were lower than Radarposhteh site. Tree diversity and evenness mean in Anjilbon were higher than Radarposhteh, whereas tree richness in Radarposhteh was higher than Anjilbon site. Also, mean of diversity, evenness and richness of tree regeneration in Anjilbon were higher than Radarposhteh site. The mean of diversity and richness of herbaceous layer in Anjilbon were lower than Radarposhteh, whereas evenness mean in Anjilbon was higher than Radarposhteh.

P2089. Species Diversity of Undergrowth Plants in Phu Poe Community Forest, Kalasin Province, Thailand.

S. Homchuen, C. Paweena Pimpao;
Khon Kaen University, Khon Kaen, Thailand.

Abstract

Phu Poe community forest in Tumbon Naboan, Ampur Kammuang, Kalasin Province, Thailand, consists of compound dry dipterocarp forest with mixed deciduous forest. The main objective of this study is to compile a checklist of undergrowth plants and explore their ethnobotanical information. The belt transect method, 10 meters wide with 1,200 meters long from ground level to the top of the mountain, was applied for plant collection. There were all together 16 belt transects with an interval of about 250 meters each. The plant specimens were collected from July to October 2003. General morphology and habitat of the plant collected with their uses (if any) were documented. A total of 101 species (72 genera in 49 families) were enumerated with one species each of non - seeded plant and the gymnosperm, 20 species (11 genera in 7 families) of the monocotyledonae and 79 species (59 genera in 40 families) of the dicotyledonae. Family Zingiberaceae were the greatest in number (10 species) of all the specimens collected.

P2090. Floristic similarity among fir forests on the Trans-Mexican volcanic belt, Central Mexico.

A. Sanchez-González[1], L. Lopez-Mata[2], D. Granados-Sanchez[3];
[1]Universidad Autónoma del Estado de Hidalgo, Pachuca, Mexico, [2]Colegio de Postgraduados, Montecillo, Mexico, [3]Universidad Autonoma Chapingo, Texcoco, Mexico.

We studied the structure and floristic composition of a fir forest on the northern Sierra Nevada, Mexico based on sampling of 12 1000-m^2 plots for trees, 12 500-m^2 plots for shrubs, and 36 54-m^2 plots for herbaceous plants. The species structurally important were defined based on their relative importance value. In addition, we evaluated floristic similarity of this and other 12 fir forest sites located on the Trans-Mexican volcanic belt (TMVB). Floristic similarity was evaluated using classification and ordination techniques. The flora of these fir forests contains 76 families, 222 genera, and 510 species. A small percentage of the most common families contains a very high proportion of the genera and species. The differences in floristic composition among all sites are related with the geographical distance and elevation. A low proportion of species is common for all the fir forests studied which are important in defining forest structure at local and regional scales.

P2091. Laws of plant continuity

T. Zhitlukhina;
Central Forest State Nature Biosphere Reserve, Tver Region, Nelidovo District, Russian Federation.

Laws of plant continuity are formulated so:

1. Phytocenotic continuity is unique for every landscape, and continuity transitions are determined by species area covering.
2. The plant continuity in the landscape is determined by the climatic background.
3. Environmental-phytocenotic species ranges are changed according to certain standard, that is if several landscapes are ordinated according to background bioclimatic conditions improvement gradient, then environmental-phytocenotic species ranges and their phytocenotic optima will be displaced according to this gradient inside landscapes in the area of less favourable conditions.

These conclusions were made according to the examples of plantings in 4 landscapes. Three landscapes were investigated in the northern Transbaikalie, one landscape - in the Western Siberia. Types of communities for every landscape were ordinated into monocentric schemes according to: thermal factor, lythomorphic and hydromorphic. Then along the landscape gradient changes in environmental-phytocenotic species ranges were traced. 29 species of life forms and general for 3 or 4 landscapes were analyzed.

P2092. Species composition and stand structure of the beech forest in Taiwan

T. Y. Chen[1], C. F. Hsieh[2], J. C. Wang[3];
[1]Department of Natural Resource, National I-lan University, I-lan, Taiwan Republic of China, [2]Institute of Ecology and Evolutionary Biology,National Taiwan University, Taipei, Taiwan Republic of China, [3]Department of Life Science, National Taiwan Normal University, Taipei, Taiwan Republic of China.

Fagus hayatae Palib. *ex* Hayata is endemic to Taiwan. Although once more widespread during the Pleistocene, this species is now only limited to a few isolated fragments on ridgetops (1,300-2,000 m asl.) in northern Taiwan. The structure and species composition of the beech forest were studied on five isolated mountains. The beech usually forms pure stands on ridgetops and is mingled with broad-leaved forest at lower slopes and warm-temperate montane coniferous forest at the upper elevation limit. Comparison of TWINSPAN groupings with the DCA ordination showed a definitive separation of communities along elevation and topographic gradients. The forest structure was characterized by a moderate density with an average basal area of 59 m^2/ha. The beech contributed more than 70% of the total basal area. However, forest understory species varied considerably in their distribution and abundance among sites. Size-class distribution indicated a unimodal pattern reflecting that a much more drastic disturbance is needed for the recruitment of the beech forest.

P2093. Biologic forest ecosystem diversity and their impact in a semi arid land , analysis and followed by remote sensing "steppe in Algeria"

A. Z. Zegrar;
National Center of Spaces Technics CNTS, Arzew, Algeria.

Steppe presents a diversity floristique and faunique, and seen the unfavourable climatic conditions in the zone, one notes a deterioration of the physical environment notably the natural forest regression.

The use of images of the stage 195-36 of LANDSAT 5 in date of May 18, 1989. and of ALSAT1 2003 , at several dates of view holds has us permits to follow this regressive evolution and to make a report at the instant t of senalba forests and sahari.

The gait adopted in this project, at summer of treaty pictures satellites of LANDSAT and ALSAT1 of the different dates, that one permitted to make a thematic analysis of physical medium in steppe of the semi-arid floor permitting to determine the physical parameters of the middle (forest populations, vegetation steppe and soil) taking account of the human activity (reclamation, cut of wood and fire). This analysis has been followed of a specific treatment of data pictures, while using indications of vegetation and classifications supervised.

result is a cartographic support identifying the various components of physical medium and phenomenon of the deforestation.

P2094. Mycosociological and mycorrhizal estatus in the temperate rainforest of southern Chile under a low depositation climate

R. Godoy[1], E. Valenzuela[2], M. Alvarez[1], M. Alberdi[1];
[1]Instituto de Botánica, Universidad Austral de Chile, Valdivia, Chile, [2]Instituto de Microbiología, Universidad Austral de Chile, Valdivia, Chile.

The temperate rainforest of southern Chile represents an important reserve of extraordinary genetic, phytogeographic and ecological significance for the world. In addition, the chemistry of precipitations in southern Chile reflects one the closest approximations of pre-industrial atmospheric conditions.

Biotic components contribute to regulate the internal circulation and output of nutrients and these natural conditions give stability to the forest ecosystems.

We have done a mycosociological and taxonomical comparative study of the *Agaricales* that fructify in *Nothofagus* forests in the Central-Southern Chile and

the results show that the number of mycorrhyzal fungi species varies between 40-50% and the saprophytic between 48 to 69%. A simultaneous analysis of the mycorrhizal status of the vascular flora of this forests was carried out, finding high proportions of plant species with arbuscular mycorrhizal symbiosis. Ectomycorrhizal plants associated exclusively with *Nothofagus* tree species.

Fondecyt Grants: 1040913 and 1050313

P2095. Structure of the forests in the Aragua River Basin, Municipio Piar, Monagas state, Venezuela.

J. J. Calzadilla, A. C. Lárez;
Universidad de Oriente, Maturín, Venezuela.

The area is located at the eastern section of The Coastal Cordillera Piedmont (10º 00’ N, 63º 20’ W, 320 - 580 m elevation).

Four parcels (250 x 20 m) were sampled, 10 cm DBH and smaller tree species were considered apart. Importance value as defined by Finol (1970) was calculated. Three main natural vegetation categories were found: 1. Riparian forest: 63 tree spp., 350 individuals/ ha, distributed in two layers, DBH average 23.97 cm, up to 20 m height, dominated by *Brownea capitella*, *Brossimum alicastrum*, *Siphoneugena dussii* and *Mouriri rhizophorifolia*; 2. Deciduous basimontane forest: 39 spp., 316 trees/ ha, which form two strata, DBH average 17.8 cm, up to 15 m height, dominated by *Bourreria cumanensis*, *Acacia paniculata*, *Pithecellobium unguis-cati* and *Cordia alba*; 3. Transition savanna-deciduous forest: 34 spp., 292 trees /ha, DBH average 13 cm, up to 12 m height, dominated by *Copaifera officinalis*, *Guapira cuspidata*, *Randia armata* and *Erythroxylum impressum*. 179 species and 57 families were recorded. Mimosaceae, Fabaceae, Caesalpiniaceae, Capparidaceae, Euphorbiaceae, Bignoniacae, Flacourtiaceae, Myrtaceae and Rutaceae were the most diverse families.

P2096. Evaluation of South-Taiga Forest Biodiversity in north-east of Kostroma Region (European Russia)

T. Y. Braslavskaya, E. V. Tikhonova;
Centre for Problems of Forest Ecology and Productivity, Moscow, Russian Federation.

Forests of 90-160 yrs in south-taiga zone were inspected to reveal level of their biodiversity and its regulating factors. Zonal fir-spruce-dominated forests with lime (Rhodobryo rosei-Piceetum abietis) have been remained primarily in small-river valleys, whereas on watersheds there are birch-pine forests with spruce (Dicrano-Pinetum), but almost everywhere without fir and lime. Community ordination by NMS reveals not very close relations between species composition and catena position. In most of inspected catenas Ŭ-diversity and ɓ-diversity of the forests are varying by contrast ways: species richness of communities and participation of ecological groups decrease along catenas upstairs, whereas ɓ-diversity (Whittaker index) increases. These trends can be explained as result of anthropogenic impact, especially periodical burning, on zonal watershed forests during 19-20th centuries. Interactions between burning and hydrogeological factors in catenas are discussed.

P2097. Plant species richness and diversity along an altitudinal gradient in the Sierra Nevada, Mexico.

L. Lopez-Mata, A. Sanchez-Gonzalez;
Colegio de Postgraduados, Montecillo, Mexico.

We studied plant species richness, and diversity associated with climatic and soil variables along a 1300 m elevation gradient on the northern Sierra Nevada in Mexico. Questions: does species richness and diversity vary significantly by elevation along the gradient? Are variations along the gradient monotonic, unimodal or otherwise? What are the main variables associated with these variations? Two 1000 m^2 plots for tree sampling, two 250 m^2 plots for shrubs and six 9 m^2 plots for herbaceous plants were placed at 21 sampling sites. The relationship between species richness and diversity and environmental variables was conducted by linear correlation and regression trees analysis (RTA). Species richness and diversity showed a unimodal pattern with high values in the lower half of the elevation gradient. Beta diversity increased steadily along the gradient, being lower between contiguous sites at intermediate elevations and nearly 100% between sites at the extremes of the gradient. The RTA suggests that differences in richness are mainly influenced by elevation and soil A_2 permanent wilting point, organic matter and horizon field capacity, and A_1 horizon Mg^{2+}.

P2098. Floristic composition and regeneration of *Chamaecyparis*-dominated forests in northern Taiwan.

C. C. Liao[1], J. C. Wang[1], S. C. Wu[2], T. Y. Chen[3], C. F. Hsieh[2];
[1]Department of Life Science, National Taiwan Normal University, Taipei, Taiwan Republic of China, [2]Institute of Ecology and Evolutionary Biology, National Taiwan University, Taipei, Taiwan Republic of China, [3]Department of Natural Resource, National Ilan University, Ilan, Taiwan Republic of China.

The mid-elevation temperate forests of Taiwan support very diverse flora, and are especially rich in relict conifers. *Chamaecyparis formosensis* and *C. obtusa* var. *formosana* are the dominant species forming extensive forests. Floristic composition and regeneration patterns of these forests were studied in northern Taiwan. The results of DCA showed that significant altitudinal and topographical gradients were present. *C. formosensis* often grows on damp ravine slopes and is intermixed with broad-leaved species at lower elevation. On the other hand, *C. obtusa* var. *formosana* usually forms pure stands interspersed with *Tsuga chinensis* var. *formosana* on higher slopes or ridges. Although natural disturbances play important roles in the regeneration of these two species, significant differences exist between them in regard to regeneration pattern. For both species abundant regeneration is dependent on large-scale disturbances such as erosions or landslides. However, coarse woody debris resulting from periodic windthrow provides additional habitat for the recruitment of *C. obtusa* var. *formosana*.

P2099. Floristic composition and plant communities at the Region of Los Loxicha, Sierra Madre del Sur, Oaxaca.

B. Rendón[1], C. Aragón[1], G. Contreras[1], M. Hernández[1], A. Luna-José[2], L. Montalvo[2], G. Hernández[1], M. Pérez[1], A. Zavala[1];
[1]Universidad Autónoma Metropolitana, México, Mexico, [2]Colegio de Postgraduados México, Texcoco, Mexico.

Region of Los Loxicha, located at the Sierra Madre del Sur, Oaxaca, is characterized by high levels of ecological integration and plant cover. It exhibits high contrasts in its plant fisonomy, due to quick changes in altitude in a relative small area. Floristic composition of an altitudinal gradient was analyzed through systematic plant records, as well as by systematic samplings of four plant communities. We obtained 541 plant species belonging to 323 genus y 110 families. The most important family through the gradient was Leguminosae. Floristic composition is represented by tropical elements like *Oreopanax*, *Miconia*, *Piper*, *Ipomoea*, and *Begonia*, as well as boreal elements like C*ornus*, *Pinus*, *Prunus, and Quercus.*

Changes in species composition and abundance were detected through the altitudinal range of 1600 m. Some genus are found only in Subperennious forest (*Miconia*), or in Deciduous forest (*Swetenia*), while others, like *Quercus* or *Pinus* are found through the gradient, but with different densities. Plant species replacement indicates high levels of diversity and the effect of geological, climate and soil factors that generated complex microenvironments.

P2100. Climber abundance and diversity in African rain forests of the Albertine rift

G. Eilu, J. M. Kasenene;
Makerere University, Kampala, Uganda.

ABSTRACT. Climber abundance and diversity were assessed in twelve 1-ha (20 x 500-m) plots in four tropical high forests of the Albertine rift, western Uganda. A total of 5484 climbers (ramets) of diameter >1 cm representing 49 families, 111 genera, and 181 species was recorded. Average climber density was 457 individuals ha^{-1}. Climber densities were higher than recorded in Asian tropical forests but lower than recorded in forests of the Amazon. There were 24 climber families and 41 genera ha^{-1}. The most abundant families in number of stems were Celastraceae (23.5% of 5484), Apocynaceae (12.1%), Rubiaceae (8.2%), Piperaceae (6.4%) and Menispermaceae (5.7%). There were 51 species ha^{-1} and the most abundant species was *Piper guineense* (Piperaceae) with 6.4% of the individuals and density of 29 ha^{-1}. Shannon's Diversity (H') ranged from 3.042 to 3.592. Climber species richness and diversity increased only slightly from forests in the south to those in the north. Based on quantitative plot data on climbers, the floras of Bwindi and Kasyoha-Kitomi are the most similar, followed by the floras of Kibale and Budongo.

P2101. Plant functional types, dispersion mode, pollination syndrome and spatial assemblage in an Amazon Forest Community, Brazil

F. M. Pina-Rodrigues[1,2], A. Louayza[1], B. Loiselle[1];
[1]University of Missouri Saint Louis, Dept of Biology, St. Louis, MO, United States, [2]Universidade Federal Rural do Rio de Janeiro; MCAF, Seropedica, Rio de Janeiro, Brazil.

Functional groups could be based on plant reproductive strategies and assembly rules. Here we intend to test the hypothesis that species with similar reproductive and functional traits also have similar patterns of spatial distribution in an Amazon Forest community. A plot of 100 ha was completely surveyed (DBH> 30 cm) and trees plotted in an x and y system. ArcInfo 9.0 tools were used to calculate paired distances between individuals. A MANOVA was carried out to define a set of spatial variables:

nearest-maximum neighbor distance, mean, standard deviation. Cluster Analyses were performed to define Distance and Plant Functional Groups; MRPP, PCA and ordination were applied to test relationships among variables, functional types, reproductive mode and distance patterns. We found a significant interaction between seed size and distance between individuals (F= 3.9; p<0.05). However, animal and wind dispersed species presented similar patterns of assemblage. Although reproductive mode and spatial patterns generally were found to be distinct among functional types, other factors also contributed to the spatial patterns of community assemblage.

P2102. Validation of ecological-coenotical plant species groups in European Russian forests

V. E. Smirnov[1], L. G. Khanina[1], M. V. Bobrovsky[2];
[1]Institute of Mathematical Problems of Biology, Pushchino, Russian Federation, [2]Institute of Physicochemical and Biological Problems of Soil Science, Pushchino, Russian Federation.

Ecological-coenotical plant species groups (ECG) are widely used in Russia to assess vegetation diversity and succession dynamics of forest ecosystems at different scales. We see ECG as a species assemblage formed under certain environmental conditions in a certain community type. We have proposed a joint expert-statistical approach to validate ECG systems obtained expertly. Ecological and coenotical species features for quantitative analysis were presented as variables of two types: (1) Ellenberg indicator values and (2) species scores derived from ordination of 2000 vegetation relevès. Discriminant analysis (DA) was used to identify misclassified species in a system of seven ECG. DA was run repeatedly on the whole set of variables and on various subsets of them with monitoring of results by experts on every step. The procedure continued until a position of every species in the ECG system fits both DA results and expert judgment. The approach allowed to greatly improve the ECG system, to put about 1000 vascular species into seven groups and to outline core and intermediate species.

P2103. Leaf anatomy of representative trees from the cerrado of São Paulo State, Brazil

A. C. Bieras, M. Sajo;
Instituto de Biociências - UNESP, Rio Claro/SP, Brazil.

The Brazilian cerrado vegetation (savanna) is one of the most unique biomes that covers around 23% of the country and comprises a very diverse flora with more than 6000 species. However, despite its importance, modern agriculture has been developed in the cerrado areas and cattle are raised in enormous planted pastures, causing massive destruction. In order to identify any common and particular anatomical features of the cerrado´s plants we studied the leaves of twenty of the more representative species of trees. In most species the leaves are hypostomatic, hairy and covered by a thick cuticle. The thickened walls of the epidermal cells are, in general, flattened at the outer periclinal side and convex at the inner periclinal side. The palisade parenchyma of the dorsoventral mesophyll occupies 50% or more of the lamina thickness and sclerified cells of different shapes are common in all representatives. All leaves have a dense and ramified vascular system. These features can be interpreted as adaptations to the environmental conditions in the cerrado areas, where high light intensities, low soil fertility, and a high frequency of fire predominate.

P2104. Variation in leaf morphology of *Quercus branti* trees in different altitudes

R. Zolfaghari[1], **M. Akbarinia**[1], V. Mozaffarian[2];
[1]1, Noor, Islamic Republic of Iran, [2]2, Tehran, Islamic Republic of Iran.

Quercus branti is the most important species in the Zagros forests of Iran. The restoration this species is hard, so identification this species help us to restore plans with a higher success percentage.
Leaves of fifty trees of *Q. branti* were sampled for morphological studies, from different altitudes (700-2700m) in a province of Iran. Every 500m height was considered as an altitude level, so 5 altitude levels were considered. Then a comparison of means was made between these levels by ANOVA analysis.
Results showed that there were a gradual decreasing of total leaf length, length of lamina, maximal width of lamina, height of maximal width, number of lobe and intercalary veins on right and left, dry weight, leaf area, volume, length of lamina from base to widest part and HMW/MWL from low altitudes to high altitudes. But there were most lobe width, distance between midvein and sinus base and distance between midvein and lobe apex in 700-1200 and 2200-2700m altitude.
This study shows that it seems 1200-1700m altitude level is best habitation for *Q. branti*.

P2105. Patterns of plant attributes in the Pyrenean Alpine vegetation

E. Carrillo, E. Illa, J. M. Ninot;
Centre de Recerca de Biodiversitat Vegetal, Barcelona, Spain.

We seek the degree of adaptation of plant communities to environment through comparative analysis of functional attributes. From all the available relevés (about 800), we have characterized each community (47 associations or subassociations) in terms of 11 attributes. A fuzzy multivariate classification based on these attributes gave 7 groups and 5 sub-groups of plant communities, most of them coinciding with high syntaxa, and corresponding to main Alpine habitats. With respect to the whole Alpine flora, the most differentiated groups include species-poor communities, frequently bearing high percentages of particular types (like chamaephytes, succulents, lichens or endozoochory), and are related to a variety of habitats, but in all cases associated to stress (scarcity of soil, unfertile or water-logged substrata). Groups less differentiated from the global spectra include in the main richer communities, with more shared dominances, and correspond to more balanced environments.

P2106. Distribution and environmental correlates of plant functional types in Germany

I. Kühn[1,2], S. Bierman[3], W. Durka[1], S. Klotz[1,2];
[1]UFZ - Centre for Environmental Research Leipzig-Halle, Halle, Germany, [2]Virtual Institute Macroecology, Halle, Germany, [3]BIOSS - Biomethematics and Statistics Scotland, Edinburgh, United Kingdom.

Ecological traits could act as surrogates for functional characteristics of plants. There are many theories linking plant functional types to environmental characteristics. Understanding such relationships will add on the knowledge of ecosystem functioning. Rarely, however, were such plant functional types brought into space to analyse distribution patterns of such types in relation to environment.
We analyse the relationship between functional diversity or relative abundance of plant traits such as pollination syndromes and ploidy levels with environmental covariates, recognising their spatial structure. Data sources are the database BiolFlor on biological and ecological traits of the flora of Germany, the distribution database of vascular plants in Germany (FLORKART) and selected environmental variables considering geology, land use and climate. Thus we are able to provide an area-wide distribution map of functional types (or functional diversity) and their relevant environments.

P2107. Many singers, one song: association between plant strategies and ecological indicators

J. Franzaring[1], R. Hunt[2], A. Fangmeier[1];
[1]University of Hohenheim, Stuttgart, Germany, [2]University of Exeter, Exeter, United Kingdom.

British comparative plant ecology has used experimental approaches to measure innate traits under standardised conditions and to derive plant ‘strategies’ or functional types (n > 1010). In contrast, a Central-European approach has emphasised the unity of plants with their natural habitats by means of indicator values (German: Zeigerwerte) which describe their ecological behaviour in the field (n > 2700). Here, we identify levels of compatibility/congruence between these two approaches using large datasets that include some previously unexamined traits. Despite there being a wide gap between the plant- and environment-based starting points, we discover that both lead to similar conclusions regarding evolutionary tradeoffs and ecological processes. In particular, the results add support to a theory of evolutionary specialization wherein plant life has to choose between those traits which confer rapid acquisition of resources and those which confer their long-term conservation.

P2108. The role of plant functional traits in determining the vegetation composition of abandoned farmlands on the Delatite peninsula, Victoria, Australia.

T. L. Meers[1], S. Kasel[1], T. L. Bell[1], N. J. Enright[2];
[1]School of Forest and Ecosystem Science, Creswick, Australia, [2]School

of Anthropology, Geography and Environmental Studies, Melbourne, Australia.

In the Northern Hemisphere species with short distance dispersal mechanisms are typically absent from abandoned farmland due to the time it takes these species to re-colonise from adjacent forests. In Australia little is known about the dispersal mechanisms and other traits of species affected by clearing for agriculture and subsequent abandonment. This study aimed to identify species' attributes associated with sensitivity to change in land use and the ability to re-colonise abandoned farmlands on the Delatite peninsula. Past agricultural land use was found to have significant effect on the present day vegetation composition when compared to adjacent native forests. The frequency of life forms and dispersal mechanisms in native species varied significantly according to past land use. These results show that species with limited dispersal ability have generally failed to re-colonise abandoned farmlands, consistent with results from the Northern Hemisphere.

P2109. Biological Characters and Application of 47 Species Climbing Plants

f. t. deng[1], j. l. lei[1], j. wang[2], z. f. yu[2], z. c. Wu[2], k. He[2], g. f. Li[2], z. q. Yang[2];
[1]yunnan kingyear ecological construction group, Kunming, China, [2]The Si-xiao Highway Constructional Command Deprtment of Yunnan, Kunming, China.

By observing the growth, blossom and fruit habits, phonological period of 47 species climbing plants, we have known the yearly net growth length, the fast growth stage, blossom and fruit characters, defoliation or evergreen habit, the climbing style of every species. All these characters are the important reference to apply rationally them to making the special environment green.

The results of application experiment showed that the species with evergreen and strong drought-hardiness characters, such as *Macfadyena unguis-cati* A., *Pueraria montana* Merr. and *Bauhinia corymbosa* Roxb. etc., are the very powerful materials that can be used to afforest the stone surface of transportation slope protection and barren hill. *Indigofera eneaphylla* L.Linn. is a good material covering the bare loess slope and the soil near the root of the tree. The rational distribution of *Pharbitis india* R.C.Fang, *Pyrostegia venusta* Miers and *Thunbergia laurifolia* Lindl with *Parthenocissus heterophylla* Merr and *Ficus pumila* L. can not only make the motorway interchange green but also beautify it.

P2110. Understorey tree-ferns: Filters or indirect faclitators for the establishment of canopy species in a New Zealand conifer-broadleaved forest.

A. Gaxiola, D. A. Coomes;
Department of Plant Sciences, Cambridge, United Kingdom.

In a New Zealand conifer-broad-leaved forest, we tested the competitive and facilitative effect of the tree-fern understorey of *Cyathea smithii* and *Dicksonia squarrosa* on the regeneration of canopy angiosperms and gymnosperms.

We surveyed epiphytic seedlings growing on fallen and standing ferns and correlated seedling height and abundance with light availability. Tree seedlings were found to be significantly more abundant on fallen tree-ferns than on standing tree-ferns. However, ones found on standing tree-ferns were significantly taller. Correlation between epiphytic regeneration and species establishment showed that more than 45% of the adult trees established on standing tree-ferns.

We quantified changes in seedling growth of 4 species of angiosperms and gymnosperms transplanted on the forest floor with and without the tree-fern layer .

Tree-fern layer removal lead to significant increases in RGR of the 4 species. In contrast, RGR of epiphytic seedlings was not affected by tree-fern removal.

Species regeneration is not only determined by competition between the forest layers, but also but also by indirect facilitation.

P2111. Litter deposition in a fragmented area in the Brazilian Atlantic Forest

F. R. Gondim, **M. G. Pereira**, F. M. Pina-Rodrigues;
Universidade Federal Rural do Rio de Janeiro, Seropedica, Brazil.

Plant litter plays an important role in tropical forest ecosystems and to the maintenance of diversity, including insects, soil micro-organisms and vegetation. We investigated how litter is distributed in four fragments of different size and degrees of isolation by agricultural activities. We selected fragments isolated (F_3= 3.2 ha; F_4= 62 ha) and connected (F_2 = 8 ha; F_1= 23 ha). Litter traps (16) were established at four distances from the edge. ANOVA, Tukey post-hoc test, correlation, PCA, ordination and cluster analysis were carried out to define the relationships among fragments. The average amount of litter supplied was 13.5 t ha^{-1} similar to other studies in Atlantic Forest. Leaves represented 60.4 %, branches (16.2%) and (6.5%). Neither distance from the edge nor isolation degree affected the litter deposition pattern along the period. Fragments` size was the most important variable separating biomass production among fragments.(***Blumen Project** supported by CNPq and BMBF-Germany Agreement- http://www.tt.fh-koeln.de/blumen*)

P2112. Frugivory and seed dispersal by birds in an altitudinal Atlantic Forest, Teresopolis-Brazil

A. C. Rudge, A. Piratelli, F. M. Pina-Rodrigues;
Universidade Federal Rural do Rio de Janeiro, Seropedica, Brazil.

Effective seed dispersal is critical to restoration of degraded areas and to successful recruitment in fragmented forests. We investigated seed dispersal by birds in and among four fragments of different sizes and degrees of isolation by agricultural activities Fragments isolated (F_3= 3.2 ha; F_4= 62 ha) and connected (F_2 = 8 ha; F_1= 23 ha) were studied by mist-netting in two sites per fragment. Bird captures were performed; seeds were collected from feces and germination was carried out in controlled chambers at 30^{o}C. Frugivores birds were more abundant (38.3%; n= 31), followed by omnivores and insectivores. Seeds of *Miconia* and *Lendra* sp. were the most frequent and were dispersed by *Chiroxiphia caudata* and *Thraupis sayaca* that promoted increasing of seed germination while *Hemitriccus diops* and *Turdus leucomelas* were not effective in breaking seed dormancy. (***Blumen Project** supported by CNPq and BMBF-Germany Agreement- http://www.tt.fh-koeln.de/blumen*)

P2113. Seed bank as bio-indicator of fragmentation in an altitudinal Atlantic Forest- Teresópolis, RJ- Brazil

E. S. Nogueira, F. M. Pina-Rodrigues;
Universidade Federal Rural do Rio de Janeiro, Seropedica, Brazil.

Although seed banks affect successional patterns in communities, few studies have investigated the demographic relationship between fragmentation and seeds in the soil. We examined the spatial and temporal variation of seed bank in four fragments surrounded by agricultural activities. We selected fragments isolated (F_3= 3.2 ha; F_4= 62 ha) and connected (F_2 = 8 ha; F_1= 23 ha) of different sizes (small < 10 ha; larger > 15 ha) in an altitudinal area of Atlantic forest in Teresopolis (RJ). Seed traps (16) were established at four distances from the edge. ANOVA and correlation were carried out to study relationships among fragments. Soil samples (10 cm depth) from eight plots (0.25 m^2) were collected at four distances from the edge. Seed germination from soil samples was performed in a nursery. The mean density was 102 seed m^{-2}. Fragment size and seed rain were correlated (r^2= - 0.96); larger fragments showed less seed germination than the small. Seed bank increased from edge to 30 m decreasing after this, except in the largest (F_4). Pioneer seeds were dominant; seed bank could be used as bio-indicator of fragment degradation in studied area.(*www.tt.fh-koeln.de/blumen*)

P2114. Seed rain as bio-indicator of forest fragmentation in an altitudinal area of Atlantic Forest, Teresópolis, Brazil

F. M. Pina-Rodrigues, **F. R. Gondim**, M. G. Pereira;
Universidade Federal Rural do Rio de Janeiro, Seropedica, Brazil.

Although forest fragmentation in Brazilian Atlantic Forest is a well-known problem, few studies have investigated the demographic patterns of seed rain as an environmental indicator of recovering or degradation. We studied the relationship between seed rain diversity in four fragments surrounded by agricultural activities. We selected fragments isolated (F3= 3.2 ha; F4= 62 ha) and connected (F2 = 8 ha; F1= 23 ha) of different sizes. Seed traps (16) were established at four distances from the edge. Correlation, PCA, ordination, species indicator and cluster analysis were applied to define the relationships among fragments. *Miconia* sp. and *Cecropia* sp (172.9 seeds/m^2), represented 24 and 29% of the total seed input and were concentrated on 35-65 m from the edge. The largest fragments showed more similarity (F_4 and F_1) and were grouped with F_2, and the small one (F_3) was completely isolated from the others. All fragments showed low diversity (H’ Ò 2.0) of seed rain, with high density of pioneer species. Bat dispersal dominance indicated their importance to seed rain. Isolation could be more related to seed rain diversity.(***Blumen Project** - www.tt.fh-koeln.de/blumen*)

P2115. Fruiting phenology in an understorey community in Manaus, Central Amazonia.

A. C. Webber, T. N. Moura;
Universidade Federal do Amazonas, Manaus, Brazil.

Fruiting patterns are directly related to tropical biotopes dynamics. The understorey, often neglected, is a species-rich layer and a source of food for the fauna. In this study, the fruiting patterns of an understorey community were characterized, within 5m from the ground, in a terra firme forest in Manaus, Brazil. The field observations were made along four transects covering one hectare, from August 2003 to December 2004. A total of 40 species from 18 families were observed, producing 85% of fleshy fruits (drupes and berries) and 15% of dry fruits (cariopse, nut and capsule). The most common fruit colours were green, black, brown and purple. Rubiaceae(10sp.) and Piperaceae(6sp.) were the richest families. All species produced fruits adapted to biotic dispersal, with 37(92,5%) species possibly endozoochorous. In relation to fruiting time, 46,2% of the species produced fruits for more than five months, 30,7% up to five and 23,1% up to four months. The understorey community showed a continuous fruiting period, with at least 8 species fruiting per month. Results reaffirm the complex and constant biotic interaction that exist in the understorey.

P2116. Re-colonization of experimental gaps by terricolous bryophytes in pine forests

T. Heinken[1], E. Zippel[2];
[1]Institute of Biochemistry and Biology, University of Potsdam,
Germany, [2]Institute of Biology, Free University of Berlin, Germany.

We studied re-colonization patterns of experimental gaps by four dominant bryophyte species over three years in north-eastern German pine forests. Vegetation and litter layer were removed on $1\ m^2$ plots within ± pure bryophyte colonies. All plots were re-colonized by the species which was dominant before gap creation. Three vegetative mechanisms interacted: (1) advance of surrounding shoots from the edge, (2) dispersal of detached shoots resulting in new colonies by continuing growth, and (3) regeneration from seemingly dead stem fragments in the humus layer. *Scleropodium purum* displayed the most rapid growth. Due to their larger vegetative diaspore bank, colonization of *Hypnum jutlandicum* and *Dicranum scoparium* was at least as fast than of *Pleurozium schreberi*, despite lower rates of advance from the edge. The different clonal colonization strategies account for the high competitive capacity and regeneration potential of the four bryophyte species despite the lack of generative reproduction. Experimental disturbance also resulted in a temporary increase of bryophyte diversity, because short-lived colonists appeared in the gaps.

P2117. *Pinus strobus* invasion spread in the Bohemian Switzerland Sandstones

V. Hadincová, Z. Münzbergová, J. Wild;
Institute of Botany, Academy of Sciences of the Czech Republic,
PrŢhonice, Czech Republic.

Pinus strobus is an invasive tree in the sandstone areas in the Central Europe. In the Bohemian Switzerland, we focused on distribution and demography parameters of *P. strobus* self-sowings in different habitats with respect to the distance of the diaspore sources. The data were confronted with a theoretical dispersal modelled on the basis of a seed terminal velocity and a known wind speed. We found that (i) *Pinus strobus* density sharply decreased up to 50 m from the seed trees and approached nearly zero at the distance of 100 m. It corresponds with the seed dispersal under the wind with the speed below 6 m/s, prevailing in the area, and with the short-range dispersal that effects most diaspores but is less relevant for driving the spatial spread. (ii) Only small fraction of the self-sowings was found further than 100 m suggesting there is only rare long-distance dispersal. Nevertheless, it may be the driving force of the whole invasion process. (iii) The significant differences in regeneration in the different stands and habitats along the sandstone microclimate gradients were found.

P2118. Application of cellular automata modeling for plants invasion model

N. V. Mikhaylova[1], N. E. Bogdanova[2];
[1]student, Pushchino, Moscow Region, Russian Federation, [2]scientist, Pushchino, Moscow Region, Russian Federation.

The models of occupation of new territories by invasive plant populations are formulated on the basis of the concept of discrete description of plant ontogenesis using cellular automata technology. The comparative rates of expansion by the autochorous and zoochorous type of dissemination have been analyzed. Species of herbaceous plants with different strategies: competitor (*Aegopodium podagraria* L.), reactive (*Stellaria holostea* L.) and stress-tolerant (*Asarum europaeum* L.) species were chosen. The model is based on the field experimental data collected in the “Bryanskii Les” State reserve in the centre of European Russia. The analysis of invasion rates on the bare territory by modeling population dynamics (number, age state spectrum) in dependence of a) combination of dispersal types; and b) heterogeneity of territory (different correspondence between empty and busy sites) was made.

P2119. Constructing biogeography: using simulation studies to investigate historical biogeography

S. A. Smith, R. C. Winkworth;
Yale University, New Haven, CT, United States.

Simulation studies may be useful for investigating historical biogeography, however such methods have not been explored widely. Here we describe a simulation method for examining the effects of various parameters on the realization of specific biogeographic patterns within a phylogenetic framework. Specifically, populations are evolved within a spatially explicit scenario, with the history of the lineage recorded as a phylogeny that can be compared to expected patterns. Simulations are modeled at the level of the individual, which also allows the effects of species abundance on speciation and competition to be considered. The approach is very flexible allowing many different scenarios to be addressed. For example, the spatial relationships between areas may change during the simulation so that the influence of specific events (e.g., continental movements or vicariance) on the resulting phylogeny to be investigated. We describe several hypothetical and a southern hemisphere example. These results suggest that simulation studies can be an appropriate tool for examining biogeographic patterns.

P2120. Genus Taraxacum Wigg. in Poland. An attempt of geographic and ecological analysis

J. K. Marciniuk, Z. Glowacki;
Department of Botany, Siedlce, Poland.

Up till know, 368 species of genus Taraxacum have been observed in Poland. Basing on the maps of dandelion distribution in the 10 km2 squares, and present ecological data, an attempt was made of classification of some species to geographic groups, determination of their site preferences, and specification of endangered species.
The classifictaion of Polish dandelions into geographic groups: endemic species - Taraxacum polonicum, T. pieninicum, T. glowackii (?), and T. podlachiacum (?); Central European species - T. subalpinum, T. paucilobum, T. subdolum, T. mendax, T. skalinskianum, T. turfosum, T. trilobifolium, T. subpolonicum, T. ancoriferum; Atlantic species - T. hollandicum, T. udum, T. lancidens; Subatlantic species - T. brachyglossum, T. disseminatum, T. gracilinum; continental species - T. bessarabicum; submediterranean species - T. erythrospermum.
Endangered species: Ex - Taraxacum madidum; E - T. balticum, T. boekmanii, T. bracteatum, T. lancidens, T. nordstedtii, T. piennicum; R - T. ethiops, T. blomgrenii, T. corynodes, T. fasciatum, T. hamatum, T. leptoglotte, T. maculatum,most of them belonging to he section Palustria.

P2121. *Eragrostis albensis* H. Scholz - a species spreading on anthropogenic sites in Poland

A. Michalewska, M. Nobis;
Instytute of Botany, Jagiellonian University, Krakow, Poland.

Eragrostis albensis H. Scholz was described as a species new to science in 1996. In the area of Poland, it was found mainly in the valleys of the Vistula and San Rivers and at first treated as *E. pilosa*. A lot of new stations of *E. albensis* were found in the southeastern part of Poland, in 2003-2004. The species occurs there in anthropogenic habitats e.g. railway-tracks, platforms, reloading areas near the railway stations, roadsides and gaps between flagstones. In many cases, *E. albensis* forms homogeneous patches with other plants which could be documented in phytosociological relevés. More than half of the relevés included *E. minor*. The results of the research have proved that we witness expansion of *E. albensis* in the anthropogenic habitats in Poland. This is the effect of biological-ecological properties of the species and anthropopressure. *E. albensis* will probably spread in Poland just like *E. minor*. Both species have the same ways of dispersal (boleochory and anemochory). The distribution of new stations of *E. albensis* in Poland, diagnostic characters, phytosociological documentation and hypotheses concerning its spread are presented.

P2122. Postglacial population expansion of *Dacrydium pectinatum* (Podocarpaceae) in Hainan, southern China, based on cpDNA *trn*L-F nocoding sequence data

Y. Su;
Sun Yat-sen University, Guangzhou, China.

CpDNA *trn*L-F noncoding sequences of individuals of a tropical coniferous species, *Dacrydium pectinatum*, collected from twelve natural populations located in Hainan, southern China, were determined. Thirty haplotypes were identified based on statistical parsimony algorithm. Populations are lack of genetic differentiation. Such a deduction was supported by observed F_{ST} values (= 0.00), high values for *Nm* (from 1.92 to 2.50),AMOVA (24.17% of molecular variance attributed to difference among populations, P >0.05) as well as the branching structure in NJ tree constructed from haplotypes. A 'star-like' pattern was exhibited in the network of *trn*L-F haplotypes established by statistical parsimony algorithm, and majority of the haplotypes coalesced near the tips in NJ tree. Gene genealogies of cpDNA haplotypes proposed a recent population expansion, which was further lent support by the results from Tajima's D test and mismatch distribution analysis. Our data in junction with geological and palynological evidences showed that in the Holocene, due to global warming, refuge populations of *D. pectinatum* in Hainan might experience a range expansion.

P2123. Distribution, migration and habitat preferences of some newer kenophytes in the territory of Poland

M. Nobis, A. Michalewska;
Instytute of Botany, Jagiellonian University, Krakow, Poland.

The natural barriers of kenophytes expansion are overcome by globalization and human impact, therefore their number in the flora of Poland is constantly increasing. Presently, there are about 270 established kenophytes in Poland (approximately 10% of the whole flora of vascular plants). The occurrence of some of the newest arrivals, which were found in the area of Poland during the last 20-30 years, is especially interesting. The specific conditions of their habitats create possibilities for the migration of their diaspores. They establish in new places and in consequence spread, sometimes becoming expansive. These problems in Poland relate to e.g. *Chaerophyllum aureum*, *Eragrostis albensis*, *Typha laxmannii* (entering semi-natural or natural plant communities and achieving the status of hemi- or holoagryophytes), *Brachyactis ciliata* and *Geranium sibiricum* (which are considered as epecophytes). Detailed studies on their distribution, migration, dynamic of population, level of establishing and share in plant communities are required. The results of these studies could be in future of a particular value for the nature conservation programmes.

P2124. Above- and belowground interaction of wheat (*Triticum aestivum* L.) and wild oat (*Avena fatua* L.)

A. Dabbagh Mohammadi Nassab, a. javanshir, f. sorkhi lalelou, f. Rahimzadeh khoyi, s. zehtab salmasi;
Faculty of Agriculture, Tabriz, Islamic Republic of Iran.

A pot experiment was designed to investigate above- and below-ground interactions of wheat with wild oat. This experiment was conducted in a randomized complete design with four treatments and four replications. The treatments include above-ground, below-ground and full interaction of wheat - wild oat and no interaction of wheat and wild oat. In both plants, full and belowground interaction decreased plant height, number of leaves, flag leaf area, chlorophyll content of flag leaf, biomass and grain yield compared to aboveground interaction and control, significantly. In wheat no significant difference observed between belowground and full interaction except wheat biomass and grain yield. All traits of wild oat reduced by aboveground interaction compared to control. In full interaction, flag leaf chlorophyll content of wheat and wild oat were reduced about 10.7% and 6.9% compared to control, respectively. Number of leaves, biomass and grain yield of wheat and wild oat showed greatest susceptibility to interaction treatments. Wheat and wild oat plant height increased by aboveground and full interaction related to no interaction, respectively.

P2125. Cacti species conservation in central Mexico. A case study in the Biosphere Reserve "Barranca of Metztitlán"

C. Jiménez-González, C. L. Jiménez-Sierra, **S. L. Camargo-Ricalde**;
Universidad Autónoma Metropolitana-Iztapalapa, México, D. F., Mexico.

The illegal extraction of plants, goat overgrazing, and deforestation have leaded to a great environmental disturbance in central Mexico. The "Barranca of Metztitlán" (Biosphere Reserve since 2000) possesses 62 cacti species (18.6% of all the Mexican cacti). Most of the cacti species are used for local people as food, fodder or living fences. This study demonstrated that *Prosopis laevigata* and *Senna wislizeni* (Leguminosae) form resource islands, not only rich in soil nutrients but in arbuscular mycorrhizal fungi, and perform as nurse plants, while the cacti (*globular) **Echinocereus cinerascens*, **Mammillaria longimamma* (endanger species), **M. magnimamma*, and **M. obconella* are nursling plants during their whole life cycle, and *Myrtillocactus geometrizans* is associated to the nurse during its first stages of life; while *Cylindropuntia imbricata* and *Opuntia streptocantha* establish better in open areas. *Prosopis laevigata* and *S. wislizeni* should be considered for ecological restoration practices within the Reserve. Conservation strategies should consider both: nurse plants and cacti, as well as the systems of management exercised by local people.

P2126. Floristic similarities between lowland and montane areas of atlantic coastal forest in northeastern brazil

E. M. N. Ferraz[1], E. L. Araújo[2], S. I. Silva[2];
[1]Centro Federal de Educação Tecnológica de Pernambuco, Recife, Brazil, [2]Universidade Federal Rural de Pernambuco, Recife, Brazil.

Using a binary matrix, and TWINSPAN analysis intents to analyse floristic similarity. Were performed on 742 tree/shrub species listed in 35 different plant surveys. These tree/shrub were divided by these analysis into two large floristic groups ombrophilous/semideciduous. The semideciduous group was formed, by forest areas located at altitudes above 700m, and could itself be divided into two subgroups. The first subgroup was located more inland, while the second subgroup was located nearer the coast. The ombrophilous group was quite heterogeneous, but could also be divided into two floristic subgroups:i)lowland forests in the states of Pernambuco, Paraiba, and in two areas of Bahia, as well as some montane forests; ii)lowlands forests in the states of Alagoas and Bahia. Nonetheless, it can be further subdivided into two smaller classes, one in Alagoas and the other in Bahia. Was demonstrate that the concept of the Atlantic Coastal Forest could also include montane ombrophilous forests.

P2127. Analysis of life forms in flora of Divcibare

I. Popovic, D. Obratov-Petkovic;
Faculty of Forestry, Belgrade, Serbia and Montenegro.

Divcibare is part of Mt Maljen which is situated in central part of western Serbia. Geological layer is serpentine. The vegetation consists of forests and mountainous meadows and pastures.

During floristic investigation we have performed ecological analyses of this area through determination life forms for each species. We could conclude that hemicriptophyta (H) are the most numerous with 260 taxa (63.35 %) in flora of Divcibara. The geophyta are presented with 46 taxa (11.16 %), terophyta with 45 (10.92 %), phanerophyta with 26 (6.31 %), chamaephyta with 20 (4.85 %), scadentophyta with 7 (1.70), parasitophyta and semiparasitophyta with 5 (1.21 %) and hydrophyta with 2 taxa (0.48 %).

Hemicriptophyta are the most numerous in flora of Balkan peninsula, generally. Number of geophyta, terophyta and chamaephyat in flora of investgated area confirms that investigated vegetation is not high mountainous vegetation.

P2128. Age dependence flowering of *Thalassia testudinum* in Champotón, Campeche and Celestún Yucatán, México

M. E. Gallegos[1], M. Merino[2], F. López[1];
[1]Universidad Autónoma Metropolitana Iztapalapa, México, Distrito federal, Mexico, [2]Universidad Nacional Autónoma de México, México, Distrito federal, Mexico.

We determine the age dependence of flowering events and flowering intensity of *Thalassia testudinum* along coast of Champotón, Campeche (19^{o}02$^{'}$ N; 96^{o}04$^{'}$ W) and Celestún (20^{o}45$^{'}$ N; 90^{o} 25$^{'}$ W) Yucatán, in the Gulf of Mexico, using the reconstruction techniques (Duarte et al 1994). In Champotón only 17 % of the shoots examined had flowered during their lives, and the mean flowering frequency for the population was estimated to be 6.7 x 10^{-3} flowers per plastochrone interval (PI^{-1}), which corresponds on average to a flowering event every 7 years. None of the shoots examined flowered before reaching an age of 21.5 PI (about 1 year). In Celestún only 12.59% of the shoots examined had flowered during their lives, and the mean flowering frequency for the populations was estimated to be 4.7 x 10^{-3} flowers per plastochrone interval (PI-1), wich corresponds on average to a flowering event every 9 years. None of the shoots examined flowered before reaching an age of 22.7 PI (about 1 year).

P2129. Effect of plant growth regulators and N, P, K fertilization on leaf pigments and other cell metabolites in shatavari (Asparagus racemosus)

N. Vijay, A. Kumar;
University of Rajasthan, Jaipur, India.

Asparagus racemosus, is a climbing plant which grows in low jungles areas throughout India. A.racemosus (Willd.) is an important plant of female fertility of the monogeneric family Asparagaceae. This tonic herb is life supporting or sattvic in its nature. Influence of different growth regulators and N, P, K were studied in the present study. One month old seedlings grown in pots were exposed to 12 foliar sprays of different growth regulators viz. IAA, IAB, NAA, GA3 and N, P, K in the form of urea, super phosphate and muriate of potash respectively of different concentration at an interval of 15 days. The control plants were sprayed with distilled water. All the treatments promote significant increase in the total biomass plants. Photosynthetic pigment was found to be maximum in the IBA and nitrogen treated plants among all the treatments. Phosphorus application at 160 mg/kg and IBA application at 50 ppm concentration significantly increased the contents of starch, reducing and total soluble sugars. The total soluble protein contents were also consistently more in all the treatments as compare to that of control plants.

P2130. Soil microbial community of a central Siberian *Pinus sylvestris* forest

S. J. Evgrafova;
Institute of Forest, Russian Academy of Sciences, Siberian Branch, Krasnoyarsk, Russian Federation.

Structure of microbial community in sandy soils of a central Siberian *Pinus sylvestris* forest was investigated. There were two closely located areas: one was covered with trees (referred to hereafter as “forest”) and second was an open area of around 225 m^2 (referred to hereafter as “glade”), for which the ground cover consisted of only by lichen species. The microbial-community structure was determined on the basis of a PLFA pattern within 100 cm soil profile in the middle of vegetation period. Thirty-eight microbial fatty acids were identified by GC-MS and used for a principal component analysis (PCA) to detect the composition differences.

PLFA-profiles of soil microbial community of both areas (“forest” and “glade”) were similar at 95%. There were some fatty acids (FA) peculiar to Gram-negative-bacteria in microbial community composition of “forest” soil only. In upper layer of ‘glade’ soil it was found FA peculiar to protozoa. It was detected a remarkable shift (20 cm deep down) in PLFA-profiles of the “forest” against the “glade” distribution of microbial community.

INTAS YSF Ref. Nr 03-55-1344 sponsors this research

P2131. Redlist of the Hungarian vineyard weeds

R. Pál[1], G. Pinke[2];
[1]Research Group for Biological Adaptation, Hungarian Academy of Sciences – University of Pécs, Pécs, Hungary, [2]University of West Hungary, Department of Botany, Mosonmagyaróvár, Hungary.

Many reports have been published in Europe (Germany, Switzerland) about decreasing biodiversity of vineyards recently. The weed flora of the Hungarian vineyards is highly influenced by intensive growing technologies (high mulching intensity, frequent soil movement, use of herbicides) as well. Abundance of sensitive therophytes (*Androsace maxima, Calepina irregularis, Medicago arabica, Thlaspy alliaceum*) and bulbous geophytes (*Gagea arvensis, Muscari racemosum, Ornithogalum boucheanum, O. umbellatum*) are decreasing. Frequency of invasive newcomers (*Conyza canadensis, Erigeron annuus*) and stoloniferous plants (*Convolvulus arvensis, Cynodon dactylon, Elymus repens*) showed however a great upsurge. Rare weeds can only be found on extensive managed fields, some of them are legally protected and some are listed in the Red Data Book of Hungary. Our aim is to assemble a list of the endangered weed species of the Hungarian vineyards. There are already preservation programs going on to protect rare weeds in some European countries. We would like to contribute with our list to possible introduction of similar programmes in the Hungarian winegrowing areas.

P2132. Photosynthetic efficiency of seeded Festuca rubra L. and spontaneously recolonized Calamagrostis epigeios (L.) Roth. at fly ash deposit of “Nikola Tesla - A” thermal power plant in Obrenovac (Serbia)

M. M. Mitrovic[1], P. Z. Pavlovic[2], D. V. Lakusic[3], L. A. Djurdjevic[1], S. Bojovic[1];
[1]Department of Ecology, Institute for Biological Research "Sinisa Stankovic", University of Belgrade, Bulevar Despota Stefana 142, 11060 Belgrade, Serbia and Montenegro, [2]Department of Ecology, Institute for Biological Research "Sinisa Stankovic", University of Belgrade,, Bulevar Despota Stefana 142, 11060 Belgrade, Serbia and Montenegro, [3]Institute of Botany and Botanical Garden "Jevremovac", Faculty of Biology, University of Belgrade,, Takovska 43, 11000 Belgrade, Serbia and Montenegro.

The paper analyzed photosynthetic efficiency of PSII (Fv/Fm) of Festuca rubra L. and Calamagrostis epigeios (L.) Roth. at fly ash deposit (FAD), which covers an area of 400 ha. F. rubra was the component of grass mixture used for revegetation of deposit. C. epigeios was populated by natural recolonization. The objective of research was to evaluate the vitality of two grasses at deposit in relation to natural site-control (NS), and coordination of their ecological potentials with the potential of ash deposit.

F. rubra was abundant at FAD, with mean Fv/Fm of 0.690±0.078 (up to 0.770). Higher values of 0.757±0.044 (up to 0.829) were measured at NS ($p<0.01$). C. epigeios formed a dense canopy cover at FAD, with mean Fv/Fm of 0.581±0.115 (up to 0.779) and of 0.668 ±0.071 (up to 0.784) at NS ($p<0.001$). Results showed higher Fv/Fm of F. rubra than of C. epigeios ($p<0.01$), and maximum values within the optimum range (0.750-0.850) in both species. According to its vitality C. epigeios should be included to grass mixture. Such vegetation established on ash deposit would provide its efficient protection from wind erosion, with minimum investment and without special land management.

P2133. Nitrogen fixing activity of diazotroph microorganisms associated to Rhizophora mangle and Avicennia germinans in the Colombian Caribbean

J. Vanegas Guerrero[1], **J. H. Polania**[2], J. Sánchez Nieves[1], A. Lozano de Yunda[1], H. Valencia Zapata[1], T. Galindo[1], L. M. Melgarejo[1], N. Moreno[1];
[1]Universidad Nacional de Colombia, Sede Bogota, Bogota, Colombia, [2]Universidad Nacional de Colombia, Sede San Andrés, San Andres isla, Colombia.

Microorganisms promoting plant growth represent an option to restore ecosystems, and to develop commercial crops in high salinity and/or low nutrient levels soils. This work assessed the nitrogen fixing activity (NFB) of bacteria isolated from mangrove seedlings of two sites at the Colombian Caribbean. For dilutions methods as well as viable cell counting isolations were done sowing rootlet segments directly on semi-solid diazotrophic bacteria media (Nfb). Nitrogenase activity was evaluated by acetylene reduction assay in 16 morphotypes. *Azotobacter vinelandii* (G10) showed best response (56.6 nmole ethilene/culture/hour). Mixtures of this and phosphate solubilizing microorganisms showed no differences in regard to individual nitrogenase activity. *Azotobacter vinelandii* was inoculated in hydroponic Río Grande tomato seedlings under salinity (EC 2.27 dSm^{-1}) during their vegetative phase. After 40 days plant growth was promoted, and best results were obtained in nitrate concentrations around 16 meq/l. Inoculated seedlings showed differences in their root length with respect to the control, despite of the salinity level.

P2134. Globular cacti microhabitat in a crassicaulleous scrub in central Mexico

C. L. Jiménez-Sierra, M. L. Matías-Palafox, I. Reyes-Jaramillo, **S. L. Camargo-Ricalde**;
Universidad Autónoma Metropolitana-Iztapalapa, México, D. F., Mexico.

Cacti survivorship and establishment are determined by climate and edaphic characteristics in the Mexican crassicaulleous scrub. Recently, it was demonstrated that globular cacti such as *Echinocereus cinerascens*, *Mammillaria longimamma* (endanger species), *M. magnimamma* and *M. obconella* may establish below the canopy of legume trees and shrubs, which create resource islands. Although globular cacti populations are more numerous in the resource islands located in the northern slope of the hills than in the southern slope, this study point out that in open areas of both slopes, these globular cacti species are capable of transforming their own microhabitat. Rhizospheric soil has similar nitrogen (30 mgKg^{-1} *vs* 28 mgHg^{-1}) and phosphorus (23 mgKg^{-1} *vs* 29 mgHg^{-1}) content as the ones found in the resource islands. In addition, globular cacti are mycorrhizal in both habitats. In open areas, cacti root length is shorter than in the resource islands but arbuscular mycorrhizal fungal colonization is more abundant. The overall of results suggests that globular cacti species transform their microhabitat as long as they establish favoring their survivorship in long term.

P2135. High temperature and accelerated aging effects on spores of different ferns.

D. Ballesteros, J. Gorgues, A. M. Ibars;
Jardi Botanic de Valencia, Valencia, Spain.

Seeds have a big trade interest. A lot of studies have been published about seeds which determine their resistance and viability. However, in pteridology circles, scant quantitative works have been carried out to determine resistance and viability of the spores, and develop with the results predictive models.

In the current work, carried out nowadays in the Valencia Botanical Garden, we’ll show our first results and hypothesis about spore’s high temperature resistance of different fern species. We’ll show the viability loss patterns and the mathematics equations calculated. The observed conclusion a priori, shows that doesn’t exist higher resistance to thermic shocks on xerophyte’s spores than hidrophilous species spores.

Also we have established viability loss curves for this species, applying accelerated aging techniques (Vertucci & Roos, 1993). T50 values (time where samples fallen off to a half of its viability) shows significative differences bettwen invasive or cosmopolite species and ferns of restricted ecological habitats.

P2136. Some Hyperacumulator Species in the Serpentinite flora of Serbia

D. D. Obratov-Petkovic, R. R. Kadovic, S. B. Belanovic, I. R. Popovic;
Faculty of Forestry, Belgrade, Serbia and Montenegro.

Serpentine mass on the Balkans is among the largest in Europe. In Serbia it takes 75% of entire territory because it occurs mostly in mountains massif (Vasic et Diklic 2001.).

The first experiments of nickel contents in soil and in plant material in Serbia, were with endemic serpentinofit *Alyssum margrafii.* The results of total nickel content in eutric cambisol profile over serpentinized peridotit on Goc and Kopaonik mountain (central Serbia) ranged 5.42 and 1.42 mg.kg^{-1} (Obratov et al. 1999.). After that many other genus were investigated such as *Thymus, Hypericum, Cytisus* etc. in the various parts of Serbia. (Blagojevic et al. 2002, Vrbnicanin et al. 2004). The concentrations of nickel in soil and plant material over serpentinite perent rock were between 0.50-5.42 mg.kg^{-1}.

Some other investigations of nickel content in soil and plant material will be presented and compared with literature data.

P2137. *Trichomanes speciosum* Willd. *(Pteridophyta, Hymenophyllaceae)* in North-Western France: from knowledge to conservation

S. Loriot[1,2], S. Magnanon[2], E. Deslandes[1];
[1]Institut Universitaire Européen de la Mer, Plouzané, France,
[2]Conservatoire Botanique National de Brest, Brest, France.

With the aim to further establish a conservation plan for the endangered *Trichomanes speciosum* Willd. in North-Western France, the Conservatoire Botanique National of Brest has carried out a study to improve the knowledge about its life cycle and ecology. Indeed, "independent gametophytes" of the fern are able to maintain vegetatively whereas, classically for Pteridophytes, they reproduce sexually to produce the perennial sporophytes generation. Moreover, in the region, sporophytes are only recorded in old wells unlike gametophytes, present in natural habitat. Both reproductive biology and ecology of the fern were examined to search for possible environmental causes involved in the life cycle disruption observed in natural habitat. In the same time, so as to eliminate the deleterious closing of many wells, specifically designed grids were installed on wells sheltering the fronds of *Trichomanes speciosum* Willd.

P2138. The bryophyte flora of Geneva past and present: an analysis of bryophyte distribution in Geneva using GIS.

L. Burgisser, M. J. Price;
Conservatoire et Jardin botaniques de Genève, 1292 Chambésy - Geneva, Switzerland.

An inventory of the bryophytes of Geneva began with the compilation of bibliographic checklists and data-basing of herbarium specimens in G. An active period between 1888 and 1930 saw 5000 bryophyte specimens collected from Geneva and 251 species reported in literature. Recent collecting efforts around the canton provide data on the current presence and distribution of species, leading to the discovery of 20 new species. The completed project database, with 6500 historical literature or herbarium records, and an estimated 10’000 recent collections, will enable us to compare changes in presence/absence of species within the canton, and in species composition for certain well-collected areas over the past 70 years. Geneva has recently undergone a large amount of change in its climate, agricultural practices and in terms of development. Our data also allows us to analyse the bryological flora of Geneva in detail using the GIS and the vegetation cover, topography, land-use, and geology layers that are available for the canton. We present our methodology and preliminary analysis of the bryophytes of the canton and discuss the application of our findings in the future.

P2139. Surface excavations and its role in floristic diversity conservation

A. S. Nowak, S. M. Nowak;
Opole University, Opole, Poland.

During last century human activities result in destruction of many natural and semi-natural habitats. Considerable amount of plant species has disappeared due to this process. However, some industrial exploitation created important alternative habitats for many threatened plants (sozophytes). This has considerable significance in disturbed urban areas were natural biodiversity diminished due to anthropogenic pressure. In such areas artificial excavations serve as a suit refugees for many sozophytes.

The distribution and occurrence conditions of red-listed vascular plant species were studied on 77 quarries, gravel-, sand- and clay-pits located in Silesia (SW Poland). In researched excavations over 140 sozophyte species were found, mainly from the IUCN *EN*, *VU*, *NT* threat categories. Analyse of the habitat use and type was done to indicate the key environmental factors determining the spatial distribution of the chosen species.

Opencast industrial excavations have an increasingly important role in the conservation of sozophytes. By controlling disturbances and properly managing reclamation undertakings, conservationist can enhance this role.

P2140. Phytosociological characteristics of the sandy desert formations of Caspian shore of Azerbaijan

V. ATAMOV, O. Cen;
Harran University, Sanliurfa, Turkey.

This The flora of sandy Caspean shores of Azerbaijan was studied and 114 flowered plant species were identified in this study performed between 1995-1996. The dominant formation was detected to be sandy-desert type vegetation and it was classified and mapped. The phytosociological characteristics and the productivity of the common formations in the area was analyzed. We have shown that the formations of *Phragmisetum, Juncusetum, Astragaletum ,Calamogrostisetum, Thyphetum, Carexetum, Salsoletum, Suaedetum* were more prevalent while the formations of *Juncuseto-Glysirrhizetum, Ephedretum, Kalidetum, Alhagetum,Tamarixetum, Salicornieto-Kalidietum, Petrosimonietum* were more localized to defined spots. The productivity of the ground surface and underground (40 cm) phytomasses were (dried grass per 25 cm²) 40-6400 gr and 50-4560 gr, respectively. The effect of changes in the water level on the common plant species and associations was analyzed.

P2141. Wildfire in an Australian alpine ecosystem: its effects on N cycling presented by a unique set of data

E. Huber[1], T. L. Bell[1], M. A. Adams[2], R. Simpson[1];
[1]University of Melbourne, Creswick, Australia, [2]University of Western Australia, Nedlands, Australia.

Australian alpine ecosystems have a long history of fire and also distinguish themselves from their northern hemispheric counterparts through different geology, glaciation, climate and soil properties. Recent landscape scale wildfire in alpine regions in south-eastern Australia in December 2002 - February 2003 has provided a unique opportunity to study the effect of unplanned fire on nitrogen (N) cycling. Five transects of approx. 70 m length were established and also sampled before the fire and comprise three vegetation types (grassland, heathland, woodland) as part of an inverted treeline. Total and inorganic N in soil and ^{15}N natural abundance of soil and foliage were analyzed before and after the fire and a comparison of root N uptake was conducted between burnt and unburnt areas. Wildfire affected the levels of ammonia but not nitrate in the soil and also changed the isotopic composition of foliage and the upper layers of soil. Plant species reacted differently to an altered nutrient situation in the burnt areas which was reflected by rates of N uptake.

P2142. Flora and vegetation of Fatik mountain, Sanliurfa, Turkey

V. ATAMOV, **C. Cenap**, A. Parmaksiz, M. Yavuz;
Harran University, Sanliurfa, Turkey.

This study was performed between 2002-2004 to determine the flora of Fatik mountain, Sanliurfa, Tukey. We determined 153 taxa belonging to 25 families and 107 genera. The dominant families are: *Fabaceae* (22), *Asteraceae* (24), *Poaceae* (31), *Apiaceae* (13), *Brassicaceae* (10), *Lamiaceae* (10) and *Caryophyllaceae* (7). Concerning the number of species the major genera in this region are as follows: *Bromus* (7), *Trifolium* (6), *Medicago* (5), *Hordeum* (4), etc. The flora of the region was analyzed according to its geographic elements, living forms and endemism features. The dominating step vegetation was classified and its map was drawn. The vegetation of the field has been exposed to antropogen effects. Seasonal and phytosociological features of the vegetation of the region has been determined. The polydominant formations in the vegetation of the region are *Astragaletum, Astragalo-Festucetum, Astragaleto-Hordetum, Onobrychetum, Phlomiseto-Aegilopsetum, Saturejeto-Teucrietum, Festucetum, Hordetum, Arrhenathenetum, Stipeto-Astragaletum etc*. Phytosociological structures of these formations show seasonal aspect and mosaicity.

P2143. Facilitative effects of alpine cushion plants in the Andes of central Chile: an ecophysiological approach

L. A. Cavieres, A. Sierra-Almeida, M. Molina-Montenegro;
Departamento de Botanica, Concepcion, Chile.

Alpine cushion plants can modify the microclimate, facilitating the establishment of other alpine plant species. However there are no studies that evaluated if the microclimatic modifications generated by cushions can improve the physiological performance of those species growing within cushions. We characterized soil humidity and temperature, and nutrient content of soil within and outside cushions of *Laretia acaulis* in the Andes of the mediterranean-type climate zone of central Chile. Additionally, we measured the gas exchange and fluorescence parameters of individuals of *Taraxacum officinale* growing within and outside cushions. Cushions maintained milder temperatures, higher availability of water, and higher nutrient content than the bare ground. Individuals of *T. officinale* growing within cushions showed a better physiological performance than those growing outside only at the end of the growing season when the aridity of the environment is high. This suggests that the provision of moisture is a key factor in the facilitation of *L. acaulis* cushions in the Andes of central Chile. Acknowledgments: FONDECYT 1030821 and P02-051-F ICM.

P2144. Micromycetes at arctic soil (Russian territory).

I. Y. Kircideli;
Komarov Botanical Institute Russian Academy of Science, St.Petersburg, Russian Federation.

The investigation of Arctic has been undertaken in preparation for detection of life in extreme environments. Micromycetes were studied at 4 northern zones of Taimyr Peninsula, Kola peninsula, Polar Ural and at some islands which were the polar deserts (high arctic tundra), the arctic, typical and south tundra.It was shown that the number of soil micromycetes ranges from 0.004 to 31.29 thousand CFU (Colony Forming Units) per gram of dry soil. The general reduced to fungal numbers have often been noted in soil along the steep gradient towards from south to the north. Severe conditions of Arctic resulted in the poverty of species, large proportion of sterile mycelium, dominance of Chrysosporium pannorum and species of genus Penicillium. Shennon index (H) of species diversity oscillates from 0.91 to 4.38. It consequently increases from north to south. The analysis between all biocenoses in the frequency of 178 species occurrence demonstrated that the resemblance between the polar desert and arctic tundra was more higher than with typical and south tundra.

P2145. Dry matter accumulation and nitrogen content of two spring geophytes in a deciduous forest

Z. Popovic[1], A. Mijovic[1], B. Karadzic[2];
[1]Institute for Biological Research, Belgrade, Serbia and Montenegro, [2]Institute for Biological Research "Sinisa Stankovic", Belgrade, Serbia and Montenegro.

Scilla bifololia L. and Arum maculatum L. are typical spring geophytes in temperate deciduous forests. An early spring ephemeroid S.bifolia reaches the reproductive phase at the start of its vegetation development. A late spring ephemeroid A.maculatum has delayed and relative shorter reproductive period then S.bifolia, and it prolong vegetation growth to the beginning of summer. During the spring period, both species accumulate dry matter in their underground organs. Allocation of dry matter responds to changes in aboveground and belowground mass nitrogen content. N-belowground content decreases at the start of vegetation cycle, when both species mobilize last seasons' accumulated matter. N-shoot content has the same tendency with slighter decreasing trend. A difference in flowering time, reproductive efforts and endurance of period of assimilation and accumulation in belowground plant structures, make differences in nitrogen dynamics. S.bifolia has greater N belowground content than A.maculatum at the start as well as at the end of vegetation growth, because of differences in reproductive investment between these species.

P2146. Boron content in coffee plantations (*Coffea arabica*) in two locations of Venezuela

A. Malavé[1], P. Carrero[2], M. Lemus[3], M. García[4];
[1]Universidad de Oriente, Maturín - Estado Monagas, Venezuela, [2]Universidad de Los Andes, Mérida- Estado Mérida, Venezuela, [3]Universidad de Oriente, Cumaná - Estado Sucre, Venezuela, [4]INIA, Caripe - Estado Monagas, Venezuela.

Samples of coffee plants and their respective soils were taken from two venezuelan coffee producing locations [Santa Cruz (8° 29' N, 71° 20' W, 622 m elevation; Mérida State) and Caripe (10° 10' N, 63° 30' W, 1120 m elevation; Monagas State)] to determine their boron content during harvest. A random block design was used, with three repetitions and nine experimental units per treatment. The plant tissue and soil samples were treated by a hot extraction procedure prior to spectrophotometric determination of boron with azomethine-H. Boron content in fruit and leaf samples were 24.96 ± 2.39, 75.86 ± 2.79 µg g^{-1} dry weight (Santa Cruz) and 9.56 ± 1.12, 29.08 ± 2.15 µg g^{-1} dry weight (Caripe). These results show significant differences in the boron content between areas and tissues ($p < 0,001$), while the boron content in soils were 9.08 ± 1.38 µg g^{-1} dry weight (Santa Cruz) and 4.42 ± 0.95 µg g^{-1} dry weight (Caripe), showing significant differences in the element content among areas ($p < 0,001$). These results indicated higher reference values for the element content in Santa Cruz than in Caripe.

P2147. Halophytic plants communities near Drogobych (Western Ukraine)

H. TrzciŒska-Tacik[1], M. Woch[2];
[1]Institute of Botany, Jagiellonian University, Krakow, Poland, [2]Institute of Botany, Polish Academy of Science, Krakow, Poland.

Halophytic plant communities (*Puccinellio-Spergularietum salinae*; com*. Salicornia europaea - Sueda prostrata*; com. *Aster tripolium* s.l.) were found on 3 localites in Drogobych region (Western Ukraine). There are isolated (”islands”) localities, up today near unknown. Halophytes grows here on salted sites, connected with the old salt industry. The floristic composition of these communities were given and taxonomic position of some critical species e.g. *Aster tripolium* ssp. *pannonicus*, *Limonium* cf. *gmellini* or *L. hypanicum*, *Sueda prostrata* were discussed. The knowledge about the halophytic flora and vegetation of these and others localities on Western Ukraine is important for maintain or reject the hypothesis of halophytes migration: from shores of the Black Sea (the Pontic Area) towards north-north-west to Central Europe after the last glaciation or from shores of the Baltic Sea to inland salted habitats. The salt production in the Drogobych region was nearly totally stopped about 1995. From that time area of salted sites diminished; that is the threat for halophytic flora and vegetation. Now the significance of presented data is clear.

P2148. Seed germination of two *Salicornia* species from Saudi Arabia.

A. Al-Huqail[1], **T. A. Al-Turki**[2];
[1]Botany Department, Girls's College of Education, P.O. Box 27104, Riyadh-11417, Saudi Arabia, [2]Herbarium, King Abdulaziz City for Science and Technology, P.O. Box-6086, Riyadh-11442, Saudi Arabia.

The germination of seeds of two annual halophytic species of *Salicornia* (*S. saudiensis* Al-Turki & Sawrup *ined*. and *S. qassimensis* Al-Turki & Swarup *ined*. (Chenopodiaceae) was examined in collections from eleven populations distributed in the central and eastern (Arabian Gulf Coast) regions of Saudi Arabia. Their responses to a wide range of fluctuating and constant temperatures and to variation of salinity were tested. Seeds of populations from the interior (e.g. Sabkhah Al-Waz) and from coastal populations (Arabian Gulf Coast) showed very high germinability (96%-100%) over the whole range of temperatures. The seeds of these populations of both species can germinate at very high salt concentrations (1200, 1500 mM NaCl at 25/15^0 C). Soil samples of these habitats were also analyzed.

Keywords: Saudi Arabia, Germination, Alternating and constant temperatures, Salinity, Salicornia, Al-Waz, Arabian Gulf.

P2149. The impact of ground water level and soil salinization on different tugai plant communities in the river of Amydarya

S. Y. Treshkin[1], S. V. Kuz'mina[2];
[1]Institute of Bioecology, Nukus, Uzbekistan, [2]Water Problems Institute, Moscow, Russian Federation.

The groundwater level equalled to 0.5-1.5 m is required for plant communities such as Salix songarica, Calamagrostis dubia, Phragmites australis, Typha angustifolia, T.minima, T.laxmanii. For communities of Salix songarica and Calamagrostis dubia the soil salinization and the groundwater level should be minimum within the first three meters - 0.1-0.3% in soils and 0.8-1.2 g/l in the ground water. The groundwater level in 2-2.5 m. is required for Populus ariana, Populus pruinosa, Elaeagnus turcomanica, Tamarix ramosissima, Halimodendron halodendron and for grasses such as Trachmithum scabrum, Glyzyrrhiza glabra. The soil salinization under such plant communities can be rather high only in the first meter layer - 0.8-1.5%. The salinization decreases with the depth reaching 0.1-0.7% in the second and 0.05-0.6% in the third meter layer. The groundwater level in 3-.5-4.5 m is bearable for:solonchakous vegetation consisting of Tamarix hispida, Lycium ruthenicum, Salsola dendroides, Halostachys belangerian; they are tolerant to soil salinization equalled to 1.6-4.5% in the first two meters of the soil layer and 9-23% in some surface horizons (10-20 cm.

P2150. Crocus albiflorus, Euphorbia verrucosa and Hypochoeris maculata: Mycorrhizal colonization and Biodiversity of symbiotic fungi

H. Stockinger[1], K. Haselwandter[2];
[1]Organismic Biology, Salzburg, Austria, [2]Department of Microbiology, Innsbruck, Austria.

The plant species listed above normally grow in nutrient-deficient meadows and pastures, and hence are negatively influenced and threatened by intense agricultural management practises.

In order to investigate their mycorrhization , roots were sampled at the Gaisberg (1000 m a.s.l.) and the Wimberg (730 m a.s.l.) in the county of Salzburg, Austria, and stained with trypan blue in lactoglycerol following a standard procedure. Soil samples were taken for extraction of arbuscular mycorrhizal fungal (AMF) spores, for determination of plant available P, total soil P and pH.

Samples taken over the vegetation period reveal that roots are constantly colonized by AMF with frequent formation of vesicles and arbuscules. In addition, the plant roots are also colonized by dark septate endophytes. Quantitative data for both types of mutualistic fungal root colonization will be provided together with a qualitative and quantitative assessment of the biodiversity of AMF spores found in soil.

P2151. Seed germination of *Anabasis setifera* Moq. (Chenopodiaceae) from Saudi Arabia.

A. Al-Huqail[1], **T. A. Al-Turki**[2];
[1]Botany Department, Girls's College of Education, P.O. Box-27104; Riyadh-11417, Saudi Arabia, [2]King Abdulaziz City for Science and Technology, P.O. Box -6086, Riyadh-11442, Saudi Arabia.

Anabasis setifera Moq., a halophytic perennial shrub in the family Chenopodiaceae, is widely distributed in coastal and inland salt marshes in Saudi Arabia. Experiments were conducted to determine the effect of temperature and salinity on seed germination and its recovery of germination from saline conditions after being transferred to distilled water. Seeds of *A. setifera* were germinated at five alternating temperatures (15/5, 20/10, 25/15, 30/20 and 35/25^0 C) and four constant temperatures (5, 15, 25 and 35) and nine different concentrations of salinities (0, 100, 200, 300, 400, 500, 600, 700 and 800 mM NaCl) at 25/15^0 C. The seeds germinated best at the relatively low temperatures and inhibited at the higher temperatures. The seeds can germinate at very high salt concentrations (9.5% 700 mM NaCl at 25/15^{0}C). Seeds recover after being transferred to distilled water and recovery was higher from higher salinity concentrations (94.5% and 75.5% at 800 and 700 mM respectively at 25/15^0 C). This result indicates undoubtedly that inhibition of germination in this species was due to an osmotic effect.

Keywords: Anabasis setifera, Germination, Halophyte, Saudi Arabia.

P2152. Plant species richness in unfertilized mountainous grassland communities - a function of the soil chemical conditions?

A. Bohner;
Agricultural research & education centre Raumberg, Department of environmental ecology, Irdning, Austria.

There is a hump-shaped relationship between plant species richness and pH. Very acidic alpine soils in the Al and/or Fe buffer range are characterized by a relative excess of H-, K-, Al-, Mn- and/or Fe-ions and by a complementary lack of Ca- and Mg-ions. Only calcifuges are adapted to the prevailing nutrient and acid stress. Therefore, species richness is very low. On the other hand calcareous soils in the carbonate buffer range are characterized by an absolute and relative excess of Ca-ions. Only calcicoles are adapted to this disharmonic nutrient supply and the resulting discrimination of individual nutrients. Therefore, species richness is moderately high. Soils in the silicate buffer range, and soils in the upper part of the cation exchange buffer range are generally characterized by a balanced composition of the soil solution and exchange complex. Therefore, both calcifuges and calcicoles can be present at these sites, allowing a high plant species richness.

P2153. The modern state of vegetation cover of the Amudarya Delta and problems of biodiversity conservation

S. Y. Treshkin, N. Mamutov;
Institute of Bioecology, Nukus, Uzbekistan.

Studying of the degradation processes of terrestrial ecosystems connected with the intensification of anthropogenic impact is of international meaning. They are especially acute in arid conditions. Here the ecosystems are characterized by specific unsuitability. They cover the wide range of changes beginning from stress conditions and finishing with rebuilding of the ecosystems’ structure that lead to their complete degradation. Vegetation is the most valuable kind of biological resources of the Amudarya delta and is characterized by high biodiversity (655 species that belong to 65 families and 210 genera) and comparatively low productivity. At present time in connection with the changes of ecological situation in Aral Sea region can observe the intensive development of desertification process and process of vegetation cover degradation. Desertification occupy over 40% of the territory of the Amudarya delta.

P2154. Plants and lichens limit the environmental risk related to abandoned asbestos mines

S. E. Favero Longo[1,2], C. Siniscalco[1], R. Piervittori[1,2];
[1]Department of Plant Biology - CEBIOVEM - - University of Torino, Torino, Italy, [2]Interdepartmental Centre for Studies on Asbestos and others Toxic Particulates "Giovanni Scansetti" - University of Torino, Torino, Italy.

Vegetation studies have been performed in the Balangero asbestos mine (NW-Italy), which was the most important asbestos mine of W-Europe, used until 1990, and which still represents a source for the air-dispersion of fibres, strongly dangerous for human health. The synchronical phytosociological analysis of the vegetation series has allowed to evaluate the diachronical succession of plant and lichen communities, which cover the asbestos-rich serpentinites of the excavation and discharge areas, limiting the air dispersion of fibres. Few decades are needed for the formation of continous plant communities which completely contain the air-exposure of the fibres in the spoil-banks. Lichen colonization, even if limited to pioneer stages of development and showing very low cover values, plays a complementary role on the walls of the mining-basin, particularly where asbestos-veins crop-out. The lichen weathering action strongly modifies the chemical composition of the fibres, enhancing their pedogenic transformations and inactivation. Plants and lichens act as spontaneous bioremediation agents in the restoration ecology of the disturbed site.

P2155. Plant Colonization and Succession on Forest Habitats Disrupted by Strip Mining for Coal in the Central United States

J. E. Winstead[1], M. E. Held[2], L. P. Elliott[3], M. Clauson[3];
[1]Southern Arkansas University, Magnolia, AR, United States, [2]St. Peter's College, Jersey City, NJ, United States, [3]Western Kentucky University, Bowling Green, KY, United States.

Coal extraction in the United States since the 1930's has disrupted over 2.4 million hectares of natural vegetation and although stringent reclamation controls were placed into law in the 1970's, well over 300,000 hectares remain untreated or unmanaged in such central states as Ohio, Kentucky, and Tennessee. Disturbed soils of abandoned strip mines are characterized by instability, erosion, extreme acidity, and variable nutrient levels which exposes natural vegetation development to multidimensional selection factors. Successional development studies of selected sites have been conducted since 1960 providing insight into adaptative patterns of native colonizers of the genera *Andropogon*, *Rubus*, *Bidens*, *Danthonia*, followed by *Acer*, *Platanus*, *Liriodendron*, and *Quercus*. Hardwood tree growth in basal area tends to accelerate 30 years after colonization and moderation of the initial low pH of soils. Understanding endemic plant succession on these unique habitats provides options to usual reclamation practices.

P2156. The changes in ground vegetation and pine needles chemistry after the wood ash and nitrogen application

I. Varnagiryte, R. Ozolincius;
Lithuanian Forest Research Institute, Girionys, Kaunas reg., Lithuania.

Wood ash experiment, consisting of 24 plots treated with 1.25-5 t/ha of raw wood ash, 180 kg N/ha, and control, was established in SW part of Lithuania in a 38-year-old Scots pine (*Pinus sylvestris* L.) stand in June 2002. The concentrations of the main plant nutrients (N, P, K, Ca, Mg) and some heavy metals (Cr, Cd, Pb, Ni, Cu, Zn) were determined in the moss *Pleurozium schreberi* and current and one-year-old needles 2 years after the application.

Wood ash influenced the concentrations of P, Ca and Mg in *Pleurozium schreberi*. Significantly higher N concentrations were found in the plots treated with N. There were slight changes of K concentrations in ash plots. Ash, containing low amount of metals had no effects on the concentrations of Cd, Pb, Ni and Cu in the moss. The increase trend was detected only for Zn and Cr.

The current and one-year-old needles were not significantly affected by wood ash. Mg and P concentrations increased, K and Ca have not changed. Addition of N fertilizers increased N concentration in the needles 9 months after the application, and such increase still remains. Not significant increase detected for Zn, Cd and Pb in the needles.

P2157. Biomass formation, nutrient uptake and release in fern stands Athyrium distentifolium on deforested areas affected by pollution: comparison with grass stands

I. TŢma, **K. Fiala**, P. Holub;
Institute of Botany, Academy of Sciences of the Czech Republic, Brno, Czech Republic.

The aim of this study was to compare the role of fern (*Athyrium distentifolium*) and grass (*Calamagrostis arundinacea*, *C. villosa*) vegetation on deforested areas in the Beskydy Mts. (Czech Republic). Fern stands at a lower aboveground biomass production (*A. distentifolium* 194-350 g m^{-2}*; C. arundinacea* and *C. villosa* 635 and 471 g m^{-2} - mean values) accumulated in it a large amount of nitrogen (*A. distentifolium* 5.8 g N m^{-2}; *C. arundinacea* 4.8 g N m^{-2}, *C. villosa* 5.3 g N m^{-2}). At the slower decomposition of fern litter (19-25 % dry mass of leaflets and 18-19 % stalks per year) than that of grass litter (35-54 % leaves, 17-30 % stalks), the release of Ca (54-55 %) and Mg (86-87 %) was faster and the amount of nitrogen immobilized in one year old fern litter reached up to 46 kg N per ha. However, a comparison of soil features indicates less favourable soil conditions in fern stands (lower pH values, Ca contents and Ca/Al ratios) than in grass stands. These data suggest that fern stand formation on deforested sites has not the same positive ameliorative effect on soil environment as that described for both *Calamagrostis* species.

P2158. Fen meadows: Mycorrhizal colonization and biodiversity of typical plant species

B. Fuchs[1], K. Haselwandter[2];
[1]Department of Organismic Biology, Salzburg, Austria, [2]Department of Microbiology, Innsbruck, Austria.

Fen meadows are habitats with high species diversity, covering an area constantly decreasing mostly due to human impact. As a result the plant cover and the soil micro-flora including the arbuscular mycorrhizal (AM) fungi are disturbed. Re-establishment of former conditions derives benefits from knowledge of the soil micro-flora known to improve plant fitness and soil health. Our project aims at the determination of mycorrhizal status of *Allium carinatum*, *Betonica officinalis*, *Filipendula vulgaris*, *Gladiolus palustris* and *Serratula tinctoria*, which are locally endangered. The plant species, which were collected at different states of plant development in 2003, are colonized by both, AM fungi and dark septate fungal root endophytes, some strains of which can be considered mycorrhizal. Soil parameters like pH, plant available P, total P content and soil water content were measured and spore counts carried out. The fungal symbionts were identified by partial amplification of rDNA.

P2159. Monitoring vegetation of the nothern Azov sea maritime spits in the light of modern tectonic and climate changes

O. V. Tyshchenko;
National Taras Shevchenko University of Kyiv, Kyiv, Ukraine.

Reinventorial mapping monitoring of 10 nothern Azov sea maritime spits was carried out by fixing the modern condition of spits vegetation on the large-scale (1:10000) maps and by comparison with similar previous maps (Popovych, 1936, Postrygan', 1939). It is established that the increase of meadow-halophytic, water-swamp and internal estuary aquatic vegetation on the background of the reduction of solonchak, sand-shell steppe and littoral vegetation during last 70 years testifies the common trends of spits changes - their flooding and washing out. Such changes are connected with specific natural factors - tectonic lowering of a continental crystal plate moving shelf in a zone of the Azov sea coast arrangement, acceleration of a modern stage of the Black sea transgression and anthropogenic-caused reasons - general sea pollution and intensive raising of the world ocean level, caused by global warming. Such tendencies have become menacing for International Wetlands and International Bird Areas integrity, for settlements and recreational institutions of the spits. Monitoring is aimed at a scientific recommendations to protection and use of spits nature.

P2160. Top-down control of plant ectoparasitic nematodes by soil microbes in natural coastal dunes.

A. M. Piskiewicz;
Netherlands Institute of Ecology, Heteren, The Netherlands.

This study is a part of the EU-EcoTrain project that examines and compares different mechanisms of control of plant parasitic nematodes in natural vegetation in coastal dune systems.
The objective of our research was to find which top-down mechanism (microbes, predacious invertebrates and nematodes) are responsible for the control of density of the ectoparasitic nematode *Tylenchorhynchus ventralis* in the root zone of *Ammophila arenaria* (Marram grass) in natural foredune systems. We chose *Tylenchorhynchus ventralis* because this species has 80 times lower densities in natural soil in field than in sterilized soil in optimal greenhouse conditions. We tested the hypothesis that ectoparasitic nematodes in coastal dunes can be controlled by microbial antagonists (fungi, bacteria) or/ and predacious invertebrates and nematodes. The results show that the microbes are the most important.

P2161. Research of soil-plant connections on kurgans in Hungary

E. Herczeg, K. Penksza, A. Barczi, M. Vona, Á. Malatinszky;
Szent István University, Department of Landscape Ecology, GödöllŖ, Hungary.

Authors undertook botanical and soil surveys on four kurgans of the Great Hungarian Plain with a Pürckhauer sampler and prepared coenological tables based on the the method of Braun-Blanquet. Alkaline and chernozem mosaics characterised the soil in the surrounding area of the kurgan called Csípo-halom. Botanical survey can be well compared with soil examinations. Besides weed species, several plants belonging to natural grasslands could be found as well. Near the peak, *Agropyro-Kochietum prostratae* association occurs. On the lower zone of the slope the association of loess steppe areas (*Salvio-Festucetum rupicolae*) can be found, preserving even *Festuca javorkae*. Excess water has got a significant role in soil formations of kurgan Pincés. Dryier soil occurs around the top, meanwhile, culture stratum below recent soil is dampening gradually. Kurgan Hegyes was built both of soils once generated on a loess ridge and of soils from salty wet areas. Top areas are dominated by *Agropyron repens* and *A. pectinatum*. Sides of the mound are covered mainly by *Alopecurus pratensis*, while characteristic species in the neighbourhood of the salty area is *Puccinellia limosa*.

P2162. Alterations in the soil seed bank associated with invasive species

M. Gioria, B. Osborne;
University College Dublin, Dublin, Ireland.

Alterations in soil seed bank diversity, composition and abundance could be a major factor in determining the invasive success of certain species. Analysis of the seed banks associated with two invasive herbaceous species, *Heracleum mantegazzianum* and *Gunnera tinctoria*, was investigated adopting the seedling emergence method. The diversity of seeds in the seed bank decreased in areas invaded by both species, although the impact varied with the site examined. *H. mantegazzianum* comprised approximately 60 per cent of the seed banks investigated, with a mean of 9,333 seedlings m^{-2}. *G. tinctoria* represented less than 20 per cent of the invaded seed banks, with a mean of 748 seedlings m^{-2}. Of the species present in the seed bank, grasses showed the greatest decrease in composition and abundance. In contrast, *Juncus* spp. and some forbs such as *Urtica dioica* and *Ranunculus* spp. seemed to be better represented in the invaded seed banks. Based on a depth-dependent analysis and germination patterns such as time of germination and germination rates, a transient seed bank was confirmed for *H. mantegazzianum*, whilst results for *G. tinctoria* indicated a persistent seed bank.

P2163. Flora of Lower Silesia (SW Poland) - Dynamics and Threats

Z. KŃcki, Z. Dajdok, E. SzczňŜniak;
Institute of Plant Biology, Wrocğaw University, Poland.

Lower Silesia is a part of SW Poland, it measures 19950 sq. km. Flora of this region counts about 1890 species of vascular plants, 83 % of them are native while anthropophytes make ca. 17 %. During the last century 332 species have became threatened and 63 died out. Endangered plant species represent 29 classes of plant communities. The most numerous are plants characteristic for semi-natural meadows, swards and thermophilous margins, open rock communities and peat-bogs. The most important reason of threat is loss of habitats due to degradation, fragmentation, exploitation and abundance of traditional farming. Apart from the process of extinction the enlargement of flora is also observed, but only three of recently discovered species are native: *Trichomanes speciosum*, *Coleanthus subtilis* and *Crassula aquatica*. The other are kenophytes which make about 10 % of the flora, some of them became invasive and have negative impact on diversity of species and habitats, mainly river valleys.

P2164. Biodiversity decline as a consequence of overgrazing in semiarid grasslands of Mexico

T. J. Arredondo, E. Huber-Sannwald;
Instituto Potosino de Investigacón Cientifica y Tecnologica, San Luis Potosi, Mexico.

In semiarid grassland ecosystems, land conversion to agricultural land and changes in grazing regimes are the two most important factors determining biodiversity loss at both the species and genotype level of plants. Semiarid grasslands in Mexico cover around 100000 Km2 but are one of the most deteriorated ecosystems of the country as a result of the interacting effects of overgrazing, long periods of drought and increasing rural development. We examined how decades of overgrazing and drought affect the diversity in these grassland ecosystems both at the species and genotype level, the latter of the most abundant grass species Bouteloua gracilis and compared these observations with plant community characteristics from areas which were allowed to recover from grazing pressure for the past 20 years. Our results show that a drastic decline in the abundance of the key species changed productivity and soil water dynamics to a larger degree than would have been expected from loss in plant cover alone. Hence, changes in species diversity and genetic diversity of Bouteloua gracilis affect community resilience and ecosystem function.

P2165. Effects of climate warming and species richness level on grassland biomass production

H. J. De Boeck, C. M. Lemmens, I. Nijs, R. Ceulemans;
University of Antwerp, Wilrijk, Belgium.

Using assembled grassland mini-ecosystems inside greenhouses, we tested for effects of both climate warming (+3°C) and species richness (communities of 1, 3 or 9 species) on plant biomass production. Warming resulted in lower production, both above and below-ground, probably due to increased water stress. Species richness stimulated above-ground biomass production in 3-species ecosystems, while it did not interact with the induced warming. Richness increased root production only in unheated 9-species communities. Below-ground biomass distribution was affected by warming, with lower root production especially near the surface in heated communities. Species richness did not alter root distribution significantly, suggesting little or no increase of below-ground complementarity. Analysis of above-ground biomass showed a slight positive complemenarity effect in multi-species communities, however. Species reacted differently to warming and the number of species in the community, but no net selection effects were observed. In conclusion: warming surpressed biomass production, while the influence of species richness was more variable.

P2166. Phenological responses to snow cover and temperature in snowbed species of the Central Alps

K. Hülber[1,2], M. Gottfried[1], K. Reiter[1], G. Grabherr[1];
[1]Department of Conservation Biology, Vegetation and Landscape Ecology, Vienna, Austria, [2]Vienna Institute for Nature Conservation and Analyses, Vienna, Austria.

Cold temperatures and short growing seasons constrain life cycles of snowbed species, which leads to a highly adapted timing of sexual reproduction. Temperature and winter precipitation, the main factors determining growing season length in snowbeds, are predicted to change under global warming, but the degree of impact on phenology will strongly depend on the environmental factor triggering the development of plants. We examined the influences of snow cover duration and temperature on phenology of selected snowbed species.

Phenological development strongly depended on the time of snowmelt. The earlier a plant became snow free the earlier all phenological phases were attained, but the time to reach a certain stage decreased with delayed snowmelt. Plants becoming snow free late in the year required significantly higher night temperatures to reach a given phase with the differences increasing from buds to fruits but there was no clear pattern for total temperature sums. We conclude that phenological development can mainly be accelerated by warm summer nights and that impacts of climate change will be particularly strong if night temperatures increase.

P2167. Responses of Arctic tundra plants exposed to extreme temperature events

F. L. Marchand, I. Nijs, L. Beyens;
University of Antwerp, Antwerpen, Belgium.

As the IPCC scenarios project extreme temperature events to increase in frequency, we exposed Arctic tundra plots during 8 days to a temperature rise of circa 9 °C, induced by infrared irradiation. Performance, both at plant level and ecosystem level, was improved during the heat wave. However, afterwards, heated plants were more stressed than unheated plants, probably because they acclimated to warmer conditions and experienced the return to ambient as stressful. Nevertheless, if higher temperatures were combined with desiccation, plants were stressed already during the heat wave. As heat waves are often ensued by desiccation, more frequent extreme temperature events in a future climate can alter/harm ecosystem dynamics. Furthermore, differences between species indicate that temperature extremes may play an important role in changing competitive interactions and thus in affecting community composition. As heated plots were a smaller sink compared to unheated plots during the heat wave, more frequent extreme temperature events may shift this biome towards a source and stimulate climate warming through positive feedback.

P2168. Global change impacts plant-insect interactions: effects on tree chemistry and insect performance

C. Schafellner, P. Baier, A. Schopf;
Department of Forest- and Soil Sciences, University of Natural Resources and Applied Life Sciences (BOKU), Vienna, Austria.

We evaluated the single or combined effects of N deposition, elevated CO_2 and rising temperature on tree nutrient quality and insect performance under different aspects of plant-insect interactions. Our model systems include conifers as well as deciduous trees (spruce, beech, oak, hornbeam), generalist and specialist insect defoliators (two lepidopterans, one hymenopteran) and a tree-killing bark beetle. Insect herbivores do not receive the same level of nutrition from their host species grown under elevated CO_2. CO_2-mediated increases were observed for C-based secondary compounds and non-structural carbohydrates while levels of N decreased. Insects feeding on enriched CO_2 foliage exhibited reduced growth, but the patterns were host species-specific. The effects of increased N deposition on leaf chemistry and insect performance were generally opposite to those of CO_2 enrichment. Rising temperatures stimulated volatiles released from bark and wood thereby modifying the chemical cues that bark beetle encounter during host selection. Thus, tree-insect interactions altered by climate change may substantially threaten forest ecosystem balances.

P2169. Sensitivity of pine stands in the inneralpine dry valley Vinschgau (Italy) against drought and parasitic infection

S. Schuster, W. Oberhuber;
University, Innsbruck, Austria.

Radial cores of 120 trees were obtained from 8 black and scots pine stands (*Pinus nigra* Arn. and *Pinus sylvestris* L., respectively) exposed to soil dryness and parasitic infection. Ring widths were measured at a resolution of 1/100 mm, dated and tree ring chronologies established. Black pines showed a much higher year-to-year variability in ring widths than scots pines (35 % and 27 %, respectively), which indicates a higher sensitivity to changing environmental conditions. Climate-growth-relationships revealed strong correlations between radial growth and precipitation in spring of the current year (especially March) and previous autumn (especially October). Accordingly, striking growth reductions found in several years were linked to drought stress occurring in these seasons. Results also revealed that black pine stands infected by the pine processionary caterpillar (*Thaumetopoea pityocampa* Denis & Schiff.) showed temporarily reduced growth rates compared to non-infected stands in severe years of infection only.

P2170. Global change and trophic interactions on a boreal mire

M. M. Wiedermann[1], A. Nordin[2], M. B. Nilsson[3], U. Gunnarsson[4], L. Ericson[1];
[1]Department of Ecology and Environmental Science, Umeå University, SE-901 87 Umeå, Sweden, [2]Umeå Plant Science Center, Department of Forest Genetics and Plant Physiology, SLU, SE-901 83 Umeå, Sweden, [3]Dept of Forest Ecology, SLU, SE-901 83 Umeå, Sweden, [4]Dept of Biology, Norwegian University Science and Technology, Trondheim, N-7491, Norway.

Effects of enhanced temperature and nitrogen availability on vegetation in a boreal, oligotrophic mire were studied in a factorial design experiment, established in 1994.

Data from the period 1995-1998 show only marginal or no vegetation response. In 2003, after eight years of continuous treatment, marked changes were observed. The closed Sphagnum carpet had declined with 68% in the N treatment and 80% in the N x T treatment. The dominant vascular plants Eriophorum vaginatum, Andromeda polifolia, and Vaccinium oxycoccos showed a striking positive response to the N, T and N x T treatments. Parasitic fungi attacking the two dwarf shrubs showed species-specific responses to the treatments. High disease levels, correlating to changes in plant chemistry, and resulting in extensive host mortality were observed in the nitrogen treatment, while enhanced temperature had a negative effect on parasitic fungi. The study shows that initially positive host plant responses may after a time lag be reversed by disease. It emphasizes the importance of long-term experiments in order to understand responses upon climate change and enhanced nitrogen availability.

P2171. Anatomical Evaluation of Tree Ring Quality for Dendroecological Study of Forest Islands of “Campos Rupestres” at Serra do Cipó, Minas Gerais, Brazil.

V. Y. Jono, G. C. T. Ceccantini;
Instituto de Biociências - USP, São Paulo, Brazil.

At Serra do Cipó, Minas Gerais, Brazil, “campo rupestre” is the main vegetation type. “Campo rupestre” occurs around bedrock outcrops higher than 700 meters in altitude, in sandy, poor and scarce soils. In places protected from erosion, we found “capões de mata” which are islands of forests surrounded by fields. The dynamics of these forests are poorly known, and there is a need for better understanding of their origins. One way to understand this dynamic is the analysis of growth rings. Rings must be annual and well marked which is uncommon in tropical ecosystems. We searched for the presence of good annual rings in 17 arboreous species of 10 families. Branches of young individuals up to 5 meters high were collected and sectioned for histological analysis. Eight of the 17 studied species exhibited growth rings characterized by flat and thickened fibers. Cabralea canjerana (Meliaceae), Guatteria vellosissima (Annonaceae) and Leandra sp (Melastomataceae) showed the best rings while rings of the other species were weaker. These promising results will lead to further dendrochronological analysis of the antiquity of “capões” including their expansion and contraction.

P2172. Prioritizing conservation of medicinal plants in Sub-Saharan African forests

C. Georges Herbert;
Trafcam, Yaounde, Cameroon.

The demand for traditional herbal medicine is increasing rapidly in Sub-Sahara countries mainly because of harmful effects of synthetic chemical drugs. Harvesting plants for medicines to treat anything from mad cow disease to malaria could help alleviate the poverty of African communities. The recent upsurge in the use of herbal medicines has led to enormous commercial possibilities but many key issues remain unresolved.

However, the future of African medicinal plants lies on enhancing people’s participation in the utilization and conservation of its forests. Worldwide a total of at least 35000 plants species are used for medicinal purposes. The subcontinent has a rich floral diversity, totalling about 24 000 species, with 4 000 species used in traditional medicine.

Protection and preservation of traditional medicine, as well as African Sub-Saharan tropical forests are essential to ensure access to traditional forms of health care. Programme activities need to be supported to reduce the rate of deforestation of the African tropical forests and conserve the biodiversity contained within them.

P2173. Plant diversity, anthropisation and invasives in tropical rainforests: use of the filmy fern (Hymenophyllaceae) community as a bio-indicator in La Réunion island.

J. Dubuisson[1], S. Hennequin[1], M. Selosse[2], I. Dajoz[3];
[1]Lab. Paléobotanique et Paléoécologie, IFR 101 CNRS, Paris, France, [2]Equipe Co-évolution, Cefe-CNRS, Montpellier, France, [3]Lab. Ecologie, ENS, Paris, France.

To study the impact of human activities on indigenous plant diversity in the La Réunion endangered hygrophilous forest, we compared, in natural and exploited plots along an altitudinal transect, taxonomic diversity and ecological preferences of Hymenophyllaceae as representing a major sciaphilous hygrophilous epiphyte community in this type of forest. Regression analyses between taxonomic variables and environmental predictors evidence a significant decrease in filmy fern diversity in anthropised areas. Additional analyses performed specifically on the most abundant taxon do not reveal an anthropisation effect on its fertility despite a decrease in the number of colonies. The decrease in Hymenophyllaceae diversity might be rather due to a decrease in diversity of appropriate supports. In open anthropised plots, invasive heliophilous pests actually delay or avoid the natural rejuvenation of indigenous trees including potential supports for indigenous sciaphilous hygrophilous epiphytes.

P2174. Genetic Variability of *Quercus humboldtti* (Roble) from the “Macizo Colombiano” using RAPDs Markers.

G. M. Paz[1], J. D. Palacio[2];
[1]Universidad del Cauca, Popayán, Colombia, [2]Laboratorio de Biologia Molecular, Instituto A.Von Humboldt, CIAT, Palmira, Valle., Colombia.

The genetics impacts of population fragmentation depend upon gene flow among fragments. With restricted gene flow fragmentation leads to greater inbreeding and loss of genetic diversity within fragments. There is genetic differentiation among fragments and greater risks of extinction in the long term, than for a single population of the same total size. This populations involves some species like *Quercus humboldtii* (roble).
In this study RAPDs markers where used to estimate the levels of genetic diversity in 120 individuals from four populations in the “Macizo Colombiano” (Colombia Andes). A total of 123 loci were obtained for all populations using 6 primers, 122 of which were polymorphic. Observed heterozygosity was 0.1172 and Gst 0.1185. Based on the results presented in this study, we recomend that a small number of populations represented by large numbers of individuals will be enough for breeding and gerplasm conservation purposes, and major attention should be paid to population Riñonada for conservation.

P2175. Vegetation survey of threatened alder (*Alnus glutinosa* (L.) Gaertn. ssp. *barbata* (C. A. Mey.) Yaltirik) forests in the Caspian lowlands, northern Iran.

A. Naqinezhad[1], B. Hamzeh'ee[2], A. Ghahreman[1], F. Attar[1], M. Assadi[2];
[1]Central Herbarium, Faculty of Science, Tehran, Islamic Republic of Iran, [2]Research Institute of Forests and Rangelands, Tehran, Islamic Republic of Iran.

The lowland forest zone, one of the altitudinal zones of Hyrcanian forests in northern Iran is characterized with small fragmented remnant alderwoods, dominated or subdominated with an Euxino-Hyrcanian element, *Alnus glutinosa* (L.) Gaertn. subsp. *barbata* (C.A. Mey) Yaltirik. As these forests are isolated remnants of a formerly more widespread lowland habitat, there is no exact information available on their vegetation and flora make-up. Alder communities subjected to Analyse Factorriel des Correspondance (AFC) and Classification Asendant Hierachique (CAH) with ANAPHYTO software and synsystematically treated following the Braun-Blanquet approach. Analysis of 133 releves from eight different studied sites resulted in six vegetation units which ecologically extend from very wet to rather dryer habitats. *Alnus glutinosa* subsp. *barbata* together with *Thelypteris limbosperma* (All.) Fuchs, *Ulmus minor* Miller, *Carex acutiformis* Ehrh., *Populus caspica* Bornm., *Pterocarya fraxinifolia* (Poir.) Spach, *Pteris dentata* Forsskahl, constitute these six communities. Also the delimitation of relevant associations and upper syntaxa are discussed.

P2176. The evolution of the Pinus sylvestris L. area in the Iberian Peninsula from the last maximum glacial (21000 BP) to 2100 under climate change

M. Benito Garzón, R. Sánchez de Dios, H. Sainz Ollero;
UAM, Madrid, Spain.

The *Pinus sylvestris* L. distribution throughout the Lateglacial and Holocene is analysed using machine learning techniques (Random Forest) and environmental variables.
Old scenarios which set off during the Last Glacial Maximum (21000 BP and 6000 BP PIMP scenarios) as well as future predictions (IPCC A1, A2, B1, B2 scenarios) have been used.
Our results show an area reduction during the LGM and a later spread agreeing with the recovery initiated 6000 years ago. The presence of isolated populations at low altitudes could show the migratory paths followed by the Northeuropean taxa.
Even the less drastic future scenarios illustrate a rather fast decrease in the Iberian *Pinus sylvestris* area. Its distribution is restricted to the Northern mountains at the most elevated cotes disappearing from the Southern and Centre montane areas.
Pinus sylvestris reachs at the Iberian Peninsula its Southern limit. This work shows the global warming effect over this kind of taxa and denotes the relevance of this tool for land conservation and management.

P2177. Herb-chronology - a handle on growth responses of perennial forbs to changing environments

H. Dietz, G. von Arx;
Geobotanical Institute ETH, Zurich, Switzerland.

Analysis of annual rings in the roots of perennial forbs (herb-chronology) may be used to reconstruct fluctuations in growth due to environmental variation. Here we ask whether and how growth trajectories of forbs change along strong environmental gradients at various scales and whether climatic fluctuations impact plant growth on top of such responses. Both forbs growing in alpine snowbank gradients and forbs occurring over pronounced elevational gradients showed considerable changes in growth patterns during their life that may be interpreted as adjustments of individual life histories. In addition, a synchronous impact of strong, large-scale climatic events on growth increments in the roots could be confirmed for a wide range of forb species in various habitats of the Swiss Alps and the continental US. Our results suggest that herb-chronology is a valuable approach to investigate how gradual environmental change (e.g. global change) and a higher frequency of climatic extremes may affect the growth behaviour and competitiveness in perennial forbs.

P2178. Climate Effects on Steppe Ecosystems and Land-use in the southern Russia

N. A. Volkova;
Institute of Water Problems of Russian Academy of Sciences, Moscow, Russian Federation.

Steppe zone in Russia has been extensively used in agriculture for 200 years. Under conditions of destabilized environment and modern climate fluctuations (increase of precipitation) new hydromorphic ecosystems are formed on the watersheds and their slopes. Increase of precipitation by 30% (comparing with long-term annual amount) and warm winters occurrence lead to abrupt jump of the waterlogged areas. Though the changes are not statistically significant (poor trends) it leads to tremendous changes of environment- these ecosystems are characterized by surplus stored moisture and high salinization of chernozem soils. Therefore these high productive soils are degrading and are replaced by fallow lands. Weed communities (reed, thistle, ambrosia, etc.) are formed. They don’t maintain steppe biodiversity and are considered as sources of biological pollution. It’s necessary to carry out monitoring of the hydromorphic ecosystems in order to make prognosis of their state and to manage the environment properly.

P2179. Impact of climate change on the coastal flora of Germany

D. Metzing;
Fak. 5: Institut für Biologie und Umweltwissenschaften, Universität Oldenburg, Oldenburg, Germany.

To evaluate the climatic sensibility of vascular plant species occurring at the German coast (North Sea and Baltic Sea), climate envelopes has been estimated for 223 taxa. Correlation of distribution patterns and climatic data allows a prediction of area dislocations caused by climatic change for particular plant taxa. Under a high scenario (warming of 2.5 K up to 2050), the climate envelopes for about 30% of the species in the model show either an expansion or a reduction within the area of the German coast. The warming of 2.5 K equals a spatial shift of about 400-600 km. The speed, at which coastal species will really react to climate change depends mainly on characteristics of their life cycle, seed dispersal as availability and fragmentation of suitable habitats, too. Dispersal by sea current, tidal movement, and wind drift along the coastline will happen faster than for species of mainland biotopes, as potential dispersal routes here are not fragmented as they are in cultivated landscapes. Hence, the German coast is an appropriate area to establish monitoring programs with the aim to detect species shifts caused by climate change and to improve the predictive models.

P2180. Fluctuations of Festuca varia grassland (Teberda Reserve, the Northwestern Caucasus, Russia) over 18 years

T. G. Elumeeva;
Moscow State University, Moscow, Russian Federation.

Dynamic of an alpine plant community dominated by tussock grasses Festuca varia Haenke and Nardus stricta L. was studied at the Mt. Malaya Khatipara (2750 m a.s.l.) in the Teberda Reserve, the Northwestern Caucasus. During the period 1987 - 2004 we counted shoot number of all plant species on 40 permanent plots 25×25 cm (total area 2,5 m2). We selected 22 abundant species for detail analysis from total number of 43 recorded over 18 years. We recognized three groups of species according to their dynamic behavior. Shoot number of Calamagrostis arundinacea, Campanula collina and Galium verum increased significantly ($p < 0,01$) over the observation period. Abundance of these species was positively correlated with maximal winter temperatures of the previous year. Shoot number of Campanula tridentata, Carex atrata, Matricaria caucasica, Minuartia aizoides and Viola altaica decreased significantly during the period of observation. Other species including main dominant Festuca varia did not show directional changes. Their number was correlated with various meteorological parameters of the previous and current years.

P2181. Phenological and physiological responses to drought of Pinus halepensis in a climate transition zone.

K. S. Maseyk[1], T. Lin[1,2], E. Rotenberg[1], J. Gruenzweig[1,3], A. Schwartz[3], D. Yakir[1];
[1]Weizmann Institute of Science, Rehovot, Israel, [2]Henan Agricultural University, Zhengzhou, China, [3]Hebrew University of Jerusalem, Rehovot, Israel.

Relatively rapid climate change will induce unknown adjustments in ecosystem function and distribution that depend on inherent abilities to respond to the new conditions. Of particular importance in many regions is the effect of increasing drought. We explore this issue by taking advantage of a *Pinus halepensis* afforestation site in a Mediterranean - Semi-arid climate transition zone, where summer drought of up to 8 months spans most of the annual foliage growth period. Hence survival depends on meeting both the phenological demands and physiological stress responses. From measurements under the natural drought and summer irrigated conditions we show that the trees have both fixed and flexible phenological responses, and up-regulate drought and damage avoiding strategies to maintain consistent, although reduced, foliage growth. Fully functional new foliage at the start of the wet season then enables optimal carbon gain through the favourable period. In addition, a strong down-regulation of summer time respiration minimizes carbon losses, and the forest is able to sustain a level of productivity that is of a similar order as ecosystems of more mesic regions.

P2182. Long-term reaction of four alpine communities for ecological conditions change: results of 16-year transplantation experiment

I. Ilina;
Moscow State University, Biological Faculty, Moscow, Russian Federation.

This work is devoted to investigation of relationship between different species and influence of abiotic factors on develop of alpine communities. The experiment was carried out in 1989 on Mt. Malaya
Khatipara at 2800 m a.s.l. in the Northwestern Caucasus, Russia. The experiment consisted of reciprocal transplantation between four investigated communities. For 16 years of observation species composition of investigated plots significantly has changed. This included significant changes in shoot amount of several species as well as introduction of species from surrounding communities. The reaction of the same species had appeared unequal in conditions of different treatments, and reaction of different species in the same conditions also was unequal. We conclude that alpine communities include species of different ecological requirements. There are species, for which the ecological optimum coincides with their real habitat, and the species, which with larger success develop in other ecological conditions.

P2183. Medicinal and aromatic plants of mountainous grasslands in Serbia

I. I. Sostaric, S. B. Acic, Z. P. Dajic Stevanovic;
Faculty of Agriculture, Belgrade, Serbia and Montenegro.

In order to estimate biodiversity and utilization potential of grasslands of the hilly-mountainous regions in Serbia, it was analyzed the presence of medicinal flora in 12 widespread communities of the classes Festuco-Seslerietea, Nardo-Callunetea and Juncetea trifidi. In these plant associations 88 medicinal and aromatic plants from 58 genera and 28 families were recorded, which accounts to 44.44% of the total number of medicinal plants officially registered in Serbia. The special attention was paid to endangered, vulnerable and locally rare plants, as well as those whose irregular exploitation may cause risk for survival of their populations. Among them the following species may be designated: *Veratrum album*, *Arctostaphyllos uva ursi*, *Vaccinium vitis-idaea, Satureja sp., Orchis sp., Micromeria sp*., etc. High floristic diversity of medicinal plants of analyzed meadow and pasture communities indicates the opportunity for alternative managing of such natural resources other than traditional agriculture, but concomitantly warn for necessity of sustainable exploitation and protection of particular areas where rare medicinal plants grow.

P2184. Synanthropisation versus changes in vertical distribution of vascular plants in Slovakia (Central Europe)

P. Strba, A. Gogolakova;
The Constantine Philosopher University, Faculty of Natural Science, Department of Botany and Genetics, Nitra, Slovakia.

The knowledge base of actual distribution area provides opportunity for evaluation of long-time changes in distribution and thus consequently provides opportunity for supposition of next changes in vegetation structure and potential endanger of worthful natural ecosystems by synanthropic and invasive species' extension. Besides the progressive, gradual extension, there can be often observed the spontaneous “jump-extension“. Vertical distribution of vascular plants was observed by GPS equipment in selected Slovak mountains during 2000-2004. According to the type of biotope and main way of distribution we recognize the species on the road-sides, in settlements, at down-hill tracks and mountain peaks. We observed new altitudinal maxima in Slovak flora and more synanthropic plant species on the vertical boarder of their distribution in West Carpathians. Spreading of species in the higher altitude is influenced by tourism, transport development and gradual climate change, too.

P2185. Contributions regarding the study of the Juncetea trifidi Klika et Hadac 1944 Class in the upper basin of the Luncavat River (the County of Valcea)

M. I. Niculescu;
Faculty of Agronomie, Craiova, Romania.

The territory under research is located along the upper course of the Luncavat River and it covers an area of about 450 square kilometres. From the geo-morphological point of view, the upper basin of the river includes two, well-defined levels of relief: the mountain region, belonging to the Capatanii Mountains, in the Southern Carpathians, and the Horezu SubCarpathian Depression, which is part of the SubCarpathian region of Oltenia.
The present paper aims at presenting the associations of the **Juncetea trifidi** Klika et Hadac 1944 Class, met in the upper basin

of the Luncavat River. In the territory under research, there were identified three vegetal associations as being part of this class: *Primulo-Caricetum curvulae* Br.-Bl. 1926 em Oberd. 1957, *Oreochloo-Juncetum trifidi* Szafer et al. 1927 and *Potentillo chrysocraspedae-Festucetum airoidis* Boscaiu 1971 *(*Syn. *Festucetum supinae Domin* 1933).

The intensive grazing has a negative impact upon the vegetation in the upper basin of the Luncavat River, because of the decrease in the vegetal biomass and in the number of species with a fodder value.

P2186. Forest expansion patterns of natural forest-grassland mosaic in southern Brazil.

E. D. Forneck[1], S. C. Müller[1], **M. L. Porto**[1], V. D. P. Pillar[1], J. Pfadenhauer[2];
[1]UFRGS, Porto Alegre, Brazil, [2]TUM, Freising, Germany.

In general, the climatic conditions in southern Brazil are suitable for forests, but actual vegetation consists of a mosaic of grassland and forest. The aim of this study is to evaluate invasion patterns of woody species into grassland in Porto Alegre, Brazil, comparing possible forest expansion into grassland through encroachment of isolated shrubs within the grassland, shifting of the forest edge and establishment of Isolated Woody Patches (IWPs). We focused on floristic and structural relations under different environmental conditions. The cluster and ordination analysis show an increase in structural complexity from small to large IWPs. The structuring and expansion process lead to an increase in diversity, and are strongly related to IWP size, source distance and isolation level. Two different main patterns types were identified: first, the early IWP, with most of the species dispersed by animals and, as it get larger and structurally more complex, it become more similar to the forest edge; the other type is characterized by gradual colonization of forest woody species into the open grassland, where they exist together with grassland woody species.

P2187. Bio-Ecological Study of Some Low Grasses of Flora of Georgia

S. Isakadze;
Ketskhoveli Institute of Botany, Tbilisi, Georgia.

The aim of the study was to investigate bio-ecological and decorative characteristics of some low grasses of wild Georgian flora; to assess the possibility of application of these characteristics.

We studied 21 families, 78 genera and 210 species of low grasses which have specific shape and decorative properties.

We defined eco-morphological types of investigated low grasses: hydrophytes, heliophytes, heterophytes, kserophytes, halophytes, drought resistant, frost resistant, light demander and shade tolerant grasses. We also defined their phenological spectrum and decorative properties.

Our study confirms that low grasses developed special vegetative organs during the process of the evolution. These organs, such as root, stolon, rhizome, buble and tuber are considered as reproductive organs. They have common functions but differ in their morphological properties, which was proven by additionally performed morphogenesis on the studied species.

P2188. Populations diversity in Neotropical savannas

Z. Baruch;
Universidad Simón Bolívar, Caracas, Venezuela.

Approximately 25 % species in northern South American savannas inhabit a wide range of sites with contrasting water and nutrient availability. As land use changes and biological invasions compromise savanna's persistence and function, it is important to evaluate intraspecific diversity to select populations suited for conservation and restoration.

Venezuelan savannas were censused and ecophysiological traits of species from contrasting functional groups were determined. Isozyme diversity was measured in the prominent grass *Trachypogon plumosus*.

In all species, specific leaf area (SLA), N, P, ^{13}C content and assimilation rate varied clinally between local populations. SLA decreased towards the driest sites whereas N and P leaf content was highest in the fertile sites. Isozyme diversity in *T. plumosus* was moderately high (H = 0.291 - 0.431) and 28% of it was interpopulational suggesting local adaptations which contribute to regional diversity. If quantitative traits and isozyme differences of other species mimic those of *T. plumosus*, then the diversity of northern South American savannas should be much higher than that represented by species richness.

P2189. Important Plant Areas of Central and Eastern Europe - priority sites for plant conservation recognised.

T. Kusik[1], S. Anderson[2];
[1]Plantlife International, Bratislava, Slovakia, [2]Plantlife International, Stirling, United Kingdom.

Important Plant Areas, the best sites for wild plant and fungi conservation, have recently been identified in 7 countries of Central and Eastern Europe (Belarus, Czech Republic, Estonia, Romania, Slovakia, Slovenia), according to consistent scientific criteria - threatened species, botanical richness, and threatened habitats. Preliminary results have been reported from countries in South East Europe (Bulgaria, Croatia, Macedonia (FYR) and Serbia and Montenegro).

Important Plant Areas (IPAs) are natural or semi-natural sites exhibiting exceptional botanical richness and/or supporting an outstanding assemblage of rare, threatened and/or endemic plant species and/or vegetation of high botanical value.

Hundreds of specialists from academic institutions, state conservation agencies, and NGOs identified almost 800 IPAs for higher plants, fungi, mosses, lichens and algae. Conservation status, threats, land use and many other data were collected about IPAs to provide essential information for conservation management and planing. The results of the project are published in a comprehensive overview of plant conservation.

P2190. Floristic and phytocoenological analysis of the meadow community Agrostietum vulgare Pavl.1955 in east Serbia

S. B. Acic, S. Vrbnicanin, Z. P. Dajic Stevanovic;
Faculty of Agriculture, Belgrade, Serbia and Montenegro.

Communities of the *Agrostietum vulgare* type have being formed after cut off of the beech woods developed in the hilly-mountainous regions in east Serbia. Floristic and phytocoenological analysis of this association was performed on the basis of a survey of its 19 stands spread on the Mt. Stol in east Serbia. Besides the edificatory species, i.e. Agrostis vulgaris L., whose values of abundance and coverage were the highest (7-8 according to the scale of Westhof and van der Maarel), the following species among the total of the 125 recorded, were asigned as characteristic: *Briza media* L., *Festuca rubra* L., *F. ovina* L., *F. valessiaca* Schl., *Filipendula hexapetala* L. *Achillea millefolium* L., *Trifolium montanum* L., *T.alpestre* L. *Stellaria graminea* L., *Rhinanthus rumelicus* Vel*., Hypochoeris maculata* L., *Holcus lanatus* L., *Trisetum flavescens* (L.) P.B., and *Thymus pulegioides* L.

By use of numerical classification (Generalized Eucliden Distance) and ordination (CA analisys) it was showed that there are three coenotic blocks, indicating the differentiation of this community due to variability in habitat conditions, primarily climate and soil characteristics.

P2191. Vegetation patterns across the timberline ecotone in the eastern Pyrenees

J. Ninot[1], E. Carrillo[1], E. Batllori[2], A. Ferré[1], J. Carreras[1], E. Gutiérrez[3];
[1]Centre de Recerca de Biodiversitat Vegetal (CERBIV), Barcelona, Spain, [2]Ecology Dept., Barcelona, Spain, [3]Ecology Dept., Barcelona, Spain.

The Pinus uncinata timberline has been analysed in 12 plots representative of the diversity of conditions (topography, bedrock type, land use) in the eastern Pyrenees. In each plot -a rectangle set along the altitude gradient and including from close forest till typical alpine pasture- three data sets were carefully recorded: tree structure (including explicit individual location), vegetation (small, intensive plant relevés along the rectangle) and substrate particularities (plant cover, bare rocky outcrops, slope).

The elaboration of our data illustrates a general upslope increase of diversity at small scale, which becomes the most pronounced not exactly at the timberline, but higher, coinciding with the decline of sub-shrubs. Site conditions (bedrock type, skeletal soils, 'natural' vs. anthropic timberlines) are related to species richness at bigger scale, definition of particular ecotone communities, or other particular trends. Upwards timberline displacement cannot be forecasted as general; where previewed, it would mean some reduction in the area of alpine pastures against more rocky surfaces.

P2192. Diversity of grassland flora and vegetation after several decades of land use changes

M. Janisova[1], E. Uhliarova[2], K. Ujhazy[3];
[1]Institute of Botany, Bratislava, Slovakia, [2]Faculty of Science, Matej Bel University, Banska Bystrica, Slovakia, [3]Faculty of Forestry, Technical University, Zvolen, Slovakia.

The detailed study of flora and vegetation was performed during the years 1994-2004 in the Protected Landscape Area and Biosphere Reserve Polana (Central Slovakia). All types of grassland ecosystems were included and compared as to the diversity of vascular plants and their communities. Phytosociological approach of the Zurrich-Montpelier school was used for the analysis of vegetation. The studied region, originally managed in the traditional manner, was subject to dramatic changes in land use since the middle of the last century. Many grasslands were abandoned or converted to the extensive use. Still, in some areas the traditional grassland management has maintained. A comprehensive analysis of distribution of both individual taxa and syntaxa supported by the analysis of relevant environmental factors was used to reveal links between the management types and the grassland diversity characteristics.

This work was supported by Science and Technology Assistance Agency
under the contract No. APVT-51-015804, and by VEGA 1/0126/03.

P2193. A study of Kotayk's (Republic of Armenia) present vegetation compared with the data of the passport system of natural fodder lands in 1946

N. H. Zakaryan;
Yerevan State University, Department of Botany, Yerevan, Armenia.

The study of the modern state of Kotayk's fodder lands vegetation, taking into account the relevant data of the passport system of natural fodder lands conducted in 1946, shows that the edificators of the natural vegetation have changed, for the last 55 years. Thus, if in 1946 edificators were *Stipa capillata* L. and *Festuca valesiaca* Gaud.*,* now they have been replaced by *Festuca valesiaca, Taeniatherum crinitum* (Schreb.) Nevski and *Artemisia fragrans* Willd.

Due to the irrational and most intensive use of those pastures, cereals and leguminous plants formations were replaced by diverse and ephemeral grasses in which weeds and other inedible plants have become prominent. Considering the total aridity of the Republic's climate, the early pasturage and excess grazing have led to emergence of the transition semi-desert vegetable grounds with *Artemisia fragrans* and *A. austriaca* Jacq. and as a result the fodder lands productivity is reduced twice.

P2194. Recent vegetation dynamics of "classical karst" (Slovenia): from habitat to landscape level

M. Kaligaric[1], M. Culiberg[2];
[1]Biology Dept., University of Maribor, Slovenia, [2]Biological Institute Jovan Hadzi ZRC SAZU, Ljubljana, Slovenia.

Cartographic material and habitat mapping were applied to reconstruct the temporal dynamics of grassland vegetation of the "classical karst" (Slovenia) for last 250 years. Pollen data were used in order to reconstruct the vegetation history of secondary grasslands since late-Holocene till Middle Ages. The 250 years old maps shows that grasslands covered 81 % of the "classical karst" pilot area of total surface of 665.8 km2. Only 25 % of the same territory was covered with grasslands in 2003. There was also substantial increase of fields, vineyards and orchards - from 1.5 to 4 % and settlements from 0.5 % to 4 %. On a sub-pilot area of 14 km2 habitat mapping in 2003 shows that less than a half of the grasslands on the sub-pilot area are still typical meadows or pastures, without signs of scrub/forest or tall-herb progression and only a few hectares are still mown or grazed. The "grassland period" of the "classical karst", associated with the beginning of civilisation and strong human influence, was neither a linear process nor a stable stage. It was a very dynamic period, with permanent species replacement due to different mode, extent and intensity of land-use.

P2195. Predicting grassland habitats distribution upon different scenarios of landscape changes

L. Halada, A. Halabuk;
Institue of Landscape Ecology, branch Nitra, Nitra, Slovakia.

Natural and semi-natural grassland habitats represent a specific feature of the Poloniny National Park (Slovakia) with the great biodiversity values. However, agricultural decline and consequent landscape changes in this region affect grassland habitats significantly. We compared grassland area and distribution in the study area in years 1949, 1987, and 2003. Significant decrease both in grassland area and structure of distribution was recorded. We attempt to predict future distribution of grassland habitat types based on different scenarios of the landscape development. The scenarios derived from different possible agricultural policies in the study area. Combination of habitat suitability modelling and landscape change modelling was used. The total area and distribution structure of respective grassland types in year 2030 upon different scenarios represent the main results of the work.

P2196. Retrogressive dynamics in the *Poion alpinae* pasturelands from the south-eastern Prealps (the Brocon Pass, Italy)

D. Gafta[1], F. Pedrotti[2];
[1]Babes-Bolyai University, Cluj-Napoca, Romania, [2]University of Camerino, Camerino, Italy.

Patches of *Trollius europaeus* assemblages (**T**) and especially, *Deschampsia cespitosa*-dominated (**D**) communities are spreading within *Poion alpinae* pastures (**P**). The ecological gradients underlying these dynamic processes were inferred by indicator species analysis performed on T, D and P releves groups, and by species response curves along the first two DCA axes. A decline in plant diversity and an increasing cover of nitrophilous species occur along the first axis, from P to T and D communities. The differentiation between T and D along the second axis is due to a decreasing cover of basophilous species accompanied by an increment of the acidophilous ones in the latter community. Whereas T forbs-dominated communities occur exclusively on dung deposits, the D ones lie on flat ridges or gentle slopes often trampled by livestock. Upper soil compaction and the accumulation of a cellulose-rich litter below the *Deschampsia* tussocks are probably responsible for the high moisture fluctuation and bases depletion. The return to a traditional use of *Poion alpinae* grasslands (alternating mowing and grazing) might stop the observed retrogressive processes.

P2197. The seedling recruitment and survival under different management regimes

K. Ļiháková;
Department of Botany, Charles University, Prague, Czech Republic.

Absence of suitable microsites is assumed to be a reason for loss of species from grasslands during degradation process. Therefore, one important aim of restoration management is to enhance the regeneration. Studies have shown that mowing and grazing promotes seedling recruitment. However these conclusions are based on single records and it is not known, whether the increased recruitment really results in higher number of established individuals.

The aim of this study is to evaluate the effect of different management regimes on seedling establishment. Abandoned pasture in Beskydy (Czech Republic), where the sheep grazing was reintroduced, was chosen as a study site. Eight blocks of permanent plots: grazed, mown and abandoned were set up for monitoring. The survival of dicots was recorded for 2 years.

The number and species composition of seedlings changed during the study period and it varied between the treatments. Overall the mortality of seedlings was very high. This shows that conclusions based on one time census only can be quite misleading. Long-term studies are needed before we conclude that the particular management can really enhance establishment.

P2198. Phytocoenotic and biogeochemical peculiarities of serpentinite steppes of Southern Ural

M. D. Ufimtseva;
Earth Crust Institute, St. Petersburg, Russian Federation.

The geochemical features of steppes landscapes are predetermined by all complex of the natural factors, mainly by lithogenic basis, which is conservative block of natural geosystems. One of the most interesting types of steppes of Southern Ural with phytocoenotic and biogeochemical positions are serpentinite steppes, which originality in arid climate is caused by direct influence of lithogenic basis. Petrophyt variants of steppes with domination of edificator Festuca valesiaca and original species-indicators are formed at close bedding of serpentinite rocks. Halophyte variants of steppes with domination of the same edificator and halophyte herbs (indicator Orostachys thyrsiflora) are formed at development of weathering crust of various genesis. Lithogenic basis predetermines also natural contents of chemical elements in plants. Ni, Co, Cr, Ti prevail in chemical structure of plants of serpentinite steppes. The concentration of accompanying elements depends on variant of steppes. The study of serpentinite flora is interesting as in evolutionary aspect, as in aspect of species tolerance to the extreme geochemical factors.

P2199. Dynamics of deserted ecosystems of Gobustan in Azerbaijan

V. J. Hajiyev, R. T. Abdieva;
Institute of Botany, Baku, Azerbaijan.

Deserted ecosystems of Gobustan, adjoining to Apsheron represent interest in connection with influence of technogenesis, proceeding on a background of actable natural ecological conditions. Formation new and serial groupings, caused by a course natural exoecogenetical changes ecotone and technogene desertification caused by the anthropogenous factor have also been observed. Species of meadow vegetations penetrate in hydrohalophyle communities or on sites of xerophyles pettyhilly deserts. Return processes have been marked also. Central Asian, Mediterranean, sometimes Transcaucasian floristic elements, in particular *Tamarix ramosissima, Halocnemum strobilaceum, Kalidium caspicum, Salsola nodulosa* and others are most active. The steppe kind *Colpodium humile* is for the present rare on degrading saline soils. Technogene character of human empact causes pollution and infringement of granulometrical structure of ground, change of a microrelief borrows the special place in this question. As consequence vegetative communities of deserts start to degrade that in general conducts to desertification of its significant territories.

P2200. The Valley of Kamienna River as a refuge of relic xerothermic vegetation in SE Poland

R. Piwowarczyk;
Institute of Botany, Jagiellonian University, Krakow, Poland.

In Poland xerothermic plants have three main centers of their concentration: in the lover parts of the Oder and Vistula rivers and uplands of southern Poland. The Kamienna river valley (left side tibutary of the Vistula) lying at the northern edge of Malopolska Upland is a significant refuge of relic xerothermic vegetation. In its territory occur some rare species in Poland, which are inserted in red data books and lists considered as an endangered. Some examples of them: *Achillea setacea, Adonis vernalis, Carex pediformis, C. supina, Cerasus fruticosa, Festuca makutrensis, Linosyris vulgaris, Orobanche alba, O. picridis, Orthanta lutea, Senecio integrifolius, Stipa capillata, S. joannis, S. pulcherrima*. The most of them have pontic-pannonian or subirano-turanian ranges. The way of migration into the Kamienna valley followed by the Vistula river. Two of metioned species eg. *Carex pediformis* and *Festuca makutrensis* have in Poland few existing sites; that make a part of their local nothern limit. This territory because of its floristic unique ought to be included to the list of protected areas in Europe scale.

P2201. Switch from facilitation into competition in an arid rangeland

M. Jnakju-Borzelabad[1,2], M. Tavakoli[2];
[1]Islamic Azad University, Meybod, Islamic Republic of Iran, [2]Yazd University, Yazd, Islamic Republic of Iran.

Plant interactions were investigated between perennial *Artemisia aucheri* and annual *Bromus tectrucm* in an arid rangeland. Temperature, luminance, and soil relative humidity were measured as paired samples from *Artemisia*-understory and neighbouring open space. Regression relationships were investigated between the microclimatic factors and *Bromus* density in understory, or *Artemisia* vigour in overstory. Our findings suggest a cyclic dynamic between the two plants. Accordingly, at the first phase there is an open space in which *Artemisia* seedlings can establish during wet years. Lower light intensity, soil temperature and evapotraspiration facilitates establishment of *Bromus* under *Artemisia* canopy. On the other hand with increasing *Bromus* density in understory, plant interactions switches from facilitation into competition which leads to lower vigour and eventual death of *Artemisia.* Water or wind erosion removes litter and accumulated soil under the dead *Artemisia*, leading to unfavourable conditions and disappearance of *Bromus*. The cyclic dynamic may also be mediated by allelopathic effects of *Artemisia* on *Bromus*.

P2202. Modification of herbaceous floodland vegetation depending on water regime changes at Gemenc, Middle-Danube-valley, Hungary

A. Márkus[1,2];
[1]Doctoral School for Botany, University of Pécs, Pécs, Hungary,
[2]Danube-Drava National Park Directorate, Pécs, Hungary.

Between 2002 and 2004 vegetation mapping and descriptions were made four times at Nagy-Gyékényes. In 2002, after the first survey, a serious flood and a long, extraordinarily high-water period occurred, followed by a longer drought in 2003. The drastically different water regime states arow each other had strong effects on vegetation. For the analysis ecological indexes and social behaviour types of species, and vegetation maps were used. The collected data simply and cleanly show that the herbaceous vegetation of the floodland reacts fast and sensitively to changes of accessible water. At first, because of the constant water coverage the species richness of the dominantly alluvial meadow vegetation, patterned based on microrelief, reduced and the dominant role was assumed by higrofilous and aquatic elements. The less water adherent vegetation types persisted only at the highest levels. In the following drought period an open herb layer remained which was soon filled up by fast propagating, disturbance tolerant weed and invasive species, furthermore the pattern became much homogenous, that all signify the vulnerability of the habitat type.

P2203. Steppe vegetation of the forest-steppe zone of Ukraine

I. A. Korotchenko;
M. G. Kholodny Institute of Botany, National Academy of Sciences of Ukraine, Kyiv (Kiev), Ukraine.

The steppe vegetation of the Forest-Steppe zone of Ukraine are diverse and endangered, now occupying less than 1% of Ukraine's area (natural percentage was ca. 30%). They belong to the class *Festuco-Brometea* Br.-Bl. et R.Tx. 1943, order *Festucetalia valesiacae* Br.-Bl. et R.Tx. 1943, and are represented by 5 alliances. Communities of the alliance *Astragalo-Stipion* Knapp 1944 unite typical steppes with domination of xerophytic herbaceous vegetation. Communities of the alliance *Fragario viridis-Trifolion montani* Korotchenko & Didukh 1997 represent the zonal meadow-steppe vegetation. The alliance *Cirsio-Brachypodion pinnati* Hadac et Klika 1944 em. Krausch 1961 contains the most mesophytic extrazonal meadow steppe communities, which are climatically and edaphically defined. Communities of the alliance *Festucion valesiacae* Klika 1931 are formed due to anthropogenic transformation of the plant cover and represent various stages of overgrazing. Communities of the *Artemisio marschalliani-Elytrigion intermediae* Korotchenko & Didukh 1997 alliance are formed on steep slopes with denuded soils and a mosaic herbaceous plant cover.

P2204. Taiga-steppe communities of the Baikal region (Eastern Siberia)

A. P. Sizykh;
Institute of Geography, Siberian Branch, Russian Academy of Sciences, Irkutsk, Russian Federation.

The presence of undergrowth and pine and larch saplings in steppe grass communities is indicative of trends toward a spatial expansion of tree ecobiomorphs in connection with an increase in yearly mean precipitation in the Prebaikalia for the last 30 years. There has been a reduction of areas occupied by steppe communities, and an active penetration of mesophytes into steppe coenoses. There is a spatial expansion of mosses characteristic for the polydominant light-coniferous - dark-coniferous taiga.

The structure of the taiga-steppe communities may be represented as a system where the coenoses consist of the tree layer dominated by pine or larch. The soil cover includes the species composition of different variations, and often complexes of mosses and xerophytes. The taiga-steppe communities are characterized by the one- or two-age composition of tree species, and by the polydominance of the shrub zone and grass cover depending on the type of coenose habitat.

P2205. Testing for belowground resource partitioning in experimental grassland communities

S. von Felten[1], M. Scherer-Lorenzen[2], N. Buchmann[2], B. Schmid[1];
[1]Institute of Environmental Sciences, University of Zürich, Switzerland,
[2]Institute of Plant Sciences, ETH Zürich, Switzerland.

Niche differentiation due to resource partitioning is a possible explanation for positive diversity-productivity relationships in terrestrial plant communities. However, experimental evidence for resource partitioning among different plant species is scarce. In addition, it is far less known whether niche separation can change along gradients of increasing species diversity. In a temperate grassland field with experimental communities of different plant species richness we tested for resource partitioning of soil nitrogen between plant species in monocultures, 3-species and 6-species mixtures. Nitrogen uptake by plants was tracked using 15N-tracer solutions and determination of the 15N/14N ratio in aboveground plant material after 48h of incubation. Six different treatment combinations consisting of three different chemical forms of 15N-labelled nitrogen (nitrate, ammonium and glycine) injected at 2 depths (3 and 12cm) were applied to each community in a split plot design.

We present species-specific nitrogen uptake patterns and discuss how these are related to niche separation along the existent gradient of plant species richness.

P2206. Contributions regarding the study of the Juncetea trifidi Klika et Hadac 1944 Class in the upper basin of the Luncavat River (the County of Valcea)

M. I. Niculescu;
Faculty of Agronomie, Craiova, Romania.

The territory under research is located along the upper course of the Luncavat River and it covers an area of about 450 square kilometres. From the geo-morphological point of view, the upper basin of the river includes two, well-defined levels of relief: the mountain region, belonging to the Capatanii Mountains, in the Southern Carpathians, and the Horezu SubCarpathian Depression, which is part of the SubCarpathian region of Oltenia.

The present paper aims at presenting the associations of the Juncetea trifidi Klika et Hadac 1944 Class, met in the upper basin of the Luncavat River. In the territory under research, there were identified three vegetal associations as being part of this class: Primulo-Caricetum curvulae Br.-Bl. 1926 em Oberd. 1957, Oreochloo-Juncetum trifidi Szafer et al. 1927 and Potentillo chrysocraspedae-Festucetum airoidis Boscaiu 1971 (Syn. Festucetum supinae Domin 1933).

The intensive grazing has a negative impact upon the vegetation in the upper basin of the Luncavat River, because of the decrease in the vegetal biomass and in the number of species with a fodder value

P2207. The effect of slug grazing on vegetation development and plant species diversity in an experimental grassland

H. Buschmann[1,2], M. Keller[1], N. Porret[1], H. Dietz[1], P. J. Edwards[1];
[1]Geobotanical Institute, Swiss Federal Institute of Technology Zurich, Switzerland, [2]Albrecht-von-Haller-Institute for Plant Sciences, University of Göttingen, Germany.

Generalist herbivores such as slugs have the potential to alter species diversity within vegetation.

We investigated the influence of slugs on plant species diversity in experimental grassland swards in field plots. Half of the plots were grazed by slugs (Arion lusitanicus).

Vegetation cover increased in the control plots from 50% in the first year to 90% in the third year. Cover was significantly lower in the slug plots in the first year while there were only small differences between treatments in the third year. Slugs reduced total aboveground biomass by more than 25% in both the first and third years.

Slugs had a negative impact on plant species diversity in the first year. In contrast, plant species diversity after three years was higher in the slug plots than in the controls.

Our results suggest that the effect of slugs upon plant species diversity changes during the course of succession. In the earliest stages slug grazing leads to reduced species diversity because favoured species are eliminated. In closed vegetation slugs may reduce the dominance of the more competitive species. As a consequence, slugs tend to cause an increase in plant species diversity.

P2208. Changes in mosaics of steppe slopes and rocky grasslands at the Balaton-highlands (Transdanubia, Hungary: Aszófo: Öreg-hegy, Balatonfüred: Péter-hegy, Litér: Mogyorós-hegy)

N. Bauer[1,2];
[1]University of Pécs, Pécs, Hungary, [2]Hungarian Natural History Museum, Department of Botany, Budapest, Hungary.

At three dolomite hills of the Balaton-highlands 50-50 pseudorandom coenological recordings (1x1 m) where carried out on rocky steppe slopes at 50x50 m plots in 2001 and 2003. Based on the classification (Glob. opt.) and ordination of the 300 datasets the followings are noted: The surveyed plots are mosaics of minimum three plant associations: 1. Chrysopogono-Caricetum humilis (C-C), 2. Stipo eriocauli-Festucetum pallentis (St-F), 3. Seseli leucospermi-Festucetum pallentis (Se-F). These associations appear as mosaics and are embedded in each other at variable rates. Clear stands, in the classical coenological sense, can be recorded only by aimed sampling and, at some places, with much smaller sampling units only Among the three sample plots smaller macroclimatic (decreasing amount of precipitation eastward) and mesoclimatic (decreasing forestation eastward) difference is characteristic. At the western plot which is mosical with karst shrub-forests it is the more closed (C-C), and at the Eastern plot it is the more opened (St-F) types of datasets that become dominant in the rocky grassland-steppe slope mosaics characterized by variable patch sizes.

P2209. Connection between geobotanical factors, landscape changes and human endangerment on the eastern part of the Dorozsma-Majsaian Sanlands, Hungary

J. Deák, I. Bárány-Kevei;
University of Szeged, Department of Climatology and Landscape Ecology, Szeged, Hungary.

The making of the actual biotop-map of the Dorozsma-Majsaian Sandlands on 1:25,000 scale started 3 years ago. In this work the connection between geomorfology, soils and vegetation was studied. It resulted that the sandveil-hills covered by humic sand soil are dominated by sandy steppe-fields.

In the depressions a new phenomen was found: the Molinia fens are situated on the northwestern parts (fenhead) while the alcali-sodic vegetation can be found only at the southeastern parts (alcali-sodic foot). The fenheads have carbonated meadow soils or boggy meadow soils while the alcali-sodic feet have carbonated solonchak-solonetz soils.

A landscape scale gradient was also found here. It means that some of the components of the alcali sodic vegetation types disappear westwards. It is also typical that westwards the open sandy grasslands become more common, while on the eastern parts just sandy steppe-fields can be found. The Molinia fens are more common in the western and mid-part of the Dorozsma-Majsaian Sandlands.

On a smaller sample area the history of the landscape was studied with the help of the 1st (1764-1787), 2nd (1806-1869) 3rd (1872-1887) millitary surveys.

P2210. Primary production and biomass of Sabarmati estuary in the gulf of Cambay, Gujarat, India

S. B. Prajapati, B. R. Pandit;
Department of Life Sciences, Bhavnagar, India.

The present study focus on the spetial and seasonal pattern of phytoplankton density, chlorophyll -a as a phytoplankton biomass and primary production in relation to some hydrographical parameters were studied for two years at five sites of the Sabarmati estuary, in the Gulf of Cambay, India, for Two years [December 2001 to December 2003.]

The phytoplankton population density varied from 980 to 2730 cells per liter. it was higher during winter season at all the sites and low during monsoon season. The pigment concentration particularly chlorophyll-a as a biomass was observed between 0.60 to 2.45 m/m^3. The maximum values were observed during winter, while lower during monsoon. The gross primary production varied between 0.0031 to 0.072 mg. carbon fixed per litter per hour.The fluctuations in some of the environmental characteristics i.e. physicochemical parameters characteristics, minerals and trace metal concentration in water have been discussed with their relative influence on the production of phytoplankton and primary production.

P2211. Apparently well-known diatoms can produce unexpected offspring

D. T. Rose, **R. Trobajo**, E. J. Cox;
The Natural History Museum, London, United Kingdom.

Whatever organisms are used, biomonitoring rests on the reliable recognition of taxa of known ecological ranges and tolerances. Diatoms are routinely used to assess river trophic status, with some taxa designated as organic pollution indicators, e.g. *Gomphonema parvulum* and many *Nitzschia* spp. Although there are exceptions, many diatoms undergo marked size reduction over their life cycle, and the extremes of the size range may appear unrelated. Observation of sexual reproduction is required to link the different morphs. Sexually reproducing clones of two *G. parvulum* varieties in culture produced offspring identified as *G. gracile* and *G. hebridense*, neither of which are considered pollution tolerant. Similarly, sexual reproduction in a small *Nitzschia* (*N. frustulum* complex) also produced markedly different offspring. The implications of these findings for diatom taxonomy and for the use of such species as bioindicators will be discussed.

P2212. Trophic Status Of The Lakes Of Bhopal,India

P. Patil;
Govt. M.L.B. Girls Post Graduate (Autonomous) College, Bhopal, India.

The present paper deals with an assesment of trophic status of the lakes of Bhopal by using Nagaard's compound quotient .There are a number of water bodies in Bhopal , the capital city of Madhya-Pradesh .The most famous among them are the twin lakes called the "Upper Lake" and the "Lower Lake " . The Upper Lake is the main source of drinking water for the city and is partly influenced by human activities .While the Lower Lake ,which occupies the central position in a thickly urbanized locality,has greater man-made disturbances .Both the lakes are being polluted by the domestic sewage and other recreational activities .As a result there is a gradual deterioration of water quality which in result affects the composition of algal flora.

Monthly algal collection were made from each lakes and water samples were analysed for different physio-chemical parameters.A total number of 603 taxa belonging to 158 genera have been identified .Out of the 603 taxa described ,27 have been considered as new record for India .These were grouped according to classes to calculate Nagaard's compound quotient to show the degree of eutrophication.

P2213. The microphytobenthos of Kyiv site of Kaniv reservoir

L. P. Yarmoshenko;
Institute of hydrobiology of NAS of Ukraine, Kyiv, Ukraine.

The microphytobenthos structure of Kyiv site of Kaniv reservoir and in particular the effect of daily mode of operations the Kyiv hydroelectric power station to structure and primary production of microphytobenthos have been investigated. Sharp reduction of quantitative indexes of algae and change in dominant complex structure after achievement of maximum water level was established.

The values of gross primary production and destruction in benthos were shown to fluctuate widely under effect of many interdependent and interaction factors, mainly hydrological and light modes, depth, type of soil, structure of the communities of thicket of aquatic macrophytes. Maximum values of primary production have been registered under stable hydrological conditions. It was ascertained that the values of gross and net primary production both on sites without thicket of macrophytes and on sites with thicket, decrease under influence of the raising of water line. The parameters of destruction in benthos on sites without thicket considerably increased, probably because of addition of chemical oxidation of the regenerated forms of chemical compounds of bottom sediments.

P2214. Biodiversity Study Of Cyanophyceae Algae Of Haranbari Dam And Mausam River Of Maharashtra (India)

S. N. Nandan;
S.S.V.P.S'S.L.K. Dr. P.R. Ghogrey Science College, Dhule, India.

Taxonomical studies of algae from various aquatic habitats were studied extensively in India but very few workers have paid attention on these aspects in Maharashtra state of India. To fulfill the lacuna in this field the present investigation was carried out by selecting Haranbari dam and Mausam river from Baglan region of Nashik district of Maharashtra state. In present investigation bio diversity study of Cyanophyceae algae was made during July 1998 to June 2000 , Eighty three algal taxa belonging to twenty five genera Cyanophyceae were recorded from Haranbari dam and Mausam river from Baglan region of Nashik district of Maharashtra state. In present study the class Cyanophyceae of algae is mainly represented by the species of *Microcystis, Chroococcus, Gleocapsa, Aphanocapsa, Synechococcus, Gomphospheria, Merismopedia, Johannesbaptistia, Hydrococcus, Arthrospira, Spirulina Oscillatoria, Trichodesmium, Lyngbya Nostoc, Schizothrix, Anabaena, Pseudoanabaena, Raphidiopsis, Microchaete, Homeothrix, Calothrix, Rivularia* and *Gleotrichia*. Twienty two species of *Oscillatoria* were recorded in present study.

P2215. Some Epipelic and Epiphytic Algae from Jajrood River Iran

F. Jamalloo, F. Fallahian, T. Nejad sattary;
sience and research campus islamic azad university, Tehran, Islamic Republic of Iran.

Diatomes are important part of algal assemblages in aquatic ecosystem . Both Epipelic and Epiphytic flora are major constituents of the algal assemblages . There algae are base of food chain in aquatic ecosystem . The survey was conducted on jajrood river . Epipelic and Epiphytic samples were gathered on monthly intervals from June 2004 through April 2005 . In this study 25 Genera were identified .*Cymbella* with 13 species showed high species diversity.

In epilithic samples *Diatoma* with 8 species was abundant from identified species .17species was observed in epipelic samples and 19 in epiphytic. 66 species were common in both samples .some more encountered species of Diatomes were:

Cymbella ,Diatoma,Navicula,Nitzschia,Cocconeis,Gomphonema, Cymatopleura,Didymosphenia,Melosira,Stephanodiscus,Amphora, Synedra,Hannaea,Tetracyclus,Achnanthes,Surirella,Achnanthidium, Peronia.

P2216. The influence of air pollution on the cell size of Xanthoria parietina phycobiont

A. K. Eskova, T. Y. Tolpysheva;
Moscow State University, Moscow, Russian Federation.

Lichens are widely used as bioindicators of pollution level. Phycobiont of lichens is probably more sensitive to pollution than mycobiont.

Lichens of 18 sites in Moscow and Moscow region were studied. *Xanthoria parietina* was found on 16 sites. The phycobiont of *X. parietina* is the green alga *Trebouxia*. The lichen was found on 10 of examined 17 tree species.

Cell diameter of phycobiont ranged from 6.25-16 µ, depending on level of pollution and substrate type. Phycobiont diameter in lichens collected on an unpolluted site did not depend on substrate type.

The smallest cells of phycobiont were in samples of lichens collected on sites with high local level of pollution. Maximum size of phycobiont cells was registered on sites with medium local level of pollution. Medium size of phycobiont cells was registered on sites with low local level of pollution and in lichens of unpolluted site (Tver region).

Size of phycobiont cells can be used as criterion for local level of pollution.

P2217. Dredging impact on the epipelic diatom species composition on mudflat from the Bahía Blanca Estuary (Argentina)

N. V. PIZANI, E. R. PARODI;
Universidad Nacional del Sur e IADO, Bahía Blanca, Argentina.

The dredging in areas of intense harbour activity is cause of considerable alterations in the conformation and dynamics of the biological communities. The aim of this work was to analyse its effects on the epipelic diatom species composition. The study was conducted in muddy tidal flats in Puerto Rosales (38° 53´S 62° 06´O) after 10 days from a dredging, in low tidal conditions. Observations were carried out parallel to the coastline from the dredging site (E3) and other two stations (E2 and E1) 200 m away. Diatom assemblages and density were sampled by the lens tissue method. The nearest station of the dredging zone (E3) showed only fine sediment particles and scarce frustules rest of phytoplanktonic diatoms that indicated the major disturbance due to deposition particles produced by nearby dredging. There were important taxonomic structural changes in the diatom-dominated and no differences in their density between the rest stations. E2 was dominated by *Surirella minuta* while in the farthest (E1) *Cylindrotheca closterium* and *Gyrosigma spencerii* were the most abundant. The presence of alive benthic diatom populations indicated an active biogenic process.

P2218. Communitary structure of algae in relation with physical and chemical parameters of the Laguna Piaz, la Libertad,Peru

N. C. Flores;
Universidad Nacional Mayor de San Marcos, Lima, Peru.

The composition and communitary structure of microalgae was studied in a lake of Peru, which had a strong influence by gold mining activity.

Contamination by arsenic, lead and zinc was found in the main tributary and the initial and medium zone of the lake; it had reported the variability of physical/chemical characteristics of the water during three years and within different seasons between 1999 and 2002.

A total of 55 species have been found; where Scenedesmus bijuga, Oocystis parva, Cosmarium quadratulum and Coelastrum proboscideum presented the greater occurrences and abundances. The diatoms Nitzchia palea and Navicula pseudobryophila presented a greater occurrence in the lake and the main tributary. It was the first time that it has been registered in Peru what kind of species lives in this ecosystem.

The ecosystem of lake has a low abundance, low diversity, dominance and a few temporary variations of species.

The cluster and correspondence analysis established the associations of the algae communities, the distribution of species in relationships with the physical/chemical parameters.

P2219. Phytodetection of ambient ozone toxicity in Ukraine

O. B. Blum[1], N. P. Didyk[1], L. A. Popovicheva[1], C. Saitanis[2];
[1]M. M. Gryshko Natl. Botanical Garden, Natl. Acad. Sci. of Ukraine, Kyiv, Ukraine, [2]Agricultural University of Athens, Athens, Greece.

Ambient ozone toxicity using ozone sensitive (Bel-W3) cultivars of tobacco (*Nicotiana tabaccum*) and clover (*Trifolium subterraneum* cv. Geraldton) was assessed. Test-plants cultivated in ozone-free air were exposed in the field (Natnl. Bot. Garden, Kyiv, Ukraine) during the summers of 1995 and 2004. The ambient ozone concentrations were continuously monitored by UV ozone analyzer and the moving average of the short term AOT40 were calculated. The antioxidants substances EDU, quercetin and catechin, the fungicide agrochemical “Topaz” (containing 10% of penconazol), as well as water extract from leaves of marigold (*Tagetes patula*) were applied as foliar sprays. The results obtained shows that ambient ozone concentrations were high enough to cause visible leaf injury in subterranean clover and tobacco. The short term AOT40 was positively correlated with visible injury. Not only had the well-known EDU protected test-plants against ozone, but also other applied antioxidants.

P2220. Ozone injury and antioxidative substances in *Trifolium* and *Centaurea*.

J. F. Severino[1,2], K. Stich[2], G. Soja[1];
[1]ARC Seibersdorf research GmbH, Seibersdorf, Austria, [2]Vienna University of Technology - Institute of Chemical Engineering, Vienna, Austria.

Ozone-sensitive (NC-S clone) and resistant (NC-R clone) plants of white clover (*Trifolium repens*) and brown knapweed (*Centaurea jacea*) have been used in an open air experiment to analyse the development of visual ozone injuries and antioxidant concentrations. Visible injury assessments and harvests were performed as indicated in the protocol of UN-ECE ICP-Vegetation. Between August and October 2004, leaf material of different ages with and without visible ozone injuries was collected for chemical analysis of ascorbic acid, total phenolics and antioxidative capacity. Ascorbic acid (AA) concentrations of young *Centaurea* leaves (1 week) were about 100 % higher than in old ones (10 weeks). Ozone-injured leaves were by 25 % lower in AA than healthy ones. Age differences (1 vs. 4 weeks) in AA concentrations of clover leaves were mostly <10 %. Leaves of the resistant NC-R clover clone had about 50-60 % higher AA concentrations than the sensitive NC-S clone. Additionally, in small open-top chambers an ozone-fumigation experiment was performed with clover plants.

P2221. Ozone alters the relative allocation of resources to vegetative and reproductive growth in European wild plant species

J. Bender[1], E. Bergmann[2], **H. Weigel**[1];
[1]Institut of Agroecology, Braunschweig, Germany, [2]Institute of Agroecology, Braunschweig, Germany.

Little is known about ozone (O3) effects on species from semi-natural vegetation. For wild species with different ecological strategies traits that relate most directly to ecological fitness (e.g. reproduction, ressource allocation) are more revelant for assessing (O3) effects than e.g. visible symptoms. Experiments with more than 30 common plant species with different life-forms and different families were performed to investigate the effects of (O3) on plant growth and reproductive development. The relative O3 sensitivities of the different species in terms of leaf biomass differed from those inferred from total, aboveground biomass and seed or flower production. Although O3 caused comparable reductions in both vegetative and reproductive biomass in a number of species, in a few species resources were switched to vegetative growth at the expense of reproductive growth. Germinability of seeds was affected such that germination rate was up to 30 % lower in O3-treated plants compared to control plants.

P2222. Some aspects concerning the reply reactions of some gymnosperms to the action of solid industrial pollutants

L. Ivanescu, M. M. Zamfirache, C. Toma, I. Toma, R. I. Apetrei;
University Al. I. Cuza Iasi, Faculty of Bioloy, Iasi, Romania.

The investigations we made concerning the micromorphology of the foliar surfaces of two gymnosperms species *Pinus sylvestris* and *P. nigra* from Bicaz and Tasca industrial areas (Romania) continue another study (In *Proceedings of the Ecological Protection of the Planet Earth, Xanthi, Greece, 2001).* The electronic microscopy investigations (S.E.M.) made on necrotic and/or chlorosis surfaces of the leaves showed changes of the cuticular surface, caused by the total disappearance of the parallelism between the cuticular prints, the chaotic setting of the stomata and their smaller dimensions, the closing of the ostiols with amorphous wax, which could be an indicator of the “suffering” of the leaf mesophyll in general. So, revealed the role of the solid deposits in the phenomenon of partly or total defoliation of the individuals. Such deposits deactivate important photosynthetic active parts; they hinder the respiration and perspiration and modify the characteristic cuticular relief.

P2223. Characteristics and limiting factors of soil fertility in sand coastal plain vegetation (Restinga Forest) of the litoral area in the state of São Paulo, Brazil

J. C. Casagrande[1], R. M. R. Duarte[1], C. A. Sato[1], M. S. Galvão-Bueno[2];
[1]Bioscience Institute, Rio Claro, Brazil, [2]University São Judas Tadeu, São Paulo, Brazil.

The sand coastal plain vegetation (Restinga Forest) is a type of ecosystem associated with the Atlantic Forest constituted of mosaics, which occur in areas of great ecological diversity. This work was carried out in several points of Restinga Forest in the litoral coast of the state of São Paulo. One sample was made of 15 subsamples of each area collected in each depth (one in 0 - 5, 5 - 10, 10 - 15, 15 - 20, and another in 0 - 20, 20 - 40, 40 and 60 cm). Soil characteristics analyzed were pH, P, Na, K, Ca, Mg, S, H + Al, Al, B, Cu, Fe, Mn, Zn contents and base saturation, cation exchange capacity and aluminum saturation. The high aluminum saturation and low calcium values to Restinga Forest determine superficial root system, restricting the vegetation growth. The nutritional reserve is mainly in the vegetable biomass. Leaves and root aluminum analyses indicated that does not exist a mechanism of aluminum retention in the root system.

P2224. River vegetation of the Upper Volga Region (Russia)

A. A. Bobrov, E. V. Chemeris;
I. D. Papanin Institute for Biology of Inland Waters of the Russian Academy of Sciences, Borok, Russian Federation.

Study of aquatic vegetation, in particular it coenotic structure, has a quite long history in Russia. However, the main results are received on water objects with stagnant waters (lakes, reservoirs, oxbows, etc.). The knowledge of very peculiar stream and river vegetation remains weak till now. Investigation of vegetation cover in streams and rivers of the Upper Volga Region are being carried out since 1994. Vegetation communities of the watercourses are presented by 80 associations from 26 alliances, 14 orders and 10 classes of Braun-Blanquet system. The river vegetation differ by high patchiness and tier structure, diversity of macrophyte groups (macroalgae, liverworts, bryophytes and various groups of vascular plants), penetration of submerged semiaquatic plants into hydrophyte communities, abundance of hybrid, frequently of relict character, plants. The obtained results have shown features of the river vegetation in comparison with vegetation of waterbodies, and its difference from the most well investigated vegetation of rivers of the Western Europe, the latter is predetermined in many respects by more continental and boreal climate of the region.

The research is supported by Russian Fund of Basic Researches (project N° 04-04-49814) and Fund of Support to Native Science.

P2225. Nitrogen content among species of pine forests growing along ammonia concentration gradient

A. Stikliene, V. Marozas, **E. Kupcinskiene**;
University of Agriculture of Lithuania, Kaunas-Akademija, Lithuania.

Among nitrogen species in the atmosphere and their deposition on to terrestrial vegetation, ammonia is considered to be the foremost. Estimated by passive diffusion tubes ammonia concentrations along the 22 km transect from the nitrogen fertilizer factory ranged between 0.4-75 µg m-3. Along the selected transect there was tendency for more frequent growth of nitrophilic species, (specially Chelidonium majus) in Scots pine stands where higher concentrations of ammonia were documented. In the assimilative organs of Galium album, Chelidonium majus, Sambucus racemosa, Stellaria media, Anthriscus sylvestris, Rubus idaeus, Calamagrostis epigeios concentration of nitrogen was higher (24-39 µg g-1 d.w.) than in the needles of Scots pine. Concentration of nitrogen in the needles of Scots pine was approaching physiological optimum. Along the transect herbaceous plant species like pines did not differ according to the amount of nitrogen in the leaves, although nitrogen content was among the highest compared to that described in literature. Data obtained show that nitrogen from ammonia deposition is more effectively used by understory species than by pines.

P2226. Phytoindication of the Surface Waters of the Canyon of the River Smotrych (NNP "Podilsky Tovtry")

I. Fedorchuk[1], I. Gumenyuk[2], M. Musienko[1];
[1]Kiev National Taras Shevchenko University, Kiev, Ukraine, [2]N.G. Kholodnyi Botany Institute of National Academy of Sciences of Ukraine, Kiev, Ukraine.

The research was held on the territory of National Nature Park (NNP) "Podilsky Tovtry", the biggest in Ukraine and the second big as for the territory in Europe.

In course of the research the spreading and ecological peculiarities of the growth of macrophytes-indicators according to hydrological and hydrochemical conditions were established. The index of phytoidication (If) was indicated, which characterizes the condition of waters of the canyon of the river Smotrych as unsatisfactory. The valuations of condition of water ecosystem under of influence of anthropogenic press was given in the comparison of data of phytoindication researches with hydrophysical and hydrochemical parameters.

On the whole phytoindication researches are rather actual especially on the nature protected territories. They give the opportunity to define integral level of pollution as well as general state of water ecosystems. At the same time we have an opportunity to make the discreet control with the help of hydrochemical methods and only in the definite periods of time. And some changes between observations.

P2227. Effects of disturbances on growth dinamic of the seagrasses *Posidonia oceanica* assessed by lepidochronology technique

F. Rende, **R. Cozza**, A. M. Innocenti;
University of Calabria, Cosenza, Italy.

The seagrass *Posidonia oceanica* (L.) Delile represents one of the most important primary producers of the Mediterranean coastal zone. *P. oceanica* forms meadows with a multifunctional role: produce and export biomass and energy, host diversified animal and algal community and stabilise coastal sediments protecting from erosion. However, the plant is sensitive to environmental disturbances and useful as bioindicator for environmental conditions: distribution pattern, shoot morphometry and dynamics of *P. oceanica* meadows are employed to detect an integrated response to disturbances.

In this work we have used the lepidochronology tecnique (that estimate the age leaf sheath persisting on the rhizomes after the leaf blade fall) as a tool to analyse seagrass dynamic. We analysed two meadows placed along the Dino Island (South Italy) subject to different environmental stress. The results show a decline in the shoot leaf production in *P. oceanica* shoots sampled in the disturbed site *vs* the preserved one; furthermore the same data provide evidence of the lepidochronology as suitable methods for detecting environmental disturbances.

P2228. Antioxidative responses of duckweed (*Lemna minor* L.) to short term copper exposure

J. Razinger[1], M. Dermastia[1], D. Drobne[1], A. Zrimec[2], J. Dolenc Koce[1];
[1]Biotechnical Faculty, Ljubljana, Slovenia, [2]Institute of Physical Biology, Grosuplje, Slovenia.

We estimated the potential use of duckweed (*Lemna minor* L.) as an indicator of environmental metal contamination and a biomarker for oxidative stress. Oxidative stress was evaluated during different exposure times and concentrations of the metal salt $CuSO_4$, using two antioxidant parameters: the activity of antioxidant enzymes (glutathione reductase - GR, catalase - CAT and guaiacol peroxidase - GPOD) and the ratio between oxidized - GSSG and reduced glutathione - GSH. We observed that the enzymes exhibit different sensitivity to copper exposure and that these changes in their activities are time-dependent. GPOD activity of plants exposed to copper was similar to that of controls at low and intermediate concentrations of copper, however, at the highest concentration tested (100 µM Cu) the enzyme activities of exposed plants were higher than that of controls. On the contrary, GR activity was higher than in controls at low copper concentrations, and lower than in controls at high copper concentrations. CAT activity did not differ a lot from control activity, except at 2 µM Cu, where it was higher than that of controls. Potential use of each enzyme test will be discussed.

P2229. The use of bryophytes as monitors of freshwater ecosystems

C. Vieira[1], C. Sérgio[2], A. Séneca[1];
[1]Botanical Department, Science Faculty and Research Centre on Biodiversity and Genetical Resources (CIBIO), Porto University, Porto, Portugal, [2]Natural History National Museum, Museum and Botanical Garden of Lisboa, Lisboa, Portugal.

Nowadays the aquatic ecosystems present several physical and chemical disturbances with their own selective forces. Plant species have been used as efficient tools in bio-indication and bio-monitoring studies to indicate water quality and anthropogenic disturbances.

Bryophytes have been efficiently used as bio-monitors of water quality because of their sensibility to the geomorphologic, geologic and ecologic river characteristics, as well as to water pH, alkalinity, conductivity, hardness, oxygen concentration, nutrients content and pollution. Furthermore, aquatic bryophytes are nutritionally independent of their growing substrate, and their nutritional and accumulation patterns are entirely dependent on the water-body characteristics, on ectohydric water transport and on the ecological context.

This work presents a method of bio-indication with aquatic bryophytes that consists of a model relating anthropogenic disturbances and freshwater ecosystems health with bryophyte assemblages and bio-indicator species in the streams and rivers of North-West Portugal.

P2230. Cadmium effects on Pisum sativum root nuclei

A. Fusconi[1], E. Bona[2], C. Gallo[1], O. Repetto[2], G. Berta[2];
[1]Dipartimento di Biologia Vegetale-CEBIOVEM, Torino, Italy,
[2]Dipartimento di Scienze dell'Ambiente e della Vita, Alessandria, Italy.

Primary seedling roots are an useful experimental system to test the effects of toxic substances, as they quickly respond with morphological alterations and reduced growth, related to the lowering of the mitotic activity at the apex. Moreover, their meristematic cells show a number of aberrations when subjected to genotoxic substances. Pisum sativum has a low number (2n=14) of relatively large chromosomes and therefore is a suitable species for genotoxic studies. We administrated cadmium (Cd), as CdCl2, at different concentrations, to a number of pea genotypes, to test its effect on growth, mitotic activity and induction of mitotic aberrations. Cv Frisson pea plants were highly susceptible to Cd, as mitotic index of their apices fell to zero after 24 h from Cd treatment. Nevertheless, in 250µM Cd treated seedlings, about 3% of nuclei showed a condensed, prophase-like chromatin, and a 4C DNA content, but did not proceed into mitosis. Prophase-like nuclei have previously been described for animal, fungal and plant cells subjected to stress. Their presence also in plant cells treated with cadmium, may indicate a general occurrence in different stressing situations.

P2231. Analysis of a scrub community on two mining areas in SW Spain

V. De la Fuente, L. Rufo, R. Gamarra;
Universidad Autonoma de Madrid, Madrid, Spain.

A scrub community dominated by the species *Genista hirsuta* subsp. *hirsuta* and *Cistus ladanifer* occurs in the Luso Extremadurense subprovince, included in the Mediterranean-Iberoatlantic province, at the southwest of the Iberian Peninsula.

This community (Genisto hirsutae-Cistetum ladaniferi Rivas Goday 1956) represents a substitution stage of the oak and cork oaks forests, developed on acid soils.

In our study, this community is found in two mining areas with geochemical anomalies, the only regions with those characteristics in the european territory, the Tinto river mines (Huelva province), and Almaden mines (Ciudad Real province).

We analysed the occurrence of heavy metals (Fe, Cu, Pb, Zn, Hg) into the characteristic plants of the community, and also in the soils. Finally, we compare the floristic composition between the mining areas, and the absortion levels of those metals in the selected species.

P2232. Estimation of Cu, Zn phytoextraction by weeds grown on contaminated sites

R. Szollosi, E. Mihalik;
Dept. of Botany, Szeged, Hungary.

Phytoextraction is one of the potential methods for “curing” contaminated places, particularly mine wastes, therefore we have to know whether weeds that grow there could extract or accumulate anorganic pollutants e.g. heavy metals. Four weed species of Asteraceae family (Tanacetum vulgare, Tussilago farfara, Ambrosia elatior, Erigeron canadensis) were collected from three sites: uranium spoil, carbon spoil and control. The content of Cu and Zn was measured by AAS and data are given in mg /kg DW. We found that plants generally collected much more Zn than Cu according to higher Zn concentration in the soil. Metal content was usually higher in aboveground parts, almost in leaves, but there were differences between annual and perennial species. Data show that metal concentration depends on the site also e.g. Zn- content was higher on control site and C-spoil in the perennial plants, while in Tanacetum and Tussilago rather in the spoils.

P2233. Estimation of Cu, Zn phytoextraction by weeds grown on contaminated sites

R. Szollosi, E. Mihalik;
University of Szeged, Szeged, Hungary.

Phytoextraction is one of the potential methods for "curing" contaminated places, particularly mine wastes, therefore we have to know whether weeds that grow there could extract or accumulate anorganic pollutants e.g. heavy metals. Four weed species of Asteraceae family (Tanacetum vulgare, Tussilago farfara, Ambrosia elatior, Erigeron canadensis) were collected from three sites: uranium spoil, carbon spoil and control. Metal content was usually higher in aboveground parts, almost in leaves, but there were differences between annual and perennial species. Data show that metal concentration depends on the site also e.g. Zn- content was higher on control site and C-spoil in the perennial plants, while in Tanacetum and Tussilago rather in the spoils.

P2234. Seed germination as biotests for indication of heavy metals toxicity in drinking water reservoirs

M. Grzesik[1], Z. Romanowska-Duda[2];
[1]Department of Ornamental Nursery and Seed Science, Research Institute of Pomology and Floriculture, Skierniewice, Poland,
[2]Department of Plant Growth Regulation , University of Lodz, Lodz, Poland.

The aim of study is to assess the effect of different concentrations of heavy metal salts dissolved in water on seed germination and length of root of several plant species, in order to select the seeds sensitive to pollution and prepare the biotests for indication of heavy metal toxicity in drinking water reservoirs.

Seeds of white mustard, cuckoo, lettuce, cucumber, carrot, parsley, soybean, corn and red clover were germinated on filter paper moistened with solutions of lead nitrate, cadmium nitrate, zinc sulphate or copper sulphate, in concentration of 0,6 - 1280 mg L^{-1}. Every day the germinated seeds were counted and the length of roots and hypocotyls were measured. The obtained results show that the used salts, at concentrations of 0,6-1280 mg L^{-1}, generally did not decrease germination rate of majority species tested. Toxic effect of the used salts has been exhibited by decreased root and hypocotyl length. In seeds germinated during 1 day, white mustard, cuckoo and lettuce, roots and hypocotyls were shorter than in control, on 2nd and 3rd day after seed sowing. Shortened roots and hypocotyls, in the 3rd day, were affected by all the salts used at dosages of 5 mg L^{-1}.

P2235. Seed germination as biotests for indication of heavy metals toxicity in drinking water reservoirs

M. Grzesik[1], Z. Romanowska-Duda[2];
[1]Research Institute of Pomology and Floriculture, Skierniewice, Poland,
[2]University of Lodz, Lodz, Poland.

The aim of study was to assess the effect of different concentrations of heavy metal salts on seed germination and seedling growth of some plant species, in order to prepare the biotests for indication of heavy metal toxicity in drinking water reservoirs.

Seeds of white mustard, cuckoo, lettuce, cucumber, carrot, parsley, soybean, corn and red clover were germinated on filter paper moistened with solutions of lead nitrate, cadmium nitrate, zinc sulphate or copper sulphate, in concentration of 0,6 - 1280 mg L-1. Every day the germinated seeds were counted and the length of roots and hypocotyls were measured. The obtained results show that the used salts, at concentrations of 0,6-1280 mg L-1, generally did not decrease germination rate of majority species tested. Toxic effect of the used salts has been exhibited by decreased root and hypocotyl length. In seeds germinated during 1 day, white mustard, cuckoo and lettuce, roots and hypocotyls were shorter than in control, on 2nd and 3rd day after seed sowing. Shortened roots and hypocotyls, in the 3rd day, were affected by all the salts used at dosages of 5 mg L-1.

P2236. Aspect about growth of the vegetation on the anthropic soils from the perimeter of the deposit of domestic waste from Tomesti Iasi, Romania

M. T. Costica, N. M. Costica, C. Secu, A. Lupascu;
Alexandru Ioan Cuza, Iasi, Romania.

The deposit of the domestic waste from Tomesti-Iasi is placed at the river meadow Bahlui on the clayey argillaceous with sandy intercalations from Quaternary period.

The formation of the soil in this region is taking place within in the temperate - continental climate with excessive nuance. These circumstances favour the relative, rapid mineralization of the organic substances with animal and vegetal sources.

The anthropic soil in the perimeter of the deposit has an alkaline pH (9,35-7,47), contains ions H+, OH-, Ca2+ etc and microelements Cd, Pb, Zn etc.

The installation of the vegetation begins with pioneer species from Solanum, Taraxacum, Amaranthus, Kochia sort and continues to a final vegetation, represented by spontaneous vegetation associations like: Kochietum scopariae, Atriplicetum tataricae and Ivaetum xanthiifoliae, with a 55 total of cormophyta species. In the storage’s slops, algae from Chlamydomonas, Euglena, Phacus, Oscillatoria, Spirulina and Chlorella sort are developing.

P2237. The influence of microcystins on the growth and activity of the katalase, dehydrogenases and phosphatases as a biochemical biomarkers in Spirodela oligorrhiza

Z. Romanowska-Duda[1], M. Grzesik[2];
[1]University of Lodz, Lodz, Poland, [2]Department of Ornamental Nursery and Seed Science, Skierniewice, Poland.

The cyanobacterial toxins microcystins are know to affect a number of processes in plant tissues and their presence may have considerable impact on the growth and development of water plants. In this study the Spirodela oligorrhiza was exposed for crude cyanobacterial extracts containing microcystins-LR and -RR. Axenic plants of Spirodela oligorrhiza were cultivated for 6 days in a medium supplemented with 0-100 µg L-1 both extracts.

All investigated showed the toxicity with relation to Spirodela, changing the activity of investigated enzymes as a catalase, dehydrogenases and phosphatase. The size of changes in the activity of enzymes was relative to the kind of the investigated enzyme and doses of toxins. The growth of plants was inhibited too.

We conclude that the use of enzymes as a biochemical biomarkers is useful to monitor the quality of drinking water reservoirs with of toxic cyanobacterial blooms. Spirodela oligorrhiza can be recommended as biosensor for the estimation of water quality.

P2238. Application of chlorophyll fluorescence to detect the PC role in metal tolerance in bryophytes.

D. K. Saxena[1], Z. Tuba[2], J. M. Glime[3];
[1]Botany Department, Bareilly, India, [2]Szent Istvan University, Godollo, Hungary, [3]Biological Science, Michigan Technological University, Houghton, MI, United States.

The present work is an attempt to screen to metal tolerance in bryophytes so that same can be recommended for the enrichment of the forest cover as well for the biomonitoring. Fv/Fm values in *Marchantia polymorpha* species ranged 0.67, while same was 0.78 in *Plagiochasma appendiculatum* collected from the same forest cover. Two Chlorophyll fluorescence measurements were taken daily during treatment with lead for the *Marchantia polymorpha* at the interval of four hours, were 0.54 and 0.50 respectively. This photo-inhibition could be due to metal stress. Average Fv/Fm value in *Plagiochasma* species was 0.71 and after four hours same measured 0.75, indicates least effect on photosynthetic function despite metal treatment and therefore, suggests that *Plagiochasma* species is not sensitive to environmental stress as the other species.

High Fv/Fm values in suggest the better tolerance potentials of the *Plagiochasma appendiculatum and same* could be due to better photosynthetic function. On the contrary low Fv/Fm values in *Marchantia polymorpha* indicates impaired photosynthesis could be as a result of meal toxicity.

P2239. Eradication of *Ipomoea carnea* Jacq. (*Convolvulaceae*), a common and onerous weed, by the application of 2, 4 - D on seedling stage.

M. Charles;
St. Xavier's College (Autonomous), Palayamkottai - 627 002, India.

A study was initiated to ascertain the effect of 2, 4 - D application on seed germination and seedlings of *Ipomoea carnea* Jacq. (*Convolvulaceae*), a common and onerous weed, one of the most serious menaces of farmers and agriculturists causing enormous loss of farm output, growing luxuriously both in land and fresh water ecosystems the world over. It is presently well known that the herbicide 2, 4 - D (Dichloro Phenoxy Acetic Acid) arrests the seed germination as well as seedling growth to a great extent effectively. Even a small percentage of the chemical (< 0.1 %) is sufficient to kill the unwanted weed within a few days of application of the chemical. The whole experiment was carried out in our laboratory to suit our conditions and be applied to the field in and around the locality / district. Thus we may be able to arrive at a solution of eradicating this antifarmer onerous weed from the face of the earth for ever.

P2240. Meta-analysis of plant species richness in the vicinity of point polluters: Are pollution effects always detrimental?

E. Asikainen, M. Kozlov;
University of Turku, Turku, Finland.

Although effects of air pollution on plants are widely studied, both at the level of community and individual species, the general pattern have not emerged yet, and sources of variation remain almost unexplored. We conducted a meta-analysis of published information on the impact of point polluters on plant species richness and diversity. We were interested in comparison of the effects on different plant groups in different regions, as well as in exploration of factors potentially explaining variation in responses. Primarily studies are highly biased: only one from nearly 100 studies was done in southern hemisphere; 66% of studies were conducted in boreal forests and 23% in temperate forests, while other biomes remain practically unexplored. Most of the studies were restricted to field layer, only 35% involved all vascular plants. Almost half of the studies were conducted in Russia and published in Russian, which naturally restricts their availability for the international scientific community. Although, as expected, diversity clearly decreased with increase of pollution, the pattern was not uniform among the plant groups. Results will be further discussed.

P2241. Plant and microfungal diversity in an aged hydrocarbon-contaminated industrial soil: from biosensing to bioremediation

C. Siniscalco, E. Barni, S. E. Favero-Longo, M. Girlanda, R. Segreto, S. Perotto;
Department of Plant Biology - CEBIOVEM - - University of Torino, Torino, Italy.

In virtue of their adaptation to local conditions, organisms naturally selected from polluted soils may be suitable candidates for *in situ* bioremediation. Plant and soil saprotrophic microfungal diversity was examined in an industrial dismissed area heavily contaminated with a complex mixture of hydrocarbon pollutants, heterogeneously distributed in the soil. Different plant succession stages were present and were mainly related to the concentration of pollutants in the soil. Pioneer shrub communities and early developed poplar woods (*Populus nigra*) colonised the most polluted areas. Community structure of soil saprotrophic microfungi correlated significantly with vegetation diversity. Association of *Populus nigra* and six microfungal species, isolated from the most polluted spots, significantly reduced pollutant concentrations under (semi)controlled conditions. These results indicate that plant communities can be used for environmental quality assessment in polluted habitats and suggest that rhizoremediation could satisfy the request of biological methods for the restoration of polluted soils.

P2242. Response of native *Pinus pinea* L. to metal pollution in an industrial area

S. Rossini Oliva[1,2], B. Valdés[1,2], M. Mingorance[3,4];
[1]Department of Plant Biology and Ecology, Seville, Spain, [2]University, Seville, Spain, [3]Department of Eearth Science and Environmental Chemistry, Estación Experimental del Zaidín, Granada, Spain, [4]Consejo Superior de Investigación Cientifica, Granada, Spain.

Needles, wood and bark samples of *P. pinea* L. have been collected along four transects in a heavy industrial area of SW Spain (Huelva) at different distances (0.5, 1, 2, 4, 6, 8 Km) from the industrial complex. Soil samples in the plough layer were taken at each plant sample site. All samples were analysed for Al, Ba, Ca, Cr, Cu, K, Fe, Mg, Mn, Pb and Zn content. Cu, Pb and Zn are accumulated in soils close to the industrial complex. The enrichment factor shows that Cu, K and Ca are the most enriched elements in plants, showing the higher mobility ratio in most of the sampling sites. The next group of elements (Mg, Mn, Pb and Zn) show mobility ratio generally between 1 and 0.1, indicate that their uptake is regulated by internal processes and that pine can be used as a bioindicator of them. Other elements (Al, Ba, Cr and Fe) with mobility ratios mostly < 0.1 are excluded by the plant and are indicative of dust source (Al).

Cu, Fe and Pb content in pine decreases when the distance from the industrial complex increases. Ca content in the different plant parts is bark> needle>wood. Correlation between metal content in *Pinus* needles, bark, wood, total plant and soil is not significant ($P>0.05$).

P2243. Vegetation variation in two polluted swamps and possible use of plants as bioindicators of pollution

R. Priso[1], N. Din[1], M. Kenne[1], A. Amougou[2];
[1]Faculty of Science, Douala, Cameroon, [2]Faculty of Science, Yaounde, Cameroon.

Degradation of vegetation in two swamps by pollutants from liquor's industries was analyzed by comparison between plants in Boadibo-Douala areas (Cameroon). Floristic inventory was carried out using the base of surveys obtained from relevés from February 1989 to February 1991, and September 1999 to March 2002. The abundance-dominance coefficient permitted to establish for each plant its presence index. Damage index gave the state of each plant. Some physico-chemical parameters of waters in the swamps were also measured. In relation to water quality, significant differences were noted concerning damaged and non damaged plants, BOD_5, total dissolved solid, turbidity and colour. Some sensitive plants in polluted plots exhibited morphological reajustments, chlorosis, necrosis and defoliation. Species like

Commelina sp. And *Mariscus longibracteatus* Vahl seem to be the most resistant to pollution.

P2244. Toxic effects of lead on tip roots onion (*Allium cepa*. L) as biological model to study about contamination for heavy metals.

I. M. Carruyo, Y. Fernández, L. B. Marcano, X. M. Montiel, Z. Torrealba;
Departamento de Biología. Facultad Experimental de Ciencias. Universidad del Zulia, Maracaibo, Venezuela.

Mitotoxic, citotoxic and genotoxic effects induces by lead on onion root cells (*Allium cepa*) were studied at different concentrations and exposure times. Bulbs were cultivated in filtered water changed each 24 h, at 25 ± 0.5°C, in darkness and constant aeration. Treatments were carried out under the same experimental conditions, using watery solutions of lead chloride at 0.25, 0.5, 0.75 and 1.0 ppm to 0, 12, 24, 48 and 72 h. A control was carried out where metal solution was substituted by distilled water. After treatment the meristems were fixed with alcohol - acetic acid (3:1) and they were colored according to Feulgen’s technique. An indirect effect was observed between root growth and mitotic index with lead concentration and exposure time. Morphologic alterations, nuclear irregularities and abnormal chromosomal morphology were also observed. That as allowed to infer a toxic effect dependent about the concentration and exposure time induced by the lead on the meristems, being able to corroborate the advantages the use of the tips root of *Allium cepa* as biological model to the study of contamination for heavy metals.

P2245. Variability of peroxidase activity and heavy metal content in the needles of Austrian pine (Pinus nigra arn.) half-sib lines

V. V. Isajev[1], V. S. Lavadinovic[2];
[1]Faculty of Forestry, 11030, Serbia and Montenegro, [2]Institute of Forestry, 11030, Serbia and Montenegro.

Enzyme activity of peroxidases of total proteins and heavy metal contents were studied in the needles of eight different half sib lines of Austrian pine. The samples were taken from generative seed orchard. Enzyme extraction was performed, by procedure Weckx and Clijsters 1996. The concentration of proteins was determined by Bradford 1976 method. For the measurement of metal concentration needles, the samples were prepared by the procedure for "dry burning".The enzyme activity of peroxidases was monitored in order to determine the effect of genetic variability of half sib lines on one of the key enzymes included in the response to stress, and responsible for the process of lignification in the cell wall. The peroxidases present as soluble in the apoplast or with covalent bond to cell wall, have an important role in lignification, suberisation, healing of injuries, defence against pathogens and atmospheric pollutants.

P2246. Multicriterion assessment of urban geosystems state by methods of bioindication

N. V. Terekhina;
Dpt. of Biogeography and Nature Protection, St.Petersburg State University, St.Petersburg, Russian Federation.

The methods of phytoindication include physiognomical, phytooptical, and biogeochemical aproaches. They were elaborated and approved by ecology assessment of St.Petersburg geosystems. Physiognomical indication is based on the registration of visible reaction of leaves (chlorosis, necrosis, ect.) on environment contamination, degree of foliation is taken into account also. All these characteristics are included in general index of functional state of green plantation. Albedo of leaves is measured on four channels by contact method. Index of vitality (ratio of visible part to IR-part of srectrum) is calculated. Content of leading chemical elements-pollutants in soil, in leaves and bark of trees reduced to index of summarized contamination (comparison with background data). The summary indexes construction method is the function of normalized initial parameters with assigned weight factors. This method gives a possibility to use amount of characteristics necessary for investigation, take into account importance of their contribution in ecological state of geosystem, and subdivided territory into districts of different ecological stress.

P2247. Flora of the ash hills formed by thermo power plants activity by KEK in Kosovo.

B. Mustafa[1], M. Xhulaj[2], E. Hoxha[3], Z. Veselaj[4];
[1]Faculty of mathemathical-Natural Sciences, Prishtina, Albania, [2]Faculty of Natural Sciences, University of Tirana, Albania, [3]Faculty of Mathemathical-Natural Sciences, University of Prishtina, Albania, [4]Faculty of Mathemathical-Natural Sciences, Prishtina, Albania.

Introduction: The area of KEK includes a surface of 5000 ha in the central part of Kosovo. From this, 110 ha are covered by ash, produced by thermo power plants activity, which has taken the form of the hills (ash hills).

In older parts of ash hills, a whacking spontaneous flora and vegetation was established. The aim of our researches was to identify all species that vegetate in ash hills, to analyze dominant species, with the aim to be cultivated in the new parts of ash hills.

Material and method: For the study the floristic material is collected in the older parts of ash hills, as well pioneer species in new parts.

Results and conclusions: This is the first study of flora of ash hills in Kosovo. Results shows that during the 2004 vegetative season are recorded: 27 families, 82 genera and 102 species of vascular plants. The richest families with species are: Asteraceae (26), Poaceae (23), Fabaceae (9).

From the list of collected species is concluded that their origin comes from fields and meadows of surrounded areas. Whacking vegetative cover is developed in the older parts of ash hills, which based on exposition and elevation of the hills, acquired the character of associations.

P2248. Use of the Moss *Pinnatella alopecuroides* (Hook.)Feisch. as a Biomonitor of Trace Element Pollution In An Industrial Area Near Mumbai.

S. Chakrabortty, G. T. Paratkar;
KET's Kelkar V.G. Vaze College Of Arts,Science and Commerce, Mumbai, India.

This study is an attempt to use the moss *Pinnatella alopecuroides*(Hook.) Feisch. to monitor the level of trace element pollution in the soil and in the atmosphere. Elemental composition of mosses and soil collected from Mahabaleshwar, a control area near Mumbai was measured. This was compared to samples of mosses and soil collected from a steel factory area near Mumbai and urban area in Karnala Bird Sanctuary. Concentration of eight trace elements As, Cd, Cu, Fe, Mn, Pb, and Zn were measured by inductively coupled plasma spectrophotometry (ICP-OES) and inductively coupled plasma-mass spectroscopy (ICP-MS). The results indicated the following (1)the area around the steel factory is heavily polluted had significantly higher levels of available lead (50 mg/kg^{-1}), Zinc(45 mg/kg^{-1}), and arsenic (1.12 mg/kg^{-1}), than urban and control area. (2)The concentration of trace element in this moss was positively and significantly correlated with the soil availability for lead and zinc, and to a lesser extent for arsenic (logelog relationship). Thus the moss *Pinnatella alopecuroides* could be used as biomonitors for soil pollution of Cd and Zn, and moderately for As.

P2249. Vanadium Pentoxide toxic effect in onion tip roots *(Allium cepa)*

X. M. Montiel, I. M. Carruyo, Y. Fernández, L. B. Marcano, Z. Torrealba;
Departamento de Biología. Facultad Experimental de Ciencias. Universidad del Zulia., Maracaibo, Venezuela.

Vanadium effects on tip roots onion (*Allium cepa*) were investigated in order to value their use as a contamination indicator by heavy metals, analyzing root growth, the Mitotic Index (MI) and of chromosomatic aberration (ChA) induction. Meristematic cells were grown in filtered water at 25 ºC and treatments were done in the same experimental conditions, using pentoxide vanadium solutions at 0.25, 0.5, 0.75 and 1.0 ppm during 0, 12, 24, 48 and 72 h. A control was carried out where metal solution was substituted by distilled water. After each treatment, meristems were fixed with alcohol - acetic acid solution (3:1) and stained using Feulgen´s technique. Results showed a negative correlation between concentration and exposure time on roots length and MI. The MANOVA demonstrated a deleterious effect of exposure time and concentrations used. In these were also observed different types of ChA: stickiness, anaphases bridges and c- mitotic effect. Duncan test showed significant increment about aberrations

frequency during the time and concentration. In conclusion vanadium toxic effect on the cell population studied was dependent about concentration and exposure time.

P2250. Remapping of epiphytic lichens in the area of town Ljubljana, Slovenia, as a measure of improvement of air quality in time period 1974-2004

F. Batiļ [1], I. Rakef[1], B. Turk[1], H. Mayrhofer[2];
[1]University of Ljubljana, Biotechnical Faculty, Ljubljana, Slovenia, [2]Karl-Franzens Universitaet Graz, Graz, Austria.

Air quality was assessed by mapping epiphytic lichens in Ljubljana; Slovenia, first in 1974/75, repeated in 1983/84, and remapped in 2004. During the first mapping the city center was lichen desert. In recent mapping city center is colonised by macrolichens such as *Parmelia sulcata, Melanelia glabratula, Flavoparmelia caperata, Punctelia subrudecta, Physcia ascendens/tenella, Evernia prunastri*. At sites within the densly settled area the cover of nitrophilous species increased indicating increased air pollution by traffic. At sites around the city some species, present in 1974 dissapeared (*Lobaria pulmonaria, Sphaerophorus globosus, Ramalina fastigiata, R. fraxinea*). This indicates that after resolving the problems with dust and sulphur compounds air pollution with nitrogen compounds and organic pollutants remains. Epiphytic lichens responded to changes in level and types of air pollution and they could be used further in biomonitoring of air quality in urban areas.

P2251. Lichens in European Russian cities: myths and reality

N. V. Malysheva;
Komarov Botanical Institute, St. Petersburg, Russian Federation.

There are many myths around the problem “Lichens in cities”. «1. Lichens don’t grow in cities». However in 88 cities the European Russia are found more than 600 species (over 50 % species known from this territory). «2. Always there are lichen deserts». But distribution of lichens is of mosaic character in megapolis, big and small cities. This is connected with the presence of suitable habitats and substrata. «3. Lichens differ from higher plants as to their habitat requirements». Like higher plants, lichens are confined to certain habitats (parks, cemeteries, a housing estate etc.). This is proved by statistics. «4. Changes in lichen flora structure are connected with atmospheric pollution». Some other factors are important as well (intensity of human activity, population number per unit of the area etc. «5. Lichens disappear in cities». Besides anthropogenic succession there are natural ones. Approximately 40 % of lichen species persist in one place for a period of 100 years.

P2252. Selected mining dumps in Slanské vrchy mountains - geochemical conditions and their influence on vegetation

E. Sitášová;
Eastern Slovakian Museum, Košice, Slovakia.

Mining dumps at Slanské vrchy Mnts (Eastern Slovakia) are the specific anthropogenetic habitats. According to the representation of ore minerals at dumps and according to their chemical composition in soils, we supposed higher concentration of some elements (As, Cu, Hg, Pb, Sb).

The results confirm the migration of heavy metals and also their accumulation in environment. Our aim was to catch also natural succession of plants at dumps, their development and stand conditions at individual localities. We discovered *Agrostis capillaries, Acetosella vulgaris, Amelanchier lamarkii, Betula pendula, Fagus sylvatica, Salix caprea, Silene vulgaris* and *Tussilago farfara*. We confirm some differences between the growth of young and old dumps. In plants the content of mercury and arsenic exceed the values of ash. The most frequently it is exhibited in the case of *Agrostis capillaris*. In another species there is a high concentration of Hg from each locality.

P2253. Monitoring environmental pollution by plants in the spill-affected Guadiamar valley (S. Spain)

J. M. Murillo[1], T. Marañón[1], P. Madejón[2], M. T. Domínguez[1];
[1]IRNAS, Sevilla, Spain, [2]Liverpool John Moores University, Liverpool, United Kingdom.

Higher plants have been widely used for monitoring the air and soil pollution. In April 1998, the Guadiamar valley (S. Spain) was severely affected by a mine spill. We have analysed the concentration of As, Cd, Cu, Pb, Tl and Zn in different organs of several plants. Leaves of the white poplar (*Populus alba* L.) accumulated Cd (up to 14 mg kg^{-1}) and Zn (up to 1200 mg kg^{-1}), and were used as pollution biomonitors. Leaves of wild olive (*Olea europaea* L.) and holm oak (*Quercus ilex* L. subsp. *ballota* (Desf.) Samp.) were also used as pollution biomonitors. Some herbaceous species, such as *Cynodon dactylon* (L.) Pers. *Hirschfeldia incana* (L.) Lagrèze-Fossat, *Raphanus raphanistrum* L. and *Plantago lanceolata* L., also accumulated some trace elements. Other organs, besides leaves, can be very relevant for ecosystemic monitoring. For example, the fruits of olives and oaks are consumed by many animals in the Mediterranean forests. In another example, it was remarkable the high accumulation of Tl found in the floral structures of the Brassicaceae herb *Hirschfeldia incana* (up to ca. 50 mg kg^{-1}) while the leaves of the same plants accumulated much less (only 2 mg kg^{-1}).

P2254. Testing water-mosses for their indicative value at three Austrian rivers (Traisen, Große Tulln and Perschling)

K. Poller, H. G. Zechmeister;
Institut of Ecology & Conservation Biology, Vienna, Austria.

In the course of this study it was evaluated whether the presence of water-mosses correlated to water quality (in terms of eutrophication), chemical composition, velocity, water-temperature, the structure of the waterbed and the banks, anthropogenic modification of the water-body and the presence of other organisms (algae). It was aimed to test the use of water-mosses as bio-indicators for these parameters.

The study was conducted at three rivers of the foothills of the Austrian Alps (Traisen, Perschling and Große Tulln) showing differing water regimes.

The occurrence of water-mosses was recorded at transects across the river, at sampling points every 2,5 km and additionally, at measurement points of the local government. Recording followed a plotless sampling design, with a distance of 10 cm for each sampling plot, additionally water-mosses at the near surroundings were also listed.

Correlation between each investigated parameter and the mosses found were calculated by a range of statistical procedures (e.g. multiple regression analysis).The application of water-mosses as bio-indicators is discussed.

P2255. Biomonitoring of road traffic emissions by mosses

H. G. Zechmeister[1], D. Hohenwallner[2], A. Hanus-Illnar[3], S. Scharf[3], A. Riss[3];
[1]University, Vienna, Austria, [2]ECOTOX - company for monitoring envirnmental pollution, Vienna, Austria, [3]Umweltbundesamt Wien, Vienna, Austria.

Mosses were used as biomonitors for estimating heavy metals and PAHs deposition deriving from road traffic emissions in Austria. A road tunnel experiment was performed and a series of transects along major roads were investigated. Twenty-two elements, mainly heavy metals, and the sixteen EPA-PAHs and coronene were analysed. Highest average enrichment factors were obtained for most PAHs, especially benzo(g,h,i)perylene, coronene and benzo(a)anthracene ,and among the other elements for Sb, Pd, Mo, Pt, Cr, As and Cu. There was a significant negative correlation to the distance from the road for most of these elements. The rate of decrease followed a reciprocal curve. Traffic density, distance from and elevation of the road were the most influencing factors. There were nearly no significant elevated deposition at road distances more than 200 m. Nevertheless, at heavily frequented roads, raised deposition of some elements were found even at a distance of 600 m. On the basis these results a regular road traffic monitoring system was established along 46 roads in Austria.

P2256. Phytoindication of the Surface Waters of the Canyon of the River Smotrych (NNP “Podilsky Tovtry”)

I. Fedorchuk[1], I. Gumenyuk[2];
[1]Kiev National Taras Shevchenko University, Kiev, Ukraine, [2]N.G. Kholodnyi Botany Institute of National Academy of Sciences of Ukraine, Kiev, Ukraine.

The research was held on the territory of National Nature Park (NNP) “Podilsky Tovtry”, the biggest in Ukraine and the second big as for the territory in Europe.

In course of the research the spreading and ecological peculiarities of the growth of macrophytes-indicators according to hydrological and hydrochemical conditions were established. The index of phytoidication (If) was indicated, which characterizes the condition of waters of the canyon of the river Smotrych as unsatisfactory. The valuations of condition of water ecosystem under of influence of anthropogenic press was given in the comparison of data of phytoindication researches with hydrophysical and hydrochemical parameters.

On the whole phytoindication researches are rather actual especially on the nature protected territories. They give the opportunity to define integral level of pollution as well as general state of water ecosystems. At the same time we have an opportunity to make the discreet control with the help of hydrochemical methods and only in the definite periods of time. And some changes between observations

P2257. *Pistia stratiotes* L. (Araceae) morphological changes in non polluted and polluted ecosystems in Douala areas (Cameroun)

R. J. Priso[1], D. N. Ndongo[1], N. L. Joel[1], E. K. Guillaume[1], A. Akoa[2];
[1]Faculty of Science, Douala, Cameroon, [2]Faculty of Science, Yaoundé, Cameroon.

Douala aquatic ecosystems are submitted to pollutants that affect distribution and morphology of plants such as *Pistia stratiotes* L. (Araceae). 40 families, 100 genera and 116 species have been recorded in Twenty swamps. Species recovery where done by abundance-dominance indexes in 0,3 ha. Physico-chemical values in swamps are variable : pH (6.32 ± 0.28 to 7.24 ±0.10), Conductivity (129.98 ± 26.24 to 3334.70 ± 7.35 meql^{-1}), TDS (1.29 ± 0.26 to 33.34 ± 0.07 meql^{-1}), NH_4^+ (0.15 ± 0.07 to 18.32 ± 5.18 mgl^{-1}), PO_4^{3-} (9.36 ± 2.64 to 42.67 ± 12.07 mgl^{-1}), NO_3^- (8.78 ± 2.48 to 27.61 ± 7.80 mgl^{-1}), Cadmium (0.001 ± 0.00 to 0.37 ± 0.01 mgl^{-1}), Oxygen demand (0.27 ± 0.07 to 0.73 ± 0.19 mgl^{-1}), BOD_5 (38,0 ± 3.5 to 212 ± 10.6 mgl^{-1}) The higher value and the lower value of each parameter were significantly different. Biological parameters are also variable: leaves mean number (7.61 ± 1.93 to 13.53 ± 3.05), root length (5.15 ± 1.43 to 20.53 ± 14.62 cm), leaf area (7.06 ± 2.23 to 86.89 ± 12.23 cm^2). *P. Stratiotes*, less abundant in sites receiving organic matters, hydrocarbons and Cadmium with flowers and seeds absent or scarce can be use for monitoring in polluted areas and help to purify water.

P2258. Algae in oil-cleaning carts: Who and how survive in extremely polluted waters?

T. A. Zakhodnova[1], M. Iankevich[2], V. Nikitina[1], V. Alekseev[3];
[1]Botanical Garden of St. Petersburg State University, St. Petersburg, Russian Federation, [2]ECOPROM Ecological Research Company, St. Petersburg, Russian Federation, [3]Zoological Institute of the Russian Academy of Sciences, St. Petersburg, Russian Federation.

Effects of oil products and 18 other chemicals on phytoplankton biodiversity and biomasses in three carts of water cleaning system of Kirishi State Oil Company, Leningrad district were studied in 2003-2004. Total number of algae species were more than 70 taxons with only 9 species belonging to Cyanophyta (*Oscillatoria granulata, O.agardii, O.ingrica, O. tenue)* , Chlorophyta *(Coelastrum microporum, Chlorella vulgaris*), Cryptophyta *(Cryptomonas rostrata)* and Euglenophyta (*Euglena anabaena, Euglena bucharica)* as the most common forms. Biomasses of dominative plankton cyanobacteria negatively correlated with SO_3 (R=-0,636; p=0,026), dried rest (R=-0,588; p=0,044), *Fe* (R=-0,351; p=0,039), total phosphorus (R=-0,355; p=0,037) and *Mn* (R=-0,609; p=0,035) and positively correlated with biological consumption of oxygen (R=0,649; p=0,00004) in the carts. Synergic effects of oil products pollution on algal community in the carts are also discussed.

P2259. Morphological and physiological parameters of *Carex hirta* under oil pollution of soil.

O. Terek, N. Dzhura, O. Tsvilynyuk;
Ivan Franko National University of Lviv, Lviv, Ukraine.

Morphological and physiological reactions of Carex hirta under soil pollution by oil were investigated. Carex hirta - long-root species, most stable to the hard conditions of ecotops, polluted by oil. Plants were harvested in 15 l pots. Oil was brought to the soil in the following concentration - 50 ml/kg (medium pollution) and 100 ml/kg (strong pollution). Control - soil without oil. After two month of growing plants we analized morphological and physiological parameters: growing and biomass accumulaton, complex of pigments, POL activity. We investigated, that strong oil pollution due to growth and development brakes, decreasing of fresh and dry weight of plants, *a* and *b* chlorophyll content, increasing POL activity and carotenoid concentration. All this suggested about physiological adaptation of Carex hirta to oil pollution.

Investigation of physiological and biochemical ways of stable plants adaptation to oil pollution is important to scientifical recomendation for phytoremediation of territories polluted by oil.

P2260. Relationship between metal concentration in moss tissues and deposition fluxes: example of a french remote area.

S. Leblond, C. Rausch de Traubenberg;
Muséum National d'Histoire Naturelle, Paris, France.

The use of mosses to estimate atmospheric trace element deposition is studied. Annual deposition rate (sum of wet and dry bulk deposition) is compared to the rate estimated by mosses (*Scleropodium purum* (Hedw.) Limpr.) collected in the same area. This estimation is obtained by the product of the concentration in the one year growth segment (upper 2 cm of the plant) with the annual biomass production per area of the plant.

The ratio value of moss to bulk deposition varies with the elements and gives the following order: Mn > Zn > V > Pb > Fe > Al, where Mn deposition is overestimated whereas Al deposition is underestimated by mosses.

The main processes observed which could explain the differences between real and estimated deposition are listed below.

- A comparison of the metal concentration in the apical and basal parts of the plant shows a specific bioconcentration of Mn and Zn in the youngest tissues.
- The physico-chemical state of the element (dissolved, particulate) seems to influence its capture and retention by the moss.
- Following an artificial contamination of the moss carpet, the retention time of the elements sprayed is lower than one year.

P2261. A test system with radish (Raphanus sativus L.) to study biological effects of low-frequency electric and magnetic fields

G. Soja, W. Giczi, A. M. Soja, B. Kunsch;
ARC Seibersdorf research, Seibersdorf, Austria.

The applicability of plant-based test methods to be used as bioindication systems for elevated electric and magnetic field strengths was studied for two years. Additionally the relations between specific ecophysiological reaction patterns and electromagnetic fields were analyzed. The most versatile test procedure consisted of a standardized cultivation of young radish plants for two weeks under the field conditions to be tested. In a next step, leaf chlorophyll fluorescence had to be measured and the results had to be fed as inputs into newly developed neural network models. The model outputs provided reliable evidence for the existence, type and strength of the electromagnetic field (0-300 Hz) if the detection limit of 3 µT or 1 kV.m^{-1} was exceeded. This test system was optimized for the use as indicator system under real-world conditions. The reactions of radish were mostly non-linearly affected by field strength. At low and medium field strengths growth and photosynthetic parameters frequently were promoted; at higher field strengths (>30 µT or >6 kV.m^{-1}), however, reductions prevailed.

P2262. Oxidative stress induced by trivalent and hexavalent chromium species in Fontinalis antipyretica Hedw.

M. Dazy, E. Béraud, S. Cotelle, P. Akinomi, L. Giamberini, J. Férard, J. Masfaraud;
Laboratoire ESE, Metz, France.

Due to its widespread use, chromium, has become one of the most abundant pollutant in aquatic and terrestrial ecosystems. It can be found in several oxidation states even if the most common and stable forms are the trivalent Cr(III) and hexavalent Cr(VI) species.

In plants, Cr(VI) and Cr(III) are both able to cross biological membranes. Then, inside the cells, they are both involved in reactive oxygen species (ROS) production. Apart from generating reactive oxygen species (ROS), Cr(III) can also inhibit metallo-enzymes systems.

We wondered whether Cr(VI) and Cr(III) could induced an oxidative stress in the aquatic moss *Fontinalis antipyretica* Hedw. Chromium was added to exposure media as chloride ($Cl_3Cr.6H_2O$), nitrate ($Cr(NO_3)_3.9H_2O$) or potassium dichromate ($K_2Cr_2O_7$). After 24 hours, 100 mg fw moss samples were analysed for superoxide dismutase, catalase, ascorbate peroxidase, guaiacol peroxidase, glutathione reductase activities, GSH/GSSG ratio and chlorophyll

contents. Chromium was localized in cells through TEM-XF analysis.
All variables responded to Cr(III) and Cr(VI) exposures, suggesting an ROS-mediated metal toxicity.

P2263. Subcellular comparison of the toxic effects and distribution of cadmium and lead in plants

M. Wierzbicka, **E. Przedpelska**;
Department of Morphogenesis, Institute of Plant Experimental Biology, University of Warsaw, Warsaw, Poland.

The toxicity of heavy metals was estimated by observations in epidermal cells of *Allium cepa* onion bulb scales. Observations of cytoplasm stream flows in cells allowed arranging the investigated metal ions by order of their toxicity in the sequence: Pb<Zn<Cd. A large difference in the toxicity of cadmium and lead was demonstrated. The magnitude of this difference was 4-fold in relation to cytoplasm flow, and 63-fold, in relation to the total contents of cadmium and lead in cells. After fractionation of tissues and enzymatic digestion of cell walls it was confirmed that the largest amount of cadmium was in cell walls, in contrast to lead, of which 97.8% was in intracellular compartments other than the cell wall. Explanation of these results was possible by locating lead in cells using electron microscopy. This study showed that an effective detoxifying mechanism exists in the epidermal cells and that it can be one of the mechanisms explaining the lower toxicity of lead than cadmium.

P2264. Adaptation of *Biscutella laevigata* L, a metal hyperaccumulator, to growth on a zinc-lead waste heap in southern Poland

M. A. Pielichowska, M. Wierzbicka;
Department of Morphogenesis, Institute of Plant Experimental Biology, University of Warsaw, Warsaw, Poland.

Biscutella laevigata is an herbal member of the *Brasicaceae* family and a typical mountain species. It has recently been identified as a hyperaccumulator of Pb, Cd and Tl. Its northern reach runs through Poland, where it is found only in the west Tatra Mountains and on calamine waste heaps in the vicinity of Olkusz. The peculiar distribution of this species in Poland prompted us to undertake studies to identify the traits that allow this typically mountain species to grow so robustly on industrial waste heaps near zinc and lead smelters in the vicinity of Olkusz. The both of plant populations were compared. It was found that the mountain and waste heap populations of *B. laevigata* differed significantly: the waste-heap population is more tolerant to heavy metals (Pb, Zn, Cd). In the presence of both Zn and Pb, growth of the waste-heap plants was stimulated, while under the same conditions, growth of the mountain population was inhibited lower than 50%. Histochemical detection of metals- dithizone in tissues showed that there ware taken up by the root hairs and transported through vascular bundles to the leaves (the epiderm and hairs). It may be a mechanism of metals detoxifying.

P2265. Occurrence of Central European threatened plants in water man-made habitats in Slovenia

V. Babij, B. Vreš;
Institute of Biology SRC SASA, Ljubljana, Slovenia.

The data of Central European threatened vascular plants (listed on Annexes II (=Natura 2000 species) and IV of the Habitats Directive, and Appendix I of the Bern Convention) have been analysed in FloVegSi database (Flora and vegetation of Slovenia) regarding their occurrence in man-made water habitats. The following 6 species occur in Slovenia: *Eleocharis carniolica* Koch, *Lindernia procumbens* (Krocker) Philcox, *Marsilea quadrifolia* L., *Salvinia natans* (L.) All., *Trapa natans* L., *Typha schuttleworthii* Koch & Sonder. Sites and vegetation community conditions were compared with the records of their natural occurrence. 5 threatened species are present in both habitats: natural and man-made. In the last century *Marsilea quadrifolia* only in man-made water bodies (fish-ponds) has been recorded. Man-made habitats are important for keeping the gene pool of many threatened species but should not become the only solution for their survival.

P2266. “Ecoflora of the Ukraine” - basic indication of ecological factors

Y. P. Didukh;
M.G. Kholodny Institute of Botany of the National Academy of Sciences of Ukraine, Kyiv, Ukraine.

Plants reacting on the changes in the environment have long been used as indicators of the environment. A number of phytoecological scales have been elaborated. Standardization of ecological scales (Ellenberg, Ramenski, Tsyganov, Landolt, Zarzycki et al.) (Didukh, Plyuta, 1994) enabled to make generalizations about ecological conditions of growth of species. This information served as a base of the multivolume edition of “Ecoflora of Ukraine” (3 volumes published so far). Descriptions of biomorphological traits; type area; phytocoenotic peculiarities; ecology; consortional links, influence anthropogenic factors; economic, landscape, and indicator importance; data on species protection and renewal; drawings and maps of distribution in Ukraine are given in the edition. Obtained ecological characteristics are used for evaluation of indicators of state, changes, and interrelations of ecological factors on the base of elaborated synphytoindication method. The method enables to evaluate species econiches, prognose vegetation changes, create ecological maps and elaborate corresponding prognostic models.

P2267. Correlation of angiosperm diversity with diversity of selected plant families in Burkina Faso

M. Schmidt[1,2], G. Zizka[1,2], H. Kreft[3], A. Thiombiano[4];
[1]Forschungsinstitut Senckenberg, Frankfurt am Main, Germany, [2]J.W.Goethe-Universität, Frankfurt am Main, Germany, [3]Rheinische Friedrich-Wilhelms-Universität, Bonn, Germany, [4]Université de Ouagadougou, Ouagadougou, Burkina Faso.

Digitization of specimen label data for Burkina Faso from the Herbarium Senckenbergianum (FR) and the Ouagadougou University Herbarium (OUA) led to a database including 18,000 specimens. Field observations from about 3,700 relevées (Braun-Blanquet method, BIOTA standard relevées, simple inventories) were added to the database and together used to model potential species distributions for Burkina Faso on a 10 minute grid. GARP was used with temperature, precipitation, humidity and elevation data. Based on these modelled distributions, overall angiosperm diversity is correlated to the diversities of the 10 families with on average the highest species numbers per grid cell (Poaceae, Fabaceae, Cyperaceae, Rubiaceae, Combretaceae, Euphorbiaceae, Mimosaceae, Asteraceae, Caesalpiniaceae, Malvaceae). The value of these families as indicators for assessing biodiversity is discussed. The results are compared to similar analyses based on relevées only.

P2268. Characterization of macrophytes in man made canals in Hungary

E. Falusi[1], G. A. Janauer[2], V. Sipos[1], N. Exler[2];
[1]Szent István University Dept. of Landscape Ecology, GödöllŖ, Hungary, [2]Department of Limnology and Hydrobotany, University of Vienna, Vienna, Austria.

In the frame of the “Multifunctional Integrated Study Danube: Corridor and Catchment” the macrophyte vegetation was characterised in five man-made canals (Danube-Tisza Canal, Main Canal, Apaji-canal, Sós-ér) in the Danube-Tisza lowland in 2002. The survey technique followed the Kohler-method, which is in accordance with the respective European Standard EN 14184, and the regulations of the Water Framework Directive. One aspect of the study was to prove that the method, which is in use in all Danube countries today, is also suitable for characterising the aquatic vegetation of anthropogenic canals.
The standardised field survey, and data processing, methodology guarantees that results are comparable between various locations. Findings include information on species number in canals as compared to other water body types in the Hungarian reach of the Danube and on distribution types of dominating canal species, of species of more conservational interest, and of neophytes.

P2269. Change of areas of rare and vanishing species of plants on territory Volynsk Polesye (Northwest Ukraine)

A. R. Baransky;
M.M.Grishko National Botanical Garden of National Academy of Sciences of Ukraine, Kyiv, Ukraine.

The flora of Volynsk Polesye includes 311 rare and vanishing species (nearly 30 % of the flora) consisting of 136 European, 63 Holarctic, 56 Boreal, 27 Subpontic, 11 Submediterranean, 8 Subatlantic, 7 Cosmopolitan, 3 endemic species, as well as 4 tertiary, 26 glacial, 32 interglacial and holocene's relics. Comparing the data on distribution of these species in XIX century on territory Volynsk Polesye with the modern data, we studied their change of areas during last 150 years. Among them 12 species (Cardamine hirsuta, Empetrum nigrum, Leymus arenarius, Linnaea borealis, Ranunculus nemorosus, Rubus chamaemorus, Orchis ustulata, Pedicularis exaltata, Marsilea quadrifolia, etc.) already have vanished, 36 species are endangered, 107 species, mainly boreal, reduce the areas, 170 species have stable areas, 27 species expand the areas on territory Volynsk Polesye from southern and western regions. These changes are connected to anthropogenous transformation (drainage of bogs, cutting down of woods) and it is possible with global warming of a climate.

P2270. Analysis of the species distribution in peatbogs from NW Iberian Peninsula using two statistical approaches

D. Romero Pedreira, M. Perille Seoane, M. Pimentel Pereira, E. Sahuquillo Balbuena;
Facultade de Ciencias, Universidade da Coruña, A Coruña, Spain.

The effects of environmental parameters on the distribution of peatbog vegetation were assessed using different approaches. The peatbogs studied are situated at the southern limit of the optimum peatbog plant communities, in Xistral and Ancares Mountains (NW Iberian Peninsula). These small peat deposits are scattered throughout this area, where some of the peatbog characteristic species remain as relict populations and also many endemic species are present.

To characterise the vegetation, linear transects were established on each bog and monitored monthly during the spring and summer of 1999-2003. Floristic inventories were carried out in each square metre along these transects and environmental parameters were measured as well. The resulting data were examined using multivariate PCA and CCA analyses, and the syntaxonomical method of the ecological profiles. Finally, our results were compared with published data, and their utility for establishing management plans to assure their conservation was evaluated.

P2271. Ecological and floristic analysis of the Pteridoflora of the Valley of Mexico

S. Acosta, M. L. Arreguín, L. D. Quiroz, R. Fernández;
Instituto Politécnico Nacional, México, D. F., Mexico.

An analysis of 113 species of Pteridophytes in the vegetation types from the Valley of Mexico is carried out. We found that 54 % of the species occur in the cloud forest, 45 % in conifers forests, 33.6 % in *Quercus* forest, 34.5 % in grasslands, 28 % in xerophilous scrubs, 22 % in pine-oak forest, 3.5 % in *Quercus* scrub, and 1.8 % in aquatic as in halophilous vegetation. 35 species are restricted to a single community, most of them to cloud forest (13 species). The affinities between the Pteridofloras of the different plant communities were analyzed through a cluster analysis (UPGMA). The temperate forests formed a cluster and on other hand the semiarid vegetation; halophilous vegetation was scarcely similar to other communities and the aquatic vegetation had no relationships with anyone. It was interesting that the pine-oak forest did not form a group with pine forest nor even with oak forest, because apparently it posses an own Pteridoflora, this fact supports the idea that it is an independent vegetation and it is not just an ecological or successional transition between the pine and the oak forests. Only five genera represent the 47.8 % of the species.

P2272. The evaluation of the flora and vegetation in the flood plain of Lower Tisza on the basis of ecological indicator values

A. Böszörményi;
University of Szeged, Department of Botany and Botanic Garden, Szeged, Hungary.

The study site situated in the flood plain of Lower Tisza (Hungary) was approx. 45 km2. The distributional ratio of the main habitat types is as follows: permanent and temporary lakes and wet meadows 3,8%, willow shrubs 0,07%, gallery forests 26,1%, degraded gallery forests 19,6%, pastures with trees 7,1%, softwood plantation forests 19,0%, agricultural areas 9,6%, cleared forests 1,3% and others 13,5%. The predominating plant species are disturbance tolerants followed by competitors and generalists. These plants require submontane broad-leaved forest climate, wet and neutral/alkaline soil without salt and a lot of sunlight. The distribution area of most of the species is eastern Central Europe and they occur in soils rich in nutrients. Out of the six coverage categories of the invasive species the category 20-50% occupies about of the half of the area. The average Németh-Seregélyes nature conservation value counted for the study area - weighted with the total area of categories - is 2.24 (the worst value is 1, the best is 5).

P2273. Yew (Taxus baccata L.) stands as priority habitat for biodiversity conservation in Mediterranean ecosystems: a case study from Northern Sardinia (Italy).

E. Farris, R. Filigheddu;
Dipartimento di Botanica ed Ecologia vegetale, Università di Sassari, Sassari, Italy.

Yew (Taxus baccata L.) is a long-lived circumboreal tree species with a limited range throughout the Mediterranean basin, where it is restricted to mountain areas in small populations. Following the EU Directive 43/92 “Habitat”, Sardinian yew stands can be ascribed to the priority habitat 9580. In northern Sardinia, yew is distributed in 6 mountain areas located in bioclimatic islands, with 11 main populations of different size. Adult density (from 5 to 460 ind/ha) is negatively affected by altitude (from 300 to 1300 m asl). Seedling and sapling densities (respectively from 0 to 8700 and from 0 to 1174 ind/ha) are both positively correlated to adult density and average age (expressed as DBH and ranging from 79.1 to 780 mm). Mortality (from 0 to 41.8 dead ind/ha) is also positively influenced by adult density and average age. Recruitment is conditioned by the presence of flesh fruited shrubs and trees. Because of the presence of mountain endemics and boreal-temperate relict species in yew stands, they show higher a-diversity in comparison to Quercus ilex L. and Q. pubescens L. ones and confirm their role as biodiversity hotspots in Mediterranean mountain ecosystems.

P2274. About "hot-spots" analysis for the rare plants conservation within the Ukrainian Carpathians

S. N. Ziman[1], F. D. Gamor[2], A. F. Gamor[3];
[1]N.G. Kholodny Institute of Botany, National Academy of Sciences of Ukraine, Kiev, Ukraine, [2]Carpathian Biosphere Reserve, Rakhiv, Ukraine, [3]Uzhgorod National University, Uzhgorod, Ukraine.

At present time the Mountain Flora of the Ukrainian Carpathians includes more than 150 rare or endangered Vascular Plant species, and within them about 50 species are concentrated in 10 to 15 "hot-spots" as the sectors of the greatest diversity of the most endangered taxa (Ziman et al., 1994-2004). Within them we regard the summits of Bliznitsa Mt. (Svidovets Range), Petros (Chernogora), Pip Ivan Marmaroshski Mt. (Marmarosh) and Negrovets Mt. (Gorgany) as the highest essential high-mountain "hot-spots" because of groving there 10 to 15 rare species within the same community (viz., unique *Anthemis carpatica*, *Astragalus krajinae*, *Gentiana nivalis*, *Campanula subcapitata*, *Salix alpina*, *Thalictrum transsilvanicum* and others). Besides, the Geredjivka Mt. (Gorgany) is the very valuable midlle-mountain "hot-spot" because *Gentiana verna* and *Carex davalliana* grow within the Ukrainian Carpathians only here, and *Primula farinosa* disappeared from this relict community about 30 years ago (Ziman, 1964, Ziman et al., 2001).

P2275. A comperative study of lichen diversity in lines and wooden-meadows, Norrtälje, Sweden.

Å. Dahlkild;
Botany Department, SE-106 91 Stockholm, Sweden.

An inventory of lichens in lines and wooden-meadows were performed in the rural district Norrtälje north of Stockholm to compare the lichen diversity in the two habitats. The inventory were performed in two lines and four wooden-meadows. The lines had a higher species divesity of lichens than the wooden meadows. The habitat was the only character that were significant different between the six different localities. Other characters that were mesured were the crown-width of the trees, circumference of the trunk, distance to dust, and distance to the closest tree of the same species. The lines are located by gravel-roads and have therefore a richer envioment than the wooden-meadows. The dust that are produced by the gravel-road make the environment on the tree trunks richer in nutrients for the lichens.

The wooden-meadows are a habitat typical for the area around the Baltic sea. They are meadows with some broad-leafed trees on them that are (or at least were) cut in a specific way. Every third to fifth year the tree crown were cut down and the branches were given to the animals as food, this is in Sweden called ”hamling”.

P2276. Effect of the Cañaveral-Arrecifes path (Tayrona National Natural Park) over the surrounding vegetation

L. Correa Uribe, M. Diazgranados;
Herbarium Pontificia Universidad Javeriana, Bogotá, Colombia.

In order to establish what would be the effect of the Cañaveral Arrecifes Path over the surrounding vascular vegetation (Tayrona National Park, Colombia), we analyzed the changes in structure, diversity and plant composition in a spatial gradient from the edge of the path to the inner part of the forest. In 10 different areas we established 7 transects (50 x 2 meters) at 0, 40, 80, 120, 160, 200 and 500 m of distance. A small variation was obtained for height and dbh curves between distances, indicating an invert “J” trend, which suggest that the forest is still well preserved, although there exists absence of some individuals of intermediate classes because of previous tree cut down. We found in total 227 species, but the values of the predominance indexes showed that *Anacardium excelsum* and *Ficus pallida* are dominant. The diversity varies between the edge and the inner part of the forest in a significant way (KW:18.11; $p<0.01$), notwithstanding it is not high as one would expect for a tropical rain forest. The richness, dominance and abundance, also were highly significant ($p<0.01$) between distances. These results suggest that the path is an important fragmentation source.

P2277. Assessment of woodlands for crop wild relatives conservation

D. N. Ryabova;
Vavilov Research Institute of Plant Industry, Saint-Petersburg, Russian Federation.

In our study we assessed the woodlands of the Leningrad region from the point of view of the *Rosaceae* Juss. family crop wild relatives (CWRs) *in situ* conservation.

For evaluating the share and importance of CWRs in the vegetation cover, we derived the phytocenotic significance index for each species on the basis of its frequency and abundance values. The conclusion about the conservation significance of an individual habitat was made on the basis of the biocenotic success of CWR species, conservation priority of these species, and the importance of the woodlands.

Assessment of CWR resources was carried out both within and outside the protected areas of the region. The high concentration of different valuable CWR species within the protected areas indicates to the necessity of additional protective measures regarding these areas. The woodlands, rich in rare CWR species, and/or possessing unique or diverse populations of these species outside the protected areas, were recommended for establishing *in situ* genetic reserves.

P2278. Influence of human damage actions and soil characteristics in the establishment and development of secondary forest in sand coastal plain vegetation (Restinga Forest) of the littoral area in the state of São Paulo, Brazil

R. M. Reis-Duarte[1], J. C. Casagrande[1], O. A. Silva[1], L. M. Barbosa[1], L. S. Sato[1], M. M. Bueno[2];
[1]Bioscience Institute, Rio Claro, Brazil, [2]Pau Brasil of Natural History Institute, São Paulo, Brazil.

The sand coastal plain vegetation (Restinga Forest) has been described as an ecosystem associated with the Atlantic Forest, constituted of mosaics, which occur in areas of great ecological diversity. This work was carried out in the Anchieta island, a State Park in the city of Ubatuba in the northern coast of the state of São Paulo, Brazil (45º02' - 45º05' W and 23º31' - 23º34' S). The soil umidity associated with the type and intensity of human damage actions, as well as the natural time regeneration, creating the soil fertility patterns, determined the vegetation physiognomies found in the mosaic of that secondary forest. Based on such information and the plasticity of the most representative plant species, was suggested a model of plantation for natural recovery of gallery forest in Restinga ecosystems.

P2279. Relationship between threatened species richness, habitat diversity and landscape structure: a case-study from a National Park in Northern Portugal

H. Hespanhol[1], C. Vieira[1], Â. Lomba[2], J. Torres[2], P. Alves[2], J. Honrado[1], F. Barreto Caldas[1], A. Séneca[1];
[1]Botanical Department, Science Faculty and Research Centre on Biodiversity and Genetical Resources (CIBIO), Porto University, Porto, Portugal, [2]Research Centre on Biodiversity and Genetical Resources (CIBIO), Porto University, Porto, Portugal.

The lack of information on biodiversity patterns and on ecological processes underlying those patterns is often an obstacle in management plans for natural and semi-natural landscapes. This is particularly critical in protected areas, which are repeatedly used as models for the development of methodologies regarding the protection and management of biological diversity, since the required ecological data is most often available for these areas and the moderate human impact allows different levels of disturbance to co-exist.

This work addresses the influence of landscape structure and distribution patterns of natural habitats on the local richness of threatened bryophyte and vascular flora. Both GIS-based spatial analyses and statistical techniques are used, since they have been proved to be powerful tools on the establishment of relationships between the variation of ecological factors and biodiversity patterns. A synthetic model relating species, habitat and landscape patterns is proposed using data from Peneda-Gerês National Park (Northern Portugal). The significance of this model for management purposes is discussed.

P2280. Old growth stands in riverine forests of the Transcarpathian lowland (Ukraine)

A. C. Drescher[1], B. Prots[2];
[1]Institute of Plant Sciences, Graz, Austria, [2]State Museum of Natural History, NAS of Ukraine, Lviv, Ukraine.

In spite of the dramatic reduction of lowland riverine forest in the Transcarpathian lowland (NE Hungarian Plain, Ukraine) highly valuable old growth stands of riverine hardwood forests have survived.

The sites are characterized by alluvial gley soils and high ground water table or flooding connected with snow melt in spring or rain periods all over the year.

The analysis of a permanent plot of 0.2 ha shows an uneven aged stand with an upper canopy dominated by *Quercus robur* and *Fraxinus angustfolia* subsp. *danubialis* with dimensions of more than 40 m height and 130 cm breath height diameter/BHD). The lower canopy is represented by a high number of stems of *Acer campestre* and *Carpinus betulus* up to 40 cm BHD, *Ulmus minor* and *U. laevis* are less frequent. The stem diameter distribution is typical for unmanaged woodland.

Beside the monitoring of the forest renewal processes the occurrence of rare or Red List species e.g. *Epipactis albensis, Hottonia palustris, Thelypteris palustris, Urtica kioviensis* are further reasons for the urgent conservation need of this largely overlooked biodiversity hot-spot and largest surviving remnant of Central European Riverine forests.

P2281. Characterization of management unities (biótopos) of a conservation unity based on landscape ecology.

J. S. Bortolotti, M. Porto;
Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil.

The Santana Hill, concerning its natural resources, represents an important area covered by woods, fields and native brushwood located in south of Brazil. It comprehends an area of approximately 1000 hectares, from which around 360 ha constitutes the Conservation Unity. Because it is a natural area amid urban centers, the types of potential uses of this Conservation Unity extend themselves to natural environment conservation use, where certain zones could be established where such uses as leisure, environment education, among others, should be allowed. The recognition of possible zones with potential diverse uses, which will constitute the management unities (“biótopos”) of the area, will be achieved utilizing the physical characteristics (declivity, altitude, solar exposition and humidity of soil), spatial structure of the landscape (landscape rates), and, we will relate the variants from the ecological processes (characterizing the dominant vegetal species) of the landscape elements. The relationship between the valuation of association vegetables and the valuation of spatial structure of the landscape will show the management unities.

P2282. How Taxonomy contributed to the Conservation of Natural Ecosystems in Suriname

M. C. M. Werkhoven;
Head National Herbarium of Suriname (BBS), Anton de Kom University of Suriname, Paramaribo, Suriname.

The Republic of Suriname, has about 90% of its land surface (164,600 sq.km) covered with forest. Since the Nature Conservation Law was promulgated in 1954 , 11 Nature Reserves, 1 Nature Park, and 4 Multiple-use Management Areas have been established. They cover 13 % of the land surface.In 1998 three existing Nature Reserves (Tafelberg, Eilerts de Haan Gebergte and Raleighvallen / Voltzberg) have been linked into the Central Suriname Nature Reserve, (CSNR), with an area 59,053 square km. In 2000, the CSNR was put on the UNESCO World Heritage List. During the Guayana Shield Priority-setting Workshop in 2002, organized by the Guiana Shield Initiative, (**GSI**), the Netherlands Committee for the World Conservation Union (**IUCN**), and Conservation International Washington (**CI**), the CSNR has been designated as a Priority 3, on a scale from 1-4 (high for Biological Priorities and Pressure). The focus will be on the endemic and rare plant species in the CSNR, and their importance for the fauna .

P2283. Monitoring the effects of human trampling disturbance on *Senecio incanus* L. and *Salix herbacea* L. fragmented small populations in the N-Apennines (Italy).

G. Parolo[1], G. Rossi[1], L. A. Zonta[1], J. A. Crawford[2], R. Gentili[1];
[1]University of Pavia, Pavia, Italy, [2]Gran Canyon National Park, Flagstaff, AZ, United States.

In the highest elevations of the N-Apennines, some species growing in small fragmented populations are considered locally rare for phytogeographical and ecological reasons. These populations are at or toward the southern border of their range, are largely isolated from populations growing in the Alps, and are dependant upon late season snow cover. An overall trend of increasing visitation and associated natural resource impacts have been detected in the N-Apennines, in particular in the Mount Prado area of Tuscan-Emilian Apennines National Park. In the Mount Prado area, *Salix herbacea* L. and *Senecio incanus* L. subsp. *incanus* are sensitive to environmental stresses and are in great danger due to human trampling disturbance and to the global warming phenomenon. Since 1999, high visitor impact stands and unimpacted stands were monitored by our research team in permanent quadrats. The measured variables included: total vegetation cover; cover and fruit number of *Senecio incanus* and *Salix herbacea*; late season snow cover.

P2284. Macrophytes and flood impact in a Danube anabranch, a “Natura 2000”-protected area in Linz (Austria)

V. Strausz[1,2], G. Janauer[1], N. Exler[1];
[1]Department of Limnology and Hydrobotany, 1091 Vienna, Austria,
[2]Institute for Plant Sciences, 8010 Graz, Austria.

In 2001 and 2002 the aquatic vegetation was surveyed in the “Mitterwasser” anabranch of the River Danube near Linz (Province of Upper Austria). Comparative field studies using the Kohler methodology were carried out four times per vegetation period in order to show fluctuations in the relative plant mass, the species composition, and distribution of the occurring macrophytes. An additional survey in 2003 showed changes in the vegetation following the flood in August 2002.

The present information is of special importance as a reference to possible future man-induced changes in this system. Today this part of the former Danube floodplain is separated from the main river channel by the levees of the run-of-river power station Abwinden-Asten near Linz. An artificial channel system is planned to ameliorate surface and ground water conditions, but the permanent inflow of cold river water may delay the germination of important aquatic plant species.

The present project was supported by the provincial government of Upper Austria and the Dr. Heinrich Jörg-Foundation (Graz).

P2285. Biodiversity value of Mediterranean temporary ponds in North-western Sardinia

S. Bagella, E. Farris, R. Filigheddu, S. Pisanu;
Dipartimento di Botanica ed Ecologia Vegetale, Sassari, Italy.

Temporary ponds are small and shallow water bodies, which exist only in a part of the year. Despite their vulnerability, their presence is often favoured by traditional pastoral and agricultural activities. The flora is mainly composed of amphibious Mediterranean species including numerous endemic and rare. The case study illustrates the botanical biodiversity of temporary ponds in a protected area (Asinara National Park) and in a close unprotected one where traditional livestock activities are still practised. Different pond types, belts (inside the ponds) and communities were analyzed. Alpha (species richness and eveness) beta and gamma diversity were assessed for each of them in terms of wetland macrophytes. In addition, rare species or unique to an assemblage were listed. Comparison inside and between the areas and with the entire regional gamma diversity were made in order to point out the conservation value of each assemblage and each area. Threats and possible mitigation were also identified. The results allow to define strategic conservation goals for temporary ponds across the landscape as a whole.

P2286. Field guide to the plants of the *páramo* of Cajas (Ecuador): an example to encourage and support biodiversity conservation

C. Ulloa Ulloa[1], S. Alvarez[2], P. M. Jørgensen[1], D. Minga[3];
[1]Missouri Botanical Garden, St. Louis, MO, United States, [2]Corporación Municipal Parque Nacional Cajas, Cuenca, Ecuador, [3]Universidad del Azuay, Cuenca, Ecuador.

The field guide to the plants of the páramo vegetation of Cajas National Park is the first illustrated guide to any protected area in continental Ecuador. It was produced in collaboration with local biologists and with support of park administrators. The guide, in Spanish and English, comprises one hundred species, is written in simple but accurate language and illustrated with color photographs. It is intended as an identification tool for the non-botanist. It will enable visitors to the Park, local guides, and authorities to recognize, name, and understand the use of the wild plants and gain an increased appreciation of the flora of this threatened ecosystem and of Ecuador in general, motivating them to better manage and conserve both the plants and their environment. We believe that through education we can conserve species in Ecuador. The guide and additional materials are also available online and reviewers and users have found the website to be one of great quality and merit.

P2287. Differentiation of woodland communities in relation to wood age in the Ojców National Park (Southern Poland)

L. Moszkowicz;
Instytut of Botany, Jagiellonian University, Cracow, Poland.

Ojców National Park (2145 ha) was established in 1956, in aim of protection floristic and community richness of the Krakowsko-Czestochowska Upland. This terrain is specific for rich relief and lime rocks. It causes that occur here kserothermic grasslands, scrubs and woodlands communities with large number species of plants. Relationship between types of forest’s communities and age of woodland were studying by comparisons map of plant communities and map of woodland ages. First one was done in support of Braun-Blanquet method. Map of woodland age was prepared independently by studying old and actual cartographic, historic and botanic documents. It was found that ancient forests consist of well-developed forest communities: Dentario-glandulosae-Fagetum, Phyllido-Aceretum, Pino-Quercetum and Tilio-Carpinetum. Most of recent woodlands established in the last 200 years represent Pino-Quercetum, Tilio-Carpinetum. As a rule, they are very poor in typical woodland herb species. Results prove that it is really long process of developing woodlands communities in recent woods. It is caused by very slow colonization new woodlands by forest plant species.

P2288. A Pilot Network of Plant Micro-Reserves in Western Crete

C. A. Thanos[1], C. Fournaraki[2], K. Georghiou[1], P. Dimopoulos[3], E. Bergmeier[4];
[1]Department of Botany, National & Kapodistrian University of Athens, Athens, Greece, [2]Seed Bank and Botanic Garden, Mediterranean Agronomic Institute of Chania, Chania, Greece, [3]Lab. of Ecology and Biodiversity Conservation, Dept. of Environmental and Natural Resources Management, University of Ioannina, Agrinio, Greece, [4]Dept. Vegetation & Phytodiversity Analysis, Albrecht-von-Haller Institute for Plant Sciences, University of Goettingen, Goettingen, Germany.

Within the framework of a LIFE-NATURE-2004 project, a Pilot Plant Micro-Reserves Network is about to be established in Western Crete, Greece (Chania Prefecture). The network is comprised by 7 reserves selected among a total of 14 locations, within the boundaries of 3 pSCI (Natura 2000 sites): Gramvousa (GR4340001), Elafonisos (GR4340002), Lefka Ori (GR4340008). Each of the 6 reserves refers to each of the 6 plant species of Community priority (Directive 92/43/EEC) growing in Chania

Prefecture: **Androcymbium rechingeri*, **Anthemis glaberrima*, **Bupleurum kakiskalae*, **Cephalanthera cucullata*, **Hypericum aciferum*, **Nepeta sphaciotica*; the last reserve encloses part of the priority habitat type 9370, *Palm groves of *Phoenix*. The micro-reserves also embrace a significant number of other important plants (endemic, rare and threatened species). The network will be implemented by enclosures, wardening and on-site mild management measures. Permanent plots and automatic stations are to be established in each reserve for long-term monitoring. In addition, ex situ management of the targeted species and an information campaign will complement the network.

P2289. Can management compensate atmospheric nutrient deposition in heathland ecosystems?

W. Haerdtle, T. Niemeyer, M. Sieber, S. Fottner;
Institute of Ecology, Lueneburg, Germany.

The increased deposition of nutrients from the atmosphere has contributed to widespread changes in both the structure and function of many heathland ecosystems throughout Europe. Therefore heathland management nowadays is considered as an important tool, to modify ecosystem impacts caused by atmospheric nutrient loads. In our study we compared the effect of mowing, prescribed burning, grazing and sod-cutting on the nutrient balance of heathland ecosystems. We analysed the atmospheric nutrient input, the output due to the removal of a particular compartment (biomass, organic layer, A-horizon), and increased leaching rates. Our results show that heathlands subjected to extensive measures will accumulate N on the long-term. Hence, N removal by means of mowing or prescribed burning cannot compensate atmospheric N deposition. As output/input relations for P exceed those for N, it is likely that N/P-ratios in the vegetation and soils on the long-term will increase. Hence, we assume that heathland ecosystems nowadays limited by N may shift to more P-limited ones on the long-term.

P2290. Modelling of the populations as a method of plant conservation ex situ.

V. I. Melnik;
M.M.Grishko National Botanical Garden of National Academy of Sciences of Ukraine, Kyiv, Ukraine.

Among the specialists in Environmental Sciences are prevailed opinion about shedding the rare and endangered species of plants from plant cover under the influence of substitution of the natural forests by artificial. Our experience of modelling the populations of rare species of the plants in cultivated coenose in National Botanical Garden of Ukrainian Academy of Sciences does not confirmed this point of view. The rare species of Ukrainian flora (Astrantia major, Crocus heuffelianus, Gymnospermium odessanum, Euonymus nana, Leucojum vernum, Lunaria rediviva, Scopolia carniolica and other) and Caucasian flora (Galanthus angustifolius, G. caucasica, G. woronowii, Erythronium caucasicum, Fritillaria caucasica and other) were formed in 60 years old artificial beech, oak, hornbeam - oak, pine and spruce forests stable populations simuler to the populations of these species in natural habitats.

The problem of the conservation rare plant species in artificial forest ecosystems is actual for all Eurasia. It's necessary to elaborate common programme of study, conservation and modelling the rare plant species population in artificial forests.

P2291. Regional landscape park “Dnieper islands” in Kiev. Its flora, vegetation, the tendency of synanthropization and measures of protection.

A. Tsukanova;
Institute of Botany of the National Academy of Science, Kiev, Ukraine.

The flora and the vegetation of the island in Kiev and a part of the Dnieper bank (together 6 000 ha) were learnt during 1999-2003. The significant floristic diversity was registered: 717 species, belonging to 356 genera and 99 families. But 40% of species are synanthropic (19% are alien species and 21% - apophytes). Nevertheless similar percentage was registered for other territories, even relatively well preserved, which reflects general tendency of synanthropization of the flora of Ukraine. Among the alien species epoecophytes and ergasiophytes prevail, 60 found species are expansive in the country. The analysis of flora shows its transitive character from forest to forest-steppe flora. The vegetation is represented by 15 cl., 24 ord., 33 all., 61 associations. Presence of 12 rare species and 5 plant communities is noted. The protection of the territory in the category of the regional landscape park is desirable. This category exists since 10 years in Ukraine. It provides the combination of the nature protection, recreation and eco-education and is suitable for such a protected area within the capital city.

P2292. Vegetation and Flora of the Serpentines of Andaman Islands, India in need of protection.

P. K. Mukherjee, S. Datta, K. Chaudhury;
Cacutta University, Calcutta, India.

Typical vegetation and flora on the serpentines of the Andaman Islands, India, has not been included in the general description of the vegetation of these islands except by Parkinson (1923). Uniqueness of the vegetation and flora and the geomorphology of the particular areas deserve attention for prioritization in conservation. Serpentine soils occur sporadically in the Andaman Islands. Only one of these localities, Saddle hills in the North Andaman has been declared as a National Park. The present study describes the characteristic serpentine ecology, vegetation and flora of Saddle Hills and the Rutland Island, South Andaman. Remote sensing analyses help to discriminate typical serpentine vegetation from the surrounding non-serpentine areas. Sparseness, dwarfing and transformation to scrubby sclerophyllous vegetation with altitude all are evident. Besides, elevated concentrations of heavy metals like Ni, Co, Cr, and Zn, the soil match to other characteristics reported from elsewhere. Presence of a number of hyper-accumulators of these elements can be related to their endimicity locally besides adding up to the list of Ni hyper accumulators.

P2293. Efficiency of the vascular plant protection for the south part of the Russian Far East in natural reserve net of Primorye and Priamurye

Z. V. Kozhevnikova, A. E. Kozhevnikov;
Institute of Biology and Soil Science, Vladivostok, Russian Federation.

The level of taxonomical diversity of the vascular plants in Primorye and Priamurye is very close to each other and counts 2592 and 2541 species of natural flora accordingly, but the degree of anthropogenic transformation of indigenous flora in Primorye is much above and reaches 22.1 % against 14.4 % in Priamurye (Kozhevnikov, Kozhevnikova, 2004). The Natural Reserve Net in Priamurye and Primorye consists of 15 Natural Reserves (NR). Total flora of 12 of them includes 1983 indigenous species and 240 adventive (alien) ones. Floristic researches in other 3 NR (Bastak, Bolonjisky and Botchinsky) are not finished yet.

The level of protection of indigenous flora in NR in Primorye makes 81.1 %, i.e. appreciably higher than in Priamurye (65.6 %); for Primorye and Priamurye this parameter as a whole is equal 76.8 %. The average adventive index of the flora of NR in Primorye and Priamurye makes 10.9 %. The high level of adventive index for NR of Priamurye is determined by Bolshehehtsirsky NR where it reaches the highest level (12.5 %) among all considered NR. As a whole, NR of Primorye differ from NR of Priamurye by higher level of presence of adventive species at their flora.

P2294. Long-Term Study on the Virgin Korean Pine-Broadleaved Forests of Ussuriisky Zapovednik in Southern Primorsky Kari, Russia

H. S. Kang[1], A. I. Kudinov[2], Y. I. Man'ko[2], D. K. Lee[1], C. D. Oliver[3];
[1]Seoul National University, Seoul, Republic of Korea, [2]Institute of Biology and Soil Science, RAS, Vladivostok, Russian Federation, [3]School of Forestry and Environmental Studies, Yale University, New Haven, CT, United States.

The Ussuriisky Zapovednik is a nature reserve of the IUCN Category (Ia), with high biodiversity and complex stand structures located in Russian Far East. To understand the stand dynamics of the virgin Korean pine-broadleaved forests, two permanent study plots were established in 1954 and 1964, respectively. Plot 7 was established in 1964 (0.35ha) and plot 10 was established in 1954 (0.36ha). Both were re-measured in 1977, 1985, 1991 and 2003. Major tree species of the two plots were Pinus koraiensis, Abies, Carpinus, Tilia, Acer, Ulmus and Juglans. At times of plot establishment, there were 13 tree species in plots 7 (in 1964) and 11 species in plot 10 (in 1954). Tree number was highest in 1977 (777 trees/ha) in plot 7 and decreased gradually to 632 trees/ha by 2003. However, in the plot 10, there were 600 trees/ha in 1978, 520 trees/ha in 1991 and 555 trees/ha in 2003. Monitoring of species composition, stand density, stock volume and natural regeneration characteristics at the study plots suggests that the dominant species, Pinus and Abies, will decrease because of low regeneration while hardwood species will rapidly increase and reach the canopy in the near future.

P2295. Relict and endemic plants of Kolkheti mires and their conservation

I. Z. Matchutadze;
Society for Conservation of Wild Nature, Batumi, Georgia.

Kolkheti lowlands, where the Sphagnum mires are situated belongs to: province - Colcheti or eastern euxinus, district - Colcheti lowland and foothills, world - oldest Mediterranean, region - submediterranean. The Kolkheti *Sphagnum* mires and its flora constitute relicts from the glacial period. Relict plant species which occurs mires of Kolkheti: *Sphagnum imbricatum, Sphanum papillosum, Drosera rotundifolia, Osmunda regalis, Carex lasiocarpa, Molinia litoralis, Rhynchospora caucasica, Rhynchospora alba, Licopodiela inundata, Hibiscus ponticus, Cladium mariscus, Kostaletskia pentacarpa, Spiranthes amoena, Dactilorhiza majalis, Rhamphicarpa medwedewii, Trapa colchica, Trapa natans, Trapa maleevi, Salvinia natans, Nuphar lutea, Nymphea colchica, Acorus calamus, Quercus imeretina, Quercus hartwissiana, Pterocarya pterocarpa, Buxus colchica, Pancratium maritimum, Asparagus litoralis, Solidago turfosa, Celtis australis etc.*

P2296. Persistence of exotic Australian fungi and genetic diversity of native fungi after eucalypt eradication in protected areas of the Iberian Peninsula

E. Fernandez, A. Muriel, J. Diez;
Universidad de Alcala, Alcala de Henares, Spain.

The introduction of Australian ectomycorrhizal fungi with eucalypts increases eucalypt invasiveness in Iberian Spain. Spanish authorities, hence, promote the eradiation of these exotic trees from National Parks. We study the persistence of the exotic fungi after the eucalypt eradication, and how this affects the populations of native fungi and the fitness of native trees we plant. We studied the fungal diversity in soils of former eucalypt plantations in which native trees were planted after eucalypt eradication. We used RFLP-T and DNA sequencing of the ITS regions of the nuclear rDNA for fungal identification in soil samples. Native species were the main fungi we found in soil of the plantations of cork oak (*Quercus suber)* (i.e. *Laccaria lacata*) we studied. Our genetic analyses indicated the populations of the fungal species colonizing the roots of native trees were very diverse (i.e. *Pisolithus* spp.). Many of the Australian fungi have disappeared from the assessed areas (after the eradication of the eucalypts), though some exotic fungi still persist (i.e. *Laccaria fraterna*).

P2297. Pteridophytes of the sandy coastal plains of Rio de Janeiro state, Brazil: species richness, distribution and conservation

M. G. Santos[1], D. S. D. Araujo[2];
[1]FFP-UERJ / Museu Nacional-UFRJ, São Gonçalo, Brazil, [2]UFRJ, Rio de Janeiro, Brazil.

Restinga vegetation is found on sandy coastal plains in Brazil, and has strong links to the coastal Atlantic Forest. The most common plant communities are open scrub, beach-thicket, sedge swamp, creeping psammophytes, flooded forest and periodically flooded forest. A survey of pteridophytes found in the *restingas* of Rio de Janeiro is presented here, plus similarity indices between different restingas based on the pteridophyte flora. There are 19 families, 37 genera and 68 species; the following families are present: Aspleniaceae, Azollaceae, Blechnaceae, Cyatheaceae, Dennstaedtiaceae, Dryopteridaceae, Equisetaceae, Gleicheniaceae, Hymenophyllaceae, Lomariopsidaceae, Lycopodiaceae, Nephrolepsidaceae, Osmundaceae, Polypodiaceae, Pteridaceae, Salviniaceae, Schizaeaceae, Thelypteridaceae and Vittariaceae. The most species-rich families are Polypodiaceae (14 spp) and Pteridaceae (10 spp). *Polypodium triseriale* Sw. was found in all *restingas*. Similarity values are low for the pteridophyte floras of several restingas on the Rio de Janeiro coast. These results are important for effective conservation of the *restingas*.

P2298. Share of ancient forest plant species in recent forests as a criterion for their valuation and reconstruction: case study the Slowinski National Park (Poland)

A. Brzeg[1], **B. Jackowiak**[2], M. Kasprowicz[3];
[1]Adam Mickiewicz University, Department of Plant Ecology and Environmental Protection, PoznaŒ, Poland, [2]Adam Mickiewicz University, Department of Plant Taxonomy, PoznaŒ, Poland, [3]Adam Mickiewicz University, Department of Plant Ecology and Environmetal ProtectionTaxonomy, PoznaŒ, Poland.

The Slowinski National Park (SNP), known as the World Biosphere Reserve, is situated in central part of the Polish Baltic Seashore. As result of authors' phytosociological investigations conducted there in 2002-2003 also the real and potential natural vegetation has been mapped. An analysis of both these maps revealed significant discrepancies between types of real and potential natural vegetation. Anthropogenic forest communities of substitution occupy large areas, especially in the southern part of SNP. Their affiliation to known associations of natural character is impossible since there are mainly monocultures of birches, spruce or different pine species, which partly have been established on formerly arable areas. An attempt of using the criterion of presence of ancient forest plant species for estimation of the degree of disturbance of each forest association is presented. This criterion was also used for elaboration of documents on valuation and reconstruction of phytocoenoses of chosen types, i.e.: Betulo-Quercetum roboris, Querco-Ulmetum and Stellario-Carpinetum.

P2299. Conservation of an endangered shrub in the southeastern United States

M. S. Devall, N. M. Schiff, S. A. Skojac;
Center for Bottomland Hardwoods Research, Stoneville, MS, United States.

Pondberry [*Lindera melissifolia* (Walt) Blume, Lauraceae] is an endangered shrub that occurs in the southeast United States in seasonally flooded wetlands. Its distribution and abundance have been affected by habitat destruction and alteration. We investigated the establishment of new pondberry populations as an aid in conserving the species. In the fall of 2000 we dug equal numbers of young male and female pondberry stems from a natural population and planted them in pots. We then translocated them to five protected locations in Mississippi. Each pair of plants was surrounded by a wire cage on wooden supports, and was labeled. We watered the plants during dry spells for the first two years. We have monitored and measured the plants since they were introduced. After four years, pondberry survival has been good at three of the five sites. The Lower Mississippi Alluvial Valley, in which most present pondberry populations occur, is one of the most endangered ecosystems in the United States. Pondberry populations that die out usually will not be replaced. This study indicates that introduction of pondberry to new sites can be helpful in assuring survival of the species.

P2300. Vegetation of Altinbesik Cavern National Park (Ibradi-Akseki / Antalya-Turkey)

I. Cinbilgel, **M. Gokceoglu**;
Akdeniz University, Faculty of Arts and Sciences, Biology Department, Antalya, Turkey.

Altinbesik Cavern National Park, where eco-tourism is very important, is located in the Western Taurus Mountains between the towns Ibradi and Akseki in the east and northeast of Antalya. WWF has identified in 1999 the 100 forest areas, which are the most valuable in terms of biodiversity in Europe and which must urgently be protected, and it has been pointed out that one of these areas, which are identified as "The Hot Spots of European Forests" and nine of which are found in Turkey, is the natural areas around Ibradi-Akseki.

Within the area 9 different kinds of communities belonging to the forest, maquis, water-side, rock and scree vegetations have been diagnosed, namely **Crataegus monogyna-Pinus brutia, Tordylium ketenoglui-Juniperus excelsa, Pistacia terebinthus-Quercus coccifera, Phillyrea latifolia-Arbutus andrachne, Nerium oleander-Platanus orientalis, Onosma frutescens base community, Arabis davisii-Alkanna oreodoxa, Bupleurum erubescens-Pelargonium endlicherianum, Geranium lucidum-Ricotia sinuata.**

Within the area, a clear dominance of **Quercetea ilicis**, **Quercetalia ilicis** and **Quercion calliprini** has been identified.

P2301. Important factors for the creation of nature reserves

S. Nordström, **J. Mattsson**;
Department of life sciences, Huddinge, Sweden.

Since 1999, it is possible for local authorities in Sweden to initiate the creation of nature reserves in order to achieve a more locally founded conservation practice. So far 83 out of Sweden's 280 local authorities have taken advantage of this possibility and 169 nature reserves have been formed. The number of nature reserves is particularly low in local authority areas with dominating boreal forests which also often are the largest ones.

The reasons for these large differences between local authority areas are assessed. Primarily, the allocation of resources to the nature conservation authorities is an important factor. Further, it seems to be differences in attitude towards formation of nature reserves but also in views on how to evaluate different areas from a nature conservation viewpoint. These differences seem to be founded both on scientific studies or information as well as on less well founded prejudice.

Another important factor promoting the creation of nature reserves seems to be the presence of qualified and competent ecologists in the administration of the local authorities.

P2302. Conservation of threatened plants in the Cape Floral Region

D. C. Raimondo, I. Ebrahim, J. S. Donaldson, **A. Hitchcock**;
South African National Biodiversity Institution, Cape Town, South Africa.

The Cape Floristic Region (CFR) has over 9000 species of plants. Recognized as a Global Biodiversity Hotspot, it currently has 526 threatened plant species.

Given the large number of threatened plants, and the limited capacity of conservation organizations, monitoring the status of populations of these species is extremely challenging. The South African National Biodiversity has set up a program that capitalizes on botanical amateur expertise. Volunteers survey fragments of threatened habitats for threatened plant populations, capturing abundance data, distribution data and threats affecting each species. These data are captured in a national database used for red listing and land-use planning. In addition, volunteers contribute to conserving critical sites for threatened plants through active management and awareness creation amongst landowners. Here we provide updated information on the threat status of plants in the Cape Floral region, explore the effectiveness of using volunteers for monitoring and look at the challenges of systematically surveying areas to ensure all populations are encountered for accurate threat status analyses.

P2303. Towards a Working List of Known Plant Species

F. A. Bisby[1], A. Paton[2], Y. Roskov[1];
[1]The University of Reading, Reading, United Kingdom, [2]Royal Botanic Gardens Kew, Richmond, United Kingdom.

A gap analysis of the taxonomic coverage needed for an electronic Working List of Known Plant Species was carried out at a workshop organised by Species 2000 and the Royal Botanic Gardens, Kew, and sponsored by GBIF and the UK BBSRC. Creating such a list by 2010 is Target 1 of the CBD Global Strategy for Plant Conservation. Experts from around the world, and covering a wide range of taxa, carried out the analysis, based on existing checklist databases plus existing monographic and checklist activity, so as to identify the missing sectors which amount to approximately 45% of known plants. An attempt was made to identify contacts with groups of specialists who might assist with filling these gaps, as wide international participation will be needed if the target is to be met. The priority now is to organise and fund a progressive acceleration of activities, particularly for the missing groups. A further open 'satellite meeting' will be organised at the IBC after this session.

P2304. Global Patterns of Vascular Plant Diversity - where are the "most important areas for plant diversity"?

W. Barthlott, G. Kier, H. Kreft, W. Küper, D. Rafiqpoor, **J. Mutke**;
Nees Institute, University of Bonn, Bonn, Germany.

The diversity of vascular plants is very unevenly distributed on the globe. We present world maps of species richness and endemism for vascular plants as well as different subgroups, such as gymnosperms. Most of the global maxima of plant diversity are located in mountainous regions within the humid tropics, where suitable climatic conditions and high levels of geodiversity, i.e. the variety of abiotic conditions, coincide. Though the 20 global maxima of plant diversity (more than 3,000 vascular plant species per 10,000 km2) cover less than 7% of the land surface, they are inhabited by approximately 860 million people (about 14% of the human population). The questions to be addressed with our datasets are: 1) where are hotspots and good news areas for plant diversity, where are congruencies and differences to other global priority setting approaches 2) what are the factors causing the overlap between high diversity and high human impact, 3) is it possible to select a few indicators to asses the status of plant diversity?

P2305. The distribution of species of the tribe Neottieae (Orchidaceae) in Ukraine

I. A. Tymchenko;
M.G. Kholodny Institute of Botany, Kyiv, Ukraine.

All species of the tribe Neottieae are rare in Ukraine and included in National Red book. The complete mapping of all known localities of species of the tribe Neottieae in Ukraine is espesially important for the organisation of their conservation.

The tribe numbers 5 genera (Cephalanthera, Epipactis, Limodorum, Listera, Neottia) and 12 species. Epipactis helleborine, Listera ovata and Neottia nidus-avis are widespread in Ukraine. They occur in all forest and forest-steppe regions and the total amount of known localities is over 150. The species of genus Cephalanthera are widespread in West-bank of the Dnipro river part of Ukraine. Epipactis purpurata are found only in western and south-western regions of Ukraine. Only crimean localities are known for Limodorum abortivum and Epipactis microphylla. The last species was found in Transcarpathia at the beginning of XXth century.

The species diversity and concentration of localities decrease from west to east that may be explained by ecological and cenotic peculiarities of species, the variety of antropogenous transformation of the territories and also different level of studing of regions.

P2306. Understanding a rare species. The case of *Orthotrichum rogeri* Brid. in the Pyrenees.

L. Pokorny[1], R. Garilleti[2], F. Lara[1], V. Mazimpaka[1];
[1]Dpto. de Biología (Botánica), Fac. de Ciencias, Universidad Autónoma de Madrid, Madrid, Spain, [2]Dpto. de Botánica, Fac. de Farmacia, Universidad de Valencia, Valencia, Spain.

Orthotrichum rogeri Brid. has previously been found in Austria, Belgium, Czech Republic, Denmark, France, Germany, Greece, Hungary, Italy, The Netherlands, Norway, Poland, Russia, Spain and Switzerland and it has been considered to be a rare moss throughout its range. Due to its reduced known distribution this epiphytic moss has been included in the Bern Convention (Appendix I) and Habitats Directive (Annex II).

Orthotrichum rogeri has often been confused with other species (*O. pallens* Brid., *O. stramineum* Hornsch. and *O. pumilum* Sw.) and it is possible that its area and, especially, its frequency will change with new studies. In a recent revision it has been possible to identify some new characters that allow a safer discrimination (Garilleti, Lara & Mazimpaka, Nova Hedwigia 75 (1/2): 207-216. 2002).

The main aim of this project is to increase the existing knowledge on this species in order to contribute to the conservation of this taxon and its habitat. The study of its Pyrenean populations will permit to obtain information on its ecological requirements, reproductive biology, dispersion, demographic parameters, with the view of drawing its life history.

P2307. Bulbous plants and their protection in Azerbaijan

G. J. Qasimova;
Institute of Botany, Baku, Azerbaijan.

Bulbous plants are biannual or long-term grasses on their vital forms. Representatives of bulbous plants in Azerbaijan belong to different families: *Alliaceae*, *Amaryllidaceae*, *Poaceae, Liliaceae, Iridiaceae.* Species of *Alliaceae* and *Liliaceae* are predominating. Bulbous plants widely spread in meadows, steppes, deserts, semi-deserts and the forest natural floristic complexes. They have mezophyte, xerophyte, mezoxerophyte and other ecological types. Presently, 120 species belonging to 12 genera (*Merendera* Ram., *Gagea* Salisb., *Allium* L., *Lilium* L.,*Tulipa* L., *Muscari* Mill, *Galanthus* L., *Sternbergia* W.K., *Ixiolirion* Fisch., *Iris* L., *Gladiolus*

L., *Bellevalia* Lapeyr.) are under threat of extinction. Rare species (*Allium vavilovii, A. caespitosum, A. engenii, A. grande, A. microbulbum, A. panlii, A. pskemense, A. regelianum, A. sergii, A. trautvetteranum*) of these genera have been registered in the Red List of Azerbaijan.

P2308. The rare medicinal plants of the Ukrainian Carpathians under the conditions of introduction

M. I. Skibitska[1], V. P. Yevtukh[2], N. Y. Yavorska[1];
[1]the Ivan Franko Lviv National University, Lviv, Ukraine, [2]the Danylo Halytskyi Lviv State Medical University, Lviv, Ukraine.

It is considered that the Ukrainian Carpathians are the treasure-house of medicinal plants. According to all available information the flora of this region has about 680 species of plants, which have the medicinal properties. The endemic, rare and disappearing medicinal plants are worthy of particular attention because it is important not only for biology but for the human health as the medicinal resources. According to The Red Book of Ukraine the rare and endemically plants in this region is counted about 89 species. The most important part of common strategy of the plant's care is their preservation under the introduction conditions. It is difficult, complex task which are solved by botanical gardens as well.

As a result of the introduction investigations is created the collection The Medicinal Plants that are counted about 250 species, which concern to 146 sorts and 48 families. The medicinal plants of the Ukrainian Carpathians in collection are 30 %, including plants from The Red Book: Lilium martagon L., Lunaria rediviva L., Aster alpinus L., Coleficum autumnale L., Scopolia carniolica Jacq., Gentiana lutea L., Gentiana punctata L., Rhodiola rosea L.

P2309. The rare species of flora Ukraine in Donetsk chain of hills

M. M. Peregrym;
M.M.Grishko National Botanical Garden of National Academy of Sciences of Ukraine, Kyiv, Ukraine.

Conservation of biodiversity natural ecosystems is one of the main modern problems. A Donetsk chain of hills is unique territory, where grows relic, endemic, rare and endangered species of plants. At the same time the industrial complex of Ukraine is concentrated on this territory with a plenty of the population. This considerably complicates conservation natural ecosystems.

In territory of the Donetsk chain of hills grows: 17 species included in Red Data Book of IUCN, 25 species included in the European Red List, 64 species included in the Red Data Book of Ukraine were established. Age and spatial structure of populations of the some rare species of plants (Scutellaria creticola, Paeonia tenuifolia, Fritillaria ruthenica and others) were investigated. Regularities of distribution, ecological and coenotical features rare species of flora of Ukraine on Donetsk chain of hills were determined.

On the basis of the received data principles of construction regional econet within the framework of National econet were developed.

P2310. Islands of the Baltic Sea as Refugia for Rare Plant Species

E. A. Glazkova;
Komarov Botanical Institute of Russian Academy of Sciences, Saint-Petersburg, Russian Federation.

Islands of the Baltic Sea being refugia of many rare plant species, requiring protection and monitoring, are the centre of attention of the scientific world on an international scale.

The detailed many years' floristic researches on the numerous islands of the Gulf of Finland let identify these islands as one of the most important plant areas (IPAs) in Europe, where effective protection, monitoring and management systems should be targeted. The flora of the islands characterizes by the following features: exceptional botanical richness, the presence of many Fennoscandia and Baltic Sea endemic plant species as well as a great number of species on the boundaries of their main distribution areas.

Due to specific nature features of the islands and high degree of island ecosystems' safety, their flora contains 130 species, listed as threatened in Red Data Books of Eastern Fennoscandia and the Baltic Region. Being highly vulnerable and sensitive to human interference, the island ecosystems deserve special attention as highly unique and valuable oasis of virgin nature.

P2311. The Rare species of Vascular plants of Ukraine in flora. The Left bank of the Dnieper of Polissia.

A. Rak;
National Botanical Garden, Ukrainian Academy of Sciences, Kyiv, Ukraine.

48 rare species of Vascular plants belong to 35 genera, 22 families and 3 sections, have been found out among the flora of the Left bank of the Dnieper of Polissia. 4 species of them are listed in the European Red List of Word - Wide Threatened Animals and Plants and 1 species are listed in the Red Book of International Union Nature Protection, 44 species are listed in the Red Book of Ukraine, 6 species are listed in the Convention on the Conservation of European Wildlife and Natural Habitats (Bern convention), 21 species are listed in the Convention on the International Trade of Endangered Species of Wild Fauna and Flora (CITES), 26 species are listed in the rare species of Vascular plants list of the Polissia.

Some rare species of Vascular plants in the Left bank of the Dnieper of Polissia such as Urtica kioviensis, Rumex ucrainicus, Crategus ucrainica, Tragopogon ucrainicus deserved special attention. All these 4 species are put Lawn on the European Red List of Word - Wide Threatened Animals and Plants, but on a national level they are not protected in Ukraine. To our mind, these rare species of plants is necessary to enter at in a new issue the Red Book of Ukraine.

P2312. Monitoring of medical plants in Russian Federation

T. L. Egoshina;
Russian Research Institute of Game Management and Fur Farming, Kirov, Russian Federation.

During last 25 years there was 10-15% decrease of Vaccinium vitis-idaea L. and Arctostaphylos uva-ursi L stocks because of ecotope distruction. The stocks of ruderal plants (Achillea millefolium L., Valeriana officinalis L., Urtica dioica L.) increased to 20-50%. Anthropogenic changes in flora caused the increase of Tussilago farfara L biological stock.

There was 20% diminution of Hypericum perforatum L. and Origanum vulgare L.bushes in 1980-1995. In some regions Juniperus communis fructiferous bushes vanished. The reason of populations state deterioration is over-pasture. At the end of 20th century bushes partly restored.

In 1985-1991 bushes of Rosa acicularis Lindl.and R. majalis Herrm.decreased to 8-12%. Since 1995-1997 in view of low level of agriculture on water-meadows they began to renew. By 2004 areas of R. majalis exceeded the level of 1983. Stock fluctuation of Convallaria majalis L. did not exceed 5%.Stock regression is more significant in central and southern part of Russia.

P2313. The Italian Seed Bank Network for native species conservation (RIBES)

C. Bonomi[1], G. Rossi[2], G. Bedini[3];
[1]Museo Tridentino di Scienze Naturali, Trento, Italy, [2]Dipartimento di Ecologia del Territorio dell'Università, Pavia, Italy, [3]Orto Botanico, Dipartimento di scienze Botaniche dell'Università, Pisa, Italy.

At the beginning of April 2004 a group of approximately 20 Italian institutions involved in seed conservation met in Trento (NE Italy) to discuss the possibility to team up to manage more efficiently native seed conservation practice at national level. The idea itself was launched by the authors of this presentation who are members of ENSCONET, the European Native Seed Conservation Network, and agreed to act at national level to provide a link between ENSCONET and the Italian setting. They received enthusiastic support from all institutions contacted. Since then further meetings took place in Rome, Milan and Pavia during 2004 and 2005. A consortium agreement, a charter, various internal regulations and an action plan were discussed in detail and approved with a participative approach. The poster presents and illustrates in detail this initiative that aims to contribute to the implementation of the Global Strategy for Plant Conservation at regional and national level (targets iii, viii, xiv and xvi).

P2314. Some biological aspects affecting *Mimosa* (Leguminosae-Mimosoideae) seedling establishment in Mexican natural ecosystems

M. E. Fraile-Ortega, **S. L. Camargo-Ricalde**, A. Martínez-Bernal, R. Grether;
Universidad Autónoma Metropolitana-Iztapalapa, México, D. F., Mexico.

Seedling stage is an important phase in ecosystem natural regeneration. *Mimosa* species are well spread over Mexico and become dominant in disturbed ecosystems. This study focuses on seedling morphology and growth, and on seedling association with nitrogen fixing bacteria and arbuscular mycorrhizal fungi. Cotyledons are functional and persist during 6 weeks after germination. First eophyll is paripinnate and hypocotyl develops adventitious roots. In woody species, lignification occurs when seedlings are 4-6 weeks old. At that age, *Mimosa* seedlings also form nitrogen-fixing nodules and mycorrhizae. Mycorrhizal seedlings have more biomass than non-mycorrhizal ones, allocating more resources to the shoot than to the root; mycorrhizae improve seedling resistance to water stress and to predators, and favor soil nutrients uptake. The overall of these characteristics lead *Mimosa* seedlings to establish soon in time, becoming more competitive than those of other species. Morphological and growth features, plus symbiotic associations, may have a synergistic effect that could partially explain the ecological success of *Mimosa* species.

P2315. Study on the seed and seedling biology of nine highly endangered trees and shrubs endemic to the Caribbean: its implications for their conservation

E. Santiago[1,2], R. Rivera[3], J. Rodriguez[3], M. Caraballo[4];
[1]Herbario, Jardin Botanico, San Juan, PR, United States, [2]Departamento de Biologia, Universidad de Puerto Rico, San Juan, Puerto Rico, [3]Fideicomiso de Conservacion de Puerto Rico, San Juan, PR, United States, [4]Departamento de Biologia, Universidad de Puerto Rico, San Juan, PR, United States.

We compared the seed and seedling biology of nine highly endangered trees and shrubs endemic to the island of Puerto Rico: Calyptronoma rivalis, Cornutia obovata, Crescentia portoricensis, Eugenia woodburyana, Goetzea elegans, Harrisia portoricensis, Juglans jamaicensis, Pleodendron macranthum, and Schoepfia arenaria. They represent diverse critical habitats found on the island (humid and dry carst forest, coastal scrubs, dry serpentine forest, humid montane rainforest), as well as represent part of the taxonomic diversity of the plant species currently designated as endangered elements. Specificly, we assessed aspects of the flowering and fruiting of maternal plants, seed dormancy and germination, and seedling development in relation to their ecological requirements. Our results provide baseline data for in situ and ex situ conservation strategies of rare plant groups in the Caribbean, taking in consideration the differences in the species biology.

P2316. The Effects of Pre-Germination Treatments (GA$_3$, Polyamines KNO$_3$, H$_2$SO$_4$ and prechilling) of Endemic *Helleborus vesicarius* Aucher Seeds

S. Tansi[1], **S. Karaman**[2], N. Comlekcioglu[2];
[1]Cukurova UniversityAgricultural Faculty Field Crops Department, Adana, Turkey, [2]Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey.

Some *Helleborus* species (*H. niger, H. foetidus*) have important biological activities and medicinal effects. *Helleborus vesicarius* Aucher is an endemic species and distribute in South Anatolia from Turkey. Germination of *H. vesicarius* seeds collected from Kahramanmaras provinces during summer 2003 was evaluated using fallowing treatments: control, concentrated H$_2$SO$_4$ and than soaked 400, 600, 1000 ppm GA$_3$ concentrations, spermidine at 0,01 between 1mM, spermine at 0,01 between 1 mM, GA$_3$ at 200-400 and 600 ppm and prechilling in 0 °C at 2 or 3 weeks.

Germination was very low and first germinations were obtained after two months and germination trials were completed after 210 days. Germination ratio showed very differences ranging 0-80 % according to treatments. The highest germination 80% were obtained 200 ppm GA$_3$ concentrations. Higher GA$_3$ concentrations decreased germinations ratio. Spermine and spermidine at 0,1 mM and 0,01mM concentrations and stratification improved on germination.

P2317. *In vitro* propagation technique for conservation of two endangered *Dyckia* species (Bromeliaceae)

B. B. M. Pires[1], E. Tarré[1], A. P. Mançano[1], B. R. Silva[2], L. A. Carneiro[1], R. C. Forzza[2], E. Mansur[1];
[1]Universidade do Estado do Rio de Janeiro, Rio de Janeiro, Brazil, [2]Jardim Botânico do Rio de Janeiro, Rio de Janeiro, Brazil.

A reliable method for *in vitro* propagation of two endangered species of *Dyckia* was described. *D. pseudococcineae,* found in the coastal sand dune known as Barra de Maricá, is suffering an increasing impact caused by urbanization that leads to a significant risk of extinction. *D. ursina*, endemic to Cadeia do Espinhaço, albeit occurring in a National Park area, is highly endangered because of many kinds of external interference such as erosive processes in tracks, collapses, landslides, extractive actions, garbage and pasture. The influence of media, explant type and genotype on morphogenesis was evaluated. The general regeneration pattern was similar in the two species. The regeneration frequency and shoot production were significantly higher in *D. ursina* as compared to *D. pseudococcinea*, in all treatments evaluated. Regeneration frequency and shoot production were more efficient from leaf explants in *D. ursina*, while best results were observed in response to stem-root axis in *D. pseudococcinea*. In the system described here high multiplication rates were obtained in response to low concentrations of BAP and NAA.

P2318. Conservation of zigotic embryonic axes of Genipa americana L. (Rubiaceae) using cryopreservation in liquid nitrogen.

I. I. R. Santos, A. N. Salomão;
Embrapa Genetic Resources and Biotechnology, Brasília, Brazil.

Genipa americana L. is threatened due to predatory collection of fruits and destruction of its habitats. G. americana has intermediate seeds, that tolerate partial water content reduction, but loose viability when exposed to subzero temperature. Therefore, conservation of its seeds using the conventional methodology is not possible and alternative methods are required. The objective of this work was to develop a cryopreservation protocol for G americana axes. Seeds were desiccated over silica gel and cryopreserved in liquid nitrogen. Seeds were thawed and axes were excised and cultivated in vitro for viability assessment. Germination of axes excised from fully hydrated seeds (52% moisture content) was 97,5%. Desiccation reduced axes' viability and those excised from seeds containing 8% moisture content showed 44% germination. After cryopreservation, axes isolated from fully hydrated seeds (52% moisture content) presented 30% viability, but highest viability (100%) was attained by axes isolated from seeds with 8.1% moisture content. In conclusion, embryonic axes of G. americana can be cryopreserved with success just by adjusting their water content.

P2319. Seed Cryopreservation of Threatened and Protected in Ukraine Vascular Plant Species

E. Arapetyan[1], U. Usatenko[2];
[1]Botanical Garden and Low Temperature Center of Lviv National University, Lviv, Ukraine, [2]Low Temperature Center of Lviv National University, Lviv, Ukraine.

Long term conservation of plant genetic information within seed conservation as the element of plant reproduction is the main direction of the Global Strategy for Plant Biodiversity Conservation. The main role of the realization of the European Strategy Program of Plant Conservation is given to botanical gardens. The problem of genetic biodiversity preservation in up to date reality is the main in Ukraine as well.

In response to these challenges the Botanical Garden and the Center of Low Temperature of Lviv National University (Ukraine) began the development of national approach to conservation of genetic diversity of native plant species.

Seed conservation (in liquid nitrogen) protocols were developed for Ukrainian flora species (the rare species included).The experimental data showed the ability of method to be used in seed long term conservation with no genetic information looses.

P2320. Seed Morphology and Germination Variability of Three Native *Isatis* spp; *Isatis aucheri* Boiss (Endemic), *Isatis candolleana* Boiss (Endemic) and *Isatis glauca* Aucher ex.Boiss.

N. Comlekcioglu, **S. Karaman**;
Kahramanmaras Sutcu Imam University, Kahramanmaras, Turkey.

Isatis sp. produces indigo precursors using dye industries. Also some *Isatis* sp. are used antiviral, anticancer and antiinfective purposes. The genus *Isatis* comprises 26 species which are found in Turkey and 20 of this species are endemic. *Isatis aucheri*, *Isatis candolleana* which are endemic species and *Isatis glauca* distrubute in South and Central Anatolia. These species collected from K.Maras provinces at different localities during July 2004. Some morphological characters about fruit and seed were investigated. The effect of some factors; prechilling, water soaked, Gibberillic acid (GA_3), KNO_3, spermine and spermidine at constant and alternating temperatures on the break of seed dormancy in three *Isatis* seeds were studied. The highest germination ratio were obtained GA_3 treatment at all seeds.. Higher germination ratio were obtained spermine and spermidine, water soaked, KNO_3 and prechilling treatments than control group.

P2321. Biodiversity in the deep-freezer - „Loki Schmidt Gene Bank“ for regional resources of wild plants

H. Hurka, N. Friesen, B. Neuffer;
Department of Systematic Botany and Botanical Garden, University of Osnabrueck, Osnabrueck, Germany.

There is growing awareness of the ecological, economic and cultural significance of wild plant species and their potential value as genetic resources. *Ex situ* collections like gene banks are necessary for conservation of genetic resources, for basic and advanced science and for clearing house effects. Botanical gardens should establish seed gene banks for wild plants for promoting integrated conservation efforts and for protection and conservation of our natural plant genetic resources. At the Botanical Garden of the University of Osnabrueck we established a gene bank for wild plants of Northwest Germany. We already collected material of 1300 accessions from 370 species and 65 families. The seeds are stored in minus 20 °C under dry conditions in special plastic bags. Each accession is listed in a database and is documented by herbarium specimens in OSBU. We have proposed a decentralised network of gene banks for wild plants together with other Botanical Gardens in Germany.

P2322. Issues on ESUs: Using molecular information for the *ex situ* preservation of genetic variation in plant populations

J. Caujapé-Castells;
Jardín Botánico Canario "Viera y Clavijo", Las Palmas de Gran Canaria, Spain.

While the preservation of genetic resources is emphasized by the most important international biodiversity directives, many *ex situ* conservation strategies still disregard genetic information or use its indications in a limited way. I propose a general sampling decision scheme that uses data for molecular markers to identify population groups that fulfil the definition of Evolutionary Significant Unit (ESU) with a view to maximise the amount of genetic variation captured for *ex situ* conservation. Comparisons among groups based on the values of F_{ST} are used to determine the significance of reproductive isolation and to define general sampling areas, and the probabilities of loss of rare alleles and the basic indicators of genetic polymorphism help quantify the importance of the genetic legacy and pinpoint the populations where intensive sampling should be carried out. This methodology eliminates a considerable amount of guesswork in the design of sampling priorities for *ex situ* conservation and it allows the implementation of non-genetic variables, thereby paving the way for a multi-disciplinary, conservation-driven integration of knowledge.

P2323. Setting up a DNA Bank for the Canarian Flora

N. Cabrera-Garcia, R. Jaén-Molina, J. Caujapé-Castells;
Jardin Botanico Canario, Las Palmas de Gran Canaria, Spain.

Despite the area of the Canary Islands is only about 5% that of mainland Spain, they host more than 50% of this country’s plant endemicity and represent the most remarkable biodiversity hotspot in Europe and the northern quarter of Africa. Because ecological perturbations related to unsustainable human development are outweighing the intrinsic survival assets of many Canarian endemics, a major challenge that we have to face today is the preservation of their genetic diversity out of its natural areas of distribution. In this contribution, we set forth the organisation and philosophy of the Canarian plant DNA bank at the Jardín Botánico Canario “Viera y Clavijo” to i) discuss several methodological issues associated with sample acquisition, processing and management, ii) provide a basic guide for conservation institutions that might be interested in developing a DNA bank for their regions’ plant diversity, and iii) foster the establishment of scientific collaborations to invest our DNA funds in actions that lead to the improvement of the knowledge on the origins, diversification and conservation of the Canarian Flora through the use of molecular information.

P2324. Reproduction biology and *ex-situ* conservation of Caucasian endemic species *Dioscorea caucasica* Lipsky

T. Mikatdze-Pantsulaia, Z. Gamtsemlidze, M. Khutsishvili;
Institute of Botany of the Georgian Academy of Sciences, Tbilisi, Georgia.

Dioscorea caucasica is a relict West Caucasian endemic of local distribution. It experiences severe human impact due to its medicinal properties. As the distribution range of the species is outside the present jurisdiction of Georgia, it is impossible to study *in-situ*.

We have done the first research on reproduction biology of *D. caucasica* in order to maintain the species. *Ex-situ* collections and seed bank were created.

Propagation capacity of *D. caucasica* was studied *ex-situ*.

The species is dioecious.Generative structures are fertile. Pollen fertility is 84%; 77% germinates in artificial medium. Seed-buds are fertile; fertilization and embryogenesis proceed normally. Potential seed production capacity is 6 per flower; actual quantity of seeds is high (4), which indicates high reproductive index of the species. Proportion of seed germination and sprouting is 76-78%. Seedlings develop well; their majority is male.

It was determined, that *D. caucasica* has an actual capacity to produce viable seeds and offspring; however, pronounced deficiency of female plants along with other factors (anthropogenic etc.) causes the decline of populations.

P2325. Tools for identifying seed desiccation sensitivity: where climate meets seed biology

M. I. Daws[1], C. B. Wood[1], N. C. Garwood[2], H. W. Pritchard[1];
[1]Royal Botanic Gardens, Kew, Ardingly, United Kingdom, [2]Natural History Museum, London, United Kingdom.

For the majority of seed plants (> 92%), the ability of their seeds to tolerate desiccation is a key adaptive trait. However, the remaining c. 8% of species with recalcitrant (desiccation-sensitive) seeds, pose a significant challenge for *ex situ* conservation. In addition, because this group contains many heavily utilised tree species of socio-economic importance it is of significant conservation importance. Here, in line with Target 3 of the Global Strategy for Plant Conservation we present two tools for the identification of species with desiccation-sensitive seeds. Firstly, we have developed a desiccation screen that enables the rapid identification of desiccation-sensitivity using small quantities of germplasm (100 seeds), which we will illustrate using examples from the Palm family. Secondly, for tree species we present a globally applicable model for predicting, based on seed and plant habitat variables, the probability of seed desiccation sensitivity. This model is based on species from four continents and a variety of climatic zones: savannah / dry-land, temperate woodland, tropical semi-deciduous and wet forest.

P2326. Arboretum Dona Ines: an ex situ conservationist paradise in the Caribbean

A. E. Areces, G. Ocampo;
parquedonaines, San juan, Puerto Rico.

Counting with 12-15,000 plant species, the West Indies are one of the richest centres of evolution and ecological diversity of the neotropics.

25% of its flora is restricted to the Caribbean area, and 10% of its endemics are facing extinction. In situ conservation does not cover more that 7% of the Caribbean land, thus ex situ approach is a need.

The arboretum Parque Doña Inés of San Juan, Puerto Rico, constitutes the first serious attempt to develop a conservation collection within the Caribbean region. Since the year 2000 the Park is collecting germplasm based on concepts of infraspecific diversity in order to maximize the representation of each taxon's eco-geographical and genetic diversity. The arboretum recognizes its regional responsibility in maintaining, propagating and making available stocks of critically threatened species for scientific research and eventual reintroduction in habitat. It also recognizes itself as an institution capable to raise environmental awareness for the West Indian's magnificent biodiversity, and promoting appreciation for the Caribbean's distinctive plant and animal life.

P2327. The role of seed science in the GSPC

H. W. Pritchard, M. I. Daws, M. Sacandé, C. B. Wood;
Royal Botanic Gardens, Kew, Ardingly, United Kingdom.

The 'terms and technical rationale' for the targets of the GSPC articulate the importance of science to evidence-based decision making and delivery of conservation objectives. For the *ex situ* conservation of plants as seeds, there are five main targets (3, 8, 9, 10 and 15) our seed science has addressed. We have given prominence to recalcitrant seeds studies (Target 8) by developing two enabling methodologies (Target 3): a predictive model for encountering desiccation sensitive seeds and a protocol for the rapid assessment of seed desiccation tolerance. Currently we are developing practical conservation methods for recalcitrant seeds using cryopreservation (Target 8). Reflecting the goals of Targets 9 and 15, we have established across 14 countries a Darwin Initiative seed research network for studies on 60 tree species of value for sub-Saharan Africa. Finally, we are assessing the contribution of seed traits towards the competitive advantage of a range of invasive plant species in support of the development of management plans (Target 10).

P2328. Seed cryostorage of endangered plants in Poland

J. T. Puchalski, R. Muranyi;
Botanical Garden - Center for Biological Diversity Conservation,
Warsaw 76, Poland.

Among 2.750 taxa of Polish vascular flora 418 species are threatened with extinction. Therefore several projects were carried on *ex situ* conservation by the botanical gardens in Poland. In 1992 in the Botanical Garden of the Polish Academy of Sciences in Warsaw it was organized the National Seed Bank for the long-term seed storage of the Polish native plants with special emphasis to Red List of Endangered Plants and plants legally protected by law. For seed preservation the storage in cryogenic conditions - in the vapor of liquid nitrogen at temperature ca. -160^{o}C was chosen. Because of seed dormancy problems the special protocols for seed germination for each particular plant species were prepared. Also for each species the seed tolerance for ultra-low freezing was tested. Presently in cryogenic seed bank are preserved 78 species represented by 280 populations. Thanks to seeds preserved in the cryogenic seed bank the successful reintroduction into primary localities was done for 4 extinct in the wild or critically endangered plants species in Poland. Presently the investigations are carried on within the European Union framework project ENSCONET.

P2329. Ex situ Conservation: an Integrated Approach in the Use of a Living Collection

I. Belyaeva[1], K. Chamberlain[2];
[1]Botanical Gardens of Ural Branch of Russian Academy of Science,
Yekaterinburg, Russian Federation, [2]Rothamsted Research,
Harpenden, United Kingdom.

In the Ural Botanical Gardens of the Academy of Science of Russia, in Yekaterinburg, there is a unique collection of species from the genus *Salix* L. There are more than 2000 accessions, including 147 species from different regions of the world, 136 hybrids and 29 forms. This collection is used, not only for taxonomical and other scientific studies and for educational purposes, but also in an extensive breeding programme, which is directed at several applications: landscape-gardening, basketry and furniture production, re-vegetation and bioremediation, manipulating tannin content and increasing biomass production through short rotation coppicing. In the collection, there is a large number of accessions that combine several useful properties (characteristics) and therefore may have great potential in multipurpose breeding programmes. These characters were analysed and correlated with the taxonomy, biogeography and habitat of of the accessions.

P2330. Ex-situ conservation of Liparis loeselii (Orchidaceae) at Eotvos Lorand University, Hungary

Z. Illyés[1], E. Eszéki[2], S. Rudnóy[1], D. SzegŖ[1], Z. Bratek[1];
[1]Department of Plant Physiology, Eötvös Loránd University, Budapest,
Hungary, [2]Botanical Garden, Eötvös Loránd University, Budapest,
Hungary.

The fen orchid Liparis loeselii (L.) Rich. was formerly known from over 8 localities in Hungary, but now occurs only in four sites, which all are very vulnerable. Surveying conservation possibilities, selected European populations of L. loeselii were studied by three molecular markers (two plastid spacers and nuclear ribosomal ITS) in order to reveal the origin and the genetic connections of Hungarian populations. In addition, asymbiotic and symbiotic germination of L. loeselii were studied. Germination array was tested on different asymbiotic media (different macroelement and organic nitrogen levels) in dark and light with and without cytokinin. For symbiotic germination and growing of asymbiotically germinated seedlings with fungal partners, symbiotic fungi were isolated using different methods. "Root segment technique" was proved to be less effective than "in-situ protocorm trap" method by which symbiotic fungal partners could be isolated more successfully and causes less disturb in natural populations. Fungal partners were identified by the DNA-based method ITS sequence analysis.

P2331. Micropropagation of Gentiana lutea L. and Arnica montana L.

M. I. Petrova, K. N. Tasheva, N. A. Zagorska, T. B. Stoilova;
Institute of Genetics, Sofia, Bulgaria.

Gentiana lutea L. (yellow gentian) and Arnica montana L. (arnica) are medicinal plants species that should be protected by law as being overcollected. They contain valuable biologically active substances and are wide used in medicine and pharmaceutical industry. The purpose of this investigation was to elaborate efficient methods for in vitro propagation of both species. The explants most suitable for propagation are already identified i.e. stem segments with an axillary bud from plants that have germinated in vitro. The optimum nutrient media for germination, propagation and rooting in vitro of Gentiana lutea and Arnica montana are also characterized.
The results will contribute to the protection of both plant species and to the application of their perspective forms to produce ecologically pure products as crude matter for the industry and prevention of certain diseases.

P2332. Use of AMF in active protection of *Plantago atrata* and *Senecio umbrosus* - endangered plant species from the Tatra Mts.

S. Zubek[1], K. Turnau[1], J. Blaszkowski[2];
[1]Mycology Unit, Institute of Botany, Jagiellonian University, Krakow,
Poland, [2]Department of Plant Pathology, University of Agriculture,
Szczecin, Poland.

The flora of the Tatra Mts. is extremely rich in rare plant species. Among them, *Plantago atrata* Hoppe and *Senecio umbrosus* Waldst. & Kit. are seriously endangered. The first species is included in the world list of threatened plants and the second is extinct in the wild in Poland. Both species were found to be strongly mycorrhizal and dependent on mycorrhiza, while cultivated under laboratory conditions. The more intensive growth of mycorrhizal plants in comparison to non-mycorrhizal ones was clearly shown using diverse AMF strains. The inoculation with mixtures of strains was shown to be the most effective in plant growth stimulation. Due to the risk of plant destruction in natural sites, the investigations in the field were limited to studies carried out on arbuscular fungi that occurred in the vicinity of plant roots. AMF spores were identified and trap cultures were obtained. The strains obtained will be used for the inoculation of plant material multiplied and reintroduced into the experimental plots. Plants should be equipped with fungi suitable for multiplication under greenhouse conditions and for reintroduction into natural sites.

P2333. Mexican bamboos: *ex situ* conservation and research

T. Mejia-Saulés;
Instituto de Ecología, A.C., Xalapa, Ver., Mexico.

Mexico is represented by eight genera and 35 woody bamboo species which include 12 endemic species. They are found in the rain forest and tropical regions of Mexico from sea level to 3000 m altitude. Information on mexican bamboos is scarce and they are almost unknown. A collaboration was made between INECOL, ITC and BOTA to start a long term project “The Native Bamboos of Mexico” with a main objective to create the national bamboo collection in the botanical garden and herbarium of INECOL. These collections will be the basis for multidisciplinary bamboo studies and will be the first *ex situ* bamboo conservation collection in Latin American. Since two years of this project 60% of the species are represented *ex situ* with their respectives herbarium vouchers. Two studies were completed, Vegetative propagation of *Rhipidocladum racemiflorum* and Bamboo uses in Monte Blanco. Preliminary results have been reported in national and international congress, seminars, bamboo magazine, shorth communications as well as regional and national exhibitions.Studies in progress are conservation of endemic species, systematics, data base of uses and insects associated with bamboos.

P2334. DNA Banks: Another tool for the conservation and sustainable use of plant genetic resources

N. F. Rice, R. J. Henry;
Australian Plant DNA Bank Ltd, Lismore, Australia.

The World has an enormous amount of biodiversity that is largely unexplored, misunderstood and not adequately documented. A great deal of attention is being paid to the fate of natural resources and the potential for loss of biodiversity. The conservation of plant genetic resources is important and it is essential that many diverse methods are adopted including maintenance in natural conditions and representation in *ex-situ* collections. DNA Banks store extracted plant genomic DNA which is made available to researchers for phylogenetics, phylogeographics, population studies, gene discovery and marker development. The Australian Plant DNA Bank is an example of a plant DNA Bank which aims to preserve representative genetic information from the Australian flora and cultivated species. Information regarding the species in this collection is available via the World Wide Web (www.dnabank.com.au). The operations, technical issues, and benefits of a plant DNA bank will be discussed.

P2335. Virus field-infection in *Allium* and successful elimination of viruses in the Gatersleben Genebank

E. R. J. Keller, J. E. Keller;
Institute of Plant Genetics and Crop Plant Research (IPK), Gatersleben, Germany.

Viruses impose a common problem on the cultivation of vegetatively propagated alliums in the field and are a risk for the maintenance of genetic resources. The Gatersleben Genebank comprises a large collection of vegetatively maintained accessions like garlic, shallot, top onion, wild *Allium* species and hybrids. Virus screening tests were performed on leaves, bulbils and cloves from these materials. The occurrence of 6 viruses was recorded by means of virus identification based on ELISA-tests and tissue print immunoassay. All field accessions of garlic and shallot were infected with several viruses. All tested parts of a plant had a similar virus status. Wild alliums were specifically infected with viruses. Investigations were done to eliminate the viruses in garlic and shallots via meristem culture, thermo- and chemotherapy with the aim to establish virus-free clones *in vitro.* Virus elimination through meristem culture was successful by using small meristems. Thermotherapy and chemotherapy increased the elimination rate up to 80%. The efficiency of virus elimination was depending on the specific virus. Latent viruses were permanent and hard to eliminate.

P2336. From laboratory to field: the use of material from an *ex sit*u collection in the introduction of a rare moss

J. K. Rowntree;
Royal Botanic Gardens, Kew, Richmond, Surrey, United Kingdom.

The Micropropagation Unit at the Royal Botanic Gardens, Kew, has been involved in the *ex situ* conservation of bryophytes since 2000, with a unique project funded by the UK statutory conservation agencies. The project involves the collection, culture, cryopreservation and introduction of rare UK bryophytes. Material is in culture for six British populations of the European endangered moss *Orthodontium gracile* Schwägr. ex Bruch, Schimp. & W. Gümbel. Protonemata of *O. gracile* have been successfully cryopreserved and are in long-term storage. Cryopreserved material has been recovered and weaned onto sandstone substratum. A preliminary introduction of this material was undertaken at the Kew managed estate, Wakehurst Place, Sussex, UK in early 2005 using material collected from the vicinity. Survival, growth and development of the moss were monitored initially and continue to be observed. Preliminary data from the introduction are presented. Future development and global application of the methods are discussed.

P2337. Macromycetes of diverse plant communities: conservation *ex situ*

N. V. Psurtseva;
V.L. Komarov Botanical Institute RAS, St. Petersburg, Russian Federation.

Conservation *ex situ* of macromycetes of various ecological and taxonomical groups is a promising aspect of fungal conservation. Macromycetes diversity is preserved and maintained in pure culture in the LE (BIN) Culture Collection. Biota of macromycetes mostly has a direct correlation with plant communities in its ecotope. Macromycetes from deciduous, coniferous and subtropical forests, grassland communities, arctic tundra and alpine zones were cultured for conservation *ex situ*. Over 10 natural reserves and national parks of Russia were studied in this regard. It was shown that macromycetes of different taxonomical, ecological and trophic groups have different potentiality for growing and maintaining in culture. Ectomycorrhizal fungi were very complex for culturing and conservation *ex situ*. Most saprotrophic and especially xylotrophic fungi could be easily isolated and maintained in culture. However culturing of fungi from certain genera of these groups caused problems. Understanding of macromycetes and plants correlation makes the work on macromycetes conservation *ex situ* more productive.

P2338. Bryophyte conservation in Romania. History and Perspectives

I. Goia;
Faculty of Biology and Geology, Cluj Napoca, Romania.

Historically, bryophytes are not as well conserved as phanerograms, mainly because of their size and weak economical importance. Also, there are very few bryologists and the education on this topic is poor.

Bryophytes are primarily conserved in nature reserves or national parks, indirectly, but the instigation of Phanerogams conservation permitted the development of bryological studies in some protected areas.

From 1990, the following actions have been taken: (1) publication of comprehensive review papers (including frequency lists, chorology of Romanian mosses, red lists); (2) implementation of international legislation (Bern Convention, Habitats Directive) requested for a better identification of areas proposed for Nature 2000 network, as an EU demand for candidate countries and (3) project development (Bioplatform, Important Plant Areas).

Bryophyte conservation strategy is focussed on identifying the most important sites and habitats for bryophytes; providing educational resources on bryophytes, especially for students, foresters, national parks staff, etc. which will be involved in monitoring of some species (e.g. Buxbaumia viridis).

P2339. The native and exotic plants of Samarkand and their protection

H. N. Normuratov;
Samarkand State University, Samarkand, Uzbekistan.

It is discussed on endemic and exotic plant species of Samarkand region of Uzbekistan. The local flora of Samarkand region consists of about 4500 different species, most of them are considered as a valuable medicinal, aromatic, industrial and ethnobotanical plants. Most of these plants can be also a valuable source for industrial production of different products and they also can be used for ornamental landscaping purpose as well.

At present day, most plant species are in endangered situation.

Due to different factors, mostly anthropogenic one, the area of distribution of endemic and exotic plants as well as their biomass are degrading day after day.

It is propose different ways of protection of these plants. Long-term field and laboratory experiments showed promising technologies for their cultivation and introduction in a botanical gardens, temporarily protected areas as well as in a nurseries of educational establishments. Two special nurseries were established in the territory of forestry service of Urgut and Nurobod districts of

Samarkand region of Uzbekistan. Seedlings of endemic and exotic plants were successfully transplanted to other places.

P2340. In vitro and ex situ culture of hepatics- an innovative approach for an inventory

A. Cailliau, M. J. Price;
Conservatoire et Jardin botaniques de Genève, 1292 Chambésy - Geneva, Switzerland.

The canton of Geneva has a rich flora due to its wide diversity of micro-habitats. However, its hepatics have not been studied for over a century. The canton has undergone a large amount of environmental changes and urbanisation during this period. In the light of this, an inventory of hepatics is overdue. We now know that the rare thalloid hepatic Riella reuteri Mont. is extinct in Geneva because its specialised aquatic habitat has been destroyed. An inventory, using traditional techniques and the innovative methods of ex situ culture (soil, wood, sand), provides a complete list of species presence in the specified area in terms of the above ground flora and the soil bank diaspores. We present the results of our soil culture experiments which have revealed some species that are only present in the soil diaspore bank, such as Anthoceros agrestis Paton, a species new for Geneva. In terms of conservation, a completed inventory permits us to assess conservation risks for different species, dependant on the different habitats and soils. By using in vitro culture techniques we can propagate material for future re-introduction trials in the canton.

P2341. Cold adaptation as factor to increase re-growth efficiency in cryopreservation of vegetatively propagated germplasm in genebanks

J. E. R. Keller, M. Grübe, A. Senula;
Institute of Plant Genetics and Crop Plant Research (IPK), Gatersleben, Germany.

Living plant collections are faced by problems to safely keep germplasm of which no seeds can be stored. This is important for many vegetatively propagated crop plants. Cryopreservation is the most effective and safest method to maintain germplasm for long time. Although the general usability of this method has already been demonstrated for many species, there are still genotypes of low response in most of them. The Gatersleben genebank holds germplasm of potato (more than 1000 accessions), garlic and mint in cryopreservation. In all these species, low temperature pretreatments support the cryopreservation effect by increasing the re-growth rates. This stimulation is present irrespective of the used methods (vitrification, droplet freezing or combination of both) in potato. In garlic, alternating temperature regimes act stronger than permanent low temperature. Alternating temperatures are also effective in mint. Cold adaptation and the underlying physiological processes are discussed in general with respect to their use for germplasm storage. Furthermore, general aspects of the cryopreservation technology in the IPK genebank are summarized.

P2342. The Use of Herbarium Resources to Improve the Targeting of Seed Collection Programmes for *Ex Situ* Conservation

S. T. Balding;
Royal Botanic Gardens, Kew, Richmond, Surrey, United Kingdom.

Target 8 of the Global Strategy for Plant Conservation prioritises collection of threatened species for ex situ conservation. This requires careful planning at the front end of conservation programmes. The MSBP is bringing together local experts and RBG Kew specialist staff to meet this challenge. The team are using information from herbarium specimens and literature to prioritise species for conservation, and produce collection guides.
We extract, database and geo-reference information from both the Kew and Paris (Francophone partners only) Herbaria. When available, we combine this with data from the Herbaria of the country where collections are being made. The data is then subjected to geographical information systems analysis to provide i) recorded distributions; ii) preliminary assessments of extinction risk. In parallel with the data extraction, digital images of herbarium specimens are taken to provide partners with visual tools for rapid identification of target species in the field. So far 11 collection guides have been produced for six countries. The difficulties in this approach and the benefits of its products will be outlined.

P2343. Asymbiotic germination of *Dendrobium aqueum* Lindl. - a rare and endemic orchid of India.

S. Kaliamoorthy;
National Orchidarium & Experimental Garden, Botanical Survey of India, Southern Circle,Yercaud, Salem District, TN, India.

An efficient protocol for a rapid multiplication of *Dendrobium aqueum* Lindl., a rare and endemic orchid species of southern India, was made through asymbiotic germination method. The cultural requirements for *in vitro* seed germination, protocorm growth and seedling proliferation have been studied. The percentage of seed germination on different media compositions viz., modified Knudson C, Phytamax and Murashige and Skoog, enriched with the addition of 10% coconut milk, was ranged between 80 and 95%. Among the three media compositions used, modified Knudson C supplemented with 10% coconut milk was found to be more effective in terms of number of protocorm like bodies (PLBs) and shoot proliferation. The observations made on the effect of various complex organic additives showed that the banana pulp was more effective followed by coconut milk and citrus juice. Root formation was observed in 10 to 20% of the shoots cultured either with banana pulp or coconut milk. The root induction was otherwise achieved with modified Knudson C basal medium without added supplements. More than 70% of the seedlings were successfully established in the community pots.

P2344. Ecology of *Carica candicans* A. Gray (Caricaceae) in four hills of Lima - Peru

J. Mansilla, R. Jimenez, N. Canto, R. La Rosa;
Faculty of Natural Sciences and Mathematic. Federico Villareal University, Lima, Peru.

Carica candicans “mito” is a plant that can live under low water conditions. Nevertheless, excess of leaf eating for herbivorous and a deficient regeneration because of unsuccessful germination in natural conditions, has put to *C. candicans* in risk of extinction. The present work was carried out in four of the main hills in Lima - Perú, Lachay hills, Amancaes hills, Carabayllo hills, Villa Maria hills. In all of these hills pH and electric conductivity of soils were ranging 4 - 7.8 and 0.61 - 1.33 mS, respectively. Moreover, it was evident a little number of individuals of *C. candicans*. So, in Lachay hills exist 154 individuals (37 female and 117 male), in Amancaes hills exist 4 (3 female and 1 male), in Carabayllo hills exist 5 (all male), Villa Maria hills exist 11 (4 female and 7 male), all of them associated with rocks, stones and shrubs and herbaceous vegetation. We registered biometric data of fruits, ranging length 50 - 168 mm, width 40 - 60 mm and weigh 50 - 200 g, number of seeds 75 - 190. We collected fruits in order to maintain their seeds for regeneration works, so 29 months (880days) after sow first plants are flowering.

P2345. Conservation study of endangered Potamogeton species in Japan: DNA sequence data allow the differentiation of a hybrid.

Y. Ito[1], N. Tanaka[2], A. Momohara[1], K. Uehara[1];
[1]Faculty of Horticulture, Chiba University, Matsudo, Japan, [2]Tsukuba Botanical Garden, National Science Museum, Tokyo, Tsukuba, Japan.

The destruction of wetland environments in recent years has been extensive, and as a result of this habitat loss many aquatic species are in danger of extinction. For conservation purposes, this study used molecular data to investigate Japanese species of *Potamogeton*. *Potamogeton* × *inbaensis* is considered a hybrid between *P. lucens* var. *teganumensis*, which is classified as critically endangered, and *P. malaianus*. Typical individuals that are intermediate in morphology and leaf petiole length are usually used for identification. In the field, however, the variable leaf morphology of these three *Potamogeton* species makes it more difficult to identify them. We used sequences of the internal transcribed spacers of the nuclear ribosomal DNA (ITS) and a non-coding spacer between *atpB* and *rbcL* on the chloroplast DNA to reveal their interspecific genetic relationships. Investigation showed that leaf morphology and stem anatomy are not suitable for identification purposes; in the future, therefore, we will rely on molecular data.

P2346. Ex situ conservation in the Balkan Botanic Garden of Kroussia (N Greece): the Balkan endemic Cerastium decalvans Schlosser & Vuk.

K. Grigoriadou, K. Papanastassi, N. Krigas, E. Maloupa;
Laboratory of conservation and evaluation of native and floricultural

species, National Agricultural Research Foundation, Thessaloniki, Greece.

Cerastium decalvans, as a Balkan endemic not cultivated in Botanic Gardens, falls into the plant conservation priorities of the Balkan Botanic Garden of Kroussia (BBGK). Its cultivation in BBGK offers the potential of future re-introduction in case of decline of its natural populations. Wild growing individuals were collected at forest clearings of Mt Vermion (NC Greece) at c. 2000m. Although flowers appeared at sea level, no seed production has been observed yet at the mother plantations. Rooting of leaf cuttings has been studied using various concentrations of auxins at different seasons of the year. Optimal success was obtained in autumn, 19 days after they were treated with 4000 ppm indole-3-butyric acid (IBA), in peat: perlite (1:3) mixture, under mist. Young plants were transplanted at trays, where they remained for 45 days. Survival percentage exceeded 90% and plants were re-transplanted in 2.5 liter pots while growth and development of the plants were monitored for 45 days. Plants were finally established in the BBGK at c. 600m. Almost all the laxly caespitose plants survived both the dry summer season and the winter cold period but no flowering appeared yet.

P2347. Phenology of *Ismene amancaes* (r&p) Herbert. (Amaryllidaceae) and feasibility of its reintroduction in hills of Lima - Perú

R. Jimenez, J. Mansilla, N. Canto, R. La Rosa;
Faculty of Natural Sciences and Mathematic. Federico Villareal University, Lima, Peru.

Human activities have put to *Ismene amancaes* (R&P) Herbert “Amancaes” in vulnerable condition. The objective of this work was to evaluate the biological cycle of “amancaes” and feasibility of its reintroduction in hills of Lima - Perú. We evaluated this specie in Villa Maria Hills (12° 08’11” LS-76° 55’ 27” LW) at 588 m over sea level (m.o.s.l.); and we estimated the age of bulbs observing thickness of outer dry cataphylls and diameter of bulbs, also we registered phenology of this specie during 2003 and 2004. *I. amancaes* growths from 535 m.o.s.l. to 750 m.o.s.l. where we can find it flowering during winter months but disperse. Collected seeds were sowed in trays and maintained at 26°C±2° in darkness until a little bulb rise, then a standard substrate (Promix B5) was added observing a good growth of bulbs. The biological cycle of this specie is limited for high temperatures, soil humidity and changing environmental conditions, resulting in a later and accelerated growth during 2003, and earlier and wide growth during 2004.

P2348. Conservation efforts over native flora in Central Chile

M. Ricci;
Corporación Nacional Forestal – VI región, Rancagua, Chile.

The area located between 25º - 40ºS in central Chile presents a Mediterranean climate characterized by cold and rainy winters and variable period of drought in summer. The natural vegetation in this area was disappeared principally by road constructions, felling of trees and shrubs for industry and energy, agriculture, overgrazing, fires and mining working. O`Higgins region (33º - 35º01’S - 70ºW) has a principal economic activities the fruit culture for exportation, wine production and mining exploitation, with human perturbation beginning in XVI century.

Notwithstanding, this region its present north limit of several species, endemisms very endangered as *Neoporteria horrida* var *aspillagae* (Cactaceae), *Avellanita bustillosii* (Euphorbiaceae), *Beilschmiedia berteroana* (Lauraceae), *Leucocoryne codehuensis* (Alliaceae), and so on.

During this year CONAF and Regional Government began a project “Red Book of terrestrial flora and fauna, and interesting site for conservation of region del Libertador Bernardo O’Higgins”, and collecting seeds and other material for propagation of endangered species.

P2349. Botanical-geographical diversity of the calcareous mountains in West Transcaucasus (Colchis, Georgia)

S. K. Shetekauri;
Institute of Botany of the Georgian Academy of Sciences, Tbilisi, Georgia.

In Georgia calcareous biotopes occur only in its west part: Abkhazia, Samegrelo, Svaneti (not very common), Racha-Lechkhumi, Imereti. Partitioned relief, karst forms and canyons feature the calcareous ranges in the gorges of rivers Bzifi, Okumi, Enguri, Chanistskali, Khobi, Tekhuri, Tskhenistskali, Rioni.

Many plant species specific to calcareous habitats are regional Colchic endemics and relicts: *Thymus ladjanuricus, Galanthus schaoricus, Asperula kemulariae, Muscari alpanicum,* (Racha-Lechkhumi); *Potentilla kemulariae, Kemulariella colchica, Allium albovianum, Betula megrelica* (Samegrelo); *Campanula kemulariae, C. irinae, Veronica galathica, V. imeretica, Scrophularia imerethica, Aquilegia colchica* (Imereti); *Campanula mirabilis, Arabis sachociana, Pimpinella idea, Gentiana paradoxa, Aquilegia gegica* (Abkhazia).

Colchic understory (*Laurocerasus officinalis, Rhododendron ponticum, Rhamnus imeretica, Ilex colchica, Vaccinium arctostaphylos*) and *Buxus colchica* forests with *Staphylea colchica* in the gorge of the river Tsachkhuri (Samegrelo) create unique landscapes in the botanico-geographic province of Colchis.

P2350. Genetic Resources of Native and Wild Ornamental Bulbous Plants in Hyrcanian Region of Iran

S. Khangholi[1], A. Rezaeinodehi[2], H. Moradi[3], A. Shokohian[4];
[1]Faculty of Agricultural Sciances, University of Shahed, Tehran, Islamic Republic of Iran, [2]Department of Horticulture , University of Shahed, Tehran, Islamic Republic of Iran, [3]Department of Horticulture , University of Mazandaran, Sari, Islamic Republic of Iran, [4]Faculty of Agriculture, University of Mohaghegh-e-Ardabili, Ardabil, Islamic Republic of Iran.

Genetic variability is the base of variation in ornamental plants. Hyrcanian region in north of Iran has high plant diversity because the topographic, edaphic and climatic conditions is very variate. This research was conducted to morphological and ecological studing and introduction important wild bulbous plants in this region such as *Lilium ledeburii, fritillaria spp., Tulipa spp., Gagea spp., Bellevalia spp., Ornihtogalum spp*., *Scillia spp., Allium spp., Erithronium denscamsis, Muscari spp., Leucojum aestivum*, *Galanthus nivalis, Sternbergia spp., Narcissus spp., Iris spp., Crocus spp., Gladiolus spp., Colchicum spp.,* etc. Some of the plants are ornamentally used but their wild releatives are valuable as genetic resources. Also Some of them such as *Lilium ledeburii* is exposeing to endangering and genetic erosion due to human activity, natural damages and cultural practices. Thus in respect to valuability of gene pool for breeding programs including compatability to unfavorite conditions and introducing new cultivars it is necessary that organisations and research institutes try to protect these natural resources from destroy and endangering.

P2351. First approach to the biology of *Polygala vayredae* Costa (*Polygalaceae*), an endemic plant from Oriental pre-Pyrenees

S. Castro[1,2], P. Silveira[1], J. Paiva[3], L. Navarro[2];
[1]Departamento de Biologia, Universidade de Aveiro, Campus Universitário de Santiago, 3810-193 Aveiro, Aveiro, Portugal, [2]Departamento Biología Vegetal y Ciencias del Suelo, Universidad de Vigo, Vigo, Spain, [3]Departamento de Botânica, Faculdade de Ciências e Tecnologia, Universidade de Coimbra, Coimbra, Portugal.

There is a consensus that studies on the reproductive biology of endangered, rare or threatened species may be useful for understanding why they are endangered, rare or threatened. Information obtained from such studies may be useful for evaluating alternative *in situ* and *ex situ* management strategies. *Polygala vayredae* Costa is an endemic species from oriental Pyrenees and a relic that survived to the glaciation’s period in the Tertiary, perhaps because it refugeed in the enclave where it actually occurs. This species is poorly known, and because of its restricted distribution area it is protected and very important for conservation. In the present study, we investigated aspects of the reproductive cycle of *P. vayredae*. For that, morphological and functional characteristics of flower and pollen source were analysed as they have major effects on the reproductive success. The first approach gives us information about the reproductive system of this species. With this information we intend to increase the knowledge on the reproductive biology of this species and provide relevant know-how that is essential for a correct management and conservation of *P. vayredae.*

P2352. Ecology and management of an endemic subspecies - *Tephroseris longifolia* subsp. *moravica*

I. Skodova, M. Janisova;
Institute of Botany, Bratislava, Slovakia.

Tephroseris longifolia subsp. *moravica* is a critically endangered taxon endemic of the Western Carpathians with a restricted geographical distribution on the border of Slovak and Czech Republic. Since it is known, it occurred only on restricted number of localities, where it survived almost exclusively in small populations. Taxon occurrence is restricted to a very specific vulnerable ecotonal habitats. Knowledge of both the taxon life cycle and its ecological requirements is still insufficient. Recently, decreasing taxon abundance and reducing number of flowering individuals was observed which could be a consequence of unfavorable weather excesses as well as unsuitable agricultural practices during the last centuries.

The detailed analysis of plant communities with the taxon occurrence supported by the analysis of relevant environmental factors is an attempt to estimate the main ecological characteristics of the taxon. The results of recent censes are evaluated and the perspectives of maintaining the viable populations are sketched. Necessary recommendations of suitable management types are offered and some notes are made to the monitoring methods.

This work was supported by Science and
Technology Assistance Agency under the contract No. APVT-51-015804, and by VEGA
2/5084/25.

P2353. Seed conservation activities for narrow endemic species in the Italian Alps

C. Bonomi[1], **G. Rossi**[2], A. Mondoni[2], A. Bertolli[3], F. Prosser[3], V. Carasso[4], B. Gallino[4], M. Mucciarelli[5], G. Caniglia[6], G. Cassina[7];
[1]Museo Tridentino di Scienze Naturali, Trento, Italy, [2]Dipartimento di Ecologia del Territorio dell'Università, Pavia, Italy, [3]Museo Civico di Rovereto, Rovereto, Italy, [4]Ente Gestione Parchi e Riserve naturali cuneesi, Chiusa Pesio, Italy, [5]Dipartimento di Morfofisiologia Veterinaria, Grugliasco, Italy, [6]Dipartimento di Biologia dell'Università, Padova, Italy, [7]Orto Botanico dell'Università, Padova, Italy.

From 2002 onwards four *ex situ* seed conservation projects for endangered and narrow endemic alpine species were devised and put in operation independently in four distinct geographical districts of the Italian Alps, being based in Chiusa Pesio (southern Piedmont, western Alps) Pavia (Lombardy, cental Alps) Trento (Trentino, central-eastern Alps) and Padua (Veneto, eastern Alps). These initiatives were supported by a very diverse range of funds and local expertise, including volunteer work, jet they aimed to serve the same purpose and employed roughly the same consolidated methodology. Highlights of the target species selected, include the three alpine endemic genera *Berardia*, *Physoplexis* and *Rhizobotrya*, and many point endemics such as *Viola comollia*, *Daphne reichsteinii*, *Callianthemum kernerianum*, *Campanula petraea*, *Moltkia suffruticosa* etc. In the context of the newly born Italian seed bank network these projects will act in a co-ordinate way to provide a regional unit within the Italian network. Future perspectives would naturally extend the conservation action to the alpine bio-geographical region seeking trans-boundary partners.

P2354. Reproductive Biology of Goetzea elegans Wydler, an endangered Caribbean tree

M. Caraballo, E. Santiago;
Herbario, Jardin Botanico y Departamento de Biologia, San Juan, PR, United States.

Endangered species commonly confront constraints in their reproductive biology. However, although knowledge of these processes are of primary importance for implementing sound conservation measurements, little data is available for most endangered species of the Caribbean islands. *Goetzea elegans*, an endangered tree endemic to the island of Puerto Rico, represents an illustrative case study on rare plant conservation in the region. The species is known from little over a hundred reproductive individulas, whose flowers are visited by vertebrates and invertebrates, including native and invasive species. We studied the reproductive biology of *Goetzea elegans* in order to assess implications for its conservation. Specificly, we determined the breeding systems of the species by experimental flower manipulations and compared pollination efficiency between the invasive bee *Apis mellifera* and the native bird *Coereba flaveola.* Additional objectives included to determine parameters that are responsible of the differences in reproductive success observed between trees in the wild, and to study the biology of the seeds and the seedlings.

P2355. Consolea (Cactaceae, Opuntioideae) an endemic West Indian genus threatend with extinction.

G. Ocampo[1], A. E. Areces-Mallea[2];
[1]Parquedonaines, San Juan, Puerto Rico, [2]parquedonaines, San juan, Puerto Rico.

Consolea (Lemaire) is a genus of flat-stemmed opuntioids endemic of the Caribbean region. Consolea differs from opuntioids in the continent particularly in their undetermined central stem from which asymmetrical lateral branches grow. Consolea is a handsome group that flowers twice a year or more. Its exotic looking and colorful flowers make them attractive as ornamentals. Unfortunately, island floras are often composed for ecologically restricted populations which are not capable of adapting to drastic environmental changes. Groups as Consolea inhabit costal areas, which are particularly affected by human growth, clearing for agriculture, burning, and hurricanes. On the other hand, lack of systematic studies creates confusion on delimitation of taxa which in turns expose entire populations to be wiped out. This work presents a morpho-anatomical study supported with DNA sequences to delimitate taxa among this poorly studied group, and thus its narrow geographical distribution. We recognize nine species and three sub-species in the Consolea genus, and we suggest a sound management plan for their in situ and ex situ conservation.

P2356. Use of population genetic data for the *ex situ* conservation of *Crambe pritzelii* and *C. tamadabensis*, two threatened endemics from the island of Gran Canaria.

M. Soto, A. Roca, B. Vilches, J. Naranjo, B. Navarro, Á. Marrero, J. Caujapé-Castells;
Jardín Botánico Canario "Viera y Clavijo". Cabildo de Gran Canaria, Las Palmas de Gran Canaria, Spain.

Crambe pritzelii and *C. tamadabensis* (Brassicaceae, sect. Dendrocrambe) are two threatened monophyletic taxa endemic to the island of Gran Canaria that require urgent conservation action. We apply population molecular markers (allozymes) to explore the extent of genetic differentiation in 12 populations that represent the known range of occurrence of these closely related endemics and use the resulting data to (1) construe and compare their levels of genetic variation, (2) assess whether these populations exhibit significant genetic structuring in space, and (3) integrate this information to streamline sampling strategies that allow us to represent a significant amount of their genetic variation in the seed bank of the Jardín Botánico Canario “Viera y Clavijo” while minimising sampling effort and storage space. Despite their restricted distribution, these taxa exhibit levels of genetic variation that are substantially higher than those reported for other island endemics, thereby adding to the emerging picture of a higher genetic variation in Canarian plants than in those from other oceanic archipelagos.

P2357. Antheridiogen effects in the allotetraploid *Dryopteris corleyi* and its parent species

A. Jiménez[1], L. G. Quintanilla[1], S. Pajarón[2], E. Pangua[2];
[1]Escuela Superior de Ciencias Experimentales y Tecnología, Móstoles, Spain, [2]Facultad de Biología, Universidad Complutense, Madrid, Spain.

Theoretical studies predict that increased selfing may enhance the establishment and persistence of polyploids among their diploid progenitors. *Dryopteris corleyi* is an allotetraploid fern derived from *D. aemula* and *D. oreades*. Its narrow geographic range (a 60 x 10 km strip on the North Spanish coast) overlaps that of *D. aemula*, and backcrosses, giving rise to sterile hybrids, have been detected. Isolated gametophytes of *D. corleyi* and diploid parents were cultured in a nutrient rich substratum. The gametangia sequence of the three species was protogynous. The same substratum was used as antheridiogen source in a new culture experiment. The three species were combined as source and target of pheromone action (i.e. nine species pairs). The exudates of the three species had the same intra- and interspecific effects: they slowed gametophyte growth rate and induced presexual-to-male transtition. Consequently, antheridiogens favour intergametophytic fertilization and hybridization. The implications for conservation of the narrow endemic *D. corleyi* are discussed.

P2358. Rare and threatened liverworts: An overlooked area of conservation in the New Zealand botanical region.

M. J. von Konrat[1], J. E. Braggins[2], M. Renner[3], J. J. Engel[1], P. de Lange[4];

[1]The Field Museum, Chicago, IL, United States, [2]Auckland War Memorial Museum, Auckland, New Zealand, [3]School of Biological Sciences, University of Sydney, Sydney, Australia, [4]Science & Research Unit, Department of Conservation, Auckland, New Zealand.

New Zealand has been identified as one of the twenty-five richest and most threatened biodiversity reservoirs on Earth. New Zealand's islands harbour a remarkable concentration of endemic species, including approximately 80% of its flora. Historically, New Zealand has experienced exceptional loss of habitat, and currently, invasive species pose as the largest threat to the flora and fauna. Of worldwide significance is the fact that New Zealand is home to an estimated 5-10% of the world's liverwort species, including over 200 endemic species. Moreover, New Zealand has 48 of the 73 liverwort families. First, this study identified potential threats to the New Zealand liverwort flora, and second, assigned categories of threat to develop a preliminary checklist. Selection of species was based on field studies spanning three decades, extensive herbarium records, and bibliographic references. Case studies illustrating the different categories of threat include examples from monotypic families and genera. We conclude that research relating to the conservation biology of the New Zealand liverwort flora requires great urgency and recommend areas of priority.

P2359. Floristic diversity, endemism and conservation in semi-arid Caatingas of NE Brazil

A. M. Giulietti[1], R. M. Harley[2,1], L. P. Queiroz[1], N. P. Taylor[2], F. França[1], D. Zappi[2];
[1]Universidade Estadual de Feira de Santana, Feira de Santana, Bahia, Brazil, [2]Royal Botanic Gardens, Kew, Richmond, United Kingdom.

The semi-arid Caatinga biome of Brazil covers an area of c. 1,000,000 km², occupying part of eight Northeastern States from Piaui to Bahia, and part of N. Minas Gerais. The area is climatically unstable, and severe droughts occur, yet supports a farming population who, over 400 years, have used the available natural resources in an unsustainable way. In spite of this, many well conserved areas still exist, especially on rock outcrops or shallow soils unsuitable for cultivation. Vegetation is typically deciduous woodland or scrub, with spiny Mimosoid legumes, Euphorbiaceae and Cactaceae, and during the rains, temporary pools and marshes. Caatinga supports a flora of >3000 species, with c. 10% endemism and 20 endemic genera. Biogeographic studies suggest it is part of a dry forest formation extending south into Argentina, skirting the Chaco and reaching north to the Eastern Andean Piedmont of Ecuador. Although many areas suffer serious modification by human occupation, conservation of centres of biodiversity. with appropriate water management are the only hope for long-term welfare of communities who earn their living from agriculture in the region.

P2360. The most rare and endangered vascular plants from Romania

G. Negrean[1], P. Anastasiu[2];
[1]Botanical Garden, Bucharest, Romania, [2]Faculty of Biology, Bucharest, Romania.

Romanian Red lists comprise about 1400 rare, endangered and endemic plant species. Among these we critically analyze three categories: endemic and sub-endemic species (*Ajuga salicifolia* subsp. *bassarabica*, *Centaurea triumfettii* subsp. *angelescui*, *Cochlearia borzaeana*, *Colchicum arenarium*, *Dianthus dobrogensis*, *Dianthus trifasciculatus* subsp. *parviflorus*, *Linum pallasianum* subsp. *borzeanum*, *Sausurea porcii*, etc.), relic species (*Betula nana*, *Betula humilis*, *Allium obliquum*, *Geranium cinereum*, *Nitraria shoberi*, etc.) and plants that, in our country, are at their limit of area (*Asyneuma anthericoides*, *Hedysarum grandiflorum*, *Jurinea tzar-ferdinandii*, *Genista sessilifolia* subsp. *romanica*, *Plumbago europaea*, *Salvia ringens*, *Scabiosa micrantha*, *Alkanna tinctoria*, *Thlaspi jankae*, etc.). Most of these taxa are not included in Globally or European Red Lists. In this way we hope to underline the urgent necessity to save some very rare and critically endangered plant species from Romanian flora.

P2361. Vulnerable flora of Sierra de Pachuca, Hidalgo, México: proposal of one local red list.

J. Medina Cota, M. A. Barrios Rodríguez;
Escuela Nacional de Ciencias Biológicas, México D. F., Mexico.

The Sierra de Pachuca located in the north end of Mexico`s Valley occupies a surface of approximately 600 km2, there is the oldest national park of Mexico (1899): Parque Nacional El Chico.
The checklist of the Sierra de Pachuca, Hidalgo, México, was made after ten years of research, with a total of 969 species from 411 genus and 93 families, 11 gimnosperms, 755 dicots and 203 monocots.
From the total, there are 195 species of plants which geographic distribution is restricted, or their populations are of few individuals, and their permanence in this place is threatened . The set represents 20.1 % of the total flora registered by the authors on those mountains. Eleven species are strict endemics from this region, 43 are endemics from México and 141 have a wider geographic distribution, but can disappear from Sierra de Pachuca by changes in their habitats by human influence.
This region, because of its great vegetal, ecological, phisiographic and historical diversity, has a high value for the preservation of the biological diversity of the country.

P2362. The precarious future of Lepidospartum burgessii (gypsum broomscale, Asteraceae), a rare and vanishing taxon of the southwestern United States.

J. A. R. Ladyman[1,2], P. Gegick[3,4], J. A. Sanders[2];
[1]New Mexico Natural Heritage Program, Centennial, CO, United States, [2]JnJ Associates LLC, Centennial, CO, United States, [3]New Mexico Natural Heritage Program, Albuquerque, NM, United States, [4]New Mexico Museum of Natural History and Science, Albuquerque, NM, United States.

Lepidospartum burgessii, a gypsophilic shrub, is endemic to the Alkali Flats region on the border of New Mexico (NM) and Texas. During a 1991/1992 survey, little recruitment was evident and most shrubs were mature. In 1997, our objectives were to determine *L. burgessii's* fecundity and availability of pollinators. In 1997, about 15% of shrubs counted in 1991/1992 in NM were dead. Shrubs produced abundant flowers but no seed. Pollinator availability did not limit pollination. Acetocarmine stain was used to estimate potential pollen functionality. Over 9,500 pollen grains, confirmed to be trinucleate, were assayed. Potential functionality was low (<50%) but unlikely so low as to prohibit fertilization. Florescence microscopy was used to investigate *in vivo* pollen germination and 524 stigmas, either from open pollinated flowers or controlled crosses, were examined. Pollen either did not germinate or the tubes stopped growing prematurely on the stigma surface suggesting that a homomorphic, sporophytic incompatibility system operates. Genetic drift may have resulted in decreasing the number of S-alleles in the population so that reproduction is inhibited.

P2363. Population survey as a basis for conservation of the priority species Centaurea horrida Badarò (Sardinia, Italy).

S. Pisanu, R. Filigheddu;
Dipartimento di Botanica ed Ecologia vegetale, Università di Sassari, Sassari, Italy.

Centaurea horrida Badarò (Asteraceae), a narrow endemic species located only in northern Sardinia (Italy), is a vulnerable species according to the IUCN Red List of threatened plants, a protected species according to the Bern Convention and a priority species according to the EU Directive 43/92 "Habitat". C. horrida lives in rocky cliffs and internal flat areas and is fragmented into five populations. Because three of these occur in protected areas, biological and demographical studies aimed at their conservation are carried out. All the populations are mapped; the area of occupancy and the extent of occurrence are estimated. Individual census, individual size, size/age relationship by anatomical and biometrical analysis have been carried out. Data about population structure on 12 sampling areas are showed. High predominance of non-fertile achens was recorded in all the populations. Disturbance affecting populations is related to active grazing by wild mammals in protected areas and the impact due to tourist activities.

P2364. Distribution and ecology of an endemic species, *Salicornia qassimensis* Al-Turki & Swarup *ined*. from Saudi Arabia.

T. A. Al-Turki;
Herbarium, King Abdulaziz City for Science and Technology, P.O. Box-6086, Riyadh11442, Saudi Arabia.

Salicornia qassimensis Al-Turki & Swarup is a rare species reported from Al-Waz salty area, 15 km east Qassim Province, Central Saudi Arabia. It is a halophytic, succulent, leafless looking annual plant that starts its life cycle in January-February period when the salinity is low due to intermittent rainfall. Stem usually cylindrical, appearing composed of articulated segments. The plant continue to grow for about six months and produces several branches from the base. It starts flowering in October and November and apparently wither off in December. Only one population with fewer than 1000 plants is so far reported for this species. The population is facing severe threats from several external agencies, such as fire, competition with other plants, etc. Immediate conservation measures are required to save the population of this species.

P2365. Geographic range size and the explanation of spatial diversity patterns of New World palms

H. Kreft, J. Sommer, W. Barthlott;
Nees Institute for Biodiversity of Plants, Bonn, Germany.

Macroecological approaches focus on correlations between species richness and environmental predictors. Here, we investigate effects of range size in these analyses using distribution data for all native American palm species. We evaluate the contribution of range-restricted and widespread species to patterns of species richness and endemism and analyze the impact of range size on the perception of their determinants. According to their range size, species sequences were produced in ascending, descending, and random order. Sequential correlations between cumulative species richness and environmental predictors were performed. Despite the higher proportion of species with small ranges, species richness patterns are dominated by the ~20% most widespread species. Energy and water related factors account for much of the species richness patterns of widespread species but are much poorer predictors for range-restricted species. Species richness of range-restricted species is to a larger extent determined by topographical complexity.

P2366. Endemic vascular flora of Calabria (S Italy): taxonomic and conservational remarks

L. Peruzzi, D. Gargano, N. G. Passalacqua;
Museo di Storia Naturale della Calabria ed Orto Botanico, Arcavacata di Rende (CS), Italy.

The Calabria region, situated at the centre of the Mediterranean sea, is marked by 67 narrow endemic vascular plants (including species, subspecies and varieties). They belong to 25 families and 42 genera, of which the most represented are *Centaurea* (6 units); *Salix* (4); *Anthemis*, *Dianthus*, *Epipactis* and *Limonium* (3); *Achillea*, *Adenocarpus*, *Allium*, *Armeria*, *Cardamine*, *Genista*, *Hieracium*, *Salvia*, *Silene* (2); all other genera are represented by only one unit. It is noteworthy the occurrence also of one monotypic genus (*Lereschia*, Apiaceae). This endemic flora mainly grows in well defined habitats, such as beech forests, cliffs, orophilous cushion-like vegetation, primary or secondary grasslands etc. The richest areas for endemics are the Sila (13 units) and Aspromonte (9) mountains, and the dry thermo-mediterranean southernmost part of the region (7). Taxonomy, distribution, conservation status and population amount growing in protected areas for each unit was studied, also in relation to their taxonomic rank. The role and the importance of narrow endemics in the regional strategies for conservation is evaluated and discussed.

P2367. An insight into the 50 most threatened plants of China

J. López-Pujol;
GReB, Laboratori de Botànica, Facultat de Farmàcia, Barcelona, Spain.

China harbors a very rich plant biodiversity both in number of taxa and in endemics, although a significant fraction is threatened mainly due to human activities. Between 3,000-5,000 plant species are currenlty endangered in China, probably falling into one of the threat IUCN categories (CR, EN or VU), although some taxa are in a situation of extremely endargement. A few dozens of plants contain only a few individuals or they are restricted to a single locality, thus being very susceptible to both anthropogenic and natural threats. Some well-known examples are *Abies beshanzuensis*, *Pinus squamata*, *Magnolia zenii*, *Ulmus gaussenii*, *Craigia kwangsiensis*, *Gletsidia vestita*, *Carpinus putoensis*, and *Bhesa sinica*, among others. Herein we advance, in the basis of the current knowledge, a list of the probably fifty most endangered plant taxa of China, following the same philosophy of the 'Top 50' campaign launched by the Species Survival Comission of IUCN in the Mediterranean basin islands. Some basic features (distribution area, legal status, threats, etc) are included in a brief profile for each plant.

P2368. Unique floristic complexes in Armenia

G. M. Fayvush;
Institute of Botany of Armenian NAS, Erevan, Armenia.

Armenia's flora includes 123 endemic species. They can be found on the entire territory of the country, Yerevan (39) and Dareleghis (36) floristic regions, however, are the richest regions with regard to endemics. Certain small mountain ranges and volcanoes are particularly notable due to their abundance with endemic species. Examples of such territories are the area near Areni and Khachik villages in Vajk mountain range with 10 endemic species, Urts mountain range and Arteni volcano each with 9 species, mount Khustup and the southern slopes of Vardenis mountain range each with 8 species. All the mentioned territories are characterized by their aridity, diversity of soil cover and vegetation. The majority of these endemic species is neo-endemic and their abundance is arguably linked to the intensive speciation processes. Possible factors contributing to the intensity of these processes might as well be the level of aridity, proximity to geological faults, seismicity of the territory and many others.

P2369. Endemic plants of Armenia

K. G. Tamanyan;
Institute of Botany of Armenian NAS, Erevan, Armenia.

Flora of Armenia is remarkable by the high number of taxa confined to a small area, especially Armenian endemics. Political boundaries are artificial, but in spite of this fact Armenian endemism is of the same level as that of the naturally delimited, large Mediterranean islands, which are notoriously richer in this respect than mainland regions of a comparable size. The 123 species endemic to Armenia represent 3 % of the total Armenian flora. Most are of relatively recent origin, dating from the Quaternary or Holocene, and only a few palaeo-endemics, e.g. of *Pyrus,* take their roots in the Tertiary period. This reflects the relatively recent diversification in the region of flora, resulting in its present high diversity. The incidence of endemic taxa is found in the arid zones of the southern and central part of the country. *Centaurea* sensu lato has than 16 endemic species in Armenia, and *Pyrus* 13 whereas the largest genus, *Astragalus,* has only 6.

P2370. The Endemic Species of *Trigonella* L. and Their Conservation in Turkey

H. Akan[1], M. Ekici[2], Z. Aytaç[2];
[1]Science & Art Faculty, Osmanbey Campus, ķanliurfa, Turkey, [2]Gazi University, Ankara, Turkey.

Trigonella L. is represented with 52 taxa in Turkey, 21 of are endemic. The endemism rate is about 40.38%. Five taxa are known from type locality and they are local endemics. These are *Trigonella cassia* Boiss. (**CR**), *Trigonella raphanina* Boiss. (**CR**), *Trigonella pseuodocapitata* Contandr. & Quezel (**CR**), *Trigonella arenicola* Hub.-Mor. (**CR**), and *Trigonella cilicia* Hub.-Mor. (**EN**). The others are also have rare distribution and mainly localised to Mediterranean region. The distribution and threatened category of endemic plants, especially the positions of narrowly distributed endemics were not known accurately until this study. Thus, their thretened positions will be discussed with the newly observations which are obtained during the revision of genus in Turkey. In addition, the suggestions will be given for their conservation. A full photographic presentation of endemic plants and observations on their populations will be provided.

P2371. Endemics of Kazakhstan Angiospermae

N. A. Ryabushkina[1], N. Gemedjieva[2];
[1]Institute of Plant Physiology, Genetics and Bioengineering, Almaty, Kazakhstan, [2]Institute of Botany, Almaty, Kazakhstan.

Comprehensive inventory of 160 plant families of Kazakhstan described in literature has shown 20 ones included nearly all endemics. About 25% each of Alliaceae, Apiaceae, 20% each of Boraginaceae, Lamiaceae, Liliaceae, Limoniaceae, considerable amount of Zygophylaceae, Polygonaceae species are endemics. In general, endemic spp. are better represented in the south-east and south part of the country. Of 29 Kazakhstan floristic regions there are about 25% of endemics in each of Jungar, Zaylyisky Alatau, Karatau, about 15% in the west Tian-Shan and Balkhash-Alakol (including instances of "double counting"). The relative

distribution of each family endemics varies from region to region. For example in Karatau, Jungar Alatau there are considerable number of Apiaceae, Lamiaceae endemics. Alliaceae and Liliaceae endemics are in Zaylyisky Alatau and Chu-Ilyisky mountains. In Balkhash-Alakol there are numbers of Zygophylaceae, Lamiaceae ones. The considerable amount of Polygonaceae endemics is in Zaysan, Balkhash-Alakol, Kzyl-Kum desert. For all that the most of endemics grow in dry, hot environments, in mountains on stony, road-metally slopes and rocks.

P2372. Taxonomic Consideration of Glandular Trichome Types in Greek Taxa of the Genus Thymus (Lamiaceae)

A. Markantonatou[1], T. Constantinidis[2], G. Sarlis[2], G. Karabourniotis[3], C. Fasseas[1];
[1]Lab of Electron Microscopy, Dept. Agricultural Biotechnology, Agricultural University of Athens, Athens, Greece, [2]Lab of Systematic Botany, Dept. Agricultural Biotechnology, Agricultural University of Athens, Athens, Greece, [3]Lab of Plant Physiology, Dept. Agricultural Biotechnology, Agricultural University of Athens, Athens, Greece.

The genus *Thymus* L. (Lamiaceae) is a polymorphic and taxonomically difficult group of *c.* 350 taxa. In Greece, *c.* 35 species and subspecies have been reported, a few of them endemic and very rare. In spite of its interest a limited number of micromorphological studies can been found in literature.
Micromorphology and anatomy of glandular trichomes on vegetative and reproductive organs of 18 representative *Thymus* taxa (43 samples) have been studied using light, fluorescence and scanning electron microscopy. Observations were mostly made on dry material collected in Greece. The comparative use of fresh material in several taxa did not reveal any noteworthy differences.
Altogether, thirteen glandular trichome types have been found; eleven of them are reported for the first time in the genus *Thymus*; two of them are new records for the Lamiaceae family. Organ traits such as glandular trichome types, their density and distribution appear to be of taxonomic value. The observed micromorphological stability among members of the same section is of economic importance, as it offers a sound ground for the exploitation of secondary metabolites.

P2373. Introduction and selection of non-traditional horticultural plants in the National Botanical Gardens of Ukraine

S. V. Klymenko, N. V. Skripchenko, O. V. Grigorjeva;
M.M. Gryshko National Botanical Gardens, National Academy of Sciences of Ukraine, Kyiv, Ukraine.

The National Botanical Gardens of Ukraine was founded in the 1935 year. The main direction of the researches there are-reservation of biodiversity and introduction of different varieties of plants of Ukrainian natural flora, medicinal, horticultural, ornamental plants.
The traditions of introduction and selection of the non-traditional plants were began in the Kiyv by academician M. Kacshenko in the began of XX c. Rich genetic pool of non-traditional horticultural plants has been accumulated. Many such varieties of plant were realized thanks to high food and medical properties of their fruits. The perspective sorts of *Actinidia arguta*, *A. colomicta*, *A. polygama*, *A. purpurea*, *Cornus mas*, *Cydonia oblonga*, *Chaenomeles japonica*, *Diospyros kaki*, *D. virginiana*, *D. lotus*, *Hippophae rhamnoides*, *Eleagnus multiflora*, *Lonicera edulis*, *Mespilus germanica*, *Morus alba*, *Sambucus nigra*, *S. canadensis*, *Sorbus aucuparia*, *S. domestica*, *Shepherdia argentea*, *Viburnum opulus*, *Ziziphus jujuba* have been incorporated in “The Register of Plants varieties of Ukraine”.

P2374. Landscaping and living collection on the Extreme North-East of Eurasian continent

A. N. Berkutenko[1], M. A. Polezhaeva[2], A. G. Rachinskaja[1];
[1]Institute of Biological Problems of the North, Magadan, Russian Federation, [2]Ural State University, Ekaterinburg, Russian Federation.

Magadan is 100 000 people town on North-East Russia (59 30’ N 151 E) on sea of Okhotsk founded in 1939. It is located in zone of “islandic” permafrost. Peculiarity of severe climate is late spring: leaves appear on trees early June or even middle June. The first small arboretum on area 0.17 ha was established in 1935 before Magadan was awarded town status. 53 species of trees, shrubs and herbs were registered in it in 1993. They are mostly native species except Malus sp., Caragana frutex , Syringa josikaea and Convallaria majalis brought as seedlings, seeds and rhizome in 1949 from St-Petersburg. They bloom but no fruits. Parks in Magadan contain native species. On the streets also native species of trees and shrubs planted except Padus maackii on Gagarin street and Pinus sylvestris, Picea obovata, P.ajanensis and Malus sp. in vicinity Magadan. In 2000 experiment in Nagaevo Bay on introduction of species of Magadan region and adjacent territories of the Russian Far East was started. Winter 2002-2003 was unusual - snow was absent till 7 January and t= -26.1°C. Nevertheless not only many native species but also some plants from Ussurian region, China and Kamchatka overwintered.

P2375. The species, form and sort variety of the genus Corylus L. in Ukraine

I. S. Kosenko, G. Vernyuk;
National dendrological park "Sofiyivka", Uman, Ukraine.

The data about the collection of species and forms of the genus Corylus L. growing in Ukraine and the overview of the history of foundation, restoration and conservation of the National dendrological park “Sofiyivka” is given in the abstract. Nowadays Ukraine is on its first step in growing Corylus L. National dendrological park "Sofiyivka" is the the only place in Ukraine where a great collection of the genus Corylus L. was collected. One of the species Coryllus avellana L. is native for Ukraine the other species were introducted from their native growing places. The data about the wide collection of the genus Corylus L. in the National dendrological park “Sofiyivka” is given. Species, forms, sorts and hybrids of Corylus L. growing in the National dendrological parj “Sofiyivka” are the valuable base for filbert breeding. National dendrological park "Sofiyivka" is a masterpiece of landscaping architecture and a scientific institution at the same time.

P2376. Complex Education for Biodiversity Conservation in Botanic Garden of Tver State University: Towards Regional Perspective.

Y. Naumtsev, **A. Mahova**, M. Shuvalova, E. Pushai;
Botanic Garden of Tver State University, Tver, Russian Federation.

In the presentation the regional biodiversity conservation work done by Botanic Garden of Tver State University will be described. Since 1999 onwards Botanic Garden of Tver State University has started complex project “Biodiversity Conservation Strategy of Tver Region” which is meant to facilitate biodiversity conservation in the region. Alongside with endangered plants special attention is paid to the following aspects: specific characteristics of ecosystems, harmonious interaction of the man and nature, the art of development recreational zones and landscape design in urban environment. Scientific research carried out in the Garden provides necessary content and methodological basis for educational activity focused on regional biodiversity conservation problems. In the framework of the project great attention is paid to the raising of biodiversity awareness of the population of Tver Region. Garden employs a wide range of awareness activities: plant expositions “Living red data book”, guided tours, lectures, interactive games, joint pilot-projects with NGO, mass media projects, publishing activities, family holidays, festivals etc.

P2377. Aburi Botanic Gardens Role in Conservation of Medicinal Plants in Ghana

G. Owusu Afriyie;
Aburi Botanic Gardens, Aburi, Ghana.

The World Health Organisation estimates that up to thirty percent of the World’s population rely on plants for their primary health needs. In Ghana most people in rural areas depend almost entirely on herbal medicine. Even in urban areas where orthodox medicine is available there is considerable reversion to herbal cures due to the high cost of conventional medicine. All plants used in primary health care in Ghana are collected from the wild by over 500,000 practitioners. These herbs are thus threatened not only by habitat destruction but also by the unsustainable harvest from the wild.
The need to initiate actions to reduce the pressure on these treasures became the concern of Aburi and of other stakeholders. Based on results of ethnobotanical surveys undertaken by Aburi, with interviews in selected communities, a concept was developed and activities initiated to conserve threatened and most frequently used plants. The on-going efforts to promote sustainable use of local plants for local needs and thus to improve the livelihood of

local people is Aburi's contribution to conserve medicinal plants for the present and future generation.

P2378. The greenhouse collection of succulents in Saint-Petersburg's botanical garden during the World war 2 and the reconstruction of the collection after the war

I. M. Vassiljeva;
Komarov Botanical Institute RAS, St. Petersburg, Russian Federation.

St. Petersburg's Botanical Garden was founded by Piter the Great in 1714.

World War 2 brought a lot of harm to all living collections of the Botanical Garden. In the year 1941 over 50 inflammatory bombs were thrown down on the territory of Garden; and in 1942-1943 85 artillery missiles more, as a result practically all the greenhouses were destroyed. During the Leningrad siege nearly all the tropical plants died, and the biggest part of the saved species were cacti and other succulents. Gardeners kept them in their own flats. According to official data from 1947 10 samples of succulents, representing 19 families, 75 genera and 354 species had survived the wartime.

In 1946 big number of plants arrived from the Sukhumy dendrarium-park, including agaves, yuccas and others. The other resource of restoring the collection was the delivery of plants from the defeated Germany following to reparations in 1945 - 1947. In 1949 a lot of succulents were bought from the German firm "Kakteen-Haage".

Nowadays the succulent collection consist of 2302 taxa (305 genera, 35 families) and overcomes the collection of the Emperor's Botanical Garden in its best times by number and contents.

P2379. Conservation and Utilization of Plant Genetic Resources in Nepal

R. Bhandari;
Himalayan Resources Institute (HIRI), GPO Box: 13880,
Budhanilkantha, Kathmandu, Nepal.

The plant biodiversity of Nepal consists: cereals, grain legumes, vegetables, industrial crops, oilseeds, spices, fruits, ornamentals and herbs. The contribution of plant biodiversity to food supply, agriculture, forestry, medicine and industry is enormous. Nearly 54 percent of Nepal's physical landscape is covered with vegetation (37 % forested area, 5 % shrub land and 12 % grass land). A total of 118 ecosystems with 75 vegetation and 35 forest types have been identified in Nepal. Though Nepal possesses only 0.1% of the total landmass of the world, it harbors nearly 2.5 % flowering plants, 3% pteridophytes and 6 % bryophytes of the world's flora. There is high degree of endemism (246 species), which accounts for 30 % for whole of the Himalayan region. There are more than 6,500 plant species of which more than 500 plant species are edible, 700 species of medicinal plants have been identified and a total of 10,736 accessions of 90 crops have been documented. Nepal is considered to be one of the countries of origin of rice in the South Asia. Existence of more than 120 species of wild relatives of cultivated crops is an additional dimension to the plant genetic resources of Nepal.

P2380. How selfing and intra- and interspecific crossing influence seed set, morphology and ploidy level in *Euphrasia*: An experimental study of species occurring in the Alps of Switzerland

B. Liebst, J. Schneller;
Institut für Systematische Botanik, Zürich, Switzerland.

Annual alpine species rely on selfing rather than on cross-pollination for successful reproduction. However, insect visits may occasionally cause cross-pollination not only within but also between closely related species. The aim of this study was to investigate four species of *Euphrasia* for their efficiency in spontaneous selfing and their success in intra- and interspecific crossing. We used the seed sets that followed spontaneous selfing and artificial cross- and selfpollination to measure the breeding success. We verified the hybridogenous origin of plants resulting from interspecific crosses using RAPD patterns and determined their ploidy level using flow cytometry. While spontaneous seed set was high in the two small-flowered species, seed set in the large-flowered species was small and affected by external circumstances. F1 and F2 hybrids from interspecific crosses of two diploid species were obtained, including polyploid individuals in both generations.

P2381. Species relationships within Arisaema (Araceae) as inferred from an improved chloroplast phylogeny

J. Murata[1], T. Ohi-Toma[1], L. Zhang[2], S. S. Renner[3];
[1]The University of Tokyo, Tokyo, Japan, [2]Department of Biology, Colorado State University, Fort Collins, CO, United States, [3]Ludwig Maximilians University Munich, Munich, Germany.

Arisaema comprises 150 species of herbs that occur from the Himalayas to Japan and SE Asia; three species occur in the New World, a few in East Africa, and one ranges from Africa across Arabia to Nepal. Our earlier analysis (Am. J. Bot. 91; 881-888. 2004) of chloroplast sequences from representative species of ten of the eleven sections recognized by Murata (1984, 1990, 1991) showed that several sections are polyphyletic. We have now added data from the psbB-psbH cpDNA intergenic spacer as well as numerous additional species, especially from Japan. Combined rpl20-rps12 and psbB-psbH data reveal that A. flavum, the above-mentioned widespread species and only member of section Dochafa, is sister to the Asian A. jacquemontii, and that both are sister to A. tortuosum and related Asian species from section Tortuosa Engl. The remainder of section Tortuosa, including the American A. dracontium and Mexican A. macrospathum, is confirmed as highly polyphyletic, implying that the striking spadix appendages to which the section owes its name evolved several times in the genus.

P2382. Prospects of biofuel production from plants in India

A. Kumar;
Biotechnology LAB. Department of Botany, University of Rajasthan, Jaipur, India.

Plants undertake photosynthesis to convert light energy to chemical energy

and some plants convert it to directly to liquid fuels. Laticiferous plants yield hydrocarbons which provide liquid fuels. The methods for obtaining liquid fuel from plants varies from plant to plant and the contents vary from season to season. Different factors promote and regulate the biosynthesis of hydrocarbons in plants. Detailed investigations have been carried out on the selection of plant species providing maximum hydrocarbon contents. The optimal conditons for the maximum latex biosynthesis have been determined. Different inorganic fertilizers have increased the latex biosynthesis and phosporous is one of the most important factor to promote the hydrocarbon yield. Plants could be used to provide renwable and clean biofuels. India has over 130 million ha of wasteland which could be utilized for biofuel production. Details shall be presented

P2383. Is competition important in alpine plant communities? Removal experiment in the Northwest Caucasus

M. A. Gerasimova, V. G. Onipchenko;
Biological Faculty, Moscow State University, Moscow, Russian Federation.

The aim of our study was to answer two questions: 1) is the net effect of the surrounding plant community to stress or benefit different alpine species in comparison with growth alone? 2) How does the role of competition change among communities with different productivity? We use a method of removing all but one species from plots within a community to create the monocultures. Role of competition as community structuring mechanism was estimated according to Goldberg (1994) approach. The experiment was conducted during 6 years in alpine area of the Teberda State Reserve, Russia. The importance of competition in the communities increases in the order: *Festuca varia* grasslands < alpine heaths, snowbeds < *Geranium* - *Hedysarum* meadows. Competition was more important in the most productive alpine community. Unexpected intermediate position for low-productivity communities of stressful environment and the last position of relatively productive *Festuca varia* grassland were obtained. Our results support Fretwell-Oksanen hypothesis that competition in communities of intermediate productivity is less important than in low or high productive communities.

P2384. Preonanthus: An Independent Genus Formed by Alpine Ranunculaceae Taxa

J. L. Szentpéteri;
Institute of Biology, Pécs, Hungary.

Pulsatilla, genus of Ranunculaceae family, contains more than 170 taxa, but the objective correlations between these categories are still unclear. The morphologically variable species make the correct classification really difficult. However, there are some taxa (P. alpina and its subspecies, variants), which show significant morphological difference from other Pulsatilla species. We tried to support this difference with phylogenetic studies.

Molecular phylogeny was constructed using nucleotide sequences of internal transcribed spacer (ITS) regions of nr DNA. A phylogenetic tree was constructed from the nucleotide sequence alignment using PAUP* 4.0. ITS regions seem to be valuable source in identifying different species, while significant polymorphism manifested in most of the studied taxa at species level. 2 samples showed significant polymorphism at generic level.

While these species are exactly the same, which differ in numerous morphological characters from all the other Pulsatilla taxa and were classified as Preonanthus species, we think these taxa should be considered generically different and Preonanthus genus should be recalled.

P2385. Resources of Harboi Rangeland Kalat, Pakistan as affected by Afghan Refugees

M. J. Durrani[1], S. F. Hussain[2], I. Ilahi[3];
[1]University of Balochistan, Balochistan, Pakistan, [2]University of Peshawar, Peshawar, Pakistan, [3]Kohat University of Science and Technology, Kohat, Pakistan.

Harboi rangeland, Kalat is degraded juniper forest with arid temperate climate. The study conducted during 1999-2001 revealed that there were 202 species of 45 families. The life form and leaf size spectra of flora exhibited xenomorphic features. *Juniperus polycarpos* was the only tree species. The plant communities were classified into *Bromus* type*, Seriphidium* Steppe and *Juniperus* types during spring while it shifted to *Seriphidium* steppe, *Astragalu*s steppe and *Juniperus* types during summer. Species diversity during summer (0.16-0.07) was high than in the spring (0.12-0.05). Species richness ranged from 1.67 to 2.6 in spring and 1.1 to 3.41 in summer. The over all vegetation is highly degraded and open with scattered individuals of juniper. The rangeland is suffering from overgrazing, deforestation and erosion. The degraded range condition needs ecological restoration for the sustainable future use.

P2386. Impact of Afghan Refugees ob vegetation along Durand Line, Pakistan

S. F. Hussain[1], I. Ilahi[2], M. J. Durrani[3];
[1]University of Peshawar, Peshawar, Pakistan, [2]Kohat University of Science and Technology, Kohat, Pakistan, [3]University of Balochistan, Quetta, Pakistan.

The Pak-Afghan border stretches from 1400 to 5000 m height with many small and large passes. Traditionally people along borderline freely cross the borders. During 1978 more than 3 million afghan refuges fled into Pakistan that affected the vegetation and plant diversity. The southern borders have *Artemisia-Astragalus* scrub. At Mohammand and Arundu, *Olea-Reptonia* forests changed to scattered trees. *Quercus baloot* and mixed blue pine forests occur at Dir. The alpine borders of Chitral have *Artemisia*, *Acantholimon-Acanthophylum* steppe, alpine pastures consisting of low, open, non-palatable plants. The coniferous forests along Parachinar border have been degraded. At Bajaur border oak forests have shifted to *Dodonaea* scrub. Overgrazing and deforestation has decreased the over all productivity of forest and rangeland resources and increased soil erosion. There is need to restore these resources for sustainable resource management.

P2387. Testing the geographic transposability of predictive distributions models of plant species under present and future climate scenarios

C. F. Randin[1], T. Dirnböck[2], A. Guisan[1], N. Zimmermann[3], S. Dullinger[4];
[1]LBC, Dept. of Ecology and Evolution, University of Lausanne, Dorigny, Switzerland, [2]Federal Environment Agency, Vienna, Austria, [3]WSL, Birmensdorf, Switzerland, [4]Institute of Ecology and Conservation Biology of the University of Vienna, Vienna, Austria.

Predictive habitat distribution models have been increasingly used to assess the impact of climate change on plant species. In this context, models applicable to a wide range of geographic and environmental situations are highly desirable. Models based on niche theory fit a relationship between field observations and environmental predictors, and project it into the geographical space. Due to their empirical nature, models rather fit the realized than the fundamental niche of species. For this reason, it has been argued that these models have their application limited to the specific regional and temporal domain of calibration. In order to verify this, we reciprocally fitted distribution models for more than 100 plant species in two regions of the European Alps: the western Prealps (Switzerland) and the Northern Calcareous Alps (Austria). This study aims at answering the following questions :

1) Do environmental response models of the same species differ between the regions?

2) Can we predict plant species distributions of one region using models of the other region and under present and future climate conditions?

3) Do future scenarios differ across regions?

P2388. Post-agricultural succession in areas of the Atlantic Forest, Brazil.

D. M. Silva Matos, G. C. Corsi, O. Lino-Silva, A. C. A. Neri;
UFSCar, São Carlos, Brazil.

Clearing forest for agriculture is one of the most common disturbances in tropical regions. In order to understand post-agricultural recovery and promote management projects, studies on succession need to be conducted. Studies of post-agricultural recovery may have been neglected because of the assumption that disturbances have the same effect. Post-agricultural areas are likely to be different from treefall gaps because they are larger in area and have different history, and, consequently, produce more impact on the environment. This study describes the process of succession in post-agricultural areas, within Mata Atlântica domain. A total of 0.5ha was established in each area. A survey about the dominant species was performed in order to estimate the percentage of Poaceae and Pteridophyta. All trees taller than 1.80m (the average height of *Pteridium aquilinum* stands) were tagged and measured. The most common families were Euphorbiaceae, Labiateae, Apocynaceae, Myrtaceae, Simarubaceae, Erythroxilaceae Chrysobalanaceae, Lauraceae, Leguminosae, Rutaceae. Financial support from CNPq/ASCIn.

P2389. Evaluation of the ozone-related risk for Austrian forests

S. Smidt[1], W. Loibl[2], H. Bolhar-Nordenkampf[3], F. Herman[1];
[1]Federal Research and Training Centre for Forest, Natural Hazards and Landscape, Vienna, Austria, [2]ARC System Research, Seibersdorf, Austria, [3]Institute of Ecology and Conservation Biology, University of Vienna, Vienna, Austria.

Forest ecosystems are particularly affected by the impact of stress factors. Apart from natural stressors, there are also anthropogenic ones such as air pollutants. Ozone is considered to be the most phytotoxic air pollutant in Austria on a regional scale. In the past decade, concentrations in forested areas have increased significantly by up to 1.6 ppb per year. In order to assess the ozone impact on forests, a nationwide mapping of the AOT 40 for the forested area of Austria was done with the objective to take the ozone Critical Level as defined by the UN-ECE as the basic concept and to develop a threshold value with the help of three approaches. The adaptation of trees to the pre-industrial ozone levels, the parameters affecting stomatal uptake such as light intensity and water vapour saturation deficit, and the hemeroby (altered and natural) of the forest stands were taken into consideration. 61 % of the forest area showed a level of more than 10,000 ppb.h. Lower altitude areas with predominantely altered stands were affected more heavily.

P2390. Diversity of vascular epiphytes on isolated remnant trees in the Andes of southern Ecuador

F. A. Werner, S. R. Gradstein;
Dep. of Syst. Bot., Albrecht-von-Haller Institute of Plant Sciences, University of Goettingen, Goettingen, Germany.

We studied the diversity of vascular epiphytes on isolated remnant trees of pastures at Estación Cintífica San Francisco (ECSF) in the lower montane forest belt of southern Ecuador (1800-2200m a.s.l.). The objective of this study was to document the importance of remnant trees for the survival of epiphytes following forest clearance. Twenty-one canopy trees (15 remnant trees, 6 forest trees) were divided into five zones following Johansson (1974). Bromeliaceae, Orchidaceae, Piperaceae and Polypodiaceae were relatively well represented on remnant trees in terms of species richness and abundance. Other families commonly found on forest trees such as Dryopteridaceae, Ericaceae, Grammitidaceae and Hymenophyllaceae were poorly represented on remnant trees.

Diversity, species richness and abundance of epiphytes were significantly lower on remnant trees as compared to forest trees. Impoverishment was greatest on the stem base and in the outer crown, and least in the inner crown. We suggest that microclimatic changes and increased drought stress following the isolation of the remnant trees resulted in lowered rates of establishment and survival of epiphytes.

P2391. Historical land-use legacy and Cortaderia selloana invasion in the Mediterranean region

R. Domènech[1], M. Vilà[1], J. Pino[1], J. Gesti[2];
[1]Centre de Recerca Ecològica i Aplicacions Forestals (CREAF), Bellaterra, Spain, [2]Unitat de Bòtanica, Departament de Ciències Ambientals, Universitat de Girona, Girona, Spain.

Land-use changes and species introductions threaten native species conservation. Mediterranean areas are highly susceptible to invasions and they have suffered major land-use changes, yet there is scarce research to link biological invasions and land-use change attributes: number, type, trajectory and direction. Distribution and abundance of *Cortaderia selloana*, an alien species, was analysed in 332 fields in Empordà marshes (NE Spain). We related invasion patterns to land-use spatiotemporal data (1956-2003) to determine land-use susceptibility to invasion in the last 5 years and to find out which attributes triggered invasion. Invaded fields (22.30 %) are near to urban areas and its density has been triplicated since 1998. Invasion was over-represented in pastures and old-fields and it increased with time since abandonment. *C. selloana* presence was associated to land-use changes, the most invaded fields were the ones that remained as undisturbed. Plant biomass was higher in agricultural field margins and in fields that had a disturbed land-use in 1956 and 2003. Overall, *C. selloana* invasion pattern can be explained by the historical land-use legacy.

P2392. The Northern border of the area of *Pteridium aquilinum* L. in the West-Siberian plain.

N. A. Poskalnyuk, N. I. Shorina;
Moscow Pedagogical State University, Moscow, Russian Federation.

Pteridium aquilinum is a cosmopolitan species. Its habitat has been studied in many countries (Page, 1976, 1997). But in West Siberia its distribution is not quite clear and the northern border of the area is interpreted in different ways. P.N. Krilov (1927) and L.I. Krasnoborov (1988) pointed out the territory near the town Tobolsk (å58ºN), R.M. Tryon (1941) that of the town Beresovo (å64Nº), A.I. Shmakov (1999) that of the Ob`s geobotanical district (å67ºN).

We investigated the geographical distribution and coenotic value of P. aquilinum in 2001-2004. The research area included forest-steppe and forest zones of West Siberia near the villages Sladkovo, Demianskoe, Salim, touns Ishim, Tuemen, Tobolsk, Langepas, Nizhnevartovsk, Surgut, Hanti-Mansiisk, Sovietsk, and in Ugansk and Malososvinsk nature reserves.

As a result of our analysis, the Northern border of P. aquilinum is determined. It passes near Arantur lake in the national park «Kondinskii lakes» (å60,5ºN) (Red data book HMAD, 2003 and our data). So it is more to the south of Tryon`s and Shmakov`s directions but to the north of those by Krilov and Krasnoborov.

P2393. Land use changes in savannas of Central Brazil: The impact of eucalypt plantations and *Brachiaria* pastures on water fluxes

A. C. Franco[1], S. J. Bucci[2], F. Scholz[3], W. A. Hoffmann[4], M. L. Meirelles[5], G. Goldstein[2], F. R. Meinzer[6];
[1]Universidade de Brasilia, Brasilia, Brazil, [2]University of Miami, Miami, FL, United States, [3]Universidad de Buenos Aires, Buenos Aires, Argentina, [4]North Carolina State University, Raleigh, NC, United States, [5]Embrapa-Cerrados, Planaltina, Brazil, [6]USDA Forest Service, Corvallis, OR, United States.

We compared transpiration in natural savanna, *Eucalyptus grandis* plantations of two different ages, and grazed and ungrazed pastures of *Brachiaria* decumbens. Water extraction in the *Brachiaria* pastures was mostly restricted to the superficial soil layers whereas *E. grandis* plantations and savanna vegetation accessed deeper soil layers. There was a strong linear relationship between basal area and active xylem area for both *E. grandis* and savanna trees. Stem cross-sectional area was mostly conducting tissue in *E. grandis*, but only about 36% in savanna trees. Thus, over a range of 20 to 200 cm^2 of basal area, *E. grandis* maintained daily sap flow rates that were 2 to 3-fold higher than savanna trees in the wet season. Sap flow rates of *E. grandis* increased in the dry season while savanna trees maintained rates similar to the wet period. Water loss in the ungrazed *Brachiaria* pasture was higher than that of the savanna groundlayer in the wet season. Water loss in both decreased substantially in the dry season. Thus, these changes in land use have an important impact on the hydrological cycle. CNPq, FINATEC, NSF.

P2394. Regional impact assessments of multiple environmental changes for plant diversity

T. Dirnböck[1], S. Dullinger[2], J. Greimler[3], T. F. Stuessy[3], G. Grabherr[4];
[1]Federal Environment Agency, Vienna, Austria, [2]Vienna Institute for Nature Conservation and Analysis, Vienna, Austria, [3]Botanical Institute, University of Vienna, Austria, [4]Institute for Ecology and Conservation Biology, University of Vienna, Austria.

Climate changes, the withdrawal from traditional land use practices, and invasion of alien plant species expose biodiversity to unprecedented stresses. The assessment of these impacts is challenging, particularly its interacting effects. Environmental envelop models in combination with comprehensive spatial data on environmental condition provide an opportunity to assess the consequences of multiple pressures for biodiversity. Here we present the results of several regional modelling studies by emphasising feasibility, potentialities and pitfalls of the models being applied. Scenarios of the impact of climate change and the abandonment of traditional pastures in alpine areas were developed for a region in the European Alps. Another impact assessment was carried out for a Chilean island where alien species pose severe threat to the endemic flora. The results of these studies showed that ecosystems are differentially vulnerable to environmental changes, that it is essential to consider multiple pressures, and that the models being applied can answer only part of what would be necessary to define effective measures for biodiversity conservation.

P2395. Primary successions in the new Aral seashore

L. A. Dimeyeva;
Institute of Botany&Phytointroduction, Almaty, Kazakhstan.

During first years succession is controlled according to models of facilitation and neutrality. A model of tolerance has started after lowering of ground water table and organic matter discharge of bottom deposits.

Psammosere

Initial plant colonization has started by aggregation of *Suaeda acuminata* and *Atriplex pratovii.*

Steady desalinization of light lithology soils occurs in 10 years of continental regime. The model of facilitation has become the main motive force of succession again. Transition towards tree-shrub stage with sub-shrubs (*Haloxylon aphyllum, Calligonum* spp., *Artemisia arenaria*) follows after 35-40 years of succession. Indexes of plant species diversity show low stability of species richness, high coefficient of community and a positive trend of evenness index.

Halosere

Soils are of heavy lithology. Desalinization of top horizons has seasonal character. Succession is controlled by a model of tolerance. Changes of dominants are as follows: *Salicornia europaea* (1-4 years) Ÿ *Climacoptera aralensis* (5-8) Ÿ *Halostachys caspica* (12-17) Ÿ *Halocnemum strobilaceum* (20). Indexes of plant species diversity have a tendency towards decreasing.

P2396. Deforestation effects on soil physical and chemical properties in a western Kenyan rainforest, Kakamega forest

W. M. Musila[1,2], H. Todt[2], D. Uster[2], H. Dalitz[2];
[1]National Museums of Kenya, Nairobi, Kenya, [2]University of Hohenheim, Institute of Botany (210), Stuttgart, Germany.

Deforestation has significant effects on biogeochemical and physical properties of soils, which in turn influence global nutrient cycling. In this study, changes of soil physico-chemical properties caused by converting primary forest to shrubland and grassland in Kakamega tropical rainforest up to 350cm depth were evaluated Generally, the concentrations of nutrient cations, total C and N, and EC decreased with depth except in the grasslands whereby total K and total Mg increased with depth. The forest soils had significantly higher concentrations of available K, available Ca, available Mg, pH and EC than in shrubland and grassland ($p<$ 0.05) at all depths. Total C, total N and available Mn did not vary significantly between the vegetation types. The forest soils had higher soil stocks of C, N, Ca, and Mn than the grassland and shrubland soils but lower stocks of K and Mg. It can be concluded that, the forest cover provides the most effective means for regeneration of Kakamega soils.

P2397. Modelling of forest growth in the Centre of European Russia at different land-use

A. Mikhaylov;
Institute of Physicochemical and Biological Problems of Soil Science RAS, Pushchino, Russian Federation.

The system of models, EFIMOD was used for the simulation of ecosystem dynamic under the different forest management scenarios. The system consists of tree sub model, soil sub model (ROMUL) and statistical climate generator (SCLISS).

The forest selected for the simulation modeling is situated on Central East European Plain with continental climate of the border between coniferous and broad-leaved forest and consists of 104 forest inventory units.

Four simulation scenarios were compiled for the analyzing of forest dynamic at different silvicultural regimes: a) natural development; b) Russian authorized practice; c) selective cutting system; d) unauthorized practice.

The EFIMOD runs have been performed for 200-years stand growth and soil changes in every forest compartment for four scenarios of forest management.The results obtained allow for the conclusion on the advantage and shortcomings of different regimes of forest management for their correspondence to the concept of sustainable forest management. Selective forest technology has clear advance over all other regimes with cuttings.

P2398. Statistics of Change for Land Cover In Mexico

A. Victoria;
Instituto Nacional de Estadistica, Geografia e Informatica, Aguascalientes, Mexico.

Through the years the land cover in Mexico has seen big changes in its original distribution and its floristic composition sometimes drastically.

As a reference the experience acquired during 35 years of geographic activity at INEGI and specifically in elaborating the information of land use and land cover 1:250 000 scale. The statistics of change in land cover in Mexico throughout 30 years are presented in this work.

The information for setting up statistics are the vectorial files of the land use and land cover maps elaborated during three periods of time or time series: Series I (80’s), Series II (90’s) and Series III (2002).

All this information provides surface data of land cover (natural and induced vegetation at a level of vegetation type and secondary stages as arboreal, shrubs and herbaceous.) and land use (agricultural and crops). The objective of presenting in a clear way the changes in the types of natural and induced vegetation.

For each series is possible show the country percentages by areas without original vegetation:
80`s: **20.66 %**
90`s: **21.28 %**
2002: **25.97 %**

P2399. Post-fire resprouting in woody plant species of a brazilian savanna.

M. B. Medeiros[1], H. S. Miranda[2];
[1]Embrapa Recursos Genéticos e Biotecnologia, Brasília, Brazil, [2]Universidade de Brasília, Brasília, Brazil.

The objective of this work was to evaluate resprouting patterns after annual fires in woody plants, in an open savanna phytophysionomy, at the Ecological Reserve of Brazilian Institute of Geography and Statistics, Brasília-DF, Brazil. The area was protected against fire for 23 years and it was burned in 1998, 1999 and 2000. All plants of woody layer with diameter larger than 2,0 cm at 30 cm from soil level were marked and identified. After prescribed fires, damage type (total or partial) was determined. The number of basal and underground sprouts was measured after prescribed fires. The diameter and height were measured for each marked sprout. A total of 1307 sprouts were measured. The main impact of fire on resprouting was the decreasing of sprouts number, with 684 sprouts after the first burning to 248 sprouts after the third burning. The frequent fires did not affect the sprouts size. However, it was observed a high mortality rates of sprouts, after the second and third burnings (34,8% and 37,8%, respectively). The results showed that the interval between fires should be insufficient for sprouting regeneration of woody plants in the current Cerrado fire regime.

P2400. Conservation of biological diversity in Vyatsko-Kamskii region on a base of ecological optimization of structure and functions of agriculture landscapes

N. R. Veselkova, V. V. Tuganaev;
Udmurt State University, Izhevsk, Russian Federation.

Forming of agriculture landscapes in the Udmurt republic (UR) (a part of Vyatsko-Kamskii, VK region) has been started since the beginnings of agriculture and live-stock farming there (about 2500-3000 years ago). The result is a sizeable transformation of landscapes. We have investigated plant cover conditions in UR, rare plants and vegetation communities. We have started a project of the ecological optimization of structure and functions of the agriculture landscapes in VK region on a base of ecotopes ecological conditions and social concernments of the natural and anthropogenic lands taking into consideration the necessity of biodiversity conservation at all landscape levels. We have shown a necessity of the expansion of the nature-conservative measures from the highly protected natural territories to the whole regional level. Highly protected natural areas occupy no more than 3 per cent of the republic square and there are amassed no more than 30 per cent of the UR species diversity.

P2401. The modern status of flood plain ecosystems in the broad-leaved forests zone (river basin middle Elbe and Sejm) in connection with changes of river flow and climate conditions

Z. V. Kuz'mina[1], S. Y. Treshkin[2];
[1]Water Problems Institute, Moscow, Russian Federation, [2]Institute of Bioecology, Nukus, Uzbekistan.

Regulated of SHC (small and middle low-dammed hydrotechnical construction) lead to stabilization of humidifying regime and to change of fluctuations GWT (ground water table) in floodplain that produces change of all components of ecosystems, change of soil and vegetative covers.

At the end of the XX century a trend of decreasing the fluctuation amplitude of water flow and level is observed in the middle Elbe and Sejm rivers basins. This is a serious cause for increasing the groundwater depth in the vegetation period, for the gley formation in upper and middle soil horizons and hence for injuring the natural wood-shrubby vegetation (Quercus robur, Ulmus spp., Tilia spp., Salix spp. etc.) in the river floodplain.

From the end of 70s in 20th century the periodically changing frequency of floods has being destroyed and leads to degradation of forest communities (Quercus and Ulmus) on the upper flood plain terraces.

P2402. Change of main type of flora of the south of the Aral Sea region as a result of environment degradation

N. K. Mamutov, P. Reymov, V. A. Statov, S. J. Abdireymov;
GIS Center of Karakalpak University, Nukus, Uzbekistan.

Modern vegetation covering of the Aral Sea basin consists of tugai, psammophytic and halophytic types of plants. Flora of this region has 176 endemic species, 15 relict species, and 33 wild congeners of the culture plants. Families Chenopodiaceae, Asteraceae, Polygonacae, Bogarinaceae, Cyperaceae, Cryophyllaceae and Tamaricaceae have most diversity of species.

Habitat's environment changes have various consequences for many types of plants in. There are deepest changes of flora in the deltaic plains of the lower course of Amu-Darya. Portion of the flooded holmme decreased from 35% to 5%. Part of the hydromorphic plant communities thinned from 40% to 25%. In the same time number of plant association, representing salted and desertified sites, increased from 25 to 70% of total area of delta.

Psammophytic vegetation (Ammodendron, Salsola Calligonum, Artemisia, Carex etc) could be described as rarefied low-productive communities with predominance of non-pabular plants. Halophytic vegetation (Salsola, Halostachys, Karelinia, Zygophilum) increases its area. Special measures should be developed to maintain natural plant resources of the Aral Sea region.

P2403. Evolution of Neogene climate dynamics - forcing and results

H. Freund;
Institute of Chemistry and Biology of the Marine Environment, Wilhelmshaven, Germany.

The Cenozoic was an important period in Earth's climatic history, since it records the change from greenhouse climates during the early Palaeogene to icehouse climates in the Quaternary. Some of the causes of the centennial to millennial scale climate fluctuations during the Quaternary are clear but others are not well understood up to now. The main forcing mechanisms have been considered as changes in the Earth's orbit that result in periodic variations of solar radiation, the tectonic development of the earth and solar variability. These external mechanisms influencing climate changes forced internal feedbacks within the climate system e. g. changes within the internal ocean or athmospheric circulation dynamics. There is a need for interdisciplinary palaeoecological and palaeobotanical investigations to understand the importance of these complex causal factors in the initiation, evolution, and variability of the quaternary climatic system. Furthermore it is important to understand the mechanisms of “natural climatic variations” to compare them with climate changes forced by man which play an important role in todays climate discussions.

P2404. Lateglacial vegetation and climate changes in the high mountains of Bulgaria (Southeast Europe)

E. D. Bozilova, S. B. Tonkov;
Sofia University, Sofia, Bulgaria.

The Lateglacial vegetation history in the high mountains of Southern Bulgaria (Rila, Pirin, Western Rhodopes) is reconstructed by means of pollen analysis, plant macrofossils and radiocarbon dating of sediments from lakes and peat-bogs located between 1300 and 2200 m a.s.l. The vegetation response to the climate fluctuations after 13000 ^{14}C yrs. BP in the Rila Mountains is bound for the first time to a detailed chronological framework. Two stadial and one interstadial phases are delimited analogous with the Oldest Dryas-Bolling/Allerod-Younger Dryas cycle for Western Europe. During the stadials mountain-steppe vegetation composed of *Artemisia*, *Chenopodiaceae, Poaceae* and other cold-resistant herbs dominated at high elevation with sparse stands of *Pinus*, *Betula*, and shrubland of *Juniperus* and *Ephedra*. The climate improvement in the interstadial resulted in the initial spread of deciduous and coniferous trees (*Quercus, Tilia, Corylus, Carpinus, Abies, Picea*) from their local refugia below 1000 m. The palaeoecological record from the climate deterioration during the Younger Dryas is documented in thin sections of the cores investigated.

P2405. Late Tertiary/Early Quaternary range splits of the Eurasian steppe plant *Clausia aprica* (Brassicaceae)

A. Franzke[1,2], H. Hurka[1,2], D. Janssen[1,2], B. Neuffer[1,2], N. Friesen[1,3], M. Markov[4,5], K. Mummenhoff[1,2];
[1]University of Osnabrück, Osnabrück, Germany, [2]Department of Biology, Systematic Botany, Osnabrück, Germany, [3]Department of Biology, Botanical Garden, Osnabrück, Germany, [4]State University of Tver, Tver, Russian Federation, [5]Department of Geography, Tver, Russian Federation.

Several vegetation belts stretch continuously from Europe to Asia, taiga and steppe being most prominent. Numerous plant species within these vegetation belts share a conspicuous distribution area, which is longitudinally contracted or disrupted approximately along longitude 70°E. To date no hypothesis for this intriguing distribution pattern has been put forward. We detected molecular footprints in the contemporary genetic composition in nuclear DNA (ITS1, ITS2) and chloroplast DNA (*trn*L-*trn*F spacer region) of the steppe element *Clausia aprica* (Brassicaceae) providing evidence for a severe longitudinal range split and genetic differentiation east of the Ural Mountains about 1 million years ago caused by Quaternary climatic oscillations. *Clausia aprica* provides the first phylogeographical analysis on the intraspecific evolution of an Eurasian steppe plant.

P2406. Late Pleistocene vegetation history at Colli Euganei (Padova, Italy)

A. Miola[1], **S. Piovan**[2], G. Valentini[1];
[1]University of Padua - Dept. of Biology, Padua, Italy, [2]University of Padua - Dept. of Geography, Padua, Italy.

The Colli Euganei is a hill area in the venetian alluvial plain. It has been considered glacial refugium for thermophilous plants during LGM and actually some Mediterranean elements (e.g. *Cistus salvifolius* L., *Erica arborea* L., *Arbutus unedo* L., *Spartium junceum* L.) survive in the area. The studied site is located in a perieuganean depression (3 m a.s.l.) in the south-eastern part of Colli Euganei near the village of Galzignano. The site location is interesting because it is related both to the surrounding hills and the alluvial eastward plain (5-7 a.s.l.). Pollen analysis of a 50 m deep core reveals the main features of the vegetation history from the Last interglacial to the Last Glacial Maximum (MIS 5, 4, 3?, 2). The chronology of the sequence is based on three radiocarbon dates in the upper part of the core. Pollen data have been correlated with 150-ky core records from the south-eastern Po Plain. It is noteworthy the presence of *Abies* cf. *nordmanniana, Keteeleria* and *Zelkova* at the bottom of the core.

P2407. Dendrochronological evaluation of historic changes in Lake Stirniai (Lithuania) water level

I. Stasytyte, R. Pakalnis;
Institute of Botany, Vilnius, Lithuania.

Dendrochronological research was carried out on Pinus sylvestris L. timber extracted from Lake Stirniai (55°15’04” latitude (N) and 25°38’49” longitude (E)). As a result, the tree ring width floating chronology spanning 213 years was compiled. Radiocarbon dating of the samples indicated that pines grew from 1103±80AD to 1315±80AD.

Fragments of stems and roots of pines were found waterlogged in 1 m water layer. It means that in the Medieval Warm Period, the ground water level in the habitat of archaeological pines was bellow the nowadays lake level for at least by 1 m.

The growth conditions became unfavourable in ~1270±80AD. At the end of the 13th century the climate became damper, lake transgression started, the trees of Scots pine became dry. The basic cause of transgression seems to be the bogged bed of the rivulet Stirna flowing out of the lake. This phenomenon was caused by the changed climate conditions.

The formant analysis of the radial increase of the stems of archaeological Scots pine in Lake Stirniai revealed 52,9; 30,3; 21,1; 17,5; 15,0; 11,2 year long-term fluctuation cycles. Comparison of the obtained data with the present cycles is foreseen.

P2408. Human impact on the vegetation of Upper Dnister Plain (Western Ukraine) during the Holocene

N. Kalinovych[1], K. Harmata[2];
[1]Division of Botany of National University, Lviv, Ukraine, [2]Institute of Botany of Jagellonian University, Kraków, Poland.

The aim of investigation was to recognize the interference between the natural environment and the human activity at the foreland of the western part of the Ukrainian Carpathians in the area of upper Dnister. This study focused on vegetation and land-use reconstruction of the last 7,000 years. Pollen analysis of fossil peat deposits have provided information about vegetation history, climate and human impact in the Dnister River valley and surrounding hills. Pollen analytical investigations were carried out in an archaeological context. On the base of six pollen diagrams, which together cover the period from the Mesolithic to the Middle Ages, different phases of human impact on the environment were detected and described. Radiocarbon dating have provided a chronology for the palynological events. It may be concluded that the studied area was used by early Neolithic tribes. It was associated with a decrease in forest areas in different scale. From the time of 2,500 years before present the agrophytocenoses and other anthropogenic plant communities provoked deforestation in the large scale.

P2409. Holocene snow avalanches and their long-term impact on subalpine vegetation in Tyrol (Austria)

J. N. Haas;
Department of Botany, Innsbruck, Austria.

Snow and ice avalanches belong to the most destructive natural hazards in the Alps. However, the Holocene history and frequency of large avalanches as well as their long-term impact on vegetation was unknown up to very recently. Here we will present results performed in the Ziller Valley (Tyrol) within an interdisciplinary research programme between palynologists, dendrochronologists, foresters, modellers as well as avalanche experts (HOLA -

Evidence and Analysis of Holocene Avalanche Events', http://bfw.ac.at/800/2089.html) showing that avalanches did contribute to plant diversity changes at timberline for at least the last 6000 years.

Extrafossils such as algal cysts or fungal spores thereby clearly add to our understanding of (palaeo-)ecological change at high altitude and allow to assess the relative importance of climatic change and of prehistorical human impact in the Eastern Alps. Cysts from snow algae such as *Chlamydomonas* and *Chloromonas* may hereby help to reconstruct the long-term avalanche frequency as well as to quantify winter snow amounts for the Holocene.

P2410. Botanical investigations in a 6000-3370- B. P. highland rock shelter in Central Sahara

G. B. L. Coccolini;
Dipartimento di Bilogia Vegetale, Rome, Italy.

The 6.035 ±100 and 3.700±40 B. P. layers in Uan-Muhuggiag rock shelter in Tadrart Acacus, Fezzan, have yielded a few plant macro-remains. Among these it has been possible to find wood belonging to Cupressaceae, Leguminosae, Oleaceae, Tamaricaceae and some fruit-stones of *Balanites aegyptiaca* and fruits of *Zilla spinosa*. These species look to be present in the area at the time as seen through pollen and macro-remains analysis leaded by many researchers. The man gathering plants could also collect plants far away the shelter during his outing the area. The preference he made clearly shows that prehistoric saharian native had a good understanding of use of wood and the properties of the plants. In the level examined up to now, the former, UM/A-1, besides sudanian species also shows a less amount of saharo-arabian species; in the older layer, UMb/2b, mostly sudanian species look to be present. Charcoal from different sites in eastern and central Sahara gives evidence that shifts to the north of tropical climate and vegetation belts happened in the Holocene.

P2411. The Late Neolithic settlement of Pestenacker, Lkr. Landsberg/Lech, Bavaria. Implications for the landscape - human impact and/or climate

F. Bittmann[1], S. Jacomet[2];
[1]Lower Saxony Institute for Historical Coastal Research, Wilhelmshaven, Germany, [2]Institute for Prehistory and Archaeological Science IPAS, Basle University, Basle, Switzerland.

At the Late Neolithic settlement of Pestenacker, 20 km south of Augsburg, four superimposed settlement phases belonging to the Late Neolithic Altheim Culture were distinguished archaeologically on the border of a little valley. Phase Ia, established in 3496 BC, was partly destroyed by fire after four years and rebuilt (Phase Ib). After another 15 years the settlement was abandoned. Thirty years later Phase II began on the same site. The duration of Phase II is unknown due to poorer preservation conditions caused by artificial drainage of the valley since 1930. Therefore Phases III and IV are almost totally represented by carbonised plant remains alone. Altogether, approximately 300 taxa could be recognised. The most important crop was Emmer followed by Einkorn. A little barley and tetraploid wheat of the *T. turgidum/durum*-type were found in every phase. Flax, opium poppy and peas were cultivated in addition to the main crop. The gathering of wild fruit played a large role in nutrition. The detection of a dung-heap behind one of the houses and the large number of grassland species identified, together with pollen analytical evidence suggest the gathering of hay.

P2412. Rice and foxtail millet cultivation reconstructed from weed seed assemblages in the Chengtoushan site, central China

H. Nasu[1], A. Momohara[2], Y. Yasuda[1], H. Jiejun[3];
[1]International Research Center for Japanese Studies, Kyoto, Japan, [2]Faculty of Horticulture, Chiba University, Matsudo, Japan, [3]Institute of Archaeology, Hunan Province, Changsha, China.

Crop weeds have been successfully used for evaluation of farming practices in archaeological sites and reconstruction of the environmental condition. In rice agricultural sites in East Asia, however, a few studies of crop remains have been attempted. We evaluated the crop husbandry based on plant macrofossils including crop grains and weed seeds in the Chengtoushan site, Hunan Province, central China, which is one of the oldest rice agricultural site around the Yangtze River Basin. In the moat surrounding the site that is located on a loess plateau that juts out into the alluvial plain, we recognized three cultural layers during the Daxi Culture. Plant macrofossils in silty clay deposits in the moat consist of abundant rice and foxtail millet grains with many weed seeds. Radiocarbon age of these fossils shows that rice and foxtail millet cultivation dated back to 6400 cal. years B.P. The weed seed composition characterizes farmland and ruderal environments in the site surrounded by the moat. We assumed foxtail millet and rice cultivation practiced within the site on loess plateau, along with a paddy style rice cultivation in the alluvial lowland outside of the site.

P2413. Regional Cartographic Models of Vegetation Cover

A. N. Polezhaev;
Institute of Biological Problems of the North, Magadan, Russian Federation.

Digital vegetation maps scale of 1: 2500 000, 1: 1000 000, 1: 200 000 for the North of the Russian Far East (Magadan Region, Chukotsky autonomous district, Korjaks autonomous districtas) are created. Polygons are shown on the map. Withing these polygons real vegetation comlexes are shown. Vegetation comlexes determined airvisualy. Each map included in separate GIS project as the whole polygonal coverage. Data base of these projects includes information on each polygon: area, perimeter, index of predominant vegetation cover type, procent correlation of the main vegetation types in complex. Cartographic models are used in botanical researches for decoding remote sensing data, species plants communities distributions. GIS projects on reindeer ranges of Magadan Region, Chukotsky autonomous district, Korjaks autonomous districtas are elaborated also. Data bases of these projects contain information on season forage storages and reindeer range capacity.

P2414. Floristic and phytocoenological analysis of the ass. Lemnetum minoris Th. Müller et Görs 1960 (the Blace Lake, southern Serbia)

S. V. Perisic, B. Karadzic, L. Djurdjevic, M. V. Velickovic;
Institute for Biological Research "Sinisa Stankovic", Belgrade, Serbia and Montenegro.

The Blace Lake is located near the Blace town, in southern Serbia. Habitats of the ass. Lemnetum minoris are open water surfaces and the coastal zone of the lake, from which, during summer, water partially or completely retires. Such habitats are colonized with the meadow species. The ass. Lemnetum minoris was determined, based on ten phytocoenological releves contain 66 species. The primary edificator of this community is *Lemna minor* L., while the characteristic species are: *Ceratophyllum submersum* L., *Lemna minor* L. and *Schoenoplectus lacustris* (L.) Palla. Ten floristic elements are registered, within the spectrum of the areal-types with the domination of the following: sub-eurasian (25.7%), cosmopolitain (13.7%) and Eurasian (13.6%). At the investigated locality seven life forms were registered. The dominant are hemicryptophytes (42.4%), geophytes (33.3%), therohemicryptophytes (10.6%) and helio-hydrophytes (6.1%). From the ass. Lemnetum minoris, the three subassociations are derived: typhetosum prov., lemnetosum prov. and caricetosum prov.

P2415. Karst mires in Tula region (Middle-European Russia)

O. Galanina[1], E. Volkova[2];
[1]Komarov Botanical Institute RAS, St.-Petersburg, Russian Federation, [2]Lev Tolstoy Pedagogical University, Tula, Russian Federation.

Mire inventory was carried out in Tula region, Russia (54°N 37°E). Different mire types were distinguished. They are valley fens, bogs and karst mires. Tula region is situated in the northern part of the Middle-Russian Upland where limestone structures dominate. Karst phenomenon is displayed by the development of dolin depressions which can be sometimes very deep. The depressions are often filled with ground water, and many of them have become lakes or ponds. Later, due to a process of overgrowing, some of them have turned into mires. Mires are formed through a paludification process as well as in a case of shallow depressions which collect surface water. Karst mires are small (<1 ha) and they have a clearly circular form. Very often they can join together due to the ongoing karst process and form "cascades". Key areas with a series of karst mires were studied in Tula city surroundings. Data on vegetation, pH of mire water, peat deposits, productivity of communities and microbiological activity were obtained. Large-scale vegetation mapping was made as well. The studied karst mires are mainly mesotrophic (pH ~6). Vegetation communities are typical of forest taiga swamps.

P2416. Vegetation of fresh alluvial habitats

T. V. Balyuk;
Water Problems Institute, Moscow, Russian Federation.

The pioneer vegetation on pointbars of the Allier and Volga shows many similarities. However, there are also some clear differences related to: hydrodynamics, morphodynamics (sedimentation and erosion), and physical conditions (sediment characteristics). The structure of pioneer vegetation on pointbars of the Allier is more complex due to the variable composition of the bed material. The upstream coarse gravel part of the pointbar is generally almost without plant cover, or with some Populus or Salix seedlings. In the central part of the pointbar, with mixture of gravel and sand, communities with Corrigiola litoralis and Portulaca oleracea appear. On sandy areas, normally found in the downstream part of the pointbar, communities with Eragrostis pilosa, Xanthium orientale are present. The pioneer communities exist only for one summer season: during the next flood they are either covered by fresh alluvium, moved away with the flow, or develop into the next stage of succession.

P2417. Study of pteridophyte communities present in humid mountain forests of central Cuba.

J. Garcia Lahera[1], C. Sánchez Villaverde[2];
[1]Jardín Botánico Sancti Spiritus, Sancti Spiritus, Cuba, [2]Jardín Botánico Nacional, La Habana, Cuba.

It is analyzed, for the first time in Cuba, the taxonomical composition and the structures, in the space and seasonal scale, of the communities of ferns and allied plants (pteridocenosis) integrated to different vegetation units. The chosen formations were: the cloudy closed forest, the mountain rainforest and the humid evergreen forest, located in altitudinal order in the north hillside of “Teta de Juana", hummock elevation of Sancti Spiritus's mountains. Two aleatory samplings were made, one in dry and another in rainy season. Was registered 64 species. The taxonomical composition of the communities was evaluated by means of indexes that measure: the species richness, the heterogeneity and the evenness. The structure was studied starting from the analysis of the biological spectrum. It was also carried out a nodal analysis. Significant space differences were observed in the taxonomical composition and the structures of the pteridocenosis settled down in the three habitats, being the highest values in species richness and heterogeneity in the rainforest, followed by the evergreen forest.

P2418. Floristic and fitocenological characteristics of pyramidal europian silver fir (*abies alba var. pyramidalis* Carr.) in southwest Serbia

L. B. Rakonjac[1], M. Ratknic[1], M. Matovic[2], V. Lavadinovic[1];
[1]Institute of Forestry, Belgrade, Serbia and Montenegro, [2]Faculty of Natural Sciences, Kragujevac, Serbia and Montenegro.

The natural stand of pyramidal silver fir at Ogorijevac locality (at Pešterska visoravan) is the unique fragment in Europe because of stand floristical and fitocenological characteristics, as well as morphological, anatomical and other characteristics. Pyramidal European silver fir (Abies alba var. pyramidalis Carr. is characterized by the branches which leaves the made stem under an acute angle, where as with age, the angle of branch insertion increases and the shoots growing on these primary branches are negatively geotropic. The number of leaves on the shoots of pyramidal European silver fir is highest than that of European silver fir. The former leaves are radial arranged all stem, and the latter lie in a horizontal plane sideways. Ecological indexes for pyramidal silver stand are developed and compared with ecological indexes of stands in which this form of fir is not present.

P2419. The cryptogamic flora of the Zgurasti Cave and surroundigs. (Apuseni Mountains, Romania)

A. Sass-Gyarmati, K. Molnár, S. Orbán, T. Pócs;
Hungarian Academy of Sciences, Eger, Hungary.

The Zgurasti Cave lies in the Bihor Mountains in the Romanian Western Carpathians. In fact it is 35-40 m diameter and 50 m deep pithole with a cave joining to it, carved in limestone. In the cave there is a temporary underground lake on clay ground. In spite of the fact that the cryptogamic flora of Bihor Mountains is relatively well investigated, till now the cyanobacteria, lichens and bryophytes were not reported from this peculiar carstic depression. We could provide new data to the floristical knowledge of the studied area. It is the first time reported from Bihor Mountains Ptilidium pulcherrimum (Weber) Hampe, Tritomaria exsecta (Schrad.) Loeske. Other interesting species are Anastrophyllum hallerianum (Nees ex Lindb.) Schust., Nowellia curvifolia (Dicks.) Mitten, Ditrichum crispatissimum (Müll. Hal.) Paris, Orthothecium rufescens (Brid.) B.S.G., Rhynchostegiella tenella (Dicks.) Limpr.

P2420. Floristic composition in the Aragua River Basin, Municipio Piar, Monagas state, Venezuela.

A. C. Lárez[1], J. J. Calzadilla[2];
[1]Universidad de Oriente, Maturín, Venezuela, [2]Universidad de Oriente, Postgrado en Agricultura Tropical, Maturín, Venezuela.

Explorations made during five years provide information on the floristic composition of a little studied area, between the Llanos and the Coastal Cordillera (eastern sector) regions (10º 00 ' N, 63º 20' W, 320 - 580 m elevation). 528 spp., 361 genera and 107 families were identified. The most diverse families include Fabaceae, Euphorbiaceae, Asteracae, Mimosaceae, Caesalpiniaceae, Rubiaceae, Poaceae, Bignoniaceae and Malvaceae. The area is covered by a mosaic of savannas and heterogeneous forests. The savanna (97 spp.) occur on the slopes and some hilltops (400-580 m), with low fertility sandy or rocky soils; tree and shrub savannas occur in shallow depressions with poor drainage. The gallery forest (107 spp., where evergreen trees dominate, also lianas and epiphytes occur) are located on flat or gently undulating fertile soil plains with stony profiles, adjacent to the Aragua River or its effluents (320-420 m). Deciduous forest (103 spp.), predominate in the valley or are found as secondary vegetation in logged and farmed areas. This zone has a rich vascular plant flora, with 53 species not represented on the adjacent floristic regions.

P2421. Local scale variation in plant community attributes in the Semi-arid region, Northeastern Brazil

M. J. N. Rodal, A. B. Lins-e-Silva, K. C. Costa;
UFRPE, Recife, Brazil.

At local scale, variations in floristics and structure associated to abiotic factors are reported for the typical vegetation of Northeastern Brazil semi-arid, Caatinga. We tested if six adjacent biotopes with distinct altitudinal (450-690m) and pedological aspects present different woody plant attributes of structure and physiognomy. In each biotope, a 20 x 50 m plot was established, divided into 10 sub-plots. Maximum distance between sample plots was 7 km. For each biotope, relative density, basal area and frequency were calculated for all families and species. Based on results of floristics and structure of plant communities in each biotope, two matrixes were created: one based on presence/ absence of species by sub-plot and other with number of stems per species in each sub-plot. A total of 2,055 stems, 23 families, 64 species was recorded. Clear altitudinal or pedological local-scale gradient could not be defined along *a priori* defined biotopes, which hold in fact two phytocoenoses: Plateau Summit, at greatest altitude, with distinct physiognomy and exclusive taxa; and lower altitude community, presenting physiognomical and structural similarity.

P2422. The relation of present vegetation and environment at Chipei Island

S. Shiao[1], **S. Chiu**[2], K. Yang[1];
[1]Institute of Ecology, Providence University, Shalu, Taichung County, Taiwan Republic of China, [2]National Museum of Natural Science, Taichung, Taiwan Republic of China.

Low elevated Chipei Island, lying northern Penghu Archipelagoes, constituting of basalt at east half and sand beach at west half, is primarily covered with herbaceous vegetation. Based on the investigation of 113 homogenous sampling areas of each 2×2 m^2, 90 native, 25 naturalized and 12 cultivated species were recorded including 40 families, 101 genera and 127 taxa. By the TWINSPAN, the vegetation could be classified to 4 types such as (1) afforestation at southwestern part to avoid the winter gale, (2) bushes at southern slope or indented abandon farming areas, (3) wildspread grassland , (4) sand beach vegetation at northeastern and western coasts. The herbaceous vegetation near the tidal coast was dominated by the native *Zoysia matrella* and it’s hardly invaded by introduced species. With low coverage of vegetation at western broad Golden Coast, its majority consisted of *Ipomoea imperati*, whose habitat area is however the greatest in Taiwan. An unstable sand beach under sever environmental stress due to the assailing by northeastern winter gale and corrosion by the ocean current is a characteristic for Chipei's vegetation.

P2423. Treeline Vegetation of the River Chirukhistskali (South Colchis, Georgia)

D. Kharazishvili;
Batumi Botanical Garden of the Georgian Academy of Sciences, Makhindjauri, Georgia.

The paper presents the survey of the treeline vegetation of the high mountainous region of the river Chirukhistskali (South Colchis, Georgia). The major part of the treeline vegetation of the area is experiencing strong anthropogenic and zoogenic pressure. However, it is noteworthy, that such undamaged communities as *Festuco-Piceetum* and *Fago-Betuletum* have remained here. The associations *Abieto-Piceetum, Rhododendro-Piceetum* occurring in the region are distinguished by great specific diversity and forests of *Picea orientalis* by abundance of endemics.

We consider it essential to take appropriate nature protective measures to avoid landslides, mud-streams and avalanches in the studied area. It is also necessary to allocate protected territories, prohibit overgrazing and deforestation for obtaining firewood as well as extend haymaking areas at the expense of pastures.

P2424. Syntaxonomy of the Northern Black Sea Region vegetation

D. V. Dubyna, P. A. Tymoshenko;
M.G. Kholodny Institute of Botany National Academy of Sciences, Kyiv, Ukraine.

An area of the Northern Black Sea Region covers unique natural landscapes (2 mln ha) created as a result of fluvial and sea activities. In consequence of enlarging human impact the problem of diversity conservation in the industrial and agrarian south of Ukraine is the pointed one. According to the UN Convention on biodiversity conservation the Institute of Botany, the National Academy of Sciences of Ukraine within the international scientific cooperation executed the work "Syntaxonomical diversity of psammo- and halophytes of the Eastern Mediterranean within Ukraine". Vegetation's classification of the region includes 24 classes, 37 orders, 59 alliances, 274 associations, among which 60 are meadow-wire, 55 - aquatic, 40 - psammophyte, 19 - salted, 47 -saline marsh, 38 - violated, 46 - occur only in area of Ukraine, 3 are the new. The prodrome is a stage of the project of the Formation Program of European Econet of the seaside National Azovo-Black Sea ecocorridor. The next tasks of researches are to study communities' dynamics, to map vegetation in detail, to do monitoring and management of phytocoenoses, including of rare syntaxa into the Green Data Book of Ukraine.

P2426. Inter-annual variations in the population structure of an herbaceous community of *Caatinga* vegetation in Pernambuco, Brazil

E. L. Araújo, A. S. Reis, E. M. N. Ferraz, A. N. Moura;
UFRPE, Recife, Brazil.

The influence of climatic variations on the herbaceous component of the *Caatinga* vegetation was examined in the state of Pernambuco. A total 35 1x1m-plots were in a level microhabitat, 35 in a riparian microhabitat, and 35 in a stony microhabitat were established. During two consecutive years all of the herbaceous plants in these plots were counted, measured and collected. The density, frequency, dominance, importance index and Shannon-Wiener diversity index for each species was calculated for each year. The herbaceous flora was composed of 71 species. The families with the greatest species richness were Malvaceae, Euphorbiaceae, Poaceae, Convolvulaceae, Fabaceae, and Portulacaceae. The diversity indices were 2.66 and 3.01nats.ind^{-1} in 2002 and 2003, respectively. Annual seasonal climatic variations greatly modified these populations structure emphasizing the fact that long-term studies are needed in order to better understand the dynamics of the herbaceous component of the *Caatinga*.

P2427. Current situation of flora of "Puerto Viejo" Wetlands, Lima - Peru

M. La Torre, R. Jimenez, J. Mansilla, N. Canto;
Faculty of Natural Sciences and Mathematic. Federico Villareal University, Lima, Peru.

"Puerto Viejo" wetlands are located at the south of Lima (71 km toward south), in the province of Cañete and district of San Antonio de Mala (12° 34' 39'' LS and 76° 42' 21'' LW), with an area of about 200 ha. This is supplied of water from Mala River, but it became salty. There are many pools with different deeps. The vascular flora is composed for 31 species, 29 genuses and 17 families, where Magnoliopside has 21 (67.74%), Liliopside has 9 (29.03%) and Pteridophyte has 1 (3.22%). The most representative families were Poaceae, Asteraceae, Chenopodiaceae, Amaranthaceae, Cyperaceae, Fabaceae, Solanaceae; with predominance of herbaceous plants (90.32%) and shrubs (9.67%). Also it was considered forms of life, so pterophytes has 32.5%, hydrophytes and helophytes 29.03%, hemicriptophytes 19.35%, camephytes 19.35% and nanophanerophytes 3.22%, and we identified 6 plants communities: aquatic plants, bulrushs, reeds, cyperaceous, shrubs and lawns.

P2428. Sustainability of *Elaeodendron transvaalensis* harvesting in Venda region, Limpopo province.

M. P. Tshisikhawe[1], M. W. Van Rooyen[2];
[1]University of Venda for Science and Technology, Thohoyandou, South Africa, [2]University of Pretoria, Pretoria, South Africa.

Several years earlier, the Chiang Mai Declaration had noted that, since medicinal plants form the basis of medicines used by the majority of the population of most developing countries, the loss of certain medicinal plant species and reduced supply of other important plants would have a direct impact on human health and well being.

Elaeodendron transvaalensis is one of the medicinal plants used very often by people in the Venda region. It is known to treat a variety of diseases. The diseases treated by the plants include; cleaning of stomach from any disorder, treatment of ulcers, treatment of veneral diseases (STDs), and treatment of fungal infections.

Due to its wide usage by traditional healers it has found its way into the muti markets and it is amongst the seven most commonly traded plants in the Venda region. The study investigates the impact of bark harvesting on this species.

Bark harvesting for medicinal purpose is the major contributor to the loss of *E. transvaalensis* since people only utilize it for firewood when it is dry. Cultivation intervention is therefore necessary to reduce the stress experienced by *E. transvaalensis*.

P2429. Phenological analysis and land cover classificaction for the Papaloapan watershed vegetation using MODIS imagery, México.

G. Hernandez Cardenas[1], **F. Mora Flores**[2];
[1]Universidad Autonoma Metropolitana - Iztapalapa, Mexico City, Pitcairn, [2]Centro de Investigación en Geografía y Geomática, Mexico City, Mexico.

The most recent technology to evaluate vegetation status includes the use of satellite images derived from sensor MODIS (MOD13 product). It contains EVI and NDVI indices used for the phonological analyst. NDVI indices have been intensively used from 80s with AVHRR imagery. Nevertheless, their spatial resolution spatial (~1.1km) of this images is low compare with ~250m of MODIS sensor. Additionally, the applied MODIS enhanced narrows bands, canopy background and atmospheric corrections, and also applied the BRDF. So, we generated sequential images from years 2000 to 2004 with monthly images with the MVC technique. For the phenological analysis, a dimension reduction technique, based on principal component analysis (PCA) was then applied. The first five components of a PCA on annual series (12 monthly images) explained ~91% of vegetation variability and were used for an unsupervised classification (ISODATA) obtained 60 classes. From each class averages of sequential images a classification was produced using cluster analysis. From these procedures a final new classification was produced to represent information classes into land cover categories.

P2430. Widespread Of Pine Pine Pinus Peuce Grisebach, 1839 On Pelister And Surounding Mountains

N. D. Hristovski[1], N. Randzelovic[2], V. Randzelovic[3], B. Zlatkovic[2];
[1]Faculty of Biotechnical Sciences, Bitola, The former Yugoslav Republic of Macedonia, [2]Faculty of Sciences, Nis, Serbia and Montenegro, [3]Faculty of Sciences, Nis, Serbia and Montenegro.

Pinus peuce Grisebach, 1839 was found in Pelister 1839 by Austrian botanist August Grisebach**.** *Pinus peuce* is widespreaded in surrounding hills and mountains as Ilinska, Bigla, Plakensko-Snegovski massif. Also exist two stunted examples of this pine in Bitola at 650m altitude.
Now exist examples of this pine in Bitola at 650m altitude.
On the *Pinus peuce* tree are nested the following birds: *Fringilla coelebs, Carduelis chloris, Parus ater, Columba palumbus,* until the following bird eat seed of pine pine: *Passer montanus, Loxia curvirostra, Serinus serinus*, *Cocothraustes cocothraustes*, *Pyrrhula pyrrhula, Carduelis chloris, Carduelis spinus, Carduelis carduelis, Fringilla coelebs, Fringila montifringilla, Parus caeruleus, Parus major, Columba palumbus,* and mammals: *Sciurus vulgaris* and *Apodemus sylvaticus*.As a result of global warming 2002 in spring months by snow weith many thousands threes were claming down and damages.

P2431. Postfire reproductive dynamics in *Pinus halepensis* (Aleppo pine) forests of northern Euboea Island, Greece

E. N. Daskalakou[1], K. Albanis[1], G. Vassilopoulos[1], C. A. Thanos[2];
[1]Institute of Mediterranean Forest Ecosystems & Forest Products Technology, Athens, Greece, [2]Department of Botany, National & Kapodistrian University of Athens, Athens, Greece.

Pinus halepensis is a typical Mediterranean pine that has evolved several adaptive traits in response to fire. It is an obligate reseeder and its perpetuation depends on both the yearly production of prolific seed crops and the safeguarding of a fraction of seeds within serotinous cones. The reproductive dynamics of even-aged, Aleppo pine populations were studied in three forests of northern Euboea Island (Gouves, Rovies and Pili) burned in 1994, 1996 and 1997, respectively. In each forest, four permanent observation plots were established (summer 2004) at randomly selected sites and a number of pine saplings were tagged for long-term monitoring. Extensive field measurements of pine sapling density, individual growth (height, canopy size) and reproductive capacity were carried out at the end of the 2004 growing season. It is noteworthy that a significant fraction (35.8, 32.4 and 26.2%, respectively) of each pine population had already produced cones in close correspondence to both their age and average height. In addition, mature cones from each population were collected and data on cone, seed and germination characteristics were obtained in the laboratory.

P2432. Floristic diversity in silver fir - beech forest on Croatian karst explained with ecological and forest stand structural factors

S. D. Jelaska[1], M. Bo iĺ [2], O. Antoniĺ [3];
[1]OIKON Ltd. - Institute for Applied Ecology, Zagreb, Croatia, [2]Faculty of Forestry, University of Zagreb, Zagreb, Croatia, [3]RuĽer Bo koviĺ Institute, Zagreb, Croatia.

Silver fir - beech forest represents almost continuous area of 3000 km^2 making it the most widely distributed altimontane forest on Croatian karst. Its syntaxonomical status is still not completely resolved. To give further insight into its ecological and floristic characteristics, survey across complete areal was carried out. Sample consisted of 151 plots (cca. 500m^2) with two smaller ones (cca. 80m^2) positioned insight each of them, i.e. 302 small plots. Data about floristic composition of over 200 species, available light (measured with hemispherical photographs), stand structures (e.g. increment, crown damage, volume) and geographic coordinates were sampled in the field. In frame of the GIS, data about altitude, climatic variables, and DEM derived variables (e.g. slope, aspect) were sampled. Using multivariate analyses (cluster and ordination analyses) several distinct groups were identified based on their floristic profile, with most important ecological and forest stand structural factors recognized.

P2433. Fragmentation and biodiversity. An approach to the structural characterization of the vegetation of the council of Vila Real (Northern of Portugal)

C. P. Fernandes[1], A. L. Crespí[1], A. S. Castro[1], S. Bernardos[2], F. Amich[2];
[1]Herbarium, Botanical Garden, CETAV, Vila Real, Portugal,
[2]Department of Botany, University of Salamanca, Salamanca, Spain.

The area selected in this work is located in the municipality of Vila Real (North of Portugal). Based on this vegetational differentiation and on the sucessional process from pioneer states to the climacic ones, eight types of communities were selected: one tilled and ruderal communities, three shrubbly communities and, finally, three forest communities. Fifty five relevés were distributed per the eight different types of vegetal communities. The three matrices were oined in a contingency matrix to analyse the information derived from the different basic structural matrices. In the present case 34 contingency variables were proposed. The results obtained indicate a very important “landscape connectivity”, as a capacity of connectivity among the different types of communities and inside each of them. These floristic-structural combinations will be significantly based on the generalist species (*heterogeneous undivided habitat* effect). The access of the generalist species will improve floristic-structural combinations: the anthropic activities must be considered in the preservation of the biodiversity presented in the agroecosystem.

P2434. Complex research on the flora, habitats and traditional land use of Putnok Hills (North-East Hungary)

Á. Malatinszky[1], K. Penksza[1], C. Centeri[2], A. Barczi[1], E. Herczeg[1];
[1]Szent István University, Department of Landscape Ecology, GödöllŖ, Hungary, [2]Szent István University, Department of Nature Conservation, GödöllŖ, Hungary.

Valuable plant taxa found in the Putnok Hills (Northern Hungarian Mountains) and unique for a bigger area can be preserved in their original habitats by sustaining traditional agricultural management patterns. Old agricultural activities on diverse habitats resulted in specially structured landscape mosaics. Regularly mowed wet meadows along the streams maintained large sedge communities with *Carex cespitosa* and *C. buekii*, tall herb fringe communities with *Inula helenium* and molinia meadows with *Iris sibirica*, *Orchis laxiflora* subsp. *elegans*, *Dactylorhiza incarnata* and *Eriophorum* species. Pastures (grazed by sheep) with *Juniperus communis* formations preserve *Orchis morio*, *Dianthus deltoides* and *Platanthera bifolia*. Regularly mowed lawns of extensively cultivated orchards hide *Aster amellus*, *Iris aphylla* subsp. *hungarica* and *Orchis purpurea*. Valuable species in abandoned grapeyards are *Pulsatilla grandis*, *Polygala major*, *Linum falvum*, *Orchis tridentata* and *Stipa pennata*. Extensively cultivated small parcels of arable land give home for rare weed species such as *Agrostemma githago*, *Euphorbia salicifolia* and *Rapistrum perenne*.

P2435. Vegetation survey of Quercus pubescens-stands N of Graz (Austria)

G. Heber, A. Drescher;
Institute for Plant Sciences, Graz, Austria.

Xerothermic vegetation-complexes including stands of *Quercus pubescens* s. l. (downy oak) located on S-exposed slopes of a calcareous hill chain on the fringe of the Eastern Alps N of Graz (Styria, Austria) have been studied. The vegetation mosaic includes the associations Geranio sanguinei-Quercetum pubescentis, Ligustro-Prunetum, Cotoneastro-Amelanchieretum, Peucedanetum cervariae and Seselietum austriaci. These complexes are surrounded by stands of Cyclamini-Fagetum, the dominant forest type in the investigated area. 163 relevés have been processed using the Braun-Blanquet approach. A digital vegetation map based on aerial photographs (scale 1:2800) has been produced with ArcView GIS 3.2 software. In the course of our studies, some of the xerothermic patches have been nominated as a NATURA 2000 area. The species-rich communities characterized by a mixture of submediterranean and dealpine elements are endangered by succession as well as the invasion of the alien species *Robinia pseudacacia* and *Ailanthus altissima.* A synoptic table has been prepared to elucidate the synchorological and synsystematical position of the downy oak-stands N of Graz.

P2436. Change of the species composition of the flora Karelian Isthmus (Leningrad region)

A. J. Doronina;
Sainkt-Petersburg State University, Sainkt-Petersburg, Russian Federation.

Karelian Isthmus is territory in the North-West Russia between Finland golf on the west and Ladoga lake on the east, river Neva on the south and Finland and Karelia on the north (15 000 km²). Check-list include 1186 wild vascular plants (817 aboriginal species) from 114 families and 114 genera. The own field investigations in 1994-2004, work in Herbariums (LE, LECB, WIR, H, HSI, KUO, TUR) exposed the changes of plant diversity for 160-year period with beginning at first herbarium collections. The work include characteristic of nature condition and vegetation, systematic structure, geographical, ecological-biological (life forms, dispersal, phytocoenological structure) aboriginal flora, classification of the adventive elements, post-glacial development and characteristic of the threatened plants of the flora, floristic division into districts, maps of distribution for 467 species.

P2437. The Effect of Elevation, Slope and Geographic Aspect on Plants Biodiversity in Caspian Beech Forets

S. Hosseini[1], A. Ghomi[2];
[1]Natural Resources Faculty of Tarbit Modarres University, Noor, Islamic Republic of Iran, [2]Natural resources faculty, Noor, Islamic Republic of Iran.

Biodiversity covers the number, variety, and arrangement of living organisms. It is typically described, quantified, managed, and used for various living organisms groups. Biodiversity is affecting by environmental factors such as elevation, slope and aspect. Sixty permanent sample plots with an area of 1000 m2 and per plot including 5 micro plots with 9m2 surface were selected in two types of *Fagetum* and *Fageto-Carpinetum* in Nowshahr research forest in the north of Iran. The woody plants biodiversity were considered in every sample plots by the use of current indices and the regeneration were inventoried in micro plots. The results show negative and significant correlation between biodiversity indices and elevation that it maybe related to temperature decrease with elevation. There is a significant and positive relation between beech regeneration and elevation. The slope effect was not significant on regeneration and woody plants biodiversity but the aspects effect was different in various indices. The total results show the effect of elevation is more than aspect and the effect of aspect is more than slope on biodiversity and regeneration in beech forest.

P2438. The Study of Natural Regeneration of Woody Species after 15 years in Alder Plantation Site in Mazandaran Forests

M. Akbarinia, L. Vatani, S. Jalali, K. Espahbodi;
Natural Resources Faculty of Tarbit Modarres University, Noor, Islamic Republic of Iran.

In the lower forests of wood and paper industry forest in Mazandaran province four sites of 15 years old of Alder plantation as well as one site of witness forest was selected for the study of regeneration of woody species in planted site after 15 years. In each site three plots 20x20m were selected. The number of woody plants was counted, diameter and height of generated species was measured in each plot. Species diversity was examined by using of Shanon-Wiener function index as well as evenness and richness by using Simpson and Menhinic indexes.
The results of study show that 8 tree and shrub species observed in planted sites. The amount of diversity index in one planted site was higher while in other three sites was lower than natural forests. The evenness also in one planted site was higher than natural forest while in three other sites it was lower than natural forest. The species richness in tow planted sites was higher than natural forest.

P2439. The Nature Reserve Park „Heidenreichstein“ in Lower Austria: An example for conservation, management and economic significance of a regenerating peat bog

W. Adlassnig[1], **M. Emmer**[1], M. Peroutka[1], R. Sprinzl[2], K. Piringer[2], W. Pois[3], G. Steiner[4], I. K. Lichtscheidl[1];
[1]Institution of Cell Imaging and Ultrastructure Research, University of Vienna, Vienna, Austria, [2]Verein Naturpark Heidenreichsteiner Moor, Heidenreichstein, Austria, [3]Faculty Center of Ecology, University of Vienna, Vienna, Austria, [4]Department of Conservation Biology, Vegetation- and Landscape Ecology, University of Vienna, Vienna, Austria.

The Northern Waldviertel in Lower Austria contained many peat bogs by reason of a suboceanic climate combined with Granite or Gneiss as bedrock. Most of the bogs were either turned into farm land or cut over for fuel production. Only very few sites remained and one of them, the “Heidenreichsteiner Moor”, was protected in the 1970s and became a nature park. The land owners, a forest co-operative, built a pathway for visitors with information boards about values and functions of the mire and the surrounding forest. A wooden platform and a watch over were constructed to enable people to see the beauty of the site either from the ground or from above. In a nearby museum, people can get additional information about peat land ecology, conservation issues and threats.
Taking this as an example, we present in a scientific film the ecosystem functions together with possibilities of mire management and protection and strategies to make a nature park of this kind economically successful and accessible for people. We show the measures of nature park managers to maintain the integrity of the habitat and to improve its infrastructure as a recreation area and a place to learn more about nature.

P2440. Pasture flora on family farms in Istria (Croatia)

I. Vitasovic Kosic, M. Britvec, I. Ljubicic;
University of Zagreb, Faculty of Agriculture, Zagreb, Croatia.

Autochthonous vascular pasture flora was researched at the locality of family owned farms which breed sheep, in Istria, Croatia. On Istrian agricultural farms, a total of 328 plant taxa (species, subspecies and varieties) were found. The taxa belonged to 200 genera and 47 families. Part most of them were *Compositae* (16.5%), followed by *Gramineae* (14.6%), *Leguminosae* (10.9%) and *Labiatae* (9.5%). It should be noted that pasture flora in Istria supports numerous species that are rare or endangered, for example those from the *Orchidaceae* family, in addition to species of the genus *Narcissus*, *Crocus*, *Helleborus*, *Dianthus* etc.
These results as preliminary investigation into the pasture flora may play as a guide for the management of pastures and pasture vegetation on family farms in Istria, which contributes not only to the full utilization of th e pasture, thus advancing livestock production, but also to the plant preservation of pastures.

P2441. The Rangelands of Iran

N. Bassirani, I. A. Sadeghi Azar;
Zabol University, Zabol, Islamic Republic of Iran.

Rangelands are sometimes defined as unimproved grasslands, shrublands, savannas, deserts, and tundra. They occupy 51% of the earth's land surface and contain about 36% of the total living and dead plant carbon. Small changes in extreme temperatures and precipitation have disproportionately large effects in these regions because of the vulnerability to water availability and water balance The rangelands of Iran comprise all of that area which is grazed extensively by livestock according to the tradition of common law and the peoples ancestral rights. this includes mountains, foot- hills and plains hacking natural vegetation of herbs, grasses, fords, and bushes. Iran comprises od 165 million hectares of which about 90 mil, ha.(54.5%) is rangelands. the reaming 75 mil. ha comprise 23.8 mil.ha. of agriculture land, 12.2 mil. ha. of wood land, 35.3 mil, ha. od Desert & degraded lands, 307 mil. ha. of inland water bodies; urban & rural areas and others. The rangelands of Iran are classified three classes according to vegetation cover.

P2442. Steppes in Towns - Naturalistic planting design in open urban space

S. Plenk;
Institute of Horticulture, Fruitgrowing and Viticulture, Vienna, Austria.

During the past decades the scientific approach to planting design was determined by the use of plants in accordance with typical habitat sites.
Habitat interrelated to garden sites means to consider a wide range of components such as local aspects and requirements of single species or individual development and influence of plant communities in suitably defined habitats. Contemporary understanding of nature and the tendency to conserve and manage it brings us to a new understanding of gardens. Naturalistic gardening has begun be accepted as an aesthetic value in open urban space.
Due to the location in the Pannonic climatic zone, Vienna’s townscape is predestined for naturalistic planting design - in accordance with the surrounding native herbaceous vegetation as Steppe Sites and Xerotherm Vegetation and with the need of low maintenance ecological planting design in open urban space. In the year 2000 the group for Plant Use and Planting Design (BOKU) started a project in cooperation with the local authority (MA 42), with the aim to establish Pannonic Plants in a public

garden. Theoretical background, experiences and results will be shown in a poster presentation.

P2443. Introduction of exotic Australian ectomycorrhizal fungi with eucalypt plantations and its spread to native potential hosts in the Iberian Peninsula

J. Diez, E. Fernandez, A. Muriel;
Universidad de Alcala, Alcala de Henares, Spain.

Here we describe the introduction of Australian ectomycorrhizal fungi with plantations of eucalypts in the Iberian Peninsula, and whether these fungi can spread to potential native hosts. When we studied the diversity of ectomycorrhizal fungi in eucalypt plantations, we found fruit-bodies of ectomycorrhizal fungi specific to Australasian trees; such as *Hydnangium carneum*, *Hymenogaster albus*, *Hysterangium inflatum* or *Setchelliogaster rheophyllus*. Mycorrhizas of other exotic ectomycorrhizal fungi (unable to fruit outside its natural geographic range) were identified using molecular tools (RFLP-T and DNA sequencing of the ITS regions of the nuclear rDNA). We assessed then the potential spread of such Australian ectomycorrhizal fungi to native ectomycorrhizal plants. We found that exotic fungi spread beyond the eucalypt plantations depends on their compatibility with native hosts; i.e. of the Australian species *Laccaria fraterna* (=*L. lateritia*), which was found in Mediterranean shrub-lands in association with roots of the ectomycorrhizal shrub *Cistus ladanifer*.

P2444. Research on the drought-resistant capabilities of 47 lianes for quarry reclaimation

y. y. Xu[1], **s. Liu**[1], h. zhang[1], y. r. Zheng[1], l. s. Xie[2], j. c. Yao[3];
[1]Shenzhen Techand Landscape Co. Ltd., Shenzhen, China,
[2]Shenzhen Institute of Landscape Gardening, Shenzhen, China,
[3]Shenzhen Flower Association, Shenzhen, China.

In order to apply Liane to greening abandoned querries' slopes, the drought-resistant capabilities of the selected Liane species were tested. This research uses water physiological indexes, including temporary wilting ratio and leaflet water-holding ratio, so that the drought-resistant capabilities of the test varieties can be understood. The results show that the “hundred-mark system” synthetic evaluation method at the base of temporary wilting ratio and leaflet water-holding ratio can accurately reflect the drought-resistant capabilities of the Lianes, because of the results coinciding with that of the observation. The following Lianes were identified as drought tolerant and thus useful in land reclaimation efforts: *Pereskia aculeata* Mill, *Parthenocissus heterophylla*(Bl.) Merr, *Macfadyena unguis-cati*(L.)A., *Bauhinia corymbosa* Roxb.,*Ficus Pumila* L., *Thunbergia grandiflora* Roxb, *Cryptolepis sinensis* Merr., *Ficus tikoua* Bureau, *Tetrastigma obtectum* pl., *Tetrastigma jinxiuense* C.L.Li., *Tetrastigma caudatam* Merr.-et chun, *Ampelopsis cantoniensis* PL., *Ampelopsisheterophylla* var. *kulingensis* C.L.Li, *Pueraria montana* Merr.

P2445. Pseudoendemics and endemism mania (some examples from Cruciferae)

A. N. Berkutenko;
Institute of Biological Problems of the North, Magadan, Russian Federation.

There is temptation describe isolated populations as new endemic species. In Cruciferae this tendency appeared in case with Schivereckia Andrz.described from Podolia (S.podolica Andrz.). Each isolated population in Ural and Privolzhsk Hills were described by M.Alexeenko as separate species (5 species for Russia). In fact in Russia just one species occurs: S.hyperborea (L.) Berkut. There are 8 genera and 115 species endemic Cruciferae in “Flora of China”. “More material- less endemics” - this assertion can be illustrated by the following: over 80 years genus Borodinia N.Busch considered as endemic of Eastern Siberia and Russian Far East. Arabis alashanica Maxim. described from China and considered as endemic of China for over 120 years is identical Borodinia tilingii (Regel.)Berkut. and as a result of taxonomic revision Borodinia was placed in Arabis. The type Draba macrophylla Turcz. was revealed by D.German. D. macrophylla is earliest description of species referred before Borodinia. New combination in the genus Arabis will be published in Novitates Systematicae. Taxonomic revisions on wide base can reduce the number of pseudoendemics in Russia and China.

P2446. The environmental conditions of the development of Nymphaeid-dominated habitats

E. Szalma[1], J. Kiss[2], J. Szanyi[3], G. Kitka[4];
[1]University of Szeged Dep. of Biology, Szeged, Hungary, [2]Eötvös Geophysical Institute of Hungary, Budapest, Hungary, [3]Hungarian Geological Survey, Szeged, Hungary, [4]University of Szeged Dep. of Physical Geography, Szeged, Hungary.

In the course of our research we have been searching for the answer to the question what are the major environmental conditions that determine the development of nymphaeid-dominated habitats. We have compared the hydrobotanical data of habitats with the results obtained from hydrogeological, geological and geophysical data. On the grounds of hydrogeological data we have found that (1) the nymphaeid-dominated habitats can all be spotted in the discharge zone of groundwater. In the course of geophysical examinations we compared the gravity lineaments derived from the digital data-processing of gravity data with the data showing the territorial placement of nympaeid-dominated habitats. On the basis of this we could establish the following: (2) In every case the habitats can be found along the boundaries of gravity causative bodies (from Bouguer anomaly map), and they are on the 'brink /boundary/' of the geological tectonic grabens. (3) Under each nymphaeid-dominated habitat we can find tectonic or micro- and macro-structural lines, or the development of the habitats can be directly related to them.

P2447. Application of fluorescence induction parameters to assess the environmental adaptability of endemic plants on the island of Crete

E. Navakoudis[1,2], N. E. Ioannidis[1,2], E. Avramakis[1], E. Hatzinikolaki[1], K. Kotzabasis[1,2];
[1]Department of Botany, Natural History Museum of Crete, Heraklion, Crete, Greece, [2]Department of Biology, University of Crete, Heraklion, Crete, Greece.

Certain plant species of the families Campanulaceae, Dipsacaceae and Valerianaceae exist as endemic ones on the island of Crete. In order to screen the environmental adaptability of these plants, fluorescence induction kinetics were recorded on the field and then processed by JIP-test analyses. Additionally to the quantum yield of photosynthesis (F_v/F_m), specific fluxes and activities of the photosynthetic apparatus were estimated. We present data concerning the reaction centre density, the photosynthetic antenna size, non photochemical quenching constants and other data that allow for a comparative study on the overall performance of these species in their natural environment. First evidence shows that most of these endemic plants experience stress conditions in the natural environment of Crete, such as high solar irradiation, meaning that probably they are not properly adapted to it.

P2448. Ecophysiological responses of some dune species to experimental burial under field and controlled conditions

J. Perumal[1], A. M. Maun[2];
[1]La Sierra University, Riverside, CA, United States, [2]University of Western Ontario, London, ON, Canada.

Field, greenhouse, and growth chamber experiments were conducted to determine the effects of different burial treatments on photosynthesis, chlorophyll-a fluorescence, leaf area, biomass, leaf thickness, chlorophyll content and chlorophyll a/b ratio of nine sand dune species: *Cakile edentula, Corispermum hyssopifolium, Strophostyles helvola, Cirsium pitcheri, Elymus canadensis, Oenothera biennis*, *Xanthium strumarium*, *Agropyron psammophilum,* and *Panicum virgatum.* Although there were significant differences between the species, all of them exhibited stimulation in growth following burial in sand. However, this stimulatory response lasted only for the first two to three weeks after burial and then leveled off or declined. The positive effects of burial were more pronounced in the two perennial grasses, *A. psammophilum* and *P. virgatum* due to higher energy content in roots, rhizomes, and underground stems. The main reasons for the stimulation in growth were, increase in leaf area, leaf thickness and CO_2 exchange rate post-burial. The total chlorophyll content of the leaves of buried plants of the two perennial grasses were higher than the controls.

P2449. Selection of elite poplar clones for phytoremediation of soil contaminated by heavy metal: in-field and glass-house experiments.

G. Lingua[1], S. Castiglione[2], V. Todeschini[1], C. Franchin[3], T. Fossati[2], E. A. Peterson[1], B. Stefania[3], G. Berta[1];
[1]Dipartimento di Scienze dell'Ambiente e della Vita - Università del Piemonte Orientale, Alessandria, Italy, [2]Dipartimento di Biologia - Università di Milano, Milano, Italy, [3]Dipartimento di Biologia E. S. - Università di Bologna, Bologna, Italy.

In the framework of a project on the use of poplar for phytoremediation, three large-scale experiments were set up. During the spring of 2003, 140 clones (12 cuttings per clone) of *Populus alba*, *P. nigra* and commercial hybrids were planted on an area contaminated with Cu and Zn. Five clones, selected according to survival, were evaluated for metal and polyamine content. They were used to set up a new experimental field the following year. Survival, photosynthetic activity, metal content and mycorrhizal status were evaluated. The clones Villafranca and Jean Pourtet, inoculated with the mycorrhizal fungi *Glomus mosseae* and *G. intraradices*, were grown in a glasshouse on soil supplemented with Cu and Zn. Survival, photosynthetic activity, morphometric parameters, mycorrhization, metal content and soil remediation were evaluated. Results provide information on the best performing clones for phytoremediation, on metal accumulation and translocation, on polyamine variations under metal stress conditions, and on the effect of mycorrhiza on several of these parameters.

Granted by MIUR, PRIN 2003077418_002.

P2450. Growth phenology of *Cenchrus ciliaris L.* accessions established in experimental station in the south of Tunisia

L. Mnif, **M. Chaieb**;
U.R. Biologie et Ecophysiologie des plantes des milieux arides, Faculty of Sciences of Sfax, Sfax, Tunisia.

Ojective of this work was to study the growth phenology of Cenchrus ciliaris accessions (A1, A2, A3, A4), growing in the south of Tunisia. The mesured parameters were number and length of leaves on the stem, leaf elongation and number of spikes per individual. A principal component analysis (PCA) was performed to get a synthetic appraisal of the whole data set. The main results shown that all the studied accessions have a bimodal growth season. Autumn growth was much less important than the spring growth. Main leaf and spike number were less in the autumn than in spring. An important leaf elongation was observed during the first growth period with respectively 19, 12, 16 and 16 mmj-1 for A1, A2, A3 and A4. For the second growth period, leaf elongation is less important for all accessions. In PCA, A2 and A4 were situated near the origin and better correlated with axis 1, have an important leaf number. However A1 was located at positive extremity of the axis 1. It is characterised by a great spike number. Our results show that this species appear to be adapted to arid region.

P2451. Study of competition between purple nutsedge weed (*Cyperus rotundus*), bermudagrass (*Cynodon dactylon*) and ryegrass (*Lolium perenne*) lawns

A. Rezaeinodehi, S. Khangholi, M. Amini Dehaghi, Y. Filizadeh;
Faculty of Agricultural Sciences, University of Shahed, Tehran, Islamic Republic of Iran.

Effect of purple nutsedge densities and proportions on the intraspecific and interspecific competition of the weed with bermudagrass and ryegrass lawns using the replacement series design was studied. Pure and mixture stand densities were prepared as 4, 8 and 16 plants per plot. The proportions of lawn species: nutsedge were 100:0, 75:25, 50:50, 25:75 and 0:100. Height, leaf area and dry weight of each species and the following indices: relative yield, relative yield total, aggressivity, relative crowding coefficient, relative competitive ability index were assessed. The results showed that height, leaf area and dry weight of lawns significantly decreased with increasing of nutsedge proportion in mixture. Relative yield of bermudagrass was more affected by interspecific competition compared to nutsedge. Competitive index of nutsedge in all mixture proportions was greater than bermudagrass. With respect to relative crowding coefficient, nutsedge was more competitive compared to bermudagrass. Competitive index quantities of nutsedge were greater than ryegrass. Ryegrass was more susceptible to nutsedge interference compared with bermudagrass.

P2452. Effects of environmental and competitive stress on vegetative growth and resource storage: Causes for the low competitive ability of three endangered floodplain species

K. Geissler, A. Gzik;
University of Potsdam, Potsdam, Germany.

The competitive abilties of three endangered european floodplain plant species *Cnidium dubium*, *Gratiola officinalis* and *Juncus atratus* were compared by growing each of them in a pot with a phytometer species, *Agrostis stolonifera*. Four different environmental conditions were applied, representing a variety of habitats in the river wetland.

As expected these 3 species tested had little or no negative effect on the growth of the phytometer. The reverse situation was found. *Cnidium, Gratiola* and *Juncus* showed a strong negative response to competition.

Beside the classical competition experiment our studies were also designed to address some physiological factors which may be responsible for poor competitive ability of the three species. Both carbohydrate and nitrogen metabolism were investigated.

For example the pool of free Ŭ-amino acids was partly affected by high competition intensity. The maintenance of its integrity is crucial, as it acts to insure the delivery of nitrogen to protein metabolism, .

P2453. Ecotypic variation in competitive abilities along a rainfall gradient in Israel

C. L. Ariza, K. Tielboerger;
University of Tuebingen, Institute for Botany, Department of Plant Ecology, Tuebingen, Germany.

The mechanisms of interaction between plants along productivity gradients have been the subject on an intense debate This study approaches the debate from an intraspecific perspective, using ecotypes of three annual species found along a rainfall gradient in Israel. The experiments examine if ecotypes are differentially adapted to the presence of neighbors, and which are the life stages at which plant-plant interactions are most influential. We predict that plants at the dry end are facilitated by neighbors and therefore, invest rather in adaptation to the harsh climatic conditions. On the other hand, plants at the wet end should primarily invest in above-ground vegetative growth in response to competition. Some of our trials will simultaneously test whether plasticity of traits in response to contrasting conditions of water availability and presence of neighbors changes predictably along the gradient. Our first results partly support our prediction, though the responses were highly species-specific.

P2454. The influence of neighboring herbaceous plants on survival, growth and biomass production of Scots pine seedlings

A. Wojcicka;
Institute of Plant Biology, Wroclaw, Poland.

The effect of herbaceous species, dominating in early succession stages on abandoned fields, on planted Scot pine seedlings survival, growth and biomass production was studied in 2-year field experiment. The experiment was carried out in three synusiae dominated by morphologically different species: Hieracium pilosella, Festuca rubra, Elymus repens. Four types of competition were applied as a treatments: a) full competition: below- and aboveground, b) only aboveground, c) only belowground, and d) no competition. I hypothesized if the fitness of Scot pine are determined by competition, then there would be high variation between different treatments and synusial types. All measured parameters were clearly affected by applied treatments in all synusiae. Scots pine seedlings did well in a treatment with “no competition” and synusium dominated by Hieracium pilosella and much worse in synusiae of grasses. Both above- and belowground competition strongly affect Scots pine seedlings, what was especially true for species with strongly developed root systems.

P2455. Nursery phenological observation of different Douglas-fir provenances

V. S. Lavadinovic[1], V. V. Isajev[2], L. Rakonjac[1], N. L. Markovic[1];
[1]Institute of Forestry, Belgrade, Serbia and Montenegro, [2]Faculty of Forestry, Belgrade, Serbia and Montenegro.

Douglas-fir (*Pseudotsuga menziesii* [Mirb.] Franco) is one of the most productive, coniferous species of North America and Canada and one of the most popular introduced species in Europe. Its diversity is conditioned by the width of its natural range of distribution, and the genetic variability and ecological adaptation are directly dependent on the provenance origin. The selections of introductions species need provenance testing in new environmental conditions.

Douglas-fir is a species very susceptible to early autumn and late spring frosts. Bud burst phenology is closely associated with adaptation, survival and tree height growth. The seedlings produced from original Douglas-fir seeds originating from British Columbia , Canada, were the initial material for nursery phenological observation of different Douglas-fir provenances in Serbia. Three years of phenological observation is the aim of this paper.

P2456. *Dioon purpusii* Rose population structure analysis in three sites of Oaxaca, Mexico

F. Sosa-Sosa[1], L. Yáñez-Espinosa[2];
[1]Universidad Autonoma Chapingo, Chapingo, 56230 Estado de México, Mexico, [2]Instituto de Ecología, A.C., Xalapa, 91070 Veracruz, Mexico.

The population structure description and analysis of the cycad *Dioon purpusii* Rose were carried out in three sites located in the state of Oaxaca, Mexico. Phenological and dasometric variables of 737 individuals, plant density and covering were analyzed, as well as environmental and floristic variables. Seedlings, juvenile and adult plants, both male and female, were present in the three sites. The analysis of variance revealed that significant statistical differences exist (Duncan test $p<0.05$) among sites only for stem diameter and height. Plant density and covering was higher in site 1 than in the other two sites, which could be explained because of xeric characteristics in this site, where other species of the tropical dry forest are not able to survive excepting cacti. The similarity analysis including the phenological, dasometric, environmental and floristic variables of the three sites, denoted that sites 1 and 2 were 97% similar, and site 3 was 84% similar to the other two. This suggests that the three sites represent a fragmented population, although they are 5 km and 0.5 km far one of each other, and it is threatened.

P2457. The 2002 flood impact on the aquatic vegetation in selected parts of the Austrian reach of the Danube River

B. Schmidt, N. Exler, G. A. Janauer;
Faculty of Life Sciences, Vienna, Austria.

The aquatic vegetation of the Austrian reach of the Danube River was first surveyed in 1995. Selected parts were re-examined in 2004, in the second vegetation period following a catastrophic flood in 2002, and respective changes were recorded. Three selected reaches are parts of the impoundments of hydro-electric power plants in Abwinden-Asten, Wallsee-Mitterkirchen, and Greifenstein, and one reach is situated in the non-regulated Wachau valley. The Distribution Diagram and the Mean Abundance (MMO/T), a graph and a metric describing aquatic vegetation distribution types are in common use in all countries along the Danube River. They are used here to describe the changes in macrophyte occurrence and abundance between 1995 and 2004. In general the impact of the 2002 flood is clearly shown in river parts where plant species susceptible to water flow were found. Even mosses were affected by this great flood. Modifications in distribution type are discussed in detail for some aquatic species which are important members of the macrophyte community in the Austrian reach of the Danube.

P2458. Fractal patterns in species distributions of some British scarce plants

C. Georges Herbert[1], W. E. Kunin[2], M. Pocock[2], R. Aston[2];
[1]TRAFCAM, Yaounde, Cameroon, [2]Faculty of Biological Sciences, School of Biology, Centre for Biodiversity and Conservation, Leeds University-UK, Leeds, United Kingdom.

The spatial distribution and fractal structure of two British scarce plants, *Lobelia urens* (heath lobelia) and *Phyteuma orbiculare* (round-headed rampion), have been examined at several different scales.

The two species have similar degrees of local patchiness at scale coarser than 50 km and have contrasting coarse-scale between 50 km and 1 km scales, but differed consistently in the slopes of their scale-occupancy curves distributions at scale finer than 1 km**.** The slope of the log-log plot of *L urens* is not constant, but varies systematically with **spatial** scale, and from habitat to habitat at the same **spatial** scale.

Abundance estimates suggest that the species *P. orbiculare* is found to be clumped at all scales, whereas *L. urens* is dispersed at intermediate scale. Fractal dimension analysis suggests that this changes through scale. The distribution varied in their pattern from highly clumped to randomly dispersed. Fairly predictions of *L. urens* can be made from 50 m and 200 m.

Some issues affecting management of species abundance, as well as underlying mechanisms and conservation schemes have been highlighted.

P2459. Fractal patterns in species distributions of some British scarce plants

G. Chekuimo[1], W. Kunin[2], M. Pocock[2], R. Aston[2];
[1]TRAFCAM, Yaounde, Cameroon, [2]Faculty of Biological Sciences, School of Biology, Centre for Biodiversity and Conservation, Leeds, United Kingdom.

The spatial distribution and fractal structure of two British scarce plants, *Lobelia urens* (heath lobelia) and *Phyteuma orbiculare* (round-headed rampion), have been examined at several different scales.

The two species have similar degrees of local patchiness at scale coarser than 50 km and have contrasting coarse-scale between 50 km and 1 km scales, but differed consistently in the slopes of their scale-occupancy curves distributions at scale finer than 1 km**.** The slope of the log-log plot of *L urens* is not constant, but varies systematically with **spatial** scale, and from habitat to habitat at the same **spatial** scale.

Abundance estimates suggest that the species *P. orbiculare* is found to be clumped at all scales, whereas *L. urens* is dispersed at intermediate scale. Fairly predictions of *L. urens* can be made from 50 m and 200 m.Some issues affecting management of species abundance, as well as underlying mechanisms and conservation schemes have been highlighted.

P2460. Pollination disturbance by alien species in Ogasawara Islands.

T. Abe;
FFPRI, Tsukuba, Japan.

Pollination network in the oceanic island, Ogasawara, was heavily disturbed by alien lizard and introduced honeybee. Human inhabited Chichi-jima and Haha-jima Island had less diverse visitor fauna than in uninhabited satellite islands. Introduced honeybee highly dominated for flower visitation rate in Chichi-jima and Haha-jima. Especially, the alien flowers were visited more frequently mainly by honeybee in these islands but less frequently than the native flowers in satellite islands where the native pollinator fauna was preserved. Thus, the alien plants could overcome one of barriers for naturalization at least on pollination stage in Chichi-jima and Haha-jima.

Food experiment showed that alien anole lizard was aggressive predator for native visitors. In addition, the distribution among islands and introduced history of the anole suggested that this predation pressure was the main reason of native pollinator decline. These two aliens may not only disturb the plant reproduction but also shift the plant-pollinator co-evolutionary direction through the pollination disturbance.

P2461. Herbivory and Hidrodinamism: two important factors determining the community structure on a rodolith bed in southern Brazil.

F. Scherner;
Federal University of Santa Catarina, Florianopolis, Brazil.

The role of herbivory on the distribution and abundance of epiphytobenthic community associated to a rodolith bed in the Marine Biological Reserve of Arvoredo Island, Santa Catarina, Brazil, was evaluated througth herbivory exclusion experiments. Cages fully and partially covered by 1cm mesh and uncovered cages were randomly distributed at 7 and 13 meters depth on the rodolith bed for approximately 2 months. The results showed a decrease of epiphytobenthic biomass inside total and partial enclosures as compared to open control plots as well as a large heterogeneity. The increase of herbivory by mesograzers inside the cages, evading predators themselves, is suggested as a hypothesis to explain the results. However, the hidrodinamism, as the herbivory, seems to be another important conditioning factor on the studied rodolith bed. The large heterogeneity of this community points to the need to consider this premise during further ecological experiments in this environment.

P2462. The study about the conditions of the sprout of *Eurya leferox* which is in the crisis of the extinction for teaching materials

H. Miyawaki;
Biological Instiute, SAGA University, Saga, Japan.

Euryale ferox, the only species in the genus, is a very large water lily covered with numerous spines on all surfaces. *Euryale ferox* used to be a harmful plant for farmers who cultivating rice field in Japan. This plant is considered to be relic species and in a fix of the extinction in some areas of Asia as well as Japan.

They considered it is difficult to cultivate this species. But I try to cultivate this species for teaching materials. I collected wild *Euryale ferox* at Saga city, south part of Japan in August-September 2003. After 2 months of cultivation, I succeed to get 549 pieces of seeds. By using those seeds, I tried to study the conditions of sprout of *Euryale ferox*. Seeds need to store in water to prevent sprout.

After cold processing (12C 30 days) and removing the operculum, 13.3 % seeds of *Euryale ferox* sprout at room temperature and higher (20-26C).

On the other hand, without cold processing no seeds could not sprout.

With cold processing, without removing the operculum 10 % seeds sprouted.

My experiment revealed it is not impossible for school teachers and students to use this plant for teaching materials.

P2463. Seedling morphology and anatomy of *Agave marmorata* Roezl. an endemic species from the Valley of Zapotitlán, Puebla, México.

J. Lemus Cortes[1], H. Serrano[2], M. Fraile Ortega[1], M. García Suárez[1];
[1]Biology Department. Universidad Autónomas Metropolitana Iztapalapa México, D.F., Mexico City 09340, Mexico, [2]Dept. Health Sciences. Universidad Autónomas Metropolitana Iztapalapa, México, D.F., Mexico City 09340, Mexico.

The Agavaceae family has anatomic and structural characters enabling these plants to adapt to different environmental conditions, mainly to arid zones. Little is known on seedling characteristics that could correlate with their natural environment. The anatomical and morphological features that enable *Agave marmorata* seedlings to survive under an extreme environment were obtained. Seeds were germinated on perlite or a 1:1:1 sand, perlite and soil mixture, for 16 months. Seedlings structural changes were registered and anatomical description was done. Young seedlings of *Agave*, develop linear leaves from cotiledonear leaf in a levogirous rosette morphology. Theri anatomical arrangement is symmetric, the parenchyma cells have a big central vacuola, lined up sunken stomata with stomatal cavity, a wax covered epidermis whose thickness depends on the substrata where it grows. All these charecteristics enable *Agave marmorata* seedlings to establish under this harsh arid environment

P2464. Entomofauna associated to *Agave marmorata* Roezl. during its flowering period.

M. C. Herrera Fuentes[1], C. A. Romero Tapia[1], H. Serrano[2], M. D. García Suárez[1];
[1]Biology Department. Universidad Autónoma Metropolitana Iztapalapa México, D.F.B, Mexico City 093400, Mexico, [2]Dept. Health Sciences. Universidad Autónoma Metropolitana Iztapalapa México, D.F.B, Mexico City 093400, Mexico.

Agave marmorata Roezl. is an endemic perennial species from the Mexican states of Oaxaca-Puebla. It is a semelparous plant that develops its inflorescence during the months of April-June. Flowers produce considerable amount of nectar over the day which attract many visitors. Diurnal floral insect visitors were registered for this species. We selected hazardously eight flowering agaves available in the study area. Observations and collection of insects were performed from 6 am to 6 pm. All insects were collected by different methods: direct collection on the inflorescence, leaves and flowers; the use of insect net and the use of aspirators. A total of 360 specimens were captured and classified in five orders: Hymenoptera, Thysanoptera, Coleoptera, Diptera and Hemiptera. Pollination has been considered possible for hummingbirds and bats; instead insects were categorized as nectar robbers; here we suggest their possibility as pollinators due to their behaviour.

P2465. Conservation of Ecosystem: Role of Sacred Groves in India.

N. Savithramma;
S.V.University, Tirupaty, India.

The word sacred has been interpreted not in a narrow sence of religious belief alone but to cover all places which people have chosen to care for whatever be the reasons. The sacred goves(SG) are rich in biological diversity and natural ecosystems,some of which however may have aquatic features like waterfalls and subterranean water flows.Himalayan region,Easterm and Western Ghats are hotspots of India in which no.of SG with high degree of endemism and ecological gene pools.People of old generations chose many important medicinal trees for veneration and worship.A temple with water tank and some important medicinal plants is one of the basic things in villages of India. This is the method of water harvesting and In situ conservation of ecological and economic keystone species.Each SG is rich in its history which sustain and support life under a given agro-ecological condition. Unfortunately many of these SG disappearing under the influence of modernisation and ruthless exploitation of these resources to meet the industrial needs.Measures should be taken to protect and restore such of them which had lost some of their pristine glory of their earliest state

P2466. The coriander collection in the German ex situ-genebank in Gatersleben - state of conservation and evaluation

A. Prasad Bhattarai, U. Lohwasser, A. Börner;
Institute of Plant Genetics and Crop Plant Research (IPK), Gatersleben, Germany.

Coriander (*Coriandrum sativum* L., Apiaceae) is a major spice plant of the Indian sub-continent. Leaves, seeds, and essential oils are used as spice material. The species has a wide range of distribution and a formal taxonomic distinction of three subspecies with ten botanical varieties. The coriander collection of the German genebank in Gatersleben covers 457 accessions from more than 60 different areas of origin. All subspecies and varieties are available. A complete morphological description of the different leaf shapes, the colour of the flowers, the size and shape of the fruits, and the thousand grain weight is required to characterize the accessions and to determine the botanical classification. Despite optimal storage conditions (-15°C, moisture content <10%), a natural seed ageing process accompanies long-term storage in a seed bank. In order to find the longevity of the seeds a control of the germination rate is necessary at regular intervals. Genebank material should be used for scientific research also. 380 different accessions are in study to evaluate the winter hardiness and the survivability under strong environmental conditions.

P2467. Begonia Germplasm Resources of China

K. Guan;
Kunming Institute of Botany, the Chinese Academy of Sciences, Kunming, Yunnan, China.

One hundred and seventy-two taxa of *Begonia* L. are known in China. They are distributed in twenty-one provinces, regions or districts in China. One hundred and six known taxa are distributed in Yunnan, which occupies nearly 62% of the total Chinese begonias. The lowest elevation of the natural distribution of the Chinese begonias is 90m and the highest elevation is 3400m. Among 172 taxa of the Chinese begonias, 93 taxa belong to rhizomatous type, 42 taxa belong to erect-stemmed type and 37 taxa are tuberous begonias. It was noticed that over 50% of the Chinese begonias have ornamental value. Many Chinese begonias can be directly developed as ornamental plants. Some Chinese begonias are very precious germplasm for breeding purpose. Some species like *B. silletensis* have scented flowers. The yellow-flowered begonias are also valuable germplasm resources for breeding purpose. Many Chinese begonias are naturally distributed in a very small area and some begonias are threatened for surviving. Hence, the efficiency conservation of the Chinese Begonias gets no time to delay.

P2468. The Role of *Ex Situ* Institutions in Plant Conservation: Measuring Success.

K. Havens[1], P. Vitt[1], M. Maunder[2], E. O. Guerrant[3];
[1]Chicago Botanic Garden, Glencoe, IL, United States, [2]Fairchild Tropical Botanical Garden, Miami, FL, United States, [3]Berry Botanic Garden, Portland, OR, United States.

The Global Strategy for Plant Conservation (CBD, 2002) and other international policy documents have provided conservation organizations with a framework and targets for conserving plant diversity. Similarly, funding agencies generally request or require a grant recipient to demonstrate what the funding has accomplished. Botanic gardens and other *ex situ* organizations are increasingly faced with the challenge of measuring and articulating the success of their applied conservation programs. Perhaps the most appropriate yardstick for assessing success of conservation projects is, “Does it directly contribute to conserving the resource (*e.g.* plant diversity)?” Success can be measured in numerous ways including resources conserved, improved management implemented, better laws and policies, changes in knowledge, attitudes and behaviors of stakeholders, and reduction of threats to biodiversity. We discuss the results of a survey on botanic garden conservation programs, the benefits of measuring a garden’s conservation success and several tangible and quantifiable performance indicators.

P2469. The Macea University Botanical Garden Collection of Quercus I. Genus

A. Ardelean, C. Maior, I. Don;
Vasile Goldis Western University, Arad, Romania.

Member of the Botanical Gardens Association of Romania, the University Botanical Garden of Macea, 21.5 hectares, represents a scientifical collection of 2,150 wood taxons, about 1,100 herbal species.

Nowadays, consists of 42 taxons, 35 species, one variety and 6 cultivars. Among these, 10 are indigenous taxons, the rest of them are exotic oaks.

The 7 monumental examples of *Quercus robur* L. of the Garden, that are between 350 and 400 years old, are well vegetating, without showing any traces of physiological regress. Due to their advanced age, there are three monumental examples of *Quercus rubra* L.: *Q. macranthera* Fisch. et Mey and *Q. petraea* (Mattuschka) Liebl. *‘Mespilifolia’*, cited in the speciality litterature, that are lost.

Rarities of European dendroflora: *Quercus bucklet* Micon et D. Don, *Q.fabri* Hance, *Q.gambelii* Nutt., *Q. muehlenbergii* Engelm., *Q. nigra* L., *Q. shumardii* Buckl., *Q. texana* Buckl etc.

. Sectors that are intensely visited by public present oaks of ornamental value, such as *Quercus coccinea* Muenchh., *Q. shumardii* Buckl., *Q. texana* Buckl. There are also *Q. macrocarpa* Michx with a special rhytidome, *Q. robur L. Fastigata* and *Pendula”*
.
. .

P2470. Conservation and Utilization of Plant Genetic Resources in Nepal

R. B. Bhandari;
Himalayan Resources Institute (HIRI), Kathmandu, Nepal.

The plant biodiversity of Nepal consists: cereals, grain legumes, vegetables, industrial crops, oilseeds, spices, fruits, ornamentals and herbs. The contribution of plant biodiversity to food supply, agriculture, forestry, medicine and industry is enormous. Nearly 54 percent of Nepal's physical landscape is covered with vegetation (37 % forested area, 5 % shrub land and 12 % grass land). A total of 118 ecosystems with 75 vegetation and 35 forest types have been identified in Nepal. Though Nepal possesses only 0.1% of the total landmass of the world, it harbors nearly 2.5 % flowering plants, 3% pteridophytes and 6 % bryophytes of the world's flora. There is high degree of endemism (246 species), which accounts for 30 % for whole of the Himalayan region. There are more than 6,500 plant species of which more than 500 plant species are edible, 700 species of medicinal plants have been identified and a total of 10,736 accessions of 90 crops have been documented. Nepal is considered to be one of the countries of origin of rice in the South Asia. Existence of more than 120 species of wild relatives of cultivated crops is an additional dimension to the plant genetic resources of Nepal.

P2472. Impact of Afghan Refugees on Flora of Pakistan - A Case Study: Kurram Agency

I. Ilahi, S. S. Gilani, Z. K. Shinwari;
Kohat University of Science and Technology, Kohat, Pakistan.

The research area, Koh - e - Sufaid Range, lies between 33º-53´ and 34º-03´ north latitudes and 69º-50´ and 70º-51´ east longitudes, in Kurram Agency, Pakistan.

Traded fungi and medicinal plants of the area were *Morchella esculenta, Artemisia brevifolia* and *Teucrium stocksianum.* Their estimated annual consumption was 240,200 kg. Annually, 114,000 Kg of *Artemisia brevifolia* and *Teucrium stocksianum* were also smuggled from Afghanistan to Pakistan. The local people reported that, in Afghanistan, *Artemisia brevifolia* is found insufficiently as compared to *Teucrium stocksianum*. *Artemisia* of Afghanistan is of red color while that of Kurram is of green color. *Teucrium* of Afghanistan is larger than Kurram. About four trucks of *Teucrium stocksianum* while three of *Artemisia brevifolia* were brought from Afghanistan by Jagi tribe and sell to the mentioned trader. Majority collectors of these two species were men. Data analysis shows that about 64,000 kg of *Teucrium stocksianum*, while 50,000 kg of *Artemisia brevifolia* were carried in Pakistan through that route.

P2473. Enrichment of dendroflora biodiversity in Belgrade region with some alochtonous species

D. M. Drazic[1], S. Bojovic[2], L. Jovanovic[3], B. Batos[1];
[1]Institute of Forestry - Belgrade, Belgrade, Serbia and Montenegro, [2]Institute for biological research "Sinisa Stankovic", Belgrade, Serbia and Montenegro, [3]Center for multidisciplinary research, Belgrade, Serbia and Montenegro.

Belgrade region is phytocenologicaly determinate by *Quercetum frainetto cerris*, with characteristic, mostly deciduous dendroflora species. The possibility of introducing new, ecologically suitable, especially species resistant on phytopathological diseases, insects and increasing air and soil contamination, is extraordinary valuable. Introduction of coniferous is important from the different points of view. Besides the enrichment of biodiversity, the esthetic values of landscape increases and the new ambient with healthier conditions is more suitable for recreational activities. The paper presents the researching results of three very interesting alochtonous species adaptability and development on the several locations. Besides the quantitative parameters, the variability of analyzed characteristics has been presented by statistical parameters. The results confirms that these species has very intensive increment, there has not been identified any kind of harmful insects or phytopatological diseases, and the esthetic values are significant.

Key words: Belgrade region, *Cedrus atlantica glauca*, *Taxodium distichum, Quercus borealis*.

P2474. Dependency of biological impacts of fixed part (GSM) equivalence on frequency

I. Lucic[1,2], G. Soja[1], H. Haider[1], W. Giczi[1], K. Kratky[3];
[1]ARC Seibersdorf Research GmbH, 2444 - Seibersdorf, Austria, [2]Institute of Experimental Physics, Vienna University, 1090 Vienna, Boltzmanngasse 5, Austria, [3]Institute of Experimental Physics, Vienna University, 1090 - Vienna, Boltzmanngasse 5, Austria.

Considering potential electromagnetic environmental stress there is a physical, political and economic need to investigate its impacts on living beings and its consequences on environment and human society in general. For that purpose the Environmental Department of ARC Seibersdorf research GmbH developed and built a new experimental set-up for research of biological impacts of high frequency electromagnetic fields on plants. 17 chlorophyll fluorescence (CF) and 13 standardized growth parameters of red radish seedlings (*Raphanus sativus L.*) were evaluated. Univariate ANOVA tests showed significant main effects and group differences between some of the independent variables.

Here we discuss the evaluated data not only as implication of field-strength (classic viewpoint) but also as composed effect, where the field-frequency is presented as one relevant factor of the biological impacts of high frequency electromagnetic fields on plants.

Another goal of our research is that some of measured CF-evaluation parameters (like F0, F1, F2) clearly show their forecasting potential.

P2475. Ex situ plant conservation in Greece: The case of the Balkan Botanic Garden of Kroussia

E. Maloupa;
Laboratory of conservation and evaluation of native and floricultural species (NAGREF), Thessaloniki, Greece.

Conservation of the Greek and Balkan native plants involves a significant part of the research and activities taken place in the Balkan Botanic Garden of Kroussia (BBGK). Living plant material has been carefully collected from nature, accompanied with all necessary climatic, soil, location and individual species-properties, in order to withstand the treatments applied for conservation in the ex situ environment of the nursery and BBGK. Plant conservation efforts produced 855 native and floricultural species, which have been taxonomically identified and preserved ex situ in BBGK.

Despite the floristic richness and high endemism, the establishment of more new Botanic Gardens and network in Greece is limited. However, initiatives have been undertaken by BBGK at national level and moreover with neighboring Balkan. There is no previous experience and information on how to cultivate almost all of the species preserved ex situ in BBGK, therefore, efforts for the development of new propagation protocols found to be necessary, especially for 263 threatened Greek endemic taxa.

P2476. Seasonal variations in moisture, ash, and lipid content of three edible seaweeds from the Chincoteague Bay, VA, USA

M. Mitra, J. G. Schwarz, I. Khan;
University of Maryland Eastern Shore, Princess Anne, MD, United States.

Of all the bays in the Delmarva Peninsula, the southern Chincoteague Bay, Virginia, has the greatest richness of edible seaweeds. Although these seaweeds have the potential for use as a food source, few studies have examined seasonal changes in moisture, ash, and other nutritional composition in macroalgae. A preliminary study was undertaken to detect seasonal changes in some of the proximate constituents such as moisture, ash, and lipid of three abundant species of edible seaweeds from the Chincoteague Bay. The three species, Gracilaria tikvahiae (Rhodophyta), Fucus vesciculosus (Phaeophyta), and Ulva lactuca (Chlorophyta) were sampled in summer-fall and winter-spring during 2004-2005 and analyzed for moisture, ash, and fat. Results show that moisture content (%) was higher in all the three species during summer-fall than winter-spring. Ash content (% of dry weight) was lower in spring for all species. Lipid level was elevated in Fucus during the winter but fluctuated less in Gracilaria and Ulva. These seaweeds are exposed to seasonal variations of abiotic factors that could influence their metabolic and growth responses, and also impact herbivory.

P2477. The Effect of war on Agro-biodiversity In Sierra Leone

R. T. M. Chakanda;
Wageningen University and Research Center, Wageningen, The Netherlands.

Sierra Leone is recovering from a ten-year long civil war that devastated the patterns of livelihood of the farming communities that uphold agro-biodiversity. There is a need for information about the status of, and the impact of the war on agricultural biodiversity. The way this knowledge is gathered encompasses:

1) a survey in the post-conflict situation to assess the left over of on-farm diversity. This is highly dependent on farmer knowledge much of which is subject to erosion over extended periods.

2) pre- and post-war comparison of agro-biodiversity. Since there are virtually no undisturbed locations within Sierra Leone and there are hardly any records to outline pre-war and wartime crops diversity regimes. For this, a comparison is made with the border region of neighbouring Guinea.

3) assessment of the existing level of diversity in a number of crops based on morphological observations on the collected accessions, involving field trials and subsequent molecular characterization.

P2478. Modelling plant species richness on a regional scale in a man-dominated environment

J. Wahr[1], S. Klotz[1,2], T. Wohlgemuth[3], V. Mosbrugger[1];
[1]Institute for Geosciences, Tübingen, Germany, [2]Laboratoire PaleoEnvironnements et PaleobioSphere Universite Cl.Bernard, Lyon, France, [3]Swiss Federal Institute for Forest, Snow and Landscape Research, Birmensdorf, Switzerland.

Analytic studies on regional biodiversity patterns are still rare. The present study aims to reveal the potential factors of influence on the spatial biodiversity patterns (species richness) of all vascular plant species and selected species groups (native, alien, red-list) on a regional scale in a man-dominated environment (SW-Germany, Baden-Württemberg).

Floristic data rely on a regional floristic mapping scheme with a grain of 5.5*6 km per grid cell and an extent of 931 grid cells covering an area of 30,000 km^2. Out of available environmental data (climate, geology, soils, landuse, etc.) about 200 parameters are processed using GIS. To predict regional plant species richness according to environmental variables multiple linear and non-linear regression models are applied.

The results suggest that multiple linear models may explain about 40% of the variability in the total number of all plants, and up to 60% of the variability in the total species-number of specific plant-groups. Non-linear models could slightly enhance the quality of the prediction. A rough assessment of biodiversity change on the basis of land-use and climate change scenarios is done.

P2479. More humans means more plant species in the Eastern Caribbean

L. E. Chinnery;
The University of the West Indies, Bridgetown, Barbados.

Expected relationships were found for species number and area and altitude for pteridophytes in the Eastern Caribbean. However, the slope of the species-area relationship (z = 0.756) was greater than expected (~0.301) and there was a positive correlation between human population density and species number. An explanation is that with increased population there is likely to be at least one person interested in ferns and involved in activities to increase knowledge of an island's flora. If true and if the number of such individuals increases with population size, this would induce a positive correlation and contribute to the increase in the species-area slope. Alternately, the existence of unequal sampling intensities with the floras of the large islands being better known than those of the small ones would contribute to an increased value of z. Data of other groups from the 'Flora of the Lesser Antilles' were used to see if the species number/human population density relationship applies to other vascular plants or which sub-groups it applies to. For groups tested, z values were greater than expected and there were positive correlations with human population density.

P2480. Multiple-use native trees: a biodiversity recovery tool.

M. Equihua, G. Benitez, M. Pulido-Salas;
Instituto de Ecología, A.C., Xalapa, Mexico.

In Veracruz, Mexico problems and issues associated with markets in meat, coffee and sugar cane could spur changes in land use. The situation opens-up an opportunity to recover biodiversity by afforestation using native species. In Veracruz there are some 950 species of trees, which represent 43% of the 2200 tree species estimated for all of Mexico. In this study we report on 107 species that are propagated in official tree nurseries in Veracruz. The study combined a taxonomic description of these species with the review of ecological and horticultural data. Highlighted in our results are uses that seek to find viable production alternatives that also serve a conservation function. Multiuse species were considered in both agroforestry and silvicultural/pasture system. We also report on three application oriented toward increasing knowledge on species from tropical montane cloud forest, one of the most threatened communities in Mexico: a program of restoration with 11 tree species from the cloud forest, an evaluation of the meaning of contrasting conservation status of *Carpinus caroliniana*, a study of the spatial distribution and protection of *Ostrya virginiana*.

P2481. The effect of plant diversity on people's perception and appreciation of vegetation patches

P. Lindemann-Matthies[1], X. Junge[1], D. Matthies[2];
[1]University of Zurich, Zurich, Switzerland, [2]University of Marburg, Marburg, Germany.

To study people's perception and appreciation of plant diversity, we arranged (1) plants in meadow-like arrays of different diversity (1, 2, 4, 8, 16, 32, 64 species) and (2) marked vegetation patches of different levels of plant diversity along waysides. We presented the plots to more than 1000 people and recorded their estimation of plant diversity, their preferences for certain plots, and their botanical knowledge. Study participants were generally able to distinguish between different levels of diversity. However, they overestimated the diversity in the low diversity plots and underestimated the diversity of the high diversity plots. The number of species perceived increased linearly with log species number, i.e. the participants perceived each doubling of the number of species as a constant increase. People's appreciation of a plot increased continuously with species diversity. The results indicate that species-rich plant communities are appreciated, which is an important condition for their protection. However, people perceive plant diversity inadequately and may thus not notice the ongoing decline in biodiversity.

P2482. Conservation of biodiversity anthropocentrism *vs* biocentrism *in situ* and *ex situ p*aradigm shift

N. R. Kaswan, **N. R. Kaswan**;
Govt. College, Sri Ganganagar, Sri Ganganagar, India.

Biocentric consciousness and ecological awareness is a result of continuous environmental depletion caused by prevailing non-sustainable conditions created by anthropocentric activities of human society. Transformation and modification of natural assets, domestication of faunal and floral species, modernization of physical landscape, urbanization, industrialization, world wide network of means of communication and transportation have fasten the rate of environmental degradation. The biodiversity is under threat of extinction and erosion. Rapidly increasing number of endangered species is a threat to humankind for his survival and sustainability. Non-sustainable and monistic approach of anthropocentrism must be replaced with sustainable and holistic biocentric approach so as to maintain and protect biodiversity including man himself.
Attempt has been made to understand and explain in situ and ex situ paradigm shift in terms of biodiversity conservation taking into consideration biocentric holistic approach in place of anthropocentric monistic approach with the help of poster presentation.

P2483. Emergency situations and Life Support Species

P. Kapoor-Vijay;
IWS, Zurich, Switzerland.

Hazards and disasters like Tsunami have given a wake up call to human race and new awareness that science and technology needs to do more for vulnerable communities, disappearing habitats and vanishing biodiversity. Precious lives are lost along with . unique cultures who depend on prevailing precious biodiversity. New awareness in science and technologyof biodiversity is required to meet the needs of traditional communities. Life Support Species (LSS) are locally adapted unique plant, animal and microbial genetic resources which have specialised biological attributes to withstand extreme environments and are used for survival and food, nutrition, energy and environment needs by local cultures and communities. The ancient civilisations derived their knowledge from the signals provided by local plant and animal diversity of LSS to take precautions and avoid risks to life from impending disasters. The gene pool diversity of these species can meet future needs emerging due to extreme environment changes. Example of Chenopods and other such species are discussed. A Global Action Plan on LSS is recommended.

P2484. Digital mapping of fruit trees as an instrument to monitor diseases and conserve varieties

C. Kaufmann, H. Keppel, A. Spornberger;
Institute of Horticulture, Fruit Growing and Viticulture, University of Natural Resources and Applied Life Sciences, Vienna, Austria.

A computer supported method was tested to map fruit trees and host plants of fire blight. Fire blight is caused by *Erwinia amylovora* and is an infectious bacterial disease, which can attack very dangerously many Rosaceae, e. g. cultivars of apple (*Malus communis*) and pear (*Pyrus communis*). The practical work was done during the summer 2003 in Fußach, Vorarlberg, where 3463 trees on an area of 675 ha were mapped. Most of the fruit trees grow in extensive orchards ("Streuobstanbau") where lots of different and old fruit varieties can still be found. Aerial photographs saved on the pocket computer helped to orientate in the field and determine the exact position of the plants to map. The special programming of the GIS-application used made it possible to register all necessary data immediately by typing on the touch screen of the pocket computer. The result is a digital tree map, which makes the spreading of fire blight visible and allows an easy update of newly infected plants in following years. Thus, unharmed trees, which could be tolerant or resistant to the disease, can be found very easily. The method can also be useful to map fruit trees for plant conservation aims.

P2485. Ecological Factors Affecting Iranian Annual Medics

J. Mozafari, F. Ghanavati;
SPII (Seed and Plant Improvement Institute), Karaj, Islamic Republic of Iran.

Ecogeography of *Medicago* species was studied in Iran where is considered as one of the primary centers of diversity for this crop. Annual medics collected from across the country were characterized, indicating that 21 annual *Medicago* species are grown in naturally different ecological zones. Results showed annual medics were distributed mostly in the North-West, West and South of Iran. The relationship between geographical diversity and ecological factors was studied showing that altitude and precipitation were the two important factors in the distribution of *Medicago* species. Most of the species distributed from 0-2750m above the sea levels in areas with 100-400mm annual rainfall and the Mediteranian climate. Soil texture analysis showed that annual medics are generally grown in Loam or Clay soils with pH=7.0-8.0. However, some species were found in ecologically marginal and different areas. Among these species *M. rigidula* and *M. rigiduloides* are adapted to cold zones, while *M. laciniata* and *M. sauvagei* were found in Southern Iran with the annual mean temperature of 20º C. *M. littoralis* is a littoral plant which grows near the Caspian Sea and the Persian Gulf.

P2486. Origin of waxy foxtail millet

K. Fukunaga[1], M. Kawase[2];
[1]International Research Center for Japanese Studies, Kyoto, Japan,
[2]Genebank, National Institute of Agrobiological Sciences, Tsukuba, Japan.

Naturally occurring waxy and low amylose variants of foxtail millet (*Setaria italica*) arose in a limited region such as East and Southeast Asia as other cereals under human selection for sticky foods. We determined the structure of *GBSS1* gene conferring these traits by genomic and RT- and RACE- PCR, and analysed structural differences among 871 accessions with these three phenotypes by PCR. As a result we found that these traits were originated by independent insertions of transposable elements and subsequent insertions into these elements or deletion of a part of the elements. The structural analyses of transposable elements inserted into the *GBSS1* gene revealed that changes occurred from non-waxy to low amylose once, from non-waxy to waxy three times, from low amlylose to waxy once and from waxy to low amylose once. The present results and the distinct geographical distribution of different waxy molecular types strongly suggested these types originated independently and dispersed into the current distribution areas. Foxtail millet can be a new model for transposable elements- mediated evolution under human selection.

P2487. Variability of economic traits in the old varieties population of opium poppy (Papaver somniferum L.) with the Slovak origin

Z. Miklosikova, D. Tóth, B. Brezinová;
Slovak university of agriculture in Nitra, Nitra, Slovakia.

Opium poppy (Papaver somniferum L.) belongs among traditional species cultivated in the Slovak regions for many centuries. People from some Slovak regions are still cultivating old and marginal species. Collecting and reproduction of old and landraces and evaluation of their economical traits were ensured. 55 genotypes were experimentally tested. In the traits level was determined range - plant height 1102.7 - 1514.0 mm, number of capsules 1 - 9, capsules length 10.9 - 93 mm, capsules width 8 - 59.4 mm, capsules weight 1 - 29 g, weight of seeds in capsule 5.1 - 13.7 g. Significant differences were determined also in the shape and the size of the capsule, flowers color and in other traits. Experimental data were processed in the information system GENOTYPDATA Papaver. Information system provides characterisation of the genotypes according to unified classificator also with the image documentation.

P2488. An investigation of the inheritance procedure and estimating the number of controlling genes of some traits related to grain yield in barley *(Hordeum vulgare)* Afzal/Radical cross

A. Baghizadeh[1], **M. Naghavi**[2];
[1]International center of science, high technology & enviromental science, Kerman, Islamic Republic of Iran, [2]Tehran University, Tehran, Islamic Republic of Iran.

In order to study inheritance of traits related to grain yield in barley, F_1, F_2 and F_3 generations were made from Afzal/Radical cross. Parents along with F_1, F_2 and F_3 generations were planted in a randomized complete block, design with three replications. Head weight, head length, number of heads, number of spikelets per spike, awn length, hundred grain weight, grains per head and straw yield per head in different generations were recorded. Analysis of variance indicated that mean squares of generations were statistically significant for all the traits. Then, generation mean analysis was performed for all the traits. The results showed that additive, dominance and epistasis effects were effective for all the traits except awn length. Recently trait was controled with only additive and dominance effects. Also, results indicated that dominance variance was the most important for inheritance of all the traits. Average broadsense heritabilities where between%69-89% for all the traits. The number of genes for the traits were estimated to be between one and five.

P2489. Study of saffron plant (*Crocus sativus* L.) adaptability in North West of Iran

A. Shokohian[1], S. Khangholi[2], A. Rezaeinodehi[2];
[1]Faculty of Agriculture, University of Mohaghegh-e- Ardabili, Ardabil, Islamic Republic of Iran, [2]Faculty of Agricultural Sciences, University of Shahed, Tehran, Islamic Republic of Iran.

Iran is major country of high quality saffron production in the world. Traditionally the crop is produced in arid region of east of Iran (Khorasan province). An experiment was conducted to study of adaptability of the crop in Ardabil province in North West region of Iran which has cool summer and hard winter during 2002 to 2004 years. Three important ecotypes of saffron from east of Iran including, Torbat, Kashmar and Ghaen were selected and cultivated their corms in Ardebil province. Dry matter weight and length of stigma, mean yield/ha and mean yield total/ha for each ecotype were measured. The results showed that Kashmar ecotype with mean yield total/ha of 5.77 Kg had significantly higher production in compare with two others. Mean yield total/ha of Torbat and Ghaen ecotypes was 4.71 and 4.62 Kg respectively. Mean yield total/ha of the three ecotypes with 5.03 Kg was greater than their production in native region which is 3-4 Kg. Dry matter weight and length of each stigma were 0.0062 gr and 37 mm respectively. With respect to mean yield total the crop has good compatibility and tolerance to Ardabil cool and hard weather; therefore it may be profitable crop in the region.

P2490. Researches regarding the dynamics of the respiratory process in rye plants parasitized through artificial inoculation with various peptide alkaloid strains of *Claviceps purpurea* (Fr.) Tul.

M. M. Zamfirache[1], I. Burzo[2], S. Surdu[3], Z. Olteanu[1];
[1]University Al. I. Cuza, Faculty of Bioloy, Iasi, Romania, [2]Nicolae Balcescu University, Faculty of Horticulture, Bucuresti, Romania, [3]Biological Research Institute, Iasi, Romania.

The intensity of the foliar respiration at the parasitized plants depends on several factors. In the same circumstances, under the same environmental conditions, different species have different respiratory intensities. The respiratory process in rye plants was observed from the beginning until the end of the growth period of rye and of *Claviceps purpurea* parasite as well. During this period the foliar respiration presents high variations from one stage to another. The presence of the parasite determines important changes related to the predominant alkaloid type of the *Claviceps purpurea* strains, which parasite the rye. The intensity of the foliar respiratory process within the pathogen system rye -*Claviceps purpurea* is evidently influenced by the ontogenetic state of the host, by the infecting alkaloid type strains, as well as by the environmental conditions host plants are grown in, which allow a certain degree of infection in the individuals affected by the disease.

P2491. Sulfur-oxidizing rhizobacteria and *Bradyrhizobium* association for better soybean production

M. R. Banerjee, L. Yesmin;
Brett-Young Seeds Limited, Winnipeg, MB, Canada.

Present investigation was carried out to develop an inoculant product using a synergistic association between a naturally occurring sulfur (S)-oxidizing plant growth promoting rhizobacteria (PGPR) and a nitrogen (N)-fixing Bradyrhizobium that would enhance the soybean growth. Soybean (*Glysine max* L.) is a major field crop in North America especially in US and Canada. Farmers in the region are familiar with the using of N-fixing inoculant for proper root nodulation resulting in greater N supply to plants. The use S-oxidizing rhizobacteria *Delftia acidivorans* and *Bradyrhizobium japonicum* association showed improved soybean nodulation and vigorous plant growth. Results from our multi site field experiment showed that with the increased nodule number in plants soybean yield was also increased significantly with this unique microbial product. This product combines a S-oxidizer and a N-fixer, which may be the first to initiate a commercial development of a new consortium based inoculant for better soybean production.

P2492. Diversity of Musa Balbisiana Colla and its AAB/ABB hybrids in Thailand: Insights from AFLPs

T. Seelanan[1], H. Volkaert[2], S. Swangpol[3];
[1]Department of Botany, Faculty of Science, Chulalongkorn University, Bangkok 10330, Thailand, [2]Center for Agricultural Biotechnology, Kasetsart University, Kampaengsaen, NakornPathom 73140, Thailand, [3]Department of Plant Science, Faculty of Science, Mahidol University, Bangkok 10400, Thailand.

It has been speculated that Thai AAB and ABB banana may not have originated in Thailand; rather these might have been introduced from Malesia into Thailand long time ago. However, recent molecular study suggested that these Thai banana hybrids may have different origins. In order to clarify this argument, we conduct an investigation using AFLP markers in accessions from Musa balbisiana Colla and its AAB- and ABB-hybrids collected in Thailand to access their diversity and genetic relatedness. Accessions from neighboring countries were included as the reference in analyses. The results shown that ABB accessions were closely related genetically; so did AAB accessions. With respect to Thai accessions, it was suggested that there might be two origins of AAB/ABB hybrids: one possibly occurred in Thailand and the other was in the Pacific islands. These results certainly provided implication on domestication of these hybrids in Thailand.

P2493. Genetic and environmental interaction in Uzbekistan walnut nuts

S. Mapelli[1], G. V. Vildanova[2], E. S. Alexandrovsky[3];
[1]C. N. R. Institute Agricultural Biology and Biotechnology, Milan, Italy, [2]Tashkent State Agrarian University, Tashkent, Uzbekistan, [3]Uzbek Research Institute of Forestry, Tashkent, Uzbekistan.

Walnut is extended from south Europe to Central Asia. The wild forests in Uzbekistan are in western Tien-Shien and Pamir-Alay from 800 up to 2300 m. Walnuts are under the influence of anthropogenic factors and reduction of the forest goes to biodiversity erosion. Biochemical characterization of nuts from plus trees is a step to evaluate the biodiversity and environment interaction. Size and weight give a preliminary indication of biodiversity. The oil, protein and vitamin E are analyzed. Nuts from mountain trees have higher water content and some samples have higher oil percentage. This observation can be related to genetic background more than the environment because some samples from dry area have high oil percentage. From fatty acids analyses nuts with high linolenic/linoleic ratio are identified. Linolenic acid is important for oil quality. Two other fatty compounds are in oils from only one area. Also vitamin E changes in relation to the different samples analyzed. The comprehensive of the data indicate wide biodiversity and environmental action. The research will be completed to evaluate and distinguish between genetic background and environment.

P2494. Collecting Portuguese maize landraces with technological ability for bread production

M. C. Vaz Patto[1], P. Moreira[2], V. Carvalho[2], S. Pêgo[3];
[1]Instituto de Tecnologia Química e Biológica, Universidade Nova de Lisboa, Oeiras, Portugal, [2]Escola Superior Agrária de Coimbra, Coimbra, Portugal, [3]Estação Agronómica Nacional, Oeiras, Portugal.

Maize was introduced in Portugal on the XVI century. Since then, natural and human selection lead to a very diverse germplasm, recently confirmed by SSRs (Vaz Patto et al., 2004, Euphytica 137:63-72). Most Portuguese maize landraces are white flint types appropriate for bread production, representing valuable source of interesting genes. The traditional maize bread (broa) still plays an important economic and social role on rural communities, characterized by small farms relying on polycrop, quality oriented, sustainable systems. However, these are in risk of disappearing because of the progressive adoption of intensive hybrid varieties not suitable for bread production.

Expeditions were made to collect maize landraces among traditional farmers. The cultural practices and constrains, soil type, ethnobotanic parameters and associated crops were also collected (50 maize landraces, 120 varieties of different legumes and rye). We will analyse their technological ability for bread production, valorising them and promote on farm conservation and participatory breeding programs on the rural communities, contributing to a sustainable rural development.

P2495. The studies of biological pecularities of *Primula malacoides* Franch. Varieties and hybrids

J. Varkuleviļ ienā̄[1], L. Bale entienā̄[2];
[1]VMU Kaunas botany garden, Kaunas, Lithuania, [2]Lithuanian University of Agriculture, Akademija, Kauno r., Lithuania.

Primula malacoides Franch. has been cultivated in Kaunas Botanical Garden, Vytautas Magnus University for a long time, its selection started in 1946. Five new original, plentiful of flowers, high ornamental quality, and scent varieties - has been developed and legalized in 1967-1976.

New hybrids were created in 1995, perspective candidates to the new varieties - *Žydre, Vakare, Rubinas* and *Margute*. First indication data about new-created hybrids were published in 1999 to 2001 these hybrids have been registered in Lithuanian register of flower varieties.

Aim of research - to create new hybrids of *Primula malacoides* Franch., to investigate and compare biological (morphological, genetical and physiological) peculiarities of four earlier-created varieties and new-created hybrids, evaluating plants ornamental quality during the period of growing and development.

P2496. Indigenous traditional knowledge integration for forest biodiversity conservation in India

S. Biswas, A. Srivastava;
Botany Division, Forest Research Institute (Indian Council of Forestry Research & Education), Dehradun, Uttaranchal, India.

Indigenous traditional knowledge (ITK) on the flora of India is as old as ancient scriptures, bio-geographical niche, cultural history and natural resource. Indigenous communities represent nearly 430 distinct ethnic groups interspersed among 54 million tribal people under 227 linguistic groups and inhabit different phytogeographical locations. The wild resources are the result of co-evolutionary relationships between indigenous peoples and nature since time immemorial. Ethnobiological information on nearly 10,000 wild plant species including 7500 species for medicinal purpose, 3900 subsidiary food, 525 fibre and cordage, 400 as fodder, 200 pesticides have been documented. The products/outputs and services through the integrated ITK approach proposed are: characterization of ethnobiological significant areas, registration of grassroots innovations, taxonomic characterization; reintroduction of threatened species, preparation of extension materials, gender initiatives, benefit sharing, developing at organizational and local government level, accessibility to IK rich areas, and capacity building through integrated approach.

P2497. Preserving biodiversity in the farming system through sustainable management

M. Veloso[1], S. E. Pego[1], J. E. Eiras-Dias[2], L. C. Carneiro[1], E. Rosa[3], J. Baeta[4];
[1]Estação Agronómica Nacional, Oeiras, Portugal, [2]Estação Vitivinícola Nacional Nacional, Dois-Portos, Portugal, [3]Universidade de Trás-os-Montes e Alto Douro, Vila Real, Portugal, [4]Estação Florestal Nacional, Oeiras, Portugal.

Crop diversity is crucial for food production and sustainable agriculture and contributes to food security, nutrition improvement and higher incomes.

In Portugal for each crop there are several landraces that are, frequently, the result of geographic isolation.

Maize (*Zea mays* L.), common bean (*Phaseolus vulgaris* L.) and coles (*Brassica oleracea* L.) are important for food supply. Grapevine (*Vitis vinifera* L.) is used for the production of superior quality wines, contributing for higher incomes.

Maize is used for the manufacture of a special bread “broa”, that in the North, plays an important role in rural communities.

Common bean and coles are main constituents of some traditional Portuguese dishes still greatly consumed in the rural communities.

Grapevine autochthone varieties are close to 300 and most of them exist exclusively in the country. Diversity has been preserved not only between varieties but also within the varieties themselves (clonal variability). In order to preserve such diversity growers are encouraged to use a blend of clones in their vineyards and the Portuguese list of varieties for wine making was officially established.

P2498. The state of the art on the archaeobotanical study of Arslantepe-Malatya (Turkey): the role of agriculture and artisanship at the end of the IV millennium B.C.

L. Sadori, **F. Susanna**;
Dipartimento di Biologia Vegetale, Università "La Sapienza", Roma, Italy.

Arslantepe, with its millennia of buried history (from Late Chalcholitic to Neo-Hittite age) is an archaeological hill close to the Euphrates river. In the final centuries of the fourth millennium (3300-3000 B.C.) a huge monumental public complex, the first known example of a palace in the Near East, was built at Arslantepe. Only few seeds of legumes, few tens of bad preserved and fragmented wheat caryopses and some grape pips, either of wild or cultivated type, have been found sieving huge sediment quantities. Hundreds of hulled many-rowed barley caryopses were recovered from waste places or corridors and from an open area just outside the gate of the palace. This lack can not be fortuitous and it is plain that the bins were not discovered yet. Preliminary pollen analyses carried out on sediments from the drains dug in one corridor show the presence of cereals pollen and grass cuticles. Phytoliths will be investigated too. Temple B was found with a large amount of big charcoals in situ. The wood used for the big beams of the widest room was mainly of Alnus; Pinus gr. sylvestris/montana, Fraxinus Popolus and Crataegus were used as well, for beams and also likely for smaller items.

P2499. New Aspects on the Diet of the Neolithic Tyrolean Iceman „Ötzi“

W. Kofler, A. Schmidl, K. Oeggl;
University of Innsbruck, Institute of Botany, Innsbruck, Austria.

Three surgical interventions on the Tyrolean Iceman conducted in 1995, 1997 and 2000 resulted in the collection of five ingesta samples. These samples constitute a sequence from different locations of the intestinal tract: the ileum, the transverse and descendent colon, as well as the rectum. The samples encompass at least three different meals consumed of the Iceman during his last two days, which is shown by numerical analysis of the pollen flora and muscle fibres incorporated in the different ingesta samples. The macro and pollen analyses of these samples reveal that the Iceman consumed a well balanced omnivore diet. Surprising is the strong correlation between bracken (*Pteridium aquilinum*) spores and human whipworm (*Trichuris trichuria*) eggs as well as wheat (*Triticum*) pollen. This indicates an intentional consumption of bracken as anthelminthic or as starch plant. Additionally the new data corroborate the early season of his demise.

P2500. A survey of storage proteins and enzymes of Iranian diploid wheat seeds

M. Cheniany, H. Ebrahimzadeh, V. Niknam, A. Salimi;
Tehran University, Tehran, Islamic Republic of Iran.

The wheat is the most field crop in the world and also Iran. It has been investigated from different aspects by now. This investigation led to improve in quality and increase in production noticeably. Among this, diploid wheats are important because of being hexaploid wheats base. Wheat seed proteins including storage and cytosolic proteins are considerable. Our purpose in this study was the evaluation and comparison of enzymes and storage proteins of Iranian diploid wheat (including Triticum monocuccum ,T.boeotocum and T.urartu). In order to this, we used 25 native masses of diploid wheats usually from the west and the northwest of Iran. In lab, extracts were extracted by proper buffer and then the total protein and enzymes measured by spectrophotometer. For electrophoresis, SDS-PAGE and A-PAGE were used for gliadin and glutenin respectively and PAGE for enzymes and at last produced bands of these for polymorphism were compared.

P2501. Plants Used in Handicrafts by Indigenous of the Amazon Forest at the Community Monilla Amena (Colombia)

C. E. Cadena, M. Diazgranados;
Herbarium Pontificia Universidad Javeriana, Bogota, Colombia.

At the community Monilla Amena, located in the Colombian Amazon, there are at least four indigenous groups (Huitoto, Yucuna, Ocaina and Ticuna) and a mestizo group. We studied useful plants availability, management and spatial distribution. Ethnobotanical information was obtained by interviewing twenty-four adult people. Results yield 77 species used for 71 handmade articles. The most useful families are Arecaceae (25.9%), Moraceae (16.3%) and Aracea (7.6%), and the most useful genera are *Brosimum* (13.7%), *Astrocaryum* (12.9%) and *Heteropsis* (6.7%). One species of *Brosimum* highlights because is used in 23 handicrafts. Most uses involve culture and subsistence activities. Mostly plants are in flood land forest (59.5%), terra firme forest (24.4%) and cultivated zones (13%). We found that 12.8% of plants are cultivated and 87.2% are wild. Huitotos and mestizos reported more species of useful plants (72 and 55), however we did not find significant differences between the numbers of useful plants given by each of the five ethnic groups (Ŭ=0.05, p = 0.66), because there are diverse levels of knowledge between the members.

P2502. Ethnbotanical study of the materials used to build tradicional Chontal houses in Tabasco, Mexico

L. Gama, S. Cabrera-Perez;
Universidad Juarez Autonoma de Tabasco, Villahermosa, Mexico.

Chontals have a good knowledge of their resources, that is reflected on the materials used to build their houses since prehispanic times. Today many houses are constructed with bricks and asbestos. Traditions are being lost due to a lack of the materials, caused by human transformation in agricultural activities and cattle raising. The objective was to determine the used materials and to characterize the degree of landscapes modification as well as how this affects the possibility to find resourses. Aerial photos were used to delimit the area and characterize landscapes. Surveys were conducted to get information of the materials, where and how they got them and how much they paid to try to evaluate the success of keep on usisng this type of house. Thirty five species were found in the structure that came from homegardens, agricultural areas or other ecosystems from the north of Tabasco. A lost of tropical forest was found. Therefore there was a lost of materials and a change in some cases to artificial ones. Palm leaves of *Sabal mexicana* are used to build ceilings supported by stems of "jahuacte" *Bactris mexicana.* Both species resist humidity and offer a fresh construction.

P2503. Medicinal Plants Used in Mexico for the Treatment of Rheumatic Diseases.

A. Aguilar[1], A. Linares[1], E. López[2], S. Xolalpa[1];
[1]Herbario IMSSM, Mexico City, Mexico, [2]Herbario IZTA, FEZ-Iztacala, UNAM., Mexico City, Mexico.

The rheumatic diseases are officially recognized as health problem in Mexico. This fact is confirmed by study of traditional medicine herbal resources; a great number of plant species are commonly used to alleviate rheumatic disorders. The objective in this study was to establish the medicinal plants that Mexican people use for the treatment of rheumatic diseases from ethnobotanical information gathered on Herbarium IMSSM. The method applied was the examination of the herbarium vouchers, annotating scientific name, family, common name, and medicinal use. Anthropological and medical criteria were used to organizer and to analyze of the information.

We reported 109 medicinal species used for treatment and prevention of 28 popular rheumatic diseases. The more used families are Asteraceae and Solanaceae. The most common used species are Gymnosperma glutinosum (Spreng.) Less. (tatalencho); Persea americana Mill. (avocado); Solanum marginatum L. (sosa); Urtica dioica L. (stinging nettle); and Cannabis sativa L. (marihuana). Finally, we can conclude that studies in this area may bring an alternative to the first level of medical care based on herbs.

P2504. Ethnobotanical value and conservation of gallery forests species of Biosphere Reserve of Mare aux Hippopotames, Burkina Faso, West Africa

M. Belem[1], S. Guinko[2], J. Yameogo[1];
[1]INERA/DPF, Ouagadougou, Burkina Faso, [2]UFR/SVT, Ouagadougou, Burkina Faso.

The mare of Hippopotames Biosphere reserve is located in the western part of Burkina Faso. It depends on the Province of Houet. It is a part of the humid zone of Burkina Faso. Local populations have a close relationship with the reserve. They get much uses from the gallery forests species ; they get much of their needs in food products, medicine, energy, arts and crafts. The use of resources has consequences for the biodiversity, ecosystem and environment of the reserve if the manners are not sustainable. Cutting roots, barks and big stems are not sustainable techniques to the species The discussions held during ethnobotanical inquiries have permitted us to establish the main use of woody plants and to pick out the repercussion of this usage. From this it emerges that the reserve has an important floristic richness and a biodiversity unknown to both locals and authorities. These two kind of people must work together for a sustainable management of the reserve

P2505. Medical Ethnobotany of Pachycereus pecten-aboriginum (Cactaceae) in Mexico.

S. Xolalpa-Molina[1], S. Arias[2];
[1]Herbario IMSSM, Mexico City, Mexico, [2]Jardín Botánico, Instituto de Biología, UNAM., Mexico City, Mexico.

In Mexico, ethnobotanists had paid much attention to some cacti species with the most popular uses, but had been forgotten other cacti with regional importance. The objective of this work is to show the medical importance of Pachycereus pecten-aboriginum (Engelm.) Britton & Rose. The method consisted of fieldwork on the Yoreme-Mayo's region, in northwestern Sinaloa state, the record of uses in its natural distribution area, and a revision in IMSSM Herbarium, the main collection of medicinal flora of Mexico, revision of references related with this topic, as well as systematize and to analyze the information. We found that the Pachycereus pecten-aboriginum stem and photosynthates ("baba") are used to attend skin illness, traumatism, diseases related to the digestive system, respiratory and urinary system, poisonous animals, diabetes, cancer, and used like enteogenic plant. Some of these are supported by historical record but some others are novels. Finally, is remarkable the necessity to make more ethnobotanical research on those cacti species that could be promissory resources in sustainable regional options to human groups that used them.

P2506. Exploring anthropological, historical and anatomical features of different tree-barks used for the manufacture of indigenous paper in Mexico

A. P. Quintanar-Isaias[1], C. Lopez-Binnquist[2], M. Vander-Meeren[3];
[1]Universidad Autonoma Metropolitana, Mexico City, Mexico, [2]Independent Consultant, Bogor, Indonesia, [3]Instituto Nacional de Antropologia e Historia, Mexico City, Mexico.

This research focuses on the tropical tree-bark species used for the manufacture of Mexican indigenous paper. It discusses information about its historical and anthropological background and research results regarding the anatomy and histochemistry of the barks. This paper has deep cultural roots in Mesoamerica and recently has become a commercial handicraft product manufactured by the Otomi indigenous people in the Sierra Norte of Puebla region. Different aspects of the production process have been modified in order to respond to the growing demand. The bark is gathered from an increasingly expanding area within this region. New tree species have been adopted as source of bark which show anatomic and histochemical differences from the traditional ones used since pre-Hispanic periods. The latter implied changes of the traditional manufacture process with consequences in the quality and durability of the paper. The increasing intensity of bark extraction could affect the dynamic of the species populations, including *Trema micrantha* which shows a fast growing rate and is the most recent and widely used species for the manufacture of this indigenous paper.

P2507. Rural populations knowledge about Borassus flabellifer (L.) uses and their strategies to conserve it durably in southwest of Burkina Faso (West Africa).

J. Yameogo, S. Ouedraogo, J. Bayala;
CNRST/INERA/DPF, Ouagadougou, Burkina Faso.

The vegetation landscapes of of Burkina Faso southwest are dominated by Borassus flabellifer, a specie which is great exploited by rural populations. This poster concerns people knowledge about its uses and populations strategies to conserve it durably. So, investigations have been made this area.

The results revealed that each part of Borassus flabellifer is implicated in uses classified in five groups: food, craft, pharmacopoeia, building and others. About food, bot, ripe fruits mesocarp, buds, immature fruits albumen, cotyledon and ashes from male inflorescences are consumed. In craft, leaves are used to make seven domestical uses objects. In buildings, trunks are used to make rafters, frames, parcels and animals' park enclosures. About phamacopoeia, drugs made of young leaves, inflorescences, resin and mesocarp treat man sexual powerlessness, tooth and ear aches, dermatosis, parasites diseases. Some other uses are noticed : seats, bridges and hives are made of trunks.

This poster shows also rural populations strategies to conserve durably Borassus flabellifer by their methods to regulate plant densities and bot extraction.

P2508. Economic Botany Recapitulates Phylogeny in Yams (*Dioscorea* L.) .

P. Wilkin[1], L. Raz[2];
[1]Royal Botanic Gardens, Kew, Surrey, United Kingdom, [2]Fairchild Tropical Botanic Garden, Coral Gables (Miami), FL, United States.

Yams are a widespread and diverse genus (at least 450 species) of climbing monocots with underground storage organs. Diversity is highest in the seasonally dry tropics, in Madagascar, the Greater Antilles, Mexico, Northern Thailand and Southern Brasil. The underground organ (a rhizome or a tuber) of at least 70 species is used as food or medicine.

A phylogeny is presented which uses three plastid genes and 109 taxa from throughout the range of the genus for the first time. The tree topology indicates that different clades of yams have different types of use. Early branching clades, which mainly have shallowly buried rhizomes or perennial tubers, are used primarily as medicines. Their underground parts usually contain steroidal saponins, probably as a chemical protection against herbivory. It is these taxa that have been used to produce steroid drugs, including the contraceptive pill. The terminal clades, however, have deeply buried, annually replaced tubers. These taxa are used worldwide as a starch source; most tubers lack chemical protection. Thus it appears that in the genus *Dioscorea* plant morphological and chemical evolution has shaped human use.

P2509. Ethnobotany: Local Vegetables in Northeast, Thailand

S. Chamratpan[1], K. Kasipar[2];
[1]Udonthani Rajabhat University, Udonthani, Thailand,
[2]Nakhonrachasima Rajabhat University, Nakhonrachasima, Thailand.

A survey of local vegetables in Northeastern,Thailand was conducted during 1999-2004. 197 species were found belonging to 67 families. Most of them grew in natural forest and swamps. One species was alga. Three species were ferns.Others were angiosperms. The biggest family was Leguminosae (25 spp.). The second one was Zingiberaceae (17 spp.). The third ones were Umbelliferae, Gramineae, Solanaceae, and Euphorbiaceae (9 spp. each). The plant parts mostly used were young leaves, shoots, fruits and flowers. Some can be fresh eaten. These vegatables can be used in two purposes - dipped and main dish.*Marsilea crenata*, *Centella asiatica*, *Anethum graveolens*, *Spondias bipinnata*,*Colocasia gigantea*, *Ottelia alismoides*, *Polygonum odoratum*, *Lobelia begonifolia* and *Limnophila aromatica* were fresh eaten to go with chili paste. *Cleome gynandra* and *Crateva magna* were fermented before eat. Leaf crush of *Cyclea barbata* added with chili and fish sauce was delectable food. *Amorphophallus brevispathus* petioles, *Bambusa bambos*, *Wolffia globosa*, *Glinus oppositifolius*, *Caryota bacsonensis* and *Calamus diepenhorstii* young shoot were usually cooked for main dish.

P2510. Ethnobotanical Studies On The Tribes Of Puruliya District In The State Of West Bengal Of India

R. Basu;
Achhruram Memorial College, Purulia, India.

The district of Puruliya in the state of West Bengal of India with its vast ethnic and vegetational diversity offers an immense scope for ethnobotanical study. This area is a heartland of many tribe for ages. The aim is to make a comprehensive account of ethnobotany of this principal tribal area which still nurses old practices but light of changes are seen not at the very distant far. So the need of the hour is to protect this tropical - ethnobotanical - archetypal treasure before it is lost forever.

The district is under the latitude 23^0 42' - 22^0 43' N, longitude 86^0 54' - 85^0 49' E, acquires an area of 6,259 sq. km. 'Tropic of Cancer' is passed through the north of this district. Topography is roughly undulating with terraced slopes. The place has a general monotony of 'Tropical Dry Deciduous Types' of monsoon vegetation. The vegetational belt is paleotropical. The object herein is to know the plants, plant parts, plant products have been used by the tribe for food, ropes and strings, dwellings, arms and weapons, furnitures, medicines, festivals and occasions, smokes and beverages, livestock and poultry farming, manual craft and culture, cultivation, and domesticity.

P2511. Ethnobotany of Ficus (Fig) species in Nepal

R. M. Kunwar, N. Adhikari;
Himalayan Journal of Sciences, Kathmandu, Nepal.

Ficus (fig) species are the most interesting group of trees, not only for their useful value but also for their growth habits and religious significance. They are considered as one of the principal sources of sustenance among the rural people. Present paper was focused to reveal the indigenous uses of *Ficus* (Fig) species in Nepal. Primary and secondary data were reviewed and assessed. Total three field visits were carried out in July 2001 and May 2003 in Dolpa district and March 2003 in Bardia district. Of total 36 *Ficus* species in Nepal, 16 were indigenously used for edible, fodder, fuelwood, vegetable, to medicinal use, etc. Ethnomedicine of *Ficus* (fig) species in Nepal was quite noteworthy. Eight fig species were used to treat 36 ailments. The contribution from the species *F. benghalensis* was the most possessing ingredients to treat 22 ailments. Some species such as *Ficus religiosa*, *F. benghalensis*, *F. benjamina,* etc. have a high religious value for both Hindus and Buddhists and are deemed sacred.

P2511a. Nourishing Plants Wild Utilizated by the Ethnic Group Mixteco in Tepuente, Guerrero state, México.

A. Díaz Rico;
Facultad de Ciencias, UNAM., México, Mexico.

Tepuente is one site in the mountains of Sierra Madre del Sur in México. The comunity has a population of 330, most of them monolingual mixteco. Until an altitude of 850 m, with a climatic type weather half-moist. The mean annual temperature is 27°C and the pluvial precipitation is 1577 mm. The local vegetation consists of Oak forests with Quercus glaucescens, Q. elliptica and Q. peduncularis as dominant species. The aim of this project is to recover Tepuente's knowledge and natural resources management still used about nourishing plants wild. The methodological approach used is based on Gispert, 1979 proposal, with the following results: 24 nourishing plants species wild, these species are transformed in sauces, beverages, containers and wrappings for other food. The consumption of raw ingredients is widely found, and the fruits are the morphological fragments more used. These species are used daily at meals and on annual festivities, either religious or ritual. These results show that this ethnic group's traditional knowledge ancient about its environment it's still being acquired, transmitted and kept among adults, young and children of this Mixteca location.

P2512. Developing a useful antioxidant and antibacterial product from a Combretum species

J. N. Eloff, J. Famakin, V. K. Zishiri;
Phytomedicine Programme, University of Pretoria, Onderstepoort, South Africa.

Antibiotic feed additives [AFA] are used in production of poultry and pigs. Resistance development may lead to human health problems resulting in EU banning of AFA from 2006. Screening of trees indicated substantial antibacterial and antioxidant activity in leaves of a Combretum species. By using different extractants and bioassay-guided fractionation the most important antibacterial and antioxidant compound was isolated and characterized. It had an MIC of 16 µg/ml against Staphylococcus aureus and 125 µg/ml against Pseudomonas aeruginosa and Enterococcus faecalis. The Trolox equivalent antioxidant concentration [TEAC] was 7.9 times that of Vitamin E.

The compound is present in high concentration in leaves and a leaf extract was potentised by selective extraction to yield an extract with a TEAC value of 2.8 and an average MIC value of 0.08 mg/ml.

This extract was tested as replacement of AFAs in a poultry experiment. There was no significant difference in growth rate compared to the positive [bacitracin] and negative control, but there was an improvement in food conversion rates. If these results are confirmed it may lead to a commercially significant product.

P2513. Antioxidant capability of polysaccharides fractionated from mycelia of *Agaricus blazei* in submerged culture

C. Chyau, Y. Ker, R. Peng;
Hung-Kuang University, Taichung County, Taiwan Republic of China.

Five polysaccharide fractions (AB-1, AB-2, AB-3, AB-4, and AB-5) were obtained after a systemic solvent extractions and precipitations of *Agaricus blazei* mycelia with yields 5.20%, 9.03%, 2.84%, 17.47%, and 0.44%, respectively. Among which, AB-1 and AB-3 demonstrated great DPPH· radical scavenging ability around 85.0 % and 72.0 %, respectively, at a concentration of 5 mg/mL. Their ferrous ion chelating power were even more excellent at a concentration of 1 mg/mL, reaching almost over 99.65 % for fractions AB-2, AB-3 and AB-4 comparing to the reference control of citric acid (35%), at a dosage of 5 mg/mL, fraction AB-1 even showed 105% in efficiency. Moreover, GPC analysis showed that the more potent fractions were those with lower molecular weights: AB-1 (757 kD), AB-2 (887 kD) and AB-4 (631 kD). We found that the biological activities of various fractions are neither closely associated with the mean molecular weight nor pertinently related with the solubility. Apparently, the active functionality inherently borne in each individual structure and their actual availability must be acting the major role in these respects.

P2514. Classifying landraces of Ensete ventrisosum in Ethiopia: traditional and experimental approaches confirmed

K. Zippel, P. Lüdders;
Landwirtschaftlich-Gärtnerische Fakultät, Berlin, Germany.

Enset (Ensete ventricosum: Musaceae) serves as the staple or co-staple crop for 15-20 million people in southern and south-western Ethiopia. It is grown in home gardens under varying climates from 1300-3300 metres altitude among several ethnic groups. Leaf sheaths and corm provide starchy food which can be stored for a long time. Many landraces are grown. Farmers differentiate their phenotypes by size, shape and colour, and their site requirements. They distinguish three groups for consumption, and further uses for fibre, animal feed, or traditional medicine. Several landraces tolerate drought, frost, pests and diseases. With rising altitude, the number of cultivated landraces declines. Growing several landraces guarantees permanent food supply, and other products. Experiments on vegetative development, leaf anatomy and chemical content confirm the traditionally distinguished groups. In view of these results, systematics of the genus are discussed.

P2515. Usage of wild and garden plants in rural societies in surrounding of Magura National Park and Knyszynska Forest Landscape Park (Poland)

P. Klepacki;
Botanical Garden of Jagiellonian University, Cracow, Poland.

The project aims at studying the uses of plants (wild and garden species) by rural residents. The studies focused on species affecting natural and cultural environment of Polish villages. The study areas are Magurski National Park and Knyszynska Forest Landscape Park, where industrial and urban development to date has not been intensive helping the traditional uses of plants to survive. Also important is the influence of Eastern ethnic groups: Lemko people in the Magurski NP and Belarussian people in the Knyszynska Forest LP, which retained their separate cultural and religious identity.

The studies are to provide information on uses of plants, e.g. as medicines, food, commercial crops and sacred items (blessed for later use), as well as variable household uses (repelling insects, weaving baskets or making brooms, applying for decorative purposes).

The rural communities undergo major cultural and social changes with traditional values and ways of life being replaced. The knowledge of plant species and their uses might help to preserve a vanishing part of rural culture.The project is currently in progress and its completion is planned for 2006.

P2516. Plants as estimates of civilization: first we take *Oedipus,* then we take Theophrastus...

S. T. Rhizopoulou;
Section of Botany, Athens, Greece.

In ancient literature, plants are presented *via* a detailed description of their properties. It is quite possisble that such information may connect early observations to current aspects of Plant Sciences. In *Oedipus at Colonus,* Sophocles (5th century B.C.) wrote about aesthetic values of plants surrounding a sacred spot "*this place is consecrate; it blooms with laurel, olive, vine, narcissus and crocus, rayed with gold".* While, Theophrastus (4th century B.C.), a student of Aristotle, argued that the features of every plant-tissue contribute to the prevailing traits of the species. His chapters are the most important botanical works that have survived from classical antiquity (i.e. in the books *Enquiry into Plants* and *Causes of Plant*s). Examples: i)"*In some plants the flowers are more fragrant than the leaves, in others on the contrary it is rather the leaves and twigs which are fragrant, as in those used for garlands,* e.g. *myrtles like those used for garlands*". ii) The kinds of flavours, as of odours and colours are held to be 7: "*sweet, oily, bitter, dry-wine, pungent, acid, astringent, and the salty is also added to these as an eight"*.

P2517. The value of non-coding genomic regions in the authentication of medicinal plant materials

P. Shaw, K. Wong, Y. Chan, P. But;
The Chinese University of Hong Kong, Hong Kong, Hong Kong Special Administrative Region of China.

Molecular authentication provides an independent and effective means for identifying medicinal plant materials. Internal transcribed spacer (ITS) of rDNA and 5S rRNA spacer are commonly used regions for authentication. Our experience with *Dendrobium*, *Gentiana, Cinnamomum, Stemona and Strychnos* indicates that ITS is a stable marker that provides low intraspecific variation and moderate interspecific variation. On the other hand, 5S rRNA often show variation within an individual and may be used to differentiate between closely related species.

Some relatively conserved regions, such as TrnL intron and TrnL-F intergenic spacer in chloroplast genome, may be used to differentiate distinct genera. By comparing TrnL-F spacer sequences, *Solanum lyratum* can be distinguished from *Aristolochia mollissima*, an adulterant containing aristolochic acids. Amplification of chloroplast regions is less affected by fungal DNA contamination, adding advantage to using them for authentication purposes.

This work was supported in part by the Hong Kong Jockey Club Charities Trust (Project no. JCICM-2-02R)

P2518. Indigenous Healing Practices in Tibetan communities of Nepal: Review and Perspectives

K. Shrestha;
Central Department of Botany, Tribhuvan University, Kirtipur, Kathmandu, Nepal.

Traditional healers of Nepal practice folk herbal medicine in the rural areas of lowland and midhills, followed by Tibetan medicine in the high hills; whereas in the urban areas, Ayurvedic as well as modern medicine are commonly practiced. Ethnobotanical research conducted in the Tibetan communities of Nepal reveals that more than 400 species of native medicinal plants, including over 100 species of plants from lowland tropical zone, are used by Amchis to treat different ailments. Amchis or Tibetan doctors play a vital role in the Tibetan and Sherpa communities, where local people have no access of doctors and allopathic medicine. Interestingly, several species of medicinal plants used in Tibetan medicine are well-known ingredients of Ayurvedic medicine, and few species are used in folk herbal medicine too. Besides its significant role in primary health care, medicinal plants are income generation source of majority of poor people. Over exploitation of some high value species, due to high demand in trade, are seriously threatened and needs special attention for their sustainable conservation and utilization for future generations.

P2519. Herbal Product Development in Thailand

P. -. Saralamp;
Faculty of Pharmacy, Mahidol University, Bangkok, Thailand.

Similarity to other countries in Asia, Thailand, with her various geographic locations, is rich in the biodiversity especially medicinal plants. Traditional Thai medicine and Thai medicinal plants are unique with vast potential. The principle of herbal remedy is complex and involves many disciplines of sciences. Due to the world trend to use natural products for better quality of life, the National Research Council of Thailand started the new strategies for product-based research in the year 2004. An integrated project focuses on selected 5 multi-herb traditional formulas and 16 plants for monopreparation. The research emphasized on quality control of raw materials and their standardized extracts, *in vitro* and *in vivo* tests to ensure efficacy and toxicity. Clinical trails of potential well-formulated herbal products are in process. The establishment of production techniques of high quality plant material was also performed. All researched technology will be transferred to herbal industry. Those efforts are conducted for the benefit of mankind and the sustainable use of Thai herbal heritages.

P2520. Acaricidal activity of Thai medicinal plants

N. Soonthornchareonnon[1], V. Mahakittikun[2], W. Chuakul[1];
[1]Faculty of Pharmacy, Bangkok, Thailand, [2]Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand.

Ethanolic extracts from various parts of 19 medicinal plants collected in Thailand were analysed for acaricidal activity against *Dermatophagoides pteronyssinus*, the most common dust mite in Thailand. Extracts from 4 of the 19 plants showed significant acaricidal activity, the most potent being *Acronychia pedunculata* (stem bark) which killed 67% of mite after 72 hours exposure to 2.40 mg/cm^2 extract. Other effective plants are *Azadirachta indica* (seed, 60%), *Erythrophleum succirubrum* (stem, 55%) and *Trigonostemon reidioides* (root, 63%). The latter was tested at the applied amount of 1.44 mg/cm^2. However, *A. pedunculata* showed the high toxicity in the brine shrimp microwell toxicity assay, i.e., with the lethal concentration (LD$_{50}$) of 0.2 µg/ml. *E. succirubrum* showed the least toxicity (LD$_{50}$ = 245 µg/ml). Thus *E. succirubrum* is promising to be used as natural product acaricide for controlling house dust mites due to their high acaricidal activity and low toxicity.

P2521. Acaricidal activity of Thai medicinal plants

N. Soonthornchareonnon[1], V. Mahakittikun[2], W. Chuakul[1];
[1]Faculty of Pharmacy, Mahidol University, Bangkok, Thailand, [2]Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand.

Ethanolic extracts from various parts of 19 medicinal plants collected in Thailand were analysed for acaricidal activity against *Dermatophagoides pteronyssinus*, the most common dust mite in Thailand. Extracts from 4 of the 19 plants showed significant acaricidal activity, the most potent being *Acronychia pedunculata* (stem bark) which killed 67% of mite after 72 hours exposure to 2.40 mg/cm^2 extract. Other effective plants are *Azadirachta indica* (seed, 60%), *Erythrophleum succirubrum* (stem, 55%) and *Trigonostemon reidioides* (root, 63%). The latter was tested at the applied amount of 1.44 mg/cm^2. Thus *E. succirubrum* is promising to be used as natural product acaricide for controlling house dust mites due to their high acaricidal activity and low toxicity.

P2522. Some important Medicinal plants of western ghats of India

A. Sudarsanamma;
S.V.University, Tirupati, India.

Western Ghats(WG) are situated towards West side of the penensular India .WG is one among the three mega biodiversity centres of India.This hotspot region has a characteristic true Indian flora especially no. of endemic medicinal plants used for different ailments. Some of these plants are mentioned in Reg Veda (4500B.C and 1600 B.C) andlocal healers of this area are still using few plants to treat no. of diseases . Arround 1,500 endemic plant taxa are recorded from this area. Specially the rare,endemic and endangered medicinal plants like CARVIA CALLOSA(Acanthaceae),MAPPIA FOETIDA(Icacinaceae),ARDISIA RHOMBOIDEA(Myrsinaceae),DILLENIA BRACTEATA(Dilleniaceae) ,PTEROSPERMUM RETICULATUM (Sterculiacear) ,ACACIA WIGHTII (Mimosaceae), EUGENIA INDICA (Myrtaceae) , MEMECYLON SISPARENSIS (Melastomaceae) ,WRIGHTIA INDICA (Apocynaceae),PREMNA WIGHTIANA (Verbenaceae),Ixora lawsonii (Rubiaceae),BUCHANANIA BARBERI (Anacardiaceae), AGLAIA ELEAGNOIDEA (Meliaceae)and GLYCOSMIS MAURTIANA (Rutacear) etc. will be discussed

P2523. Asiatic medicinal plants acclimatized in Poland

W. Buchwald, J. Kozǧowski;
Research Institute of Medicinal Plants, PoznaŒ, Poland.

The importance and common use of *Platycodon grandiflorum* A. DC. and *Salvia miltiorrhiza* Bunge in Asia were the cause of the beginning works on their acclimatization in Poland.

It was found that *Platycodon grandiflorum* (*Campanulaceae* family) in Polish climatic conditions resists winter well and gives good crops of raw material (roots) and seeds. The germination of the seeds obtained in Poland was from 90 to100 % and they kept this ability up to 7 years. The raw material (*Platycodi radix*) contained from 3, 73 to 4, 53 % of saponins. Mean mass of fresh roots obtained from one plant after two years of cultivation was 55 g, after three years 145 g.

Salvia miltiorrhiza (*Lamiaceae* family) blooms and fruits in Poland. Its germination capacity is up to 60 %. The mean mass of fresh raw material (*Salviae miltiorrhizae radix*) from one plant after two years of cultivation was 11 g. Roots of *Salvia miltiorrhiza* obtained from cultivation in Poland contained similar amount of polyphenols and diterpenes as Asiatic commercial raw material.

This work - a scientific project - is financed by Polish Committee for Scientific Research.

P2524. Chemopreventive effect of embelia ribes in 20-methylcholanthrene induced animal model

G. P.SenthilKumar, R. Suresh, M. Gupta, U. K.Mazumder;
Jadavpur University, Kolkata, India.

Chemopreventive effect of *embelia ribes* in 20-methylcholanthrene induced animal model
Abstract
The methanol extract of *embelia ribes* fruit was evaluated for its chemopreventive properties. Chemopreventive effect of the extract was evaluated against 20-Methylchlonthrene induced fibrosarcoma. Oral administration of the extract at the doses of 200 mg/kg b.w. significantly increased the lifespan of the fibrosarcoma bearing mice and reduced the tumor volume when compared to that of untreated tumor bearing mice. Biochemical parameters such as thiobarbituric acid reactive substances (TBARS), reduced glutathione (GSH) and antioxidant enzymes such as glutathione-S-transferase (GST), glutathione peroxidase (GPx) and catalase (CAT) were estimated in the hepatic tissue. The extract at the dose of 200 mg/kg b.w. significantly restored the altered biochemical parameters. Thus from the present investigation it can be concluded that the methanol extract of *embelia ribes* exhibited significant chemopreventive properties
***Key words*:** Chemoprevention, *Embelia ribes,* Antioxidants.

P2525. Impact of Invasive Weed *Ageratum conyzoides* L. on the Vegetation Structure and Dynamics in Himachal Pradesh, India

H. P. Singh[1], R. K. Kohli[1], D. Batish[2];
[1]Centre for Environment and Vocational Studies, Panjab University, Chandigarh, Chandigarh, India, [2]Botany Department, Panjab University, Chandigarh, Chandigarh, India.

Himachal Pradesh situated in northwestern India has a rich floral diversity owing to the variation in altitude (244-6750 m) and climate (from sub-tropical to temperate to alpine). However, during the last two decades a number of exotic invasive weeds have invaded thereby adversely affecting the native vegetation. Upon invasion these bring about irreversible changes in the structure and dynamics of natural communities. These weeds possess invasive characteristics such as fast growth, efficient resource utilization, high reproductive potential, wide ecological amplitude and lack natural predators unlike the native species. In this context, *Ageratum conyzoides* (Asteraceae) is an invasive weed from tropical America that has invaded India and encroached upon agricultural lands, grasslands, pastures, and forests. It forms monospecific stands in the area of invasion at the expanse of native plants and directly affects socio-economic condition and welfare of humans. The present paper attempts to describe the impact of invasion of *A. conyzoides* on the structure and dynamics of vegetation in the different ecosystems such as forest, grasslands and plantations.

P2526. Molecular Genetic Study of Invasive Species of *Heracleum* in Europe

Š. Jahodová[1,2], S. Trybush[1], O. Booy[3,2], I. Roze[4], A. Karp[1], M. Wade[3], H. Jones[2];
[1]Rothamsted Research, Harpenden, United Kingdom, [2]University of Hertfordshire, Hatfield, United Kingdom, [3]RPS Ecology, St. Ives, United Kingdom, [4]Institute of Biology, Latvian University, Salaspils, Latvia.

Tall species of *Heracleum* (giant hogweeds) were first introduced into Europe in the nineteenth century and are now widespread in many countries. There are three invasive species of the genus in Europe: *H. mantegazzianum, H. sosnowskyi* and *H. persicum* (or *H. laciniatum*). To elucidate genetic relationships between these species and to help locate the sources of origin of the invading plants we analysed samples from more than 100 populations collected in 19 European countries. We compared amplified fragment length polymorphism (AFLP) markers of three invasive species with two native species (*H. sphondylium, H. sibiricum*) and six Caucasian species. Our results confirm that *H. mantegazzianum* was introduced to Europe from the Caucasus and point to possible invasion scenarios. Our results did not suggest that *H. sosnowskyi* from Armenia and Europe were genetically close, indicating that this species in Europe either comes from other parts of the Caucasus, or that it was subject to some modifications (e.g. breeding) prior to its introduction. We suggest that *H. persicum* and *H. laciniatum* are synonyms in Scandinavia. Several cases of misidentification will be discussed.

P2527. USDA proposes revisions to plants for planting and propagation import regulations

E. S. Rudyj;
United States Department of Agriculture (USDA), Riverdale, MD, United States.

United States Department of Agriculture (USDA) proposes revisions to regulations 7 CFR 319.37 (known as Quarantine 37) governing imports of plants for planting and propagation to ensure adequate protection for agriculture, horticulture, forestry, and the environment against plant pests and noxious weeds. The modernization effort is prompted by plant imports transitioning from limited origin, fully treated, low numbered germplasm 'starter' material to plants of worldwide origin, rapidly distributed, and treated only when quarantine pests are found. Proposed regulations might include updated plant pest mitigation strategies; significant modifications to USDA regulatory approaches; and harmonized, transparent, consistent, and clear scientific and regulatory processes. Challenges include promulgating changes while simultaneously facilitating continued access to imported plant resources meeting strengthened US regulations for safety coupled with US commitments to international commerce.

P2528. Ecological Impact of the Invasive Shrub Lantana camara

G. Mathur;
Gargi College, New Delhi, India.

The bushes of lantana are highly floriferous and reproductively successful under favorable environmental conditions. The plant uses both sexual and vegetative reproductive strategies for propagation and proliferation. Lantana burns even when it is green and hence is a fire hazard. Cutting or burning of the aerial shoots leads to production of strong suckers and more vigorous growth. The plant has a heavily armored woody stem, opposie-deccusately arranged leaves and axillary, corymbose inflorescences. The flowers are of different colours depending on the variety as well as age of the flower. The role of butterflies and thrips in pollination and birds in seed dispersal further complicate the ecological impact of this invasive species. Lantana is a preferred host for the parasitic climber *Cuscuta*. This pernicious weed is responsible for carrying thrips, which are phyto-phagous insects and *Cuscuta* to newer areas which it invades, consequently destroying the natural vegetation.

P2529. Ergasiophytes in the flora of Ukraine

I. V. Kovtun;
M.G. Kholodny Institute of Botany, National Academy of Sciences of Ukraine, Kyiv, Ukraine.

The aim of our study was to assess the influence of ergasiophytes on the natural vegetation. It has been revealed during the investigations that 210 species of plants can be classified as ergasiophytes by the mode of their immigration. By the naturalization status, there are 27 epecophytes and 53 agryophytes among them. Among agriophytes, there are 10% annuals, 30% herbaceous polycarpic plants, 10% shrubs, and 50% trees.Agriophyte trees (Acer negundo L., Elaeagnus angustifolia L., Ailantus altissima (Mill.) Swigle and others) are most dangerous for the natural plant communities; they are aggressively invading the meadows, steppe-meadows and abandoned pastures in the park. The invasives grow faster than the natives, shading their neighbors and thus stunting their grow. In some sites, these shrubs form extensive dense growths, resulting in the exclusion of other species. The shrubs affect natural areas by displacing native species, changing the vegetation structure and impending its regeneration.

P2530. Invasive plants in Armenia

M. G. Fayvush;
Yerevan State University, Yerevan, Armenia.

Armenia is one of the newly independent states presently situated in the main transport route between Iran, Georgia and Russia. The very low activity of the State Quarantine Service has facilitated the entry of a number of new species of plants into Armenia which may become invasive weeds in natural ecosystems, and further invade the territories of other countries. Today we know about penetration and spreading here of some new invasive species of plants. Unlikely, at present, modern data on the spread and distribution of invasive plant species in the territory of the Republic of Armenia, and their impact on agricultural and natural areas are missing.

On the other hand, Armenia is the motherland for numerous species of plants, which have known as invasive weeds in different countries. There are 4 Armenian plant species in the list of "100 of the World's Worst Invasive Alien Species" (ISSG/IUCN). More than 30 species are growing in Armenia, and at the same time they are very dangerous weeds in the North America. Investigation of potentially invasive species in Armenia may be very important for biological control in different countries around the World.

P2531. Invasive plants in Ukraine

V. V. Protopopova, M. V. Shevera;
M.G. Kholodny Institute of Botany, National Academy of Sciences of Ukraine, Kyiv, Ukraine.

Highly invasive species are defined in this study as aliens characterized by stress-tolerant strategies, active dispersal in large areas, high competitive ability, persistence of populations, and potential ability to invade semi-natural and natural plant communities.

Highly invasive species are represented in the Ukrainian flora by at least 91 species (0.9% of the alien fraction), including 24 archaeophytes and 66 kenophytes. By naturalization, they are subdivided into agriophytes (19 species), epoecophytes (66), and ergaziophytes (6). Annuals, xeromesophytes, and species of North American origin prevail. According to invasive ability, 5 groups are distinguished: (1) species able to occupy the whole country - 20 spp.; (2) aggressive species in different phytogeographical regions - 31; (3) aggressive species with local distribution - 12; (4) species occurring in the whole Ukraine in all suitable ecotopes, but mainly in man-made habitats - 18; and (5) potential aggressive species - 10.

P2532. The role of tree-fall gaps in the invasion of exotic plants in forests: the case of *Rubus phoenicolasius* Maxim (Rosaceae) in Maryland, USA

D. L. Gorchov[1,2], D. F. Whigham[1], A. F. Innis[1,3];
[1]Smithsonian Environmental Research Station, Edgewater, MD, United States, [2]Miami University, Oxford, OH, United States, [3]University of Maryland, College Park, MD, United States.

Invasive plants often enter forests via tree-fall gaps, but can invade an entire stand only if individuals either establish or persist under closed canopy. We evaluated the role of gaps for *Rubus phoenicolasius* in forest stands in Maryland, USA. A native of Asia, *R. phoenicolasius* is invasive in disturbed sites and successional forests in eastern USA.

We censused 15 x 15 m plots centered in gaps created in a 2002 storm vs. random points in adjacent young and old deciduous stands. In the old stand, established *R. phoenicolasius* ramets were present in 10 of 20 gaps, but only 2 of 19 random plots. Ramet density and cane length were greater in large v small gaps, and tip-rooting was limited to large gaps. In the young stand ramets were in all 4 gaps and 4 of 5 random plots.

Seedlings and fruits were frequent in the young stand. In the old stand seedlings were only in 10 gaps and fruiting occurred only in 3 large gaps.

Thus, tree-fall gaps are required for seedling establishment and fruiting in mature forest. We are investigating whether established ramets persist with canopy closure in the forest and under different shade treatments.

P2533. The Impacts Caused by the Invasion of P*rosopis juliflora* (SW) D.C. over the Structure and the Diversity of Trees in the Caatinga Vegetation, Northeast Brazil

L. Alves de Andrade[1], L. P. Félix[2], F. X. Oliveira[1], P. C. F. Lima[3], F. C. R. Vilar[1], F. J. Marques[1], D. B. Medeiros[1], L. S. B. Oliveira[1], A. S. Alves[1];
[1]UFPB/CCA/DF/LEV, Areia - Paraíba, Brazil, [2]UFPB/CCA/DF/LB, Areia - Paraíba, Brazil, [3]EMBRAPA/CPATSA, Petrolina-Pernambuco, Brazil.

Prosopis juliflora (SW) D.C.was introduced in the Brazilian semi-arid in the 40s. It was broadly divulged but it invade the caatinga, mainly gallery forests, sites which retain a great biodiversity and endemic species. In order to study this problem, invaded and non invaded sites were selected in four counties: Monteiro and Taperoá (I and II) in the state of Paraíba; Carnaúba dos Dantas and Acari (III and IV) in Rio Grande do Norte. In each county twenty 400 m^2 plots were used and 5,151 adult individuals were identified. Non invaded sites showed 35, 32, 37 and 15 trees species and Shannon-Weaver index values (H'): 2.81; 2.74; 2.33;1.96 for I, II, III and IV. The invaded sites showed: 15, 11, 04 and 06 species and H' values of 0.56; 0.80; 0.24; 0.14 for I, II, III and IV, respectively. Values of importance (VI) and cover (VC) for *P. juliflora* were: I) 212.2 and 183.7; II) 184.50 and 162.80; III) 245.2 and 189.66 IV) 245.59 and 183.09. A few native species resist to *P. juliflora*: *Capparis flexuosa* L. and *Cereus jamacaru* DC. Typical native species do not occur in the invaded areas: *Anadenanthera macrocarpa* (Vell.) Brenan; *Astronium urundeuva* (Fr. All.) and *Schinopsis brasiliensis* Engl.

P2534. Contrasted population dynamics of a dangerous, endangered species in alien and native populations

R. Salguero[1], **M. García**[2], F. Ojeda[3], J. Arroyo[1], J. A. Mejías[1];
[1]Dept. Biología Vegetal y Ecología. Universidad de Sevilla, Seville, Spain, [2]Instituto Pirenaico de Ecología (CSIC), Zaragoza, Spain, [3]Dept. Biología. Universidad de Cádiz, Puerto Real (Cádiz), Spain.

Range changes and extinctions are natural processes at evolutionary time scale. However, human activities may alter them profoundly. For instance, an endangered species in one place may become an invasive alien in distant regions.

Rhododendron ponticum L. (Ericaceae) is a Tertiary, relict species with a disjunct, narrow distribution restricted to both western and eastern ends of the Mediterranean basin. In the last interglaciar, western populations occurred as far North as Ireland, but this species went extinct from the British Isles in the last glaciar maximum. In 1763, it was re-introduced for gardening purposes, and it currently behaves as an aggresive alien in British natural communities, threatening biodiversity.

A Markov Chain approach was used to analyse population dynamics of this species in both alien and native locations. Remarkable demographic differences were found not only between both kinds of populations, but also between coastal and inland alien stands.

This predictive modelling approach will help to assessing extinction risk of native populations and potential invasiveness of alien stands in the face of Global Climate Change.

P2535. Combating Noxious Exotic Weed *Mikania micrantha* in the Field

M. Li[1], B. Wang[2], B. Liu[2], P. Yu[2], H. Yu[2], X. Cheng[2], Q. Zan[3], Y. Wang[2];
[1]National Key Laboratory of Biological Control, Sun Yatsen University, Guangzhou, China, [2]National Key Laboratory of Biological Control, Sun Yatsen University, GUANGZHOU, China, [3]Guangdong Neilingding Futian National Nature Reserve, Shenzhen, China.

Mikania micrantha is a noxious alien weeds with a slightly woody vine species belonging to Asteraceae. It was introduced to Hong Kong as early as 1884 and now spread far beyong Hong Kong. *M. micrantha* was able to use shrubs and small trees as its support and then smothered the supports with thick mantels of its shoots.

Physical removal experiment showed that uprooting all the creeping stems completely was diffilcult. The remained creeping stems sprouted in a short time and some of the slashed stems revived under considerable precipitation and the effect could only maintain for several months. Sulfometuron methyl was an effective herbisde to kill the weed. *Cuscuta campestris*, a parasitic plant, was able to suppress of *M. micrantha*. No other species was found to be dead caused by *C. campestris* within the infected circle. Restructuring plant community with multi species planting was conduct. Regional, fast growing, broad canopy and tall tree were criteria for selecting plant species. Within two years, the canopy of the community became continuous and suppressed the underneath weed, especially *M. micrantha*, indicating the effectiveness of the restoration measurement.

P2536. Root growth and environment, The carbon cost of root function in boreal forests

L. Kutschera, H. Persson;
Pflanzensoziologisches Institut, 9020 Klagenfurt, Austria.

The first function of the root is to take up the surplus of carbohydrates produced by the shoot. Even in fine roots there is a high level of stored carbohydrates (Persson 2000): The gravity turns the direction growth by the movement of water vapour inside and outside of plants. The upward growth is connected with water supply for the elongation growth from inside, the downward from outside. The root body is protected by the root cap against too early water uptake. The root cap becomes often asymmetric and in consequence the water uptake and water loss in the elongation zone is asymmetric too.

Data from various European forest stands suggest annual turnover rates of 2-4 times the average fine-root biomass. The root function is extremely costly and is enhanced by a high carbohydrate supply. The aboveground capacity to supply carbohydrates by photosynthesis governs the long-term root and mycorrhizal growth rate. Roots can grow in any direction (Kutschera et al. 2004). Carbohydrates are stored at high levels in the fine roots; starch levels of 25-30 % are frequently found. Tree roots can persist in the soil and survive for several years even when photosynthesis is restricted.

P2537. Roots and pseudobulbs of lithophytic orchids

M. N. Telepova-Texier[1,2];
[1]Muséum National d'Histoire Naturelle, Paris, France, [2]Komarov Botanical Institute, St-Petersburg, Russian Federation.

Root and pseudobulb anatomy of twenty orchid genera has been understood (mountains of Elephants Chain, Cambodia). Many of study species are lithophytic plants (60%). Generally, they have stem origin pseudobulbs, composed of 1-3-(5) internodes (Bulbophyllum, Chelonistele, Coelogyne, Eria, Flikingeria, Liparis, Pholidota genera). One of few species, who has pubescent pseudobulb is Eriodes barbata. The pseudobulb has three separated meristematic poles. One of them gives the leaves, the second - the inflorescens, and the third - the new bud. Majority of lithophytic orchids, being protected by the moss, have the green succulent roots, pasted often by pair on the rock. The long pause in life cycle of this orchids decides for development in roots and stem not only reserving, but the photosynthetic and the mecanical tissues too. The chlorenchyme and the aerenchyme are formed in their median parenchyma. In exterion parenchyme and epiderme are present numerous raphids or druses. Uncommon in this region terrestrial orchids (5%) have also the greenish pseudobulbs, who are this adaptation for the survive during the forest-fire (Arundina and Spathoglottis genera).

P2538. The root growth in the young forest ecosystems of Central Siberia

L. V. Mukhortova, E. F. Vedrova;
V.N.Sukachev Institute of Forest, Russian Academy of Science, Siberian Branch, Krasnoyarsk, Russian Federation.

To estimate annual production of fine tree roots in the forest ecosystems of main forest-forming species in Siberia we used ingrowth method.
The results of our research showed that the rate of root growth for coniferous tree species is in 7 times faster than for deciduous species.
The root growth was the fastest at the first year of the experiment. First year growth is the potential possible rate of root growth for these species under natural conditions. And all differences of root growth rate depend on species features because it was under equal environmental conditions for all cases.
In the following years the rate of root growth decreased. Mean annual tree roots growth rate made up 86.9 - 42.4 - 13.7 - 97.1 - 19.4 - 9.1g/m^2 for arolla pine, Scots pine, larch, spruce, aspen and birch, accordingly. Annual root death made up 3.1-4.6% of annual growth for coniferous species and 2.3-14.4% of annual growth for deciduous species.
The fine roots stock in the young forest ecosystems is annually renewed on 21.1-24.2% under coniferous stands and on 2.9-4.4% under deciduous stands.

This research was supported by the Projects No 03-04-20018 of the Russian Fund of Fundamental Research

P2540. Effects of copper stress on root system morphology and topology of C*annabis sativa* plants grown in hydroponic culture.

G. Berta, E. Bona;
Università del Piemonte Orientale "A. Avogadro", Alessandria, Italy.

Root system morphology is genetically determined and varies among species and individuals; it can be modified by many environmental factors, including nutrients, water availability, biotic and abiotic stress (as heavy metals). Copper (Cu) is a micronutrient, toxic for plants at high concentrations. Hemp (*Cannabis sativa*) has a potential role in phytoremediation of heavy metals but till now its ability to tolerate and/or accumulate copper has been scarcely studied. The aim of our work was to investigate the influence of two copper concentrations on the root system architecture of hemp (*C. sativa*) plants grown in hydroponic culture, using morphological and topological analyses. The presence of copper at high concentrations (50µM and 100µM) in the nutrient solution induced a drastic and highly significant reduction of all the considered parameters (e.g. root, stem and leaf fresh weights, total root length, root system branching, total root surface and projected area, mean root diameter). Moreover copper treatments influenced the topological pattern of the root system, that in treated plants was clearly herringbone-like.

P2541. Available Micro Nutrients as related to soil physical and chemical properties.

N. Bassirani, I. A. Sadeghi Azar;
Zabol University, Zabol, Islamic Republic of Iran.

Profile distribution was investigated for DTPA-extractable Zn,Cu,Mn and Fe in relation to depth and important soil characteristics in ten representative soil profiles of Hissar.There was specific pattern of distribution of available Cu,Mnand Fe due to alluvial nature of soils. A decreasing trend for available Zn with increasing depth was observed. Mean values for available Zn,Cu,Mn and Fe were .27 ,.81,4.38 and 2.98 PPM respectively. Distribution of Mn was influenced inversely by soil pH,Ec,ESP and CaCo3 content. Distribution of Fe and Cu also was influenced inversely by ESP. Distribution of Cu was influenced inversely by CaCo3 .Organic carbon content controlled dominantly of all the four Micro-nutrients.Cation exchange capacity (CEC)content controlled dominantly only the available Cu.Four multiple regression models to predict the available Micro-nutrients(Zn,Cu,Mn and Fe)OF a soil from organic carbon and CEC is also presented. The amount of correlation was 46,53,42 and 41 respectively.All the soil samples were deficient in available Zn,medium in Cu and low to medium in Mn and Fe.

P2542. Biological control of common root rot of wheat (*Bipolaris sorokiniana*)by *Trichoderma* isolates

A. Roustaii, M. Salehpour, H. R. Etebarian, G. Khodakatamian, H. Amanian;
Department of Plant Protection, Abourayhan Campus, University of Tehran, Tehran, Islamic Republic of Iran.

Trichoderma viride T112 and *T.viride*(MO), *T.harzianum*(M) and *T.harzianum*T 194 were used as potential biological agent for control of common root rot caused by *Bipolaris sorokiniana.* Cell free and antifungal metabolite produced by all *Trichoderma* isolates inhibited growth of *Bipolaris sorokiniana* The inhibition varied among isolates of *Trichoderma* and ranged from 58.2 to 93.93% using the cellophane overlay method and from 66.66 to 98.25% in volatile test. Mycelial growth of *B. sorokiniana* was numerically reduced more by *T. viride* T112 than the other isolate tested(P<0.01). The ablity of *Trichoderma* isolates to reduce the incidence of common root rot of wheat in the glasshouse condition was investigated The seed soaking treatment and also soil treatment with *T. vride* T112 and *T.viride* (MO) were the most effective in reducing infection by the pathogen compared with the healthy control (P<0.01) All isolates of *Trichoderma* plus pathogen or alone increased plant height, fresh and dry weight of root and shoots of wheat seedling compared with the corresponding controls . Among *Trichderma* isolates, *T.viride*T112 and *T.viride*(MO)) proved to be the best supporting growth of wheat (P<0.01).

P2543. Portuguese Ethnobotanical Artefacts Collection at Beja Botanical Museum

L. M. Mendonça de Carvalho[1], F. M. Fernandes[2], M. Almeida[3];
[1]Escola Superior Agraria de Beja (Museu Botânico), Beja, Portugal, [2]Escola Superior de Educação de Beja, Beja, Portugal, [3]Faculdade de Ciências e Tecnologia, Universidade de Coimbra, Portugal.

Botanical Museum of the Polytechnic Institute of Beja has a collection of artefacts made with Portuguese plant raw materials that have been assembled in the last three years with the support of the Ford Foundation (Portugal). The collection also includes the plant raw materials.
The artefacts were obtained in all regions of Portugal, including Madeira and Azores Islands.
The collection includes musical instruments (*Fraxinus angustifolia*), baskets, hats and finger protections (*Arundo donax*), cork spoons (*Quercus suber*), spoons (*Erica arborea*), baskets (*Secale cereale*, *Rubus ulmifolius* and *Salix viminalis*), dolls (*Zea mays*), sculptures (*Ficus carica*), decorative items (*Allium cepa* and *Allim sativum*), embroideries (*Gossypium* sp.), fans and brooms (*Chamaerops humilis*), toothpicks (*Salix* sp.) and others.
These artefacts will be used as reference vouchers for future studies on Portuguese Ethnobotany.

P2544. Tolerance of vascular plants in anthropogenic habitats of Ulan-Ude city

A. V. Sutkin;
Institute of general and experimental biology SD RAS, Ulan-Ude, Russian Federation.

Anthropotolerance - a private example of phytotolerance or stability of plants. In author opinion any estimation of anthropotolerance should be based on mathematical parameters, and not just on visual estimation. Proceeding from this as such parameter we choose activity of species (À) which connects in itself"occurrence or ecologo-coenotic amplitude".
We make attempt to connect a parameter of species activity in various anthropopressure zones of Ulan-Ude city with the certain values of a gemerobie scale.
As a result of our researches it is revealed, that values of plant activity can vary widely on anthropopressure zones and in case of Ulan-Ude city do not reach the greatest possible size 22,4 points. It is observed, that in spite of the fact of increase floristic variety in wooden building subzones, connected with the presence of unhumbled sites of plant cover, nevertheless there are same high active species, as in stone building subzones.

P2545. Anti-inflammatory effects of total extract of curcuma amada in a rheumatoid arthritis rat model.

H. R. Rasekh[1], M. R. Ahmadian[1], M. Kamalinejad[1], F. Madadi[2];
[1]Shaheed Beheshti School of Pharmacy, Tehran, Islamic Republic of

Iran, [2]Shaheed Beheshti School of Medicine, Tehran, Islamic Republic of Iran.

Previous studies have suggested efficacy of parenteral administration of Curcuma amada in animal models. In this study, topical effect of total extract of Curcuma amada (CA) on chronic inflammatory response induced by Freund's Complete Adjuvant in rat was studied.

The adjuvant contained heat killed mycobacterium tuberculosis suspended in mineral oil (Arlacel A) and light paraffin. Injections were made in the right ankle foot and tibio-tarsal joint region of rats. On day 15 following adjuvant administration, animals were treated with 100 mg/kg dose of the total alcoholic (50%) extract on paw daily for 20 days. Body weight, arthritic index, joint diameter and blood level of TNF-alpha were recorded during the experiment and at the last day of treatment. The data indicated the alcoholic extract could significantly ($p<0.05$) reduce joint diameter (29%) , arthritic index and blood level of TNF-alpha (61%) of treated animals compared with control group. The data points out to the potential efficacy of topical administration of CA extract in rats.

P2546. Developing of apple scab warning services in Uttaranchal Himalayas

K. P. Singh, M. s. chauhan, a. singh, J. Kumar;
College of Forestry and Hill Agriculture, Tehri, India.

Effect of temperature, rainfall, leaf wetness and relative humidity known to exert a powerful influence on scab (*Venturia inaequalis*) development, was studied under field conditions during 1993 to 2004. 608,4 to 672,6 degree-days were necessary for discharge of 50% of the ascospores. PAD were varied from 0 to >720000 from place to place in Uttaranchal Himalayas. In some of the place the PAD was very low (<1000), there were only two sprays were required at the end of the primary inoculum. In epidemic year 1996 at Bhatwari fruit belt, reducing one fungicide applications in the year under reference. In the warning system the DMI curative fungicides were used in orchards at many places of Uttaranchal hills. The same fungicides were also applied at short intervals in the protective treatment. The warning treatment under these conditions gave a reduction of spraying frequency upto 3 to 4 times compared with regular protective spray. It is concluded that the use of warning equipment (µMETOS) together with a curative fungicide gives a sufficiently safe and effective control of apple scab in Uttaranchal Himalayas. Detailed results would be presented.

P2547. The Effect Of Three Different Planting Areas And Corm Size On Some Morphological And Biological Characteristics And Yield Of Saffron (*Crocus sativus* L.) In Kocaeli Province Of Turkey

A. Çavusoglu, E. Erkel;
Kocaeli University, Kocaeli, Turkey.

Saffron (Crocus sativus L.) is a cormous plant has the most economic value as medicinal and aromatic ingredients world wide.

The study was carried out with 3 different planting areas (field, greenhouse and plastic tunnel) and 2 different corm size A (10-27 mm) B (28-45 mm) in 2003-2004 growing season, under Kocaeli (Turkey) climatic conditions.

According to the statistical data; the longest harvest period was obtained from greenhouse-B corm size with 56 days; the highest flowering was 2.66 flowers/plant in greenhouse-B corms; the tallest leaf lenght was 47.17 cm/plant in greenhouse-B corms; the highest leaf number was 29.25 leaves/plant in greenhouse-B corms; the highest rate of saffron fresh yield was 4691 g/da obtained from greenhouse-B corm size; the highest rate of saffron dried yield was obtained from greenhouse-B corms with 877.53 g/da; the highest daughter corm rate was 4.26 corms/plant obtained from greenhouse-B corms; the highest daughter corm size was obtained from plastic tunnel-B corms as 29.619 mm/corm. Dry saffron yield was harvested from greenhouse (465.765 g/da) that was higher than the yield obtained both from the field and the plastic tunnel.

P2548. Development of descriptor list for evaluation genetic resource of service tree (*Sorbus domestica* L.)

J. Cervenakova, M. Miko, J. Nôzková;
Slovak University of Agriculture in Nitra, Nitra, Slovakia.

Service tree (*Sorbus domestica* L.) belongs to introduced species in Slovakia. Most of trees succeed age more than 200 years. Adapted population is possible to use in food industry, pharmacy, landscaping and in wood-working industry too. For all that evaluation of population for purpose to determination variability quanitative and qualitative characters on trees, leaves, flowers, fruits and seeds level was realized. At leaves studied lenght range 120 - 331 mm, width range 42 - 163 mm and lenght of leaf stalk range 19 - 95 mm. Fruits lenght range 14.3 - 38.2 mm, width range 13.1 - 41.2 mm and weight range 2.9 - 36.1 g was found. Observed seeds had lenght in range 5.2 - 9.1 mm, width range 4.0 - 6.3 mm and weight range 0.02 - 0.24 g. It was found strong variability in shape of leaves, fruits and seeds. Experimental data and image documentation is used on development of descriptor list for evaluation species *Sorbus domestica* L. It makes possible characterise genotypes and determinated genotype differences.

P2549. Micropropagation of the medicinal plant *Stemona tuberosa* Lour.

N. Montri, C. Wawrosch, B. Kopp;
Department of Pharmacognosy, University of Vienna, Vienna, Austria.

Stemona tuberosa Lour. is a medicinal plant belonging to the Stemonaceae family. It has been used for the treatment of respiratory diseases in China and other East Asian countries for a thousand years. The indiscriminate collection of wild growing populations is increasing every year, which is particularly alarming because the important alkaloids are located in the rhizome of the intact plant. Vegetative propagation techniques have been developed but many problems arise due to infections and the time consuming process. In vitro propagation might allow the rapid production of disease free plantlets for field culture.

A micropropagation protocol of *S. tuberosa* was developed using shoot culture. Shoots were induced from *in vitro* shoot and node explants on solid Murashige and Skoog (MS) medium. For the multiplication step shoots were cultured on MS medium supplemented with various types and concentrations of cytokinins. Several combinations of BAP and IBA were tested, too. Shoot multiplication was best when 20 µM BAP were used. Regenerated shoots were successfully rooted on free hormone MS medium and plantlets could be established in the greenhouse.

P2550. Asymmetric fusion between protoplasts of Helianthus annuus L. and UV-treated protoplasts of H. mollis L.

S. M. Vesa[1], A. Gilbert[2];
[1]Babes-Bolyai University, Faculty of Biology, Plant Genetic manipulation Group, Cluj-Napoca, Romania, [2]INP-ENSAT, Laboratoire de Biotechnologie et Amelioration des Plantes, Toulouse, France.

Being one of the four most important oil crops in the world, sunflower is the subject of numerous breeding programs. Enlarging its genetic base will allow it to be better adapted to environmental conditions. Wild sunflower species served as genetic base for the modern sunflower, carrying traits as disease resistance, cytoplasmic male sterility.

H. annuus line HA300B protoplasts were isolated from 7-days old hypocotyls and H. mollis protoplasts from mesophyll of in vitro grown plants. The isolation and purification of protoplasts was according to Krasnyanski and Menczel (1995) protocol. H. mollis protoplasts were irradiated with UV light (2 µmol m-2 s-1) for 5 to 60 minutes and the efficiency of the treatment/protoplast viability were determined.

The protoplasts from the two species were mixed at a density of 4x106 protoplasts/ml and electrofusion was induced using 3 pulses of 50 µsec and intensity 500V/cm. The fusion products were immobilised in agarose droplets and cultivated according to Krasnyanski and Menczel (1995).

Up to this stage of experiments several hybrid calli were regenerated, some of them showing signs of regeneration (green buds on the calli).

P2551. Influence of Mannitol and Sucrose on the Olive In-vitro Culture for Iranian Cultivars (Zard and Dezful)

F. Tabesh[1], M. Peyvandi[2], M. Hosseini-Mazinani[3];
[1]Science and Research, Azad University, Tehran, Islamic Republic of Iran, [2]Dept. of Biology, North Tehran Azad University, Tehran, Islamic Republic of Iran, [3]National Research Center of Genetic Engineering and Biotechnology (NRCGEB), Tehran, Islamic Republic of Iran.

Carbohydrate source and its concentration play a significant role in improving olive proliferation procedure. This paper compares the impacts of two carbohydrates, mannitol and sucrose on microshoots growth of Iranian olive cultivars Zard and Dezful. For this purpose, initially, we collected uninodal explants removed from

3-year greenhouse grown plants. The cultivars explants were individually cultured in OM media containing sucrose or mannitol (18 and 30 g/l), augmented with 2iP (4 mg/l). Then, we performed the first explants subculture in OM media with 2iP (4mg/l), containing mannitol or sucrose (30 g/l), after five weeks. The second subculture was accomplished employing OM media containing mannitol or sucrose (30 g/l), supplemented with 2iP and BAP (1 and 2 mg/l) separately or compoundly. The results of this research work are as follows. For Dezful cultivar mannitol (30 g/l) supplemented with 2iP (2 mg/l) provides the best proliferation results in the all steps. For Zard cultivar in the initial step sucrose (30 g/l) and in the rest of successive subcultures mannitol (30 g/l) are suitable carbohydrate sources.

P2552. *in vitro* germination of seeds of *Puya raimondii* harms (Bromeliaceae)

N. Canto, F. Guzman, R. La Rosa;
Faculty of Natural Sciences and Mathematic. Federico Villareal University, Lima, Peru.

Seeds of *Puya raimondii* were collected, on July 2002, from Calipuy located in Santiago de Chuco, district of La Libertad - Perú. Sow was be held on July 2004, so seeds had 2 years of dormancy, although is known that this kind of seeds only have one year of viability.The basic medium was composed for inorganic salts used in hydroponics, plus thiamine HCl 100 ppm, riboflavin 40 ppm, pyridoxine HCl 40 ppm, nicotinamide 400 ppm, sucrose 3% (w/v), agar 0.8% (w/v) and combination of next hormones IAA (0, 0.5, 1, 1.5 ppm) and GA_3 (0, 0.5, 1, 1.5 ppm) in a factorial design, pH and electric conductivity were adjusted to 5.6 and 2.3 mS, respectively, before sterilized by autoclaving at 121°C and 15 lb/plg^2 for 15 minutes. Seeds were disinfected with sodium hypochlorite 1.5% and rinse 3 times with sterile water and sowing was held in a chamber sterilized with UV-C radiation, after that, tubes were carried to chamber for germination at 16°C ± 2°C in darkness. Germination occurs 10 days after sow, becoming to 55 % of germination in media supplied with GA3 1 ppm and IAA 0.5 ppm. Moreover, we demonstrated that this seeds can germinate after 2 years of dormancy.

P2553. Analysis effects of different factor on regeneration and transformation of three Iranian cultivar of tomato (*Lycopersicon esculentum*)

H. H. Hashemi Sohi;
NRCGEB, Tehran, Islamic Republic of Iran.

Abstract

Tomato *(Lycopersicon esculentum*) is one of the most important vegetable crops and a genetic model for improving other dicotyledonous crop plants. However, tomato transformation is still not routine nor reliable. In this research effect of three genotypes (KalG, Kal early, Su2270 as the commercial cultivars in Iran), two explants (cotyledon and hypocotyls), growth regulators (BAP $2mgl^{-1}$, zeatin $2mgl^{-1}$) and two strain of *Agro bacterium tumefaciense* (pGV3850 and LB4404)on regeneration and transformation of tomato plants were investigated. In this transformation method, no feeder layers of tobacco, petunia or tomato suspension cultures were used, Our results showed there were significant differences between genotypes and explants in shoot number formation. KalG had maximum shoot number in cotyledon and Su2270 had maximum shoot number on hypocotyle. Maximum shoot regeneration was obtained with zeatin $2mgl^{-1}$. Transformation rate was 6% for cultivar Kal early to 10% for cultivar KalG .Also it seems strain pGV3850 of agrobacterium was more efficient compared LB4404 .Transformation events were confirmed by Gus assay and PCR analysis.

P2554. Micropropagation of Hippeastrum puniceum (Lam.) Kuntze (Amaryllidaceae).

A. C. Amaral;
Universidade de Brasília, Brasília, Brazil.

The Amaryllidaceae family includes numerous Brazilian species with ornamental potential, particularly Hippeastrum puniceum (Lam.) Kuntze, an herbaceous plant with attractive flowers. This genus occurs from Mexico all the way to Argentina, and Brazil is home to 20-30 Hippeastrum species. H puniceum has not been domesticated, so little is known about its propagation. Micropropagation is a valuable technique for production of high quality plants, to intensify multiplication and to speed up propagation of target species. The aim of this study was to develop a micropropagation protocol for H. puniceum. Different explant types, growth media and growth conditions were evaluated. Bulb sections and leaf discs were excised and cultivated on Murashige & Skoog (1962) growth medium supplemented with different growth regulators, at various concentrations. The cultures were maintained under a 16 hrs light photoperiod and 25 ± 2°C. Bulb sections were highly responsive and produced 4-5 bulblets/section introduced in vitro. The bulblets developed into normal plants after transplanting to pots containing a proper substrate and transfer to the greenhouse.

P2555. Establishment of an in vitro amyloplast inducing system using cultured tobacco BY-2 cells.

Y. Miyazawa[1], A. Sakai[2], S. Yoshida[3], T. Kuroiwa[4], H. Takahashi[1];
[1]Graduate School of Life Sciences, Tohoku University, Sendai-shi, Japan, [2]Nara Women's University, Nara-shi, Japan, [3]RIKEN, Wako-shi, Japan, [4]Rikkyo University, Tokyo, Japan.

Amyloplasts are starch-containing plastids that play important roles for both plant carbon metabolism and human diet. To examine the molecular mechanisms controlling the amyloplast development, an amyloplast inducing system in cultured BY-2 tobacco cells was used. In the present study, we examined the relationship between starch-storing cell development and phytohormones on amyloplast formation. As a result, auxin addition repressed amyloplast formation, whereas, cytokinin addition accelerated starch accumulation, regardless of the timing of hormone addition. In addition, reduction of endogenous cytokinin, lead to a reduction of starch accumulation. We also found that amyloplast can be reconverted into proplastids by auxin addition. All these changes are correlated with the changes of starch synthesis gene expressions. These studies clearly demonstrated that auxin and cytokinin exert opposite effects on amyloplast formation by regulating the starch synthesis gene expression, and we propose that this simple amyloplast induction system provides an ideal model for analyzing the process of differentiation and dedifferentiation of amyloplasts.

P2556. Effect of abiotic stress on regeneration and psoralen content in a medicial plant, *Psoralea corylifolia*

D. Pande, P. S. Srivastava;
Jamia Hamdard, New Delhi, India.

World wide soil salinity has become a major argicultural threat. Substantial areas of earth's potentially producvtive lands are affected by salinity and alkalinity. Considering the importance of salt tolerant plants in reclamation of the wastelands it is beneficial to adopt biotechnological approaches to raise stress tolerant plants of varying economic utilities. Experiments were conducted to develop salt tolerant plantlets of *Psoralea corylifolia* (Fabaceae), a potential source of psoralen and isopsoralen used in the treatments of leucoderma, leprosy psoriasis and inflammatory diseases. The in vitro cultures were subjected to various concentration of NaCl (0-400 mM). NaCl incoroprated in MS medium supplemented with IAA + Kn + Ad + CH promoted growth, percent regeneration, number of shoots and leaves till 75 mM NaCl. Psoralen quantified through HPLC exhibited 2-fold enhancement at 75 mM NaCl. Higher concerntration of NaCl inhibited shoot and root growth and gradual reduction in psoralen. Proline accumulated in salt tolerant cultures as a sequel to salt stress.

P2557. Zygotic embryo culture of *Pinus heldreichii* and *Pinus peuce*

D. Stojicic[1], S. Budimir[2], L. Culafic[2];
[1]Institute of Forestry, Belgrade, Serbia and Montenegro, [2]Institute for Biological Research Sini a StankoviÍ , Belgrade, Serbia and Montenegro.

Pinus heldreichii (Christ.) and *Pinus peuce* (Gris.) are important, endemo-relict, high-mountain pines of Balkan Peninsula. These two pines are adapted to dry and very hot summer with intensive solar radiation, also to the cold conditions of the winter period. Such ecological characteristic enabled them to build powerful belt of forest vegetation, but today very degraded by human activities. *Pinus heldreichii* and *Pinus peuce* are usually propagated by seed, but seed production in natural stands is limited. Zygotic embryo culture has to be method to study the factors that control growth and differentiation of embryos. The aim of this study was to elaborate factors influencing the conversion of isolated mature zygotic embryos of *Pinus heldreichii* and *Pinus peuce* into plantlets, and to determine the influence of different nutritional factors to this conversion. Culture of isolated zygotic embryos was established to improve protocols for successful somatic embryogenesis of these two pines.

P2558. *In vitro* propagation and conservation of Thai Zingiberaceous medicinal plants

S. Prathanturarug[1], N. Soonthornchareonnon[2], W. Chuakul[1], T. Jenjittikul[3], P. Saralamp[1];
[1]Department of Pharmaceutical Botany, Faculty of Pharmacy, Mahidol University, Bangkok, Thailand, [2]Department of Pharmacognosy, Faculty of Pharmacy, Mahidol University, Bangkok, Thailand, [3]Department of Botany, Faculty of Science, Mahidol University, Bangkok, Thailand.

The project was performed to apply plant biotechnology for the production and conservation of Zingiberaceous medicinal plants. We established efficient protocols for *in vitro* propagation of *Curcuma longa*, *Gagnepainia thoreliana*, *Kaempferia parviflora*, and *Zingiber petiolatum*. The explants were cultured on MS medium supplemented with high concentrations of plant growth regulators (PGR) prior to transfer to PGR-free MS medium. Under these conditions, the shoot induction rates of 6-34 shoots/explant were obtained after 12-20 weeks of cultures. We also developed a protocol for conservation of 5 species, i.e. *Curcuma longa*, *Kaempferia galanga*, *Hedychium ellipticum*, *Zingiber petiolatum,* and *Zingiber niveum*, using slow-growth conditions. *In vitro* cultures could be effectively maintained for 6 months at 25°C on MS medium supplemented with mannitol at concentrations of 1-3% as a growth retardant. Shoots were subsequently recovered and multiplied on MS medium. Rooting was spontaneous achieved. Rooted shoots were successfully transferred to soil and grown in the field conditions.

P2559. Endemic *Aster albanicus* species: a case study on its tissue culture and possible genetic changes induced

E. Kongjika, Z. Zekaj, A. Bacu, E. Caushi, B. Preci;
Biological Research Institute, Tirana, Albania.

Aster albanicus D., an endemic endangered plant was analyzed to find the optimal conditions of propagation and possible genetic somaclonal variation imposed by “in vitro” culturing via RAPD markers.

The explants were organized (meristems, apical and lateral buds) and unorganized systems (leaf pieces). The media were: proliferation of organized explants [MS/2, ANA:GA_3 (1:1)], subculturing [BAP:ANA (10:1)], rooting [AIB:GA_3 (3:1)]. The leaf pieces were inoculated in MS, BAP:ANA (1:10). The opposite ratio was applied for the meristemoids and the regeneration of plantlets. Direct organogenesis resulted in high proliferation. Young buds of different origins showed differences in their indicators. Medium for meristems was optimal for buds; plantlets derived from apical buds developed better. A quick formation of adventitious shoots was observed. AIB induced a high index of rooting. 94.7% of pieces had callii after five weeks, and meristemoids appeared at 92% of the callii in six weeks. The high ratio BAP/ANA stimulated a big number of adventitious shoots. The fingerprinting analysis showed no genetic polymorphisms among naturally and “in vitro” made plants.

P2560. Studies on growth and productivity of Asparagus racemosus under in vivo and in vitro conditions.

N. Vijay, A. Kumar;
University of Rajasthan, Jaipur, India.

Studies on growth and productivity of Asparagus racemosus (Willd.), Shatavari, an important medicinal and ornamental plant have been conducted under in vivo and in vitro conditions. Steroidal saponins, shatavarin I-IV are the active ingredients of the plant is present in tuberous roots. Different plant growth regulators and N, P, K caused a significantly (P<0.001) increase in the number and size of tuberous roots of A. racemosus. Growth was found maximum in the plants treated with IBA (50 ppm) + P2O5 (160 mg.kg-1), where as it was reduced significantly (P<0.001) in the NAA (50 ppm) treated plants. NAA proved best at lower concentration, 10 ppm. In vitro multiple shoot formation was observed maximum in the MS medium supplemented with kinetin (2.0 mg.l-1) + NAA (0.1 mg.l-1). Plants thus raised have been transferred to field conditions which showed over 80% survival. Quantitative estimation of protein contents was also dramatically influenced. Activity of invertase, acid phosphatase and peroxidase was found to be change in in vitro grown plants.

P2561. Somatic embryogenesis in heliconia from sections of ovary and zigotic embryos

L. Willadino, C. Ulisses, T. R. Camara, G. F. Melo-De-Pinna, C. C. Albuquerque;
UFRPE, Recife, Brazil.

This work aimed to establish protocols for the induction of somatic embryogenesis in heliconia species. A first experiment used sections of ovaries of H. chartacea Lane ex Barreiros cv. Sexy Pink in MS medium with combinations of indole-3-acetic acid (AIA: 0; 1; 1,5; 2 and 2,5 mg/L) and 2,4 - dichlorophenoxyacetic acid (2,4-D: 0; 3; 4 and 5 mg/L). On the second experiment were used zigotic embryos came from immature and mature fruits of H. bihai cv. (L.) L. Lobster Claw Two in MS medium with combinations of AIA (0; 1 and 2 mg/L/) and 2,4-D (0; 5; 10; 15 and 20 mg/L). Sections of ovaries, treated with 2,5 mg/L AIA and 5,0 mg/L 2,4-D showed the presence of embriogenic cells distinguished by their small size, isodiametric shape and densely cytoplasmatic appearance in observations at stereomicroscope, besides citochemical analysis. Scanning electron micrograph (SEM) showed somatic embryos at globular stages from the embriogenic callus. At the second experiment the formation of somatic embryos took place just in zigotic embryos came from mature fruit cultivated at the absence of growth regulators.

P2562. Production of *h*GM-CSF by Transformed Root Cultures of *Digitalis purpurea* L.

S. J. Hwang, B. S. Pyo;
Department of Oriental Medicine Materials, Dongshin University, Naju 520-714, Republic of Korea.

Due to their fast growth rates and biochemical stability, transformed roots (or hairy roots) remain unsurpassed as the choice for model root system and have promise as a bioprocessing system. Granulocyte-macrophage colony-stimulating factor(*h*GM-CSF) is a glycoprotein that stimulates the production of granulocytes, macrophages ,and white blood cells. In this study, we describe the possibility that transformed root would be a good host for the production of clinically useful protein. Transformed root lines were established after the inoculation of trangenic foxglove plantlets expressing *h*GM-CSF with *Agrobacterium rhozogenes* ATCC 15834. *h*GM-CSF levels in the biomass and medium were quantified by ELISA. For transformed root grown in MS medium, the maximum level of *h*GM-CSF after 6 weeks in shake-flasks was 0.83 mg/L or 0.42% total soluble protein ; up to 11.3% of *h*GM-CSF was secreted into the medium. Total *h*GM-CSF levels were increased by addition of polyvinylpyrolidone and gelatin to the medium. *h*GM-CSF production by transformed roots had a negligible effects on growth compared with transformed roots of wild-type plants.

P2563. Somaclonal variability of plants regeneratedfrom long-term embryogenic tissues of wheat *(Triticum aestivum)*

M. K. Orazaly[1], N. K. Bishimbayeva[1], R. B. Beglov[1], A. K. Amirova[1], K. M. Bulatova[2], E. D. Bogdanova[1], I. R. Rakhimbayev[1];
[1]Institute of Plant Physiology, Genetics and Bioengineering, Almaty, Kazakhstan, [2]Kazakh Research Institute of Agriculture, Almaty, d. Almalybak, Kazakhstan.

Wide spectrum variability of plants features (R_0, R_1, R_2 and R_3 progenies) regenerated from long-term calli of wheat five genotypes and three hybrid combinations (Kazakhstan selection) has been revealed, including the useful changes on the terms of maturation, stems height, parameters of productivity and leafs width. It was established, that the character of features changes depends from initial genotype: the early ripening lines in R_2 somaclones of c. Celynnaya - 3S, short stem forms and forms with high graining heads in somaclones R_2 and R_3 of c. Otan, antocian colour of leaf ears in somaclones R_1 c. Kazakhstanskaya - 25. In spite of morphological changes the most of somaclones were identical with profiles of storage proteins of initial genotypes. At the same time was found: zero mutation on the 1D chromosome in glutenins profiles at R_1 somaclone of hybrid line H-4 and differences on ɤ -, Ŭ - zones in gliadin profiles at somaclone R_1 of c. Kazakhstanskaya - 25. The terms of phenotypic display of somaclonal mutations in regenerated plants can be decreased by the increasing of initial callus tissues subculture number.

P2564. Anti-microbial action of the essential oil of Lippia gracilis Schauer

T. R. Camara, C. C. Albuquerque, R. L. R. Mariano, L. Willadino, C. Marcelino Jr, C. Ulisses;
UFRPE, Recife, Brazil.

Antimicrobial activity of the essential oil (EO) of Lippia gracilis Schauer over fungi of vegetable tissue culture and heliconia endophytic bacteria were evaluated. For the fungi Geotrichum candidum; Trichoderma viride; Torula herbarum; Paecillomyces sp.; Fusicoccum sp.; P. aeruginens; Curvularia lunata Aspergillus nidulans; A. flavus; and A. Niger mycelian discs were inoculated in PDA medium with oil (0; 420; 440; 460; 480 e 500 mL/L). The inhibition percentage in a 420 mL/L was 95,58% and 89,40% for C. lunata and A. niger, respectively. For the other fungi, the percentage was 100%. A suspension of the Salmonella choleraceuis-diarizonae, Enterobacter asburiae, Bacillus thuringiensis, B. pumilus, B. cereus, Klebsiella pneumoniae, E. hormaechei, species was added to the NYDA medium solid, in Petri plates. In each plate wells were drilled and filled with water or EO (420 µL/L). Was assessed the diameter of the inhibition halo. K. pneumoniae was bacterial species less sensitive and E. hormaechei was more sensitive.

P2565. Influence of methyl jasmonate on 4'-Demethyl-6-methoxypodophylotoxin and 6-methoxypodophylotoxin accumulation in a Linum tauricum ssp. tauricum (Willd.) cell culture

K. M. Danova, I. Ionkova, N. Vassilev;
Faculty of Pharmacy, Medical University of Sofia, Sofia, Bulgaria.

The lignan podophyllotoxin (PTOX) is used for the semi-synthesis of the anti-cancer drugs etoposide, teniposide and Etopophos®. PTOX is restricted to only a few plant species. Because of its expensive chemical synthesis and limited supply, other sources for this rare natural lignan are required.

Here we report the initiation of conventional callus and suspension cultures of the Balkan endemic species Linum tauricum ssp. tauricum Willd., and the production of the PTOX derivatives 4Ǌ demethyl-6-methoxypodophyllotoxin (4Ǌdemethyl-MPTOX) and 6-methoxypodophyllotoxin (MPTOX) as the main lignans. MPTOX was readily identified by comparison of its HPLC retention time (11.95 min) and UV spectrum with that of an authentic sample. The second isolated lignan (8.68 min) differed from MPTOX in the absence of the 4'-O-methyl group. The levels were 0,516 mg/g dw and 0,127 mg/g dw respectively.

Experiments with addition of extracellular methyl jasmonate showed an increase of the biosynthesis of the two compounds, which is indication that lignans may be plant defence compounds and could be a useful tool for the enhancement of lignan production.

P2566. The induction of androgenic embryos of *Aesculus flava* Marshall.

D. Ĺaliĺ , S. Zdravkoviĺ -Koraĺ , L. Radojeviĺ ;
Institute for Biological Research, Belgrade, Serbia and Montenegro.

Induction of androgenic embryos of yellow buckeye (*Aesculus flava*) was achieved on solid MS medium (Murashige and Skoog, 1962), supplemented with 2,4-dichlorophenoxyacetic acid (2,4-D) and kinetin (1.0 mgL^{-1}, each). Medium for embryo multiplication consisted reduced concentration of 2,4-D (0.01 mgL^{-1}) and the same concentration of kinetin (1.0 mgL^{-1}). The development of androgenic embryos was asynchronous, so that embryos at their globular, heart-shaped, torpedo-like and cotyledon stages were observed in the same culture. Androgenic embryos *A. flava* with normal morphology were cultured on solid hormone free medium for embryo germination. Secondary embryos appeared on the radiculi of androgenic embryos grown on the hormone-free medium. The goal of the work was mass production of haploid androgenic embryos from anther culture and induction of secondary somatic embryogenesis and plantlets formation of *Aesculus flava* in order to develop efficient *in vitro* regeneration methods to be used in genetic transformation experiments applicable in the pharmaceutical industry.

P2567. *In vitro* studies on the effect of red rot toxin on the callus of sugarcane (var. CoC 671)

V. Ankalabasappa[1], S. Sundara Rajan[2];
[1]The Oxford Educational Institution, Bangalore, India, [2]137 (MIG), KHB Colony, Koramangala, Bangalore, India.

Red rot *(Colletotrichum falcatum Went)* of sugarcane has become a threatening disease for the early maturing variety CoC 671. It causes death of cane stalks and also results in low juice and reduced sucrose. There are studies on the effect of *C. falcatum* on organic metabolites of susceptible cane, while there are no reports on the effect of red rot toxin on sugarcane callus. During the present investigation, metabolic changes induced by red rot toxin was studied using callus of susceptible sugarcane cultivar CoC 671.

The pure pathogen of *C. falcatum* grown on oatmeal agar was used for toxin extraction. Sugarcane var. CoC 671 callus tissue was induced using MS medium. Different concentrations of partially purified toxin were incorporated into the MS medium (0.05- 0.5%). The flasks were inoculated with 2-3 g of friable callus of CoC 671 and were kept for incubation for 50 days and were analyzed for organic constituents such as protein, total and reducing sugars, polyphenols and proline. Result show that there was increase of protein and polyphenols content of toxin treated callus, while there was a reduction of total and reducing sugars and proline as compare to control.

P2568. Somatic embryogenesis induction and plant regeneration in carob (Ceratonia siliqua L.)

J. M. Canhoto;
Instituto do Ambiente e Vida, Dep. de Botânica, Univ. de Coimbra, Coimbra, Portugal.

Ceratonia siliqua (carob) is a leguminous tree that grows in some regions of Portugal (Algarve) and in other countries of the Mediterranean basin. Propagation of this species by cuttings is problematic because rooting is difficult to achieve. In this context, *in vitro* tissue culture techniques may offer alternative ways of dealing with the problem of carob propagation. In this work somatic embryogenesis induction and plant regeneration in carob is described. Somatic embryos were induced on immature cotyledons of several cultivars. Best results were obtained when 4.4 µM BA and 0.5 µM NAA were used in the induction medium. Media supplementation with 5 mg/l dithioerythreitol increased somatic embryo (SE) formation. SE conversion was obtained after treatment with gibberellic acid and kinetin. Poor root development was observed in the converted embryos and, in most of the cases, a further treatment with IBA was necessary to induce root formation. Histological and ultrastructural studies showed that the structures formed were in fact SE showing an independent vascular system and the accumulation of reserve compounds identical to those found in zygotic embryos.

P2569. *In vitro* propagation and flowering in the ornamental bamboo *Bambusa wamin*

S. M. Arshad[1], S. K. Bhatnagar[2];
[1]Sfri, Kanpur, India, [2]Bareilly college, Bareilly, India.

Studies have been conducted on *in vitro* multiplication of *Bambusa wamin* using mature nodal explants obtained from nearly 15 years field grown clump.After surface sterilization with 0.15% mercuric Chloride solution the nodal explants were cultured on appropriate nutrient medium. Mature nodal explants of *Bambusa wamin* produced multiple buds *in vitro* when cultured on Murashige and Skoog (1962) medium containing 5.0mg/l 6-Benzylamino purine. Rapid shoot multiplication occurred on MS medium supplemented with 2.0mg/l BAP and 0.8mg/l Kn. *In vitro* flowering occurred in cultures that were maintained *in vitro* for nearly 18 months. In addition to normal green shoots occasional formation of albino shoots was also recorded. More than 95% of *in vitro* shoots rooted on modified MS medium supplemented with IBA (7.5-10.0 mg/l) in 7-8 weeks. The *in vitro* raised plantlets after hardening and acclimatization showed 85% success on transfer to field. The micropropagated plants in field exhibited similar morphology as the mother plant with bulbous internodes.

P2570. *In vitro* morphogenetic studies in *Azadirachta indica* A. Juss

V. K. Gautam;
Deen Dayal Upadhyaya College, New Delhi, India.

The *in vitro* culture studies are helpful for improving plant quality. The improvement of trees through tissue culture is more significant as conventional methods of breeding are not of much use due to height, long life span, heterozygosity ,etc. However, somatic embryogenesis, micropropagation and production of haploids can be useful in selecting and developing superior species. For any successful approach it is necessary to develop a successful regeneration system using suitable explant. In this species anther-derived callus is highly regenerative. For shoot regeneration MS medium supplemented with various concentrations of benzyladenine (BA) alone or supplemented with NAA is most suitable. Somatic embryos were produced during second sub-culturing of callus on MS + 1 mg/l+0.1mg/l NAA or MS + 0.5mg/l BA medium. The chromosome number in regenerated roots and callus showed various ploidy levels. For checking browning of shoots, roots and callus PVP was highly effective. Thus anther can be used to develop haploids and for genetic transformations.

P2571. A protocol for micropropagation of the *Lilium ledebourii* (Baker) Boiss an endangered rare species endemic to Iran

P. Azadi;
National Research Center of Ornamental Plants, Mahallat, Islamic Republic of Iran.

The perennial plant *Lilium ledebourii* (Baker) Boiss (Liliaceae) is an endangered rare species endemic to Iran. It is under surveillance of regional Environmental Protection Agancy. Due to the collection of these plants, specially of the underground organs, the number of this species is continuously decreasing. Effect of growth regulators, sucrose concentration and scale segment on bulblet regeneration were investigated. The highest number of bulblets was formed on a MS medium with BA (0.1 mg l^{-1}) + NAA (0.1 mg l^{-1}) and 9% sucrose at basal segment. The presence of growth regulators increased fresh weight of bulblets compared with hormone free medium. The bulblets at the end of the culture period were given cold treatment at 4 ºC for 8 weeks and then transplanted to a potting mixture of sand, leaf mold and peat moss (1:1:1). The horticultural habits of the cloning plants are being investigated to introduce the germplasm into lily breeding program

P2572. *in vitro* Germination of *Gentiana olivieri* Griseb. Seeds

C. Yagci[1], C. M. Toker[2], G. Toker[3];
[1]Ankara University, Biotechnology Institute, Ankara, Turkey, [2]Ankara University, Faculty of Science, Ankara, Turkey, [3]Gazi University, Faculty of Pharmacy, Ankara, Turkey.

Gentiana genus is grown widespread on the world. It is used as a traditional medicine in many countries because of bitter secoiridoid glycosides in their roots. *Gentiana olivieri* Griseb. grows in Middle Anatolia and Southeast Anatolia and used for the reducing blood glucose level in diabetic patients especially in Southeast Anatolia. It is obtained that this activity is caused by isoorientin. Common usage of *G. olivieri* results in extinction risk because of collection from natural habitats too much. In this study, it is aimed to reproduce *G. olivieri* by *in vitro* germination with tissue culture techniques.

MS (Murashige&Skoog) and MS with WPM (Woody Plant Medium)'s macronutrients were used as the base media. Different concentrations (0.0345, 0.069, 0.139 mg/l) of Gibberellic acid (GA_3) as a plant growth regulator media and 1.01 mg/l KNO_3 added media and hormon-free media were used for the *in vitro* germination of *G. olivieri* seeds.

Approximately 400 seeds were sown each of these media aseptically and then *in vitro* germination ratio were determined. The best result obtained from the media of MS medium with WPM macronutrients with 0.069 mg/l GA_3.

P2573. Micrografting of neem *(Azadirachta indica A.Juss.)* shoot apex onto persian lilac *(Melia azedarach L.)* rootstock seedlings

S. nassiri[1], f. Bernard[2], H. Shaker-Bazarnov[2], A. Majd[3];
[1]Azad University, Zanzan, Islamic Republic of Iran, [2]Shahid Beheshti University, Tehran, Islamic Republic of Iran, [3]Tarbiat Moallem University, Tehran, Islamic Republic of Iran.

Neem *(Azadirachta indica A.Juss.),* native to the arid regions of Indian subcontinent, is a valuable tree because its fast growing rate and many technological importanc applications. We examined micrografting of the highly interested *A.indica* onto *Melia Azedarach* L. (Persian lilac) rootstock seedling, with the objective of estimating the resistance of this union to cold treatment afterwards. In these micrografting experiments the age of rootstock, the localization of graft and hormonal treatments during the time course of growth were examined under *in vitro* condition and after transfering to soil. The best shoot tips graft success was found on young rootstock in lateral hypocotyls position. Exogenous auxine in association with cytokinine was necessary to the best union and growth. If salicylic acid showed an inhibitory effect on the graft-take, salicylic acid treatment cause the highest grafting success, signifying a useful role of salicylic pretreatment in acclimatization to soil conditions for these grafted plantlets.

Key word: Azadirach indica, Auxine, Benzyl amino purine, cytokinine, Melia azedarch, Micrografting, Salicylic acid

Footnotes

P2574. Effect of calcium on growth and phenolic accumulation in cell cultures of *Hypericum androsaemum* L.

A. Paranhos;
Center for Pharmaceutical Studies - University of Coimbra, Coimbra, Portugal.

Hypericum androsaemum L. (Hypericaceae) has been used in folk medicine owing to the diuretic and hepatoprotective activities of its leaves. The pharmacological properties are attributed to the several phenolic compounds found in the plant.

Suspension cultures were established from hypocotyl-derived callus using liquid MS medium supplemented with 3% sucrose, 1 mg l^{-1} 2,4-D and 0.5 mg l^{-1} BA. Cultures were kept at 25±2ºC under a 16-h photoperiod.

The growth kinetics, over a 16-day period, was typically sigmoidal, with cells entering the stationary phase 12 to 13 days after inoculation. Cellular contents of flavonoids, hydroxycinnamic acids and total phenols declined during the first week of culture and thereafter increased gradually with time, reaching a maximum on day 14.

Cell extracts from 14-day-old cultures proved to be active superoxide radical scavengers, as assessed by evaluating its ability to inhibit superoxide-driven reduction of nitro blue tetrazolium.

Culture of cells for 7 or 14 days in nutrient media containing high concentrations of $CaCl_2$ caused a slight reduction in growth and a substantial increase in the accumulation of flavonoids.

P2575. Plant regeneration from protoplast in Banana (cv. Dwarf Cavandish)

F. Farahani[1], A. Majd[2], R. Zarghami[3];
[1]Department of Biology , Faculty of Science, Islamic Azad University, Qom Unit, Tehran, Islamic Republic of Iran, [2]Department of Biology , Tarbiat Moalm University, Tehran, Islamic Republic of Iran, [3]Agriculture of Research Biotechnology Institute, Tehran, Islamic Republic of Iran.

We investigated if the isolation & regeneration of protoplast from leaves tissues banana (cv. Dwarf cavandish) was isolated from mesophyll tissue by enzymatic digestion in 28 and 32 H with 25°C conditions and cultured using a semi-solid medium. Initiation protoplasts frequency was 90% in optimal conditions. Protoplasts were transferred to MS liquid medium without hormone. Under these conditions, protoplasts remained virtual and active. We observed cell wall formation and cell division after 5 days. Callus of frequency formation was 50-70% in MS liquid medium supplemented with BAP (0.005 mg/l) & IAA (0.002 mg/l) , calluses were 50-100 in diameter, after 4 weeks. Calluses were cultured on MS semi-solid medium supplemented with BAP (3 mg/l) & IAA (2 mg/l). Shoot regeneration efficiency was 30% via organogenesis among 143 isolated callus within 28-42 days. They showed further development of the dividing protoplasts. We succeeded isolating protoplasts from mesophyll in Dwarf cavandish. Regeneration was mentioned.

This report reveals young leaf material banana Cv. Dwarf cavandish is very recalcitrant towards regeneration from protoplasts of mesophyll tissue.

P2576. Antimicrobial Activity of Static Cultures of *Asparagus racemosus.*

S. Asmari, R. Zafar, S. Ahmad;
Jamia Hamdard, New Delhi -110062, India, New Delhi, India.

The static cultures of *Asparagus racemosus* from shoot and root explants were generated in Murashige and Skoog's (MS) medium supplemented with various growth hormones. Genetically transformed callus culture was also established by co-cultivation of leaf explants with *Agrobacterium tumefaceins* in MS medium. The in-vitro cultures developed were maintained for six month and tested for presence of various phytoconstituents. Antimicrobial activity of methanolic extracts of in-vitro cultures was carried out and compared with that of natural plant using disk diffusion method against gram positive and gram-negative bacteria. In the present investigation it was observed that the static cultures generated from plant have great potential to produce secondary metabolites present in natural plant. Methanolic extracts of root and root callus (150 µg/ml) possess significant antimicrobial activity against gram-positive bacteria.

P2577. Callus production of 3-hydrogenkwedaphnin, a potent new anti-leukimic agent

P. Fathirezaie, R. Yazdanparast;
ibb, Tehran, Islamic Republic of Iran.

A novel compound of *Dendrostellera lessertii* (Thymelaeaceae), named 3-hydrogenkwadaphnin, shows potent anti-proliferative activity especially on the leukimic cells. In order to complete our knowledge about the mode of action of this new compound and also to initiate clinical trails and other pharmaceutical investigations, large quantities of this compound are needed. Based on this limiting factor, alternative ways of 3-hydrogenkwadaphnin production should be worked out. In that respect, we evaluated its callus production under different experimental conditions and from various explants. Excised tissues (leaves and stems) of D.lessertii were cultured on M.S medium supplemented with various concentrations of 2, 4-D and Kinetin, and the optimum callus growth and maintance for leaf and stem explants were established. Although we have been successful in callus production of 3-hydrogenkwadaphnin, but more extensive research is required to maximize the production level.

P2578. Application of mutation breeding technique for producing NaCl tolerant plants of banana in tissue culture and greenhouse conditions

C. Vedadi, M. Rahimi, B. Naserian, E. Rahmani, N. Neshan;
Nuclear Research Center for Agriculture and Medicine, Karaj, Islamic Republic of Iran.

To study of possibility to induce salt tolerant clones in banana by using mutation technique, an experiment was conducted with factorial (gamma irradiation and salt cocentration factors) in a CRD design. In this research, plantlets of banana cv. Dwarf Cavendish were produced by subculture of irradiated shoot tips. It deserves to mention that consequent subcultureing was aimed at getting rid of chimera. Next, these explants were transfered to MS medium containing 2.5 mg.l^{-1} BAP and NaCl concentrations of 0, 6, 7, 8, 9 g.l^{-1} for 2 months .Then, living buds were transfered to medium without salt. After one month,we repeted the first stage.All living buds rooted and transfered to potted soil. Acclimatized plants were irragiated weekly with above NaCl solution .Other irragiation, was done with free-salt water. There was also a negative relation between salt concentration and survival - proliferation. In second salinity stress, salt had not significant difference on survival percentage. No-significant difference of effect salt on survival in second salinity stress .

P2579. Molecular instability of poplar somatic clones (*Populus nigra*) at SSR loci

A. Bittsánszky[1], G. Gyulai[1], J. Kiss[1], G. Gullner[2], Z. Szabó[1], R. Lágler[1], T. Kőmíves[2], L. Heszky[1];
[1]St. Stephanus University, HAS-SIU RG, Dept. Genetics and PB, Gödöllő, Hungary, [2]Plant Protection Institute, Hungarian Academy of Sciences, Budapest, Hungary.

Somatic clones of black poplar (*Populus nigra*) were developed from callus cultures of petioles of aseptic shoot origin and grown up in field. Molecular instability of the somatic clones developed from two trees N-SL and N-309 was determined by five microsatellite markers. Twenty SSR alleles were detected, the number of alleles per marker ranged from 1 to 6, with an average of 3.3 detected by ALF (automatic laser fluorometer). A dendrogram (SPSS11) based on the presence versus absence of alleles discriminated the groups of somatic clones (1 to 35) of N-SL from somatic clones of N-309. The polymorphic markers of WPMS2 (5 alleles), WPMS4 (6 alleles) and WPMS20 (6 alleles) revealed somatic variation in 1 clone (37) out of the 6 from the N-309 tree, and three subgroups out of the 29 somatic clones from the N-SL tree (17 and 24), (2 and 14) and (10 and 15). The new SSR-clones may provide new genetic resources to improve molecular diversity of poplar. *Source of grants: OTKA-M-04563, OECD-JA00018642, USA-Hungarian Fulbright Commission, and SzÖ-4/2003.*

P2580. Effective factors on the shoot and microtuber formation of potato under *in vitro* conditions

R. Zarghami, P. Najafi, O. Dabirashrafi;
Agricultural Biotechnology Researching Institute of Iran, Karaj, Islamic Republic of Iran.

The efficiency of *in vitro* shoot and microtuber formation of two potato commercial cultivars from single nodal explant was studied on solid and liquid MS- basal medium applying different incolation culture density.
The experimental design was complete randomized blocks with three replications .
The observations on number of shoot and microtuber per erlenmeyer flask were recorded 4 and 10 weeks after culture explants respectively.
The results revealed that the number of microtubers as well as shoots were affected by the genotype, culture media and also inoculation density of culture. The highest produced microtubers belonged to Agria cultivar. Comparative studies between solid and liquid culture media revealed that shoot and microtuber formation were more efficient in solid medium. Mean comparison also showed that there is significant differences amoung three levels of inoculation density, so that 6 and/or 9 explants per erlemeyer were superior compared with densoity of 3 regarding both trails under study .

P2581. Plant regeneration *in vitro* of *Rhodiola rosea* L.

K. N. Tasheva, G. P. Kosturkova, M. I. Petrova, N. A. Zagorska;
Institute of Genetics, Sofia, Bulgaria.

Rhodiola rosea L. (Crassulaceae) is a valuable medicinal plant. It is a perennial grass of quite limited distribution. Over the last years Rhodiola rosea L. area decreases drastically because of intensive explotation. Biologically active compounds of Rh. rosea are widely used in pharmaceutical industry. Therefore the species in included in the Red Book of Bulgaria and other countries.
The purpose of our investigation was to elaborate efficient method for in vitro propagation of Rhodiola rosea L.
Various nutrient media and explants were tested. Explants isolated from in vitro germinated seeds were more efficient for plant regeneration than explants isolated from plants grown up in nature. This system for in vitro micropropagation allows, both, reservation of this endangered species and providing biotechnology approach for production of valuable secondary metabolites.

P2582. Events of dedifferentiation during callus induction from Rubia tinctorum L. leaves

N. Orbán, I. Boldizsár, K. Bóka;
Eötvös University, Budapest, Hungary.

Callus induction is usually the first act at biotechnological protocols. Formation itself is often described but events of dedifferentiation are usually not observed.
We have investigated the early steps of dedifferentiation process. Sterile leaves were placed on MS medium and the harvested samples were observed by electron microscope, HPLC and TLC to follow the changes. We have found that chlorophyll content of leaf pieces decreased gradually while amount of anthraquinones increased. Not only concentration of the anthraquinones has changed but the composition was altered too. The most sweeping changes in the ultrastructure appeared in mesophyllar and vascular bundle sheath cells. Chloroplast structure (size of grana, starch content, number and size of plastoglobuli), amount and vacuolization of cytoplasm were altered obviously, however, even two weeks after induction chlorenchymatic cells showed no signs of divisions. Presence of proplastids and dense cytoplasm were characteristic after a few days in the transfer cell like cells. First cell divisions appeared near to venation and typical yellow cells of calli were formed at these particular places.

P2583. Embryogenic callus induction in *Stemona tuberosa* Lour

N. Montri, C. Wawrosch, B. Kopp;
Department of Pharmacognosy, University of Vienna, Vienna, Austria.

Stemona tuberosa Lour. has long been recommended in Chinese traditional medicine for the treatment of respiratory diseases. Utilization of this plant has been largely as crude drugs and the traditional propagation techniques are not economic because of low efficiency. Production by in vitro culture might be an interesting alternative. The results presented here suggest potential of

embryogenic callus induction with further application to produce large plantlets via somatic embryogenesis on a large scale.
Investigations trying to obtain the best media for callus induction were performed by employing different types and concentrations of cytokinins. The amount of compact callus was positively correlated with the concentrations of BAP and TDZ. The best results were obtained with 20 µ M TDZ. Friable callus developed from compact callus on MS media supplemented with 5 µ M 2,4-D, 5 µ M BAP, 5 µ M TDZ and 5 µ M IBA. In the third step embryogenic callus was achieved in liquid MS medium supplemented with 3 µ M 2,4-D in the dark with the subsequent formation of somatic embryogenesis.

P2584. Investigation the effect of different planting bed and the position of stem nodes on the production of minituber from tissue culture plantlets in two varieties of potato

R. Fazeli, R. Zarghami, M. Mirabdulbaghi;
Agricultural Biotechnology Researching Institute of Iran, Karaj, Islamic Republic of Iran.

The tubers from "Marfona" and "Desiree" after growing till 15-20 cm in height in greenhouse were toped and transferred to thermotherapy conditions. After four weeks, the meristems were excited and placed on Paper Bridge in liquid media and were tested for virus free. Then for propagation, three liquid media were used: MS (free hormones), MS+0.5 mg/l BAP, MS+0.5 mg/l NAA. The free hormone media produced vigorous plantlets with suitable rooting. Then for planting beds, the position of stem nodes and minituber production, apical meristem of stems and roots were removed and stems were divided to Bottom, Middle and Top and cultured on four beds: peat moss/perlite 3:1, turf/perlite 3:1, leaf mould/perlite 3:1, rice hull/turf 1:1. All beds except leaf mould/perlite 3:1 produced desirable plants. The position of nodes had effect on the ratio of compound leaf to total leaves. After harvesting minitubers and measuring the traits, rice hull/truf 1:1 planting bed, in all trait was better. In this stage, also the position of nodes except in the interaction of position of nodesxplanting bed on total minituber weight had no significant effect on minituber production.

P2585. Effect of Cryopreservation Techniques on Regeneration and Genetic Stability of Potato Genotypes

M. Jafarzadeh, R. Zarghami;
Agricultural Biotechnology Researching Institute of Iran, Karaj, Islamic Republic of Iran.

Most of the researchers in cryopreservation concentrated on vitrification technique. Results showed various potato cultivars (Agria and Picasso in this study) react differently to this method, so that; there is not a unique protocol for several cultivars. Results of preculture stage: Application of high sucrose content (0.7 M) enhances the post-freeze recovery percentage, in most cases, short duration of preculture is preferred, ABA in this stage (0.5-3 mg/l depended-cultivars) had positive effects on post-thaw recovery and regeneration. But application of ABA on donor plants had no significant effect, proline had significant effect. Results of dehydration: DMSO is not proper for lowering free water of potato meristems` tissues, concentration of cryoprotectant must be about 7M and proper duration of dehydration, without and with loading solution is 50 and 40 min., respectively. Increasing the rate of freezing and thawing steps by aluminium vials instead of polypropylene vials improved the post-thaw recovery. Also, some of freeze-induced damages in newly thawed tissues, related to free radicals which are produced from photochemical reactions.

P2586. Temporary dynamics of hyoscyamine contents in the different parts of *Datura innoxia* Mill. hairy-roots.

N. V. Khodorova[1], N. K. Koteyeva[1], J. C. Laberche[2], C. Dechaux[2], M. H. Al Balkhi[2], B. S. Sangwan[2], M. Boitel[2];
[1]Komarov Botanical Institute RAS, Saint-Petersburg, Russian Federation, [2]Jules Verne University, Amiens, France.

Using HPLC the hyoscyamine content was determined in the young (1 and 2 cm from the root tip), intermediate (3-6 cm) and old (6-10 cm) parts in 1-, 4-, 15-, 19- and 21-day-old hairy-roots. The active growth and/or tissue differentiation were observed at the stages of the 4 and 15 days. At the 21 day the growth was finished, and alkaloid content was highest in all parts of the root, but it was decreased after the transfer to the new medium (1-day-old roots). In the intermediate and old parts hyoscyamine amount was restored fast and remained practically constant at all other stages. In the young parts it was almost two-time less than in the old ones at the stages of active growth. However, after growth stops the alkaloid content was increased gradually and became similar in all parties of the root. The ultrastructural features of cortex cells related to alkaloid amount changes were observed. The biosynthesis localization, accumulation and transport of tropane alkaloids in hairy-roots were discussed.

P2587. In Vitro Prediction for Salt tolerance in wheat

M.S. Abdel-Hady, R.M. Esmail andA.M. Abdel-Hamid
Bot. Dept.t & Genetics & Cytology Dep.t, NRC,,Cairo, Egypt.

CALLUSES of three salt tolerant wheat genotypes and their hybrids were grown on MS medium supplemented with different NaCI ppm. Growth rates of calluses decreased as the salinity levels were increased in the culture medium. There were highly significant differences among the tested genotypes and their hybrids in response to salt stress in callus growth rate. The results showed that callus growth rate and plant regeneration of hybrids were less decreased as salt concentration was increased compared with that of parents. Sakha-69 and hybrid (Sak. x Giza) were the most tolerant and scored high percentage in plant regeneration. Proline content increased parallel to the increase of salinity. The results prove that the genetic differences in wheat salt tolerance could be tested early *in vitro* and the more the genotype is able to produce proline under the stress conditions, the more it will tolerate salinity .

Keywords: Wheat, Prediction, Tissue culture, Salt-tolerance, Regeneration, Proline.

P2588. The utilization of embryo culture in the interspecific hybridization between *Cucumis anguria* and *Cucumis zeyheri*

D. Skálová, M. Dziechciarková, A. Lebeda, B. Navrátilová, E. KŚstková;
Palacký University, Faculty of Science, Department of Botany, lechtitelŢ 11, Olomouc-Holice, 783 71, Czech Republic.

Wild *Cucumis* species, *C. anguria* L. and *C. zeyheri* Sonder, could be used as donors of various characters in cucumber (*C. sativus*) improvement and breeding. Both wild *Cucumis* spp. are mutually cross-compatible, however there are some physiological and genetical barriers. These obstacles can be overcome by embryo-rescue culture. The embryos were excised from the fruits of *C. anguria* one to six weeks after pollination by *C. zeyheri* and were cultivated on five different culture media (MS-medium supplemented with ascorbic acid, caseinhydrolysate, coconut water and giberelic acid). Vital plants were recovered from the embryos from fruits at least two weeks old. The hybrid characters of regenerated plants were proved by isozyme analysis (H 1.1., H 1.2., H 2). Morphological assessment of parental genotypes and plants issued from their crossings was performed continuously during the plant growth. The most significant traits indicating hybrid character of plant F$_1$ generation were till now (stage of beginning of flowering) localized on the shape of leaf blade. This research was supported by grants: 1) NAZV No. QF 4108 (MA CR); 2) MSM 153100010; 3) MSM 6198959215.

P2589. Effects of Brassinosteroid on Cotton Regeneration

N. Gozukirmizi[1], Y. Aydin[2], T. Talas-Ogras[3], Z. Ipekci-Altas[3];
[1]Istanbul University, Istanbul, Turkey, [2]Marmara University, Istanbul, Turkey, [3]Tubitak, Rigeb, Kocaeli, Turkey.

The effects of brassinolide (BR) on cotton somatic embryogenesis were examined. 10 day-old cotton (*Gossypium hirsutum* L. cvs., Cooker 312 and Nazilli M-503) seedlings were used as explant source and hypocotyls were cultured on MS basal medium (MS salts, vitamins, 30 g l^{-1} sucrose, 2.2 g l^{-1} phytagel, 1 g l^{-1} polyvinylpyrrolidone, 1 mg/l 6-benzylaminopurine, 2 mg/l kinetin) for callus induction. After one month, proliferated calli pieces were collected and cultured on the same media containing various concentrations of BR (0.1, 0.5 and 1.0 µM) in complete dark conditions at 26 ^{o}C. Differential somatic embryogenesis rates arising from BR treatment were detectable within 10 weeks. In 0.5 µM BR containing media for Cooker 312, somatic embryogenesis was earlier compared with control. For Nazilli M-503 both direct root and somatic embryo formation were observed in MS basal medium containing 0.5 and 1.0 µM BR, within 8 weeks. Embryos at different stages of development and plantlets were collected for molecular analyses of putative BR-responsive cDNA's. The data indicates BR plays a role for induction of somatic embryogenesis and root regeneration from calli.

P2590. Studies on Genetic stability of Micropropagated Iranian Date Palm Plantlets by RAPD Markers

P. Eshraghi[1,2], R. Zarghami[3], H. Ofoghi[1];
[1]Department of Biotechnology, Iranian Research Organization for Science and Technology, Tehran, Islamic Republic of Iran,
[2]Department of Biology, Khatam University, Tehran, Islamic Republic of Iran, [3]Agricultural Biotechnology Researching Institute of Iran, Karaj, Islamic Republic of Iran.

Phoenix dactylifera L. (Aracaceae) is an important source of economic revenues. The slowness of conventional methods has made in vitro tissue culture an alternative method for propagation. Identification of possible somaclonal variants at an early stage of development is considered to be useful for quality control in plant tissue culture. RAPD based detection of genetic polymorphism is useful in describing somaclonal variation in plant species. The aim was to compare genetic stability between offshoot and derived plantlets via somatic embryogenesis of Iranian cultivar “Khanizi”. Characterization of regenerated palms was performed using 10 selected primers. Of these 10 primers, 4 (40%) primers enabled the identification of polymorphism. DNA polymorphism was investigated on different palms through the analysis of mother palm and regenerated from several clones. Data were recorded as presence or absence of amplified products, correspondence analysis was performed using NTSYSpc-2.02e. The estimation of genetic similarity coefficient based on RAPD band-sharing date indicated that six regenerated plants were more than 90% similar to the mother plant.

P2591. Plant Regeneration from Immature seeds Embryons-Derived Embryogenic Calluses of *Vinca herbaceae*

A. Ataei Azimi[1], B. Delnavaz Hashemloian[2];
[1]Azad Islamic University, Saveh, Islamic Republic of Iran, [2]azad islamic university, Saveh, Islamic Republic of Iran.

Vinca herbaceae is herbs with two either opposite or whorled entire leaves , Iranian indigenous and it is growing native in north of Iran.Immature seeds are used for culture in this investigation.Immature seeds embryos formed small calluses at a frequency of 30% on MS medium supplemented with 1.5mg/l (2,4-D) with 0.1mg/l (kin) after 8 weeks of culture. After a second subculture using MS basal medium at 6-week intervals, small calluses formed a small quantity of yellowish, compact embryogenic calluses. Upon transfer to MS basal medium supplemented with 0.5 mg/l 2,4-D and 0.5 mg/l kin,embryogenic calluses gave rise to numerous somatic embryos. Embryogenic calluses cultures developed into plantlets without roots growth at a frequency of 100% when plated onto MS basal medium. The growth rates and mophological characteristicss of plantlets were different.1-The most plants have normal shape and normal growth. 2- Succulent shoots plantlets have unormal shapes and little growth speed. 3- Plantlets with 3 leaves in any nod have normal shape and normal growth.

P2592. Effect of precursors feeding on essential oil production and molecular identification of clove, *Eugenia caryophyllus* callus cultures.

M. A. Matter[1], R. S. Farag[2], F. A. Ahmed[2], M. K. El-Bahr[1], S. A. Ghaneem[1], M. R. Rady[1];
[1]National Research Centre, Giza, Egypt, [2]Faculty of Agriculture, Giza, Egypt.

Callus cultures were established *in vitro* from leaves explants of aseptically grown *Eugenia caryophullus* seedlings. The obtained calli were grown on induction medium supplemented with different concentrations of phenol or P-cymol or salicylic acid. The results clearly showed that high concentration of phenol or p-cymol in the medium resulted in the highest essential oil percentage.Qualitatively, phenol or p-cymol at concentration 160 mM is the most suitable level to produce an essential oil comparable in its composition with the already known clove essential oil. SDS-PAGE analysis for callus tissues grown in induction medium with different levels of phenol or p-cymol showed over-expression of the protein band of approximately 30 KDa. However, RAPD analysis revealed high percentage of polymorphisms within clove callus tissues grown on medium containing phenol, p-cymol, salicylic acid.**The variation in banding patterns were observed between control treatment and other treatments.**

P2593. A procedure for in vitro plant regeneration from seed-derived callus

P. O. Adebola, A. J. Afolayan;
University of Fort Hare, Alice, South Africa.

A procedure for in vitro plant regeneration from seed-derived callus was developed for Arctotis arctotoides, a plant noted for its several medicinal uses among the rural people of the Eastern Cape province in South Africa. Callus induction was initiated in basal MS salt supplemented with 3% sucrose (w/v) and 1% agar (w/v) at different concentrations of 2,4-dichlorophenoxyacetic acid (2,4-D). After two weeks, morphogenic responses were evident in cultures and deeply stained light-yellow calli were produced. The highest percentage (67.5%) of seed explants inducing callus was obtained on MS medium supplemented with 2.0mg.l-1 of 2,4-D in the dark. When the calli were repeatedly subcultured in ½MS basal medium with a 16-h photoperiod without any hormonal supplement, adventitious shoots were produced eight weeks after culture initiation. The shoots rooted two weeks later. This is the first protocol of in vitro regeneration described for A. arctotoides and will serve as a foundation for further research on tissue culture, micropropagation and germplasm conservation of this important medicinal plant.

P2594. Employment of *in vitro* morphogenesis of onion for the breeding purposes

S. A. H. Bekheet;
National Research Centre, Cairo, Egypt.

This work describes an effective method for plant regeneration of onion through *in vitro* culture of ovary and flower explants. The presense of 2,4-D or kin in culture medium is required to induce acceptable yield of gynogenic cultures from immature flower or unfertilized ovary of onion . The highest frequency of *in vitro* differentiation of the two types of explants was registered with 2 mg /l 2,4-D + 1 mg /l kin containing medium . Incorporation of culture medium with 60 mg /l adenine sulfate obviously enhanced the proliferation capacity and growth characters . Among three concentrations of IBA and NAA used for rooting , the highest percentage of root formation as well as number of roots / shoot were noticed with medium contained 2 mg /l NAA .The chromosome count indicated that fifty percent of plantlets regenerated from ovaries were haploid (8 chromosomes) . However , 33 % of flower-dervied plantlets were haploid . The obtained plantlets were successfully adapted to free-living conditions after phase of acclamatization.
Key words : Onion - Haploid - *In vitro* - Gynogenesis .

P2595. Induction of gynogenic haploids in mulberry

R. Kavyashree, **H. M. Revanasiddaiah**, M. C. Gayatri;
Bangalore University, Bangalore, India.

Gynogenic haploid plants have been obtained from unpollinated ovules of mulberry variety-S$_{54}$ when cultured on half strength LSBM supplemented with 8% sucrose and BAP (2 mgl^{-1}). After 8 weeks of culture, shoot buds were initiated, which were transferred to full strength LSBM supplemented with BAP (2 mgl^{-1}) to obtain multiple shoots. These multiple shoots upon subculture developed roots on full strength LSBM fortified with BAP (2 mgl^{-1}) and NAA (1 mgl^{-1}). The well developed complete plantlets were hardened and established in soil with 78% survival frequency. The acclimatized plants retrieved from unpollinated ovule culture were screened cytologically adopting root tip squash technique, which revealed haploid number of chromosomes n=14 in their root tips. Further confirmation of ploidy level was made in these gynogenic haploid plants by adopting chloroplast count technique, which showed the presence of 8 chloroplasts in two guard cells of the stomata.

P2596. Callus Induction and Plant Regeneration From Mature Embryos of Different Wheat Genotypes

A. G. Nasircilar, K. Turgut, K. Fiskin;
Akdeniz University, Antalya, Turkey.

Mature embryos of five *T. aestivum* and five *T. durum* cultivars formed embryogenic callus on two different media. Embryos were removed from surface sterilised seeds and placed with the scutellum upwards on a solid agar medium containing the inorganic components of Murashige Skoog and 2 mg/L 2,4-dichlorophenoxyacetic acid (2,4-D) or 1 mg/L naphtalenacetic acid (NAA). The developed calli and regenerated plants were maintained on 2,4-D or NAA free MS medium. Wheat plants can be regenerated via two different systems. There were significant differences in percentage of callus induction and regeneration capacity on the different initiation medium. Among the *T.aestivum* cultivars, Yakar had the highest regeneration capacity in both induction medium. In *T.durum* cultivars, Kiziltan gave the highest regeneration capacity in MS+2,4 D medium and Yilmaz gave the highest regeneration capacity in MS+NAA medium. A strong genotypic effect on the culture responses was found for both induction medium.

P2597. *In vitro* regeneration and field performance of *Tylophora indica* (Murm. *f.*) Merrill. - an endagered medicinal plant

M. Faisal, M. Anis;
Department of Botany, Aligarh Muslim University, Aligarh-202 002, India.

A protocol has been developed for high frequency shoot regeneration and plant establishment of *Tylophora indica* from petiole derived callus. Optimal callus was developed from petiole explants on Murashige and Skoog (MS) basal medium supplemented with 10 µM 2,4-D + 2.5 µM TDZ. Adventitious shoot induction was achieved from the surface of the callus after transferring onto shoot induction medium. The highest rate (90%) of shoot multiplication was achieved on MS medium containing 2.5 µM TDZ. Individual elongated shoots were rooted best on half-strength MS medium containing 0.5 µM IBA. When the basal cut ends of the *in vitro* regenerated shoots were dipped in 150 µM IBA for half an hour followed by transplantation in plastic pots containing sterile vermiculite, a mean of 4.1 roots per shoot were developed. The *in vitro* raised plantlets were successfully established in earthen pots containing normal garden soil and grown in green house with 100% survival. After four months of transfer to pots, the performance of *in vitro* raised plants was evaluated on the basis of selected morphological and physiological parameters and compared with *ex vitro* plants of the same age.

P2598. *In Vitro* propagation of *Echinodorus ozelot* by multiple shoots formation.

P. Lohasupthawee;
King Mongkut's Institute of Technology Ladkrabang, Faculty of Science, Dept. of Applied Biology, Bangkok 10520, Thailand.

Echinodorus ozelot is a tropical aquatic plant which is in the family of Alismataceae. This fresh water plant is a hybrid between *E. schlueteri* and *E. barthii*. It has red brown leaves with black spots so it is very popular for decorating the fish aquarium. In nature, propagation of *E. ozelot* is a slow process so tissue culture techniques are an alternative means of plant vegetative propagation in short time and space. In this work, *E. ozelot* rhizomes were surface sterilized and grown *in vitro* in liquid basal medium of Murashige and Skoog (MS) supplemented with different combinations of naphthaleneacetic acid (NAA) and benzylamino purine (BAP). No multiple shoots of *E. ozelot* were induced in the medium without BAP and increasing BAP concentration increased the number of shoot formation. Increasing NAA concentration in the medium decreased the number of shoot formation but induced the root formation. After they produced roots, they were successfully established in the aquarium.

P2599. Somaclonal variation in *Zingiber officinale* : Screening for tolerance to *Pythium aphanidermatum*

R. Kavyashree, M. C. Gayatri, S. Kiran;
Bangalore University, Bangalore, India.

Somaclonal variants tolerant to rhizome rot disease have been isolated through callus phase using *in vitro* pseudostem and sheathing leaf base explants derived from direct regeneration of *in vivo* vegetative bud of *Zingiber officinale* Rosc. Profuse, compact, creamish white callus was obtained on LSBM fortified with 2,4-D (3 mgl^{-1}), which differentiated into complete plantlets on LSBM fortified with BAP (4 mgl^{-1}). The retrieved 982 plants were screened at culture conditions and 58 morphological variants were isolated. These somaclones were subjected to *ex vitro* sick plot technique to evaluate their disease tolerance potential. The survived somaclones were established in soil for rhizome formation (V$_1$ generation). The seed rhizomes were subjected to *in vivo* sick plot technique to confirm their disease tolerance potential during V$_2$-V$_4$ generations and their tolerance:susceptible ratio was recorded. The tolerant somaclones were evaluated for quality attributes, which were found to be superior and breeding true for all the traits in successive V$_2$-V$_4$ generations suggesting their distinct fidelity over the parental plants.

P2600. Isolation of tolerant clones to culture filtrate of *Pythium graminicolum* through *in vitro* selection technique

M. C. Gayatri, V. Roopadarshini, R. Kavyashree;
Bangalore University, Bangalore, India.

Root rot disease tolerant clones of turmeric variety Suguna were isolated using continuous *in vitro* selection technique against pure culture filtrate of *Pythium graminicolum*. Profuse, compact, creamish white callus obtained from *in vivo* vegetative bud was challenged with pure culture filtrate of *P. graminicolum* to isolate survivable callus, which was further subjected to pure culture filtrate treatment. After three cycles of treatment, four cell lines CL1a$_1$ and CL1a$_2$, CL1b, CL2 tolerant to 1% and 2% culture filtrate respectively was isolated through continuous *in vitro* selection and subcultured on non-culture filtrate regeneration medium along with the non-selected callus to obtain complete plantlets through discontinuous *in vitro* selection technique. Plants from tolerant and non-selected calli were subjected to *in vitro* sick plot technique and screened for disease tolerance, which revealed a ratio of 225:49 tolerant:susceptible clones. However, plants from CL1a$_1$ and non-selected callus were susceptible under *in vitro* sick plot technique. The disease tolerant clones were hardened and established in soil with 90% survival frequency.

P2601. Genetic and Phenotypic Characterization of "TPS1" Transgenic Rice Plants

M. S. Kim, S. J. Kwon, H. J. Park, Y. M. Jin;
National institute of agricultural biotechnology, R D A, Suwoon, Republic of Korea.

We obtained the 4 T$_2$ lines transformed with TPS1 gene and assessed the phenotype and elucidated the inheritance of the transgene using advanced generations. Bar gene analysis revealed that no segregation was observed in T$_4$ generation, indicating that the transgenic lines were homozygous. A possible explanation for the segregation data obtained from the transformed line and it's descendants demonstrated that the T-DNA insertion locus was stably inherited and the linked 2 copies of the T-DNA insert from *TPS1* were incorporated into the rice genome. Drought tolerance of transgenic plants was tested through the treatment of 10% and 20% PEG. The TPS1 transgenic rice plants show no significant resistance to PEG stress compare to wild type plants due to the fact that TPS1 rice plants produced only a trace of trehalose during PEG stress. This suggests that TPS1 gene is not effective enough to protect transgenic rice plants against stress.

P2602. Isolation and characterization of microsatellites loci in the lemon (*Citrus limon*)

B. Golein[1,2], A. Talaie[2], Z. Zamani[2], A. Ebadi[2];
[1]Citrus Research Institute, Ramsar, Islamic Republic of Iran, [2]Tehran University, Faculty of Agriculture, Karaj, Islamic Republic of Iran.

Microsatelitte loci are highly informative genetic markers useful for population genetic studies, linkage mapping and parentage determination. A major limitation of SSRs is the time and cost required to isolate and characterize each locus when pre-existing DNA sequence is not available. In *Citrus*, enough sequence information is not available in database to design primers for microsatellite analysis. This study reports the isolation and characterization of seven polymorphic microsatellite loci in *Citrus*. The loci were isolated from two libraries constructed from genomic DNA nonenriched for TC and AC and enriched for AC repeats. These markers yielded 4 to 9 alleles per locus (mean 6.14) in a survey of 32 *Citrus* cultivars. Average observed heterozygosity ranged from 43 to 72% and expected heterozygosity from 57 to 78%. The levels of polymorphism found in this study suggest that these microsatellite loci can become an important tool for genetic studies in *Citrus.*

P2603. The wild species of the genus Brassica, Cucumis and Solanum in somatic hybridization

M. Greplová[1], B. Navrátilová[2], M. Vyvadilová[3], M. Klíma[3], J. Gajdová[2], D. Skálová[2];
[1]Potato Research Institute, Ltd., Dobrovského 2366, Havlíļ kŢv Brod, Czech Republic, [2]Palacky University in Olomouc, lechtitelŢ 11, Olomouc, Czech Republic, [3]Research Institute of Crop Production, Drnovská 507, Praha - RuzynŊ, Czech Republic.

The aim of the study is using wild species of the *Solanaceae*, *Cucurbitaceae* and *Brassicaceae* in somatic hybridization. The effort is introduction of resistance genes to various diseases from wild plant species to cultural crops. Protoplasts (mesophyll, hypocotyl, callus) were isolated from in vitro plants of *Armoracia rusticana*, *Brassica carinata*, *B. rapa, B. napus,* B. *oleracea*, *Cucumis sativus*, *C. metuliferus*, *C. melo*, *Solanum tuberosum*, *S. berthaultii*, *S. bulbocastanum*, *S. pinnatisectum* and *S.verrucosum*. Protoplast electrofusion was performed in chamber with 0,5 mm electrode distance. These parameters were tested: for protoplast alignment 4 - 10 V AC and 1 MHz frequency with duration of action 1 - 18 s, for fusion 1 pulse 10; 20 or 30 V DC of length 80; 40 or 30 µs. Regeneration of cell walls and first division was recorded in most cases. In Solanum genus microcolonies were found in 15 days, start of plant regeneration in 140 days. In this case 75 plants were obtained after fusion in four combinations. This study was supported by project MSMT CZ OC 843.20, MSM6010980701 and NAZV MZe CZ QF 4108, QF 4133.

P2604. Efficient co-transformation and segregation of uncoupled T-DNAs transferred to barley (Hordeum vulgare L.) by a combination of different Agrobacterium tumefaciens strains

G. Hensel[1], C. Marthe[1], S. Broeders[1,2], J. Kumlehn[1];
[1]Institute of Plant Genetics and Crop Plant Research (IPK), Plant Reproductive Biology, Gatersleben, Germany, [2]EU, JRC, Institute for Reference Materials and Measurements, RM Unit, Geel, Belgium.

Co-transformation techniques are required for independent integration of effector and selectable marker genes, or for the stacking of multiple transgenes. The removal of selectable marker genes (e.g. via segregation) is often necessary prior to transformation with another effector gene or cultivation of transgenic plants in the field. The need for the uncoupled integration of transgenes, along with our previous finding that barley can be efficiently transformed by *Agrobacterium* strain LBA4404 as well as by AGL1, led us to pursue a co-transformation approach using different *Agrobacterium* strains for the expression cassettes to be independently integrated into the barley genome. In this study we introduced a binary vector harbouring the selectable marker gene *HPT,* coupled with the *GFP* gene, into LBA4404 and another binary vector carrying the *GUS* gene without a selectable marker into either LBA4404 or AGL1. All employed transgenes were driven by appropriate constitutive promoters. The results obtained with regard to transformation, co-transformation, integrated copy numbers and segregation of the co-transformed T-DNAs in the progeny will be presented.

P2605. High frequency regeneration of Gladiolus through *in vitro* culture of nodal segments of scape and petal derived callus

S. K. Roy, P. Sinha;
Department of Botany, Jahangirnagar University, Savar, Bangladesh.

Direct shoot bud induction and regeneration of plants were achieved through *in vitro* culture of nodal segments of scape of gladiolus. Nodal segments cultured in MS medium supplemented with 1.5 mg/l BA + 0.5 mg/l NAA induced shoots in 80-85% of cultures within three weeks with 10-12 shoots per culture. Addition of 15% coconut water to the medium increased the number of shoots up to 20 per culture. The shoots were rooted in half strength of MS medium with 2.0 mg/l IBA and 6% sucrose. Callus capable of plant regeneration was initiated at high frequency from flower petals cultured in MS medium supplemented with 2.0 mg/l BAP or 1.0 mg/l 2,4-D. Callus was maintained in callus initiation medium. Shoots were regenerated from the callus in MS medium with 0.5- 2.0 mg/l Kn or/and 0.5-2.0 mg/l BAP. Highest number of shoots was regenerated in MS medium with 2.0 mg/l BAP from one-month-old callus. Shoot regeneration potential of callus decreased with the age and after fifth month no shoot was found to be regenerated. The shoots produced roots in half strength of MS medium with 2.0 mg/l IBA and 6% sucrose. Rooted shoots of both the categories produced cormels at the base of shoots in the same nutrient medium. About 80-90% cormels germinated when sown in the field and 20% of them blossomed in the first year.

P2606. Somatic embryogenesis in a transformed cell culture of*panax ginseng*

T. Gorpenchenko[1], K. V. Kiselev[1], V. P. Bulgakov[1], G. K. Tchernoded[1], E. Bragina[2], M. V. Khodakovskaya[1], G. C. Koren[1], T. B. Batygina[2], Y. N. Zhuravlev[1];
[1]Institute of Biology and Soil Science, Far East Branch of Russian Academy of Sciences, Vladivostok, Russian Federation, [2]Komarov Botanical Institute of Russian Academy of Sciences, St. Petersburg, Russian Federation.

Expression of the *Agrobacterium rhizogenes rolC* gene in *Panax ginseng* callus cells results in formation of tumors that are capable to form roots. The selection of the tumor clusters, which did not develop roots, yielded the embryogenic 2c3 callus line. The ability to form somatic embryos is independent of external growth factors. Such developmental shift is of particular interest because this is the first indication of the *rolC*-embryogenic effect and, to our knowledge, the first indication that a single gene of non-plant origin can induce somatic embryogenesis in plants. The DNA sequence analysis showed that the somatic-to-embryonic transition was not due to a mutation of the *rolC* gene inserted. Although the 2c3 somatic embryos developed through a typical embryogenesis process, they terminated prematurely and repeatedly formed adventitious shoot meristems and embryo-like structures. A part of the shoots and somatic embryos formed dramatically enlarged and fasciated meristems. The observed developmental abnormalities are similar to those that have been previously described for *Arabidopsis* embryogenic calluses where the *WUSCHEL* gene was continuously overexpressed.

P2606a. Determination of The Microspore Development Stage of Different Sized-Buds in Asparagus (*Asparagus officinalis* var. *altilis* L.) for Anther Culture

F. A. Sensoy;
Faculty of Agriculture, Antalya, Turkey.

A series of factors such as genotypes, explants, culture media, pre-treatments and incubation conditions affect the results of *in vitro* anther culture. One of these factors is microspore development stage when flower bud is excised from plant. For most species, the *in vitro* anther culture gives the best results when microspores are at the uninucleate stage or right after this period. In order to determine the optimal stage for androgenesis, male buds were divided into three groups according to their length and width (The first group: 2,5- 2 mm; the second group: 3,6- 2,5 mm and the third group: 4.0-2.5 mm). Anthers were stained with ethidium bromide (3,8-diamino-5-ethyl-6-phenyl phenanthridium bromide) and examined in fluorocence microscope. At the end of the study it was observed that polen from 4 mm length and 2.5 mm width flower buds were binucleate stage, while the others were uninucleate stage. The results revealed that this staining method could be prepared easily and its results could be observed immediately without any pre-treatments.

P2607. Produce of functional plants introduced the CD98 gene for tumor-specific protein

K. Kakuani, N. Moriura, T. Nonomura, K. Matsuda, H. Toyoda;
Kinki University, Higashi-Osaka, Japan.

In an attempt to produce physiologically functional plants exhibiting an anti-cancer effect, we prepared transgenic plants transformed with the CD98 gene for a tumor-specific, membrane-located protein. The CD98 protein plays a significant role on amino acid transport and integrin-mediated adhesion, and is strongly produced in tumorous cells of kidney, small intestine, testis and ovary. In this study, the gene of CD98 taken out of the cancer cell was inserted in binary vector (pIG121-hm), and was introduced into Louts japonicus by using an Agrobacterium -mediated method. The expression of CD98 gene in plant was detected by RT-PCR and Western blotting analysis. As a result, hygromycin-resistance lines selected were shown to successfully transcribe the introduced gene and translate the CD98 protein. Thus, the present study suggests that our approach provides an experimental basis for production of edible vaccine against CD98.

P2608. Metabolic engineering of flavonoid biosynthesis to modify flower colour-from blue to pink and yellow

Y. Tanaka[1], E. Ono[1], M. Fukuchi-Mizutani[1], N. Nakamura[1], Y. Katsumoto[1], Y. Fukui[1], K. Suzuki[2], J. Mason[3], T. Kusumi[2];
[1]Institute for Advanced Research, Suntory, Shimamoto, Japan, [2]Suntory Flowers, Shimamoto, Japan, [3]Florigene Ltd., Victoria, Australia.

Flavonoids confer various flower colours such as yellow (chalones and aurones), orange/red (typically pelargonidin), red/magenta (cyanidin) and violet/blue (delphinidin).

Torenia hybrida cv. Summerwave Blue and Violet mainly produce delphinidin. Down regulation of their respective flavonoid 3'-hydroxylase and flavonoid 3',5'-hydroxylase (F3'5'H) genes accompanied by over expression of rose or pelargonium dihydroflavonol 4-reductase (DFR) yielded pelargonodin-based bright pink flowers. Expression of snapdragon chalcone 4'-glucosyltarnsferase and aureusidin synthase genes and down regulation of anthocyanin biosynthesis produced aureusidin based yellow colour.

Nierembergia cv.Fairybells also lack pink flowers as they produce only delphinidin and flavonols. Pelargonodin-based pink flowers were generated by down regulation of F3'5'H and flavonol synthase genes accompanying over expression of rose DFR. These results indicate that engineering the flavonoid biosynthetic pathway is a powerful way to achieve novel flower colours.

P2609. Light quality influences indigo precursors production and seed germination in Isatis tinctoria L. and Isatis indigotica Fort.

S. Tozzi[1], B. Lercari[2], **L. G. Angelini**[1];
[1]Dipartimento di Agronomia e Gestione dellâ ™Agroecosistema, Pisa, Italy, [2]Dipartimento di Biologia delle Piante Agrarie, Pisa, Italy.

Isatis tinctoria L. and Isatis indigotica Fort are biennial herbaceous plants belonging to the family of Cruciferae that are used as a source of natural indigo and show several morphological and genetic differences. Production of Indigo (indigotin) precursors, Indican (indoxyl Î²-D glucoside) and Isatan B (indoxyl ketogluconate), together with seed germination ability were compared in Isatis tinctoria and Isatis indigotica grown under six different light conditions (darkness, white, red, far red, blue, yellow light) at 25 Â°C. Light quality influenced both germination and production of indigo precursors in the two Isatis species suggesting a different role played by the labile and stable phytocrome species (phyA and phyB) in the Isatan B production in I.tinctoria and I.indigotica.

Our results provide further insights on the distinct behaviour of I. tinctoria and I. indigotica that belong to two different genetic clusters and different original environments.

P2610. Associations between phenotype variation and gene alteration in induced mutations.

L. S. LEE, L. Izquierdo, Y. Chen, N. Rice, R. Henry;
Southern Cross University, Lismore, Australia.

Our research employs gamma radiation to induce genetic change in economically important species from diverse taxa. The association between genetic change at the DNA level and specific phenotypic variants is being investigated. Our work aims to correlate the expression of altered grain quality characteristics in induced mutants with specific genetic changes at the molecular level, using gene-specific PCR primers targeting food quality trait genes. The objective is to better understand the relationships between certain DNA sequences and grain quality attributes amongst our gamma mutated crop populations, which include mung beans and sorghum. For genes associated with various grain quality traits, a high resolution capillary electrophoresis system is used to identify regions which have altered DNA composition. Sequencing of the altered gene regions in mutants exhibiting changed grain quality characteristics is shedding light on the genetic determinants of grain flavour and starch properties.

P2611. Towards generation of plant N-glycans containing biantennary 1,4 galactose

M. Schaehs, H. Steinkellner, R. Strasser;
IAGZ, Vienna, Austria.

Plants are attractive hosts for the production of recombinant proteins of pharmaceutical interest. The majority of therapeutically relevant human proteins need N-glycosylation if to retain full activity. Plant derived glycoproteins contain N-glycans with (1,2)-linked xylose and core (1,3)-linked fucose residues, which are not present in humans, on the other side plant N-glycans lack terminal 1,4 galactose.

In a first approach triple knockout *A. thaliana* plants were generated, with complete deficiency of active (1,2)-xylosyltransferase and of core (1,3)-fucosyltransferase. (XT/FT). These plants synthesise complex N-glycans that completely lack xylose and fucose. To elongate these structures by galactose corresponding mammalian enzyme, 1,4 galactosyltransferase (GalT) were transferred into XT/FT lines. For generation of desired biantennary 1,4 galactose structures a series of fusion constructs containing the catalytical domain of GalT fused to different Golgi retention sequences was generated and transferred *A. thaliana* plants.

P2612. Effects of Over-expression of a Maize Bundle Sheath-specific Phosphoenolpyruvate Carboxykinase in Transgenic Tobacco on its Growth and Metabolism

K. Li[1,2], L. Chen[1,2], M. Tamoi[3], S. Shigeoka[3], N. Hirai[2], K. Ohara[4], K. Yazaki[4], K. Izui[5];
[1]Biotechnology Research Center Kunming University of Science and Technology, Kun-ming, China, [2]Graduate School of Biostudies, Kyoto University, Kyoto, Japan, [3]Graduate School of Advanced Life Science, Kinki University, Nara, Japan, [4]Research Institute for Sustainable Humanosphere, Kyoto University, Uji, Kyoto, Japan, [5]Department of Biotechnological Science, Kinki University, Wakayama, Japan.

PEP carboxykinase (PCK) serves as a decarboxylation enzyme of oxaloacetate in the bundle-sheath cells in PCK type C4 plants. For introduction of a PCK-type C4-like pathway into C3 plants, a maize bundle sheath-specific PCK gene was over-expressed in tobacco under the control of tomato rbcs-3C promoter with its transit peptide. Western analyses showed that the expressed PCK protein was localized in the chloroplasts of the transgenic tobacco. Unexpectedly a single introduction of PCK enhanced the photosynthetic activity and the phenylpropanoid synthesis such as chlorogenic acid. The transgenic tobacco had high level of chlorophyll in their mature leaves. The growth of the transgenic plants was increased significantly when they were grown in a growth chamber under normal conditions and enhanced more significantly under adverse conditions. The growth of the transgenic tobacco showed some correlation with PCK protein level in the plants. The increases in the contents of starch, sucrose, glucose and fructose and aromatic amino acids were also observed in the mature leaf of the transgenic tobacco.

P2613. Metabolic engineering of dhurrin biosynthesis in transgenic Arabidopsis plants with marginal inadvertent effects on the metabolome and transcriptome.

S. Bak, C. Kristensen, M. Morant, C. T. Ekstrøm, C. E. Olsen, B. L. Møller;
The Royal Veterinary and Agricultural University, Frederiksberg C, Copenhagen, Denmark.

Focused and non-targeted approaches were used to assess the impact associated with introduction of new high flux pathways in *Arabidopsis thaliana* by genetic engineering. *A. thaliana* plants expressing the entire biosynthetic pathway for the tyrosine derived cyanogenic glucoside dhurrin as accomplished by insertion of *CYP79A1*, *CYP71E1*, and *UGT85B1* from *Sorghum bicolor* accumulated 4% dry-weight dhurrin with marginal inadvertent effects on plant morphology, free amino acid pools, transcriptome and metabolome. In a similar manner, plants expressing only *CYP79A1* accumulated 3% dry-weight of the tyrosine derived glucosinolate, *p*-hydroxybenzylglucosinolate with no morphological pleitropic effects. In contrast, insertion of *CYP79A1* plus *CYP71E1* resulted in stunted plants, transcriptome and metabolome alterations. The pleiotrophic effects observed in plants expressing sorghum CYP79A1 and CYP71E1 were complemented by retransformation with *S. bicolor UGT85B1.* Accordingly, high flux pathways directing synthesis and intracellular storage of high amounts of natural products is achievable in transgenic plants with marginal inadvertent effects.

P2614. A functional genomics approach to unravel plant secondary metabolism in *Catharanthus roseus* by combining transcriptional profiling with metabolomics

H. Rischer[1], A. Goossens[2], M. Orešiļ [1], F. Lammertyn[2], D. Inzé[2], K. Oksman-Caldentey[1];
[1]VTT Biotechnology, Espoo, Finland, [2]Department of Plant Systems Biology, VIB-Ghent University, Ghent, Belgium.

The medicinal plant *Catharanthus roseus* has been extensively investigated during the last decades in order to utilize cell culture systems for the biotechnological production of important anticancer compounds e.g. vinblastine and vincristine. Despite considerable progress on the genetic and enzymatic level, especially the very complex regulation of the biosynthetic pathway is still poorly understood. We have applied a comprehensive profiling approach based on functional genomics, which is independent of prior sequence knowledge, to monitor jasmonate-induced changes on the transcript and metabolite profiles of cell cultures. cDNA-AFLP based transcript profiling allowed the visualization of more than 10000 gene tags, more than 500 of which were differentially regulated, and include not only structural but also regulatory genes i.e. transcription factors. Additionally, gene expression could be linked to LC-MS based metabolomics, comprising hundreds of compounds, and targeted metabolite analyis, leading one step further towards 'Systems Biology'.

P2615. Effect of salicylic acid on yield, yield components, anatomical structures and some biochemical aspects of chickpea (*Cicer arientinum L.)*

F. Fallahian[1], S. Sabaghpour[2], A. Majd[3], M. Maddah[1], F. Chalabian[3];
[1]Islamic Azad Univercity science & research campus, Tehran, Islamic Republic of Iran, [2]Dari Land Agriculture Researchs Institution, Maraghe, Islamic Republic of Iran, [3]Islamic Azad University North Tehran Campus, Tehran, Islamic Republic of Iran.

Salicylic acid (SA) is now considered as a hormone like substances which affects on plant growth and development.

A field experiment was conducted during 2004 in Shahreray Azad university to determine the effects of SA on yield , yield component and anatomical structure of chickpea cultivar Bivanij. .

The experimental design was a split plot in RCBD with 4 replications in which main plot were 2 treatment methods (spraying and watering SA) and subplot were 4 concentrations of SA (0, 0.1, 0.7, 1.5 mM).plant treatment started at beginning of flowering during 40 days.

The results showed that spraying SA was better than watering.

Yield, 100-seed weight, 100-pod weight, secondary branches, plant height ,total soluble proteins were maximum when 0.7 mM SA was sprayed.

The number of stomata increased when 0.1 mM SA sprayed.1.5 mM SA damaged parenchyma tissues in leaves when it watered, as well as sclerenchyma tissue in stems, xylem in root and the number of leaves trichomes were increased.

The patterns of peroxidase isoforms resulting from leaves were determined by means of polyacrylamid gel electrophoresis. One new lightly band was appeared when 1.5 mM SA was sprayed.

P2616. Genetic modification of soybean (Glycine max) Ŭ-tocopherol using tocopherol methyltransferase gene via A.rhizogenes transformation

H. Park, M. Kim, K. Kim, S. Kwon, J. Kim, Y. Jin;
National Institute of Agricultural Biotechnology, Suwon, Republic of Korea.

Soybean genetic modification was performed in order to alter the vitamin E composition aimed at understanding the good food quality as a change ɔ-tocopherol to Ŭ-tocopherol. Vitamin E, which is composed of the tocopherol is a lipid-soluble antioxidant and Ŭ-tocopherol has the highest vitamin E activity compared with other type of tocopherol. Meanwhile, a lot of oil plants contain more ɔ-tocopherol than Ŭ-tocopherol. In order to convert ɔ- tocopherol to Ŭ-tocopherol in soybean, we have cloned ɔ-tocopherol methyltransferase (*tmt*) gene from *Perilla frutescens*, constructed binary vector harboring *bar* and *tmt* gene and transformed soybean by *A. rhizogenes* mediated method. Putative individual transformed hairy roots were screened for transgene incorporation using PCR and genomic Southern blot analysis after *agrobacterium* decontamination. The expression of introduced-*tmt* gene was confirmed in hairy roots of soybean by Northern blot. As the tocopherol composition in the transgenic soybean hairy root was analyzed by HPLC, the data showed that more than 90% of ɔ-tocopherol in the transgenics was converted into Ŭ-tocopherol.

P2617. Brassinolide improves the physiological efficiency in growth and seed yield of black gram (Vigna mungo)

J. Prabhakaran;
Agricultural College and Research Institute, Killikulam, Thoothukudi, Tamil Nadu, India.

The imbalanced relationship between the source and sink organs causes a considerable reduction in the potential seed yield of black gram. Early leaf senescence, excessive flower drop and poor harvest index are the factors that cause less productivity. Studies were undertaken in black gram cv. ADT 5 to tap its potential yield through physiological alterations in the plant system. Naphthalene acetic acid (NAA), salicylic acid (SA), mepiquat chloride (MC), brassinolide (BR), triacontanol and a micronutrient formulation were fed to the plants as foliar application at pre-flowering stage. NAA 40 ppm caused increased plant height, more number of branches, higher leaf area index and leaf area duration. But, with regard to physiological parameters, the photosynthetic efficiency was observed high in BR 0.1ppm treated plants as evidenced by the higher specific leaf weight, chlorophyll, soluble protein, stomatal conductance and nitrate reductase activity. Among the treatments, BR 0.1ppm resulted in higher dry matter accumulation, more number of pods and seeds per plant and thereby maximum seed yield. Seed protein content was also found improved due to BR application.

P2618. Production of isoflavone in *IFS1* transgenic rice

H. Park[1], G. Yi[1], E. Jeong[1], J. Choi[1], J. Ko[1], N. Kang[1], Y. Chung[2], I. Rhee[3], M. Nam[1];
[1]YARI, NICS, RDA, Milyang, Republic of Korea, [2]University of Dong-A, Pusan, Republic of Korea, [3]Kyoung-Pook National University, Taegu, Republic of Korea.

Isoflavonoids are a diverse group of plant natural products synthesized from phenylpropanoid which play important roles in plant growth and development, and in defense against microorganisms and pests. These compounds often possess antioxidant and estrogenic anti-cancer activity, and are also receiving considerable attention as health-promoting nutraceuticals. Metabolic engineering for production of isoflavone in rice may provide the health benefits of these phytoestrogens from consumption of more widely used grains.

We cloned *IFS1* from Korean soybean cultivar, Sinpaldalkong 2 known as one of isoflavone rich cultivars with PCR and specific primers. Expression vector of *Glb-SinIFS1* for rice seed specific expression was constructed and transferred to binary vector. The plasmid was introduced into color rice containing flavanones. Expression of *Glb-SinIFS1* gene in the color rice resulted in the synthesis and accumulation of the isoflavone genistein in seeds. This study provides a good example for development of new trait rice added health promoting nutraceuticals through the genetic manipulation.

P2619. Engineering wheat with improved resistance to Fusarium head blight

M. N. Somleva[1], A. E. Blechl[2];
[1]University of California, Davis, CA, United States, [2]USDA-ARS, WRRC, Albany, CA, United States.

Fusarium head blight or scab is one of the most destructive fungal diseases of wheat, causing significant reductions in grain yield and quality. Trichothecene mycotoxins (e.g. deoxynivalenol or DON) produced during infection further reduce grain quality. Our goal is to improve host resistance to scab by introducing genes whose products might induce wheat defense responses or decrease the toxicity of trichothecenes. In order to limit initial fungal infection, wheat was transformed with genes controlled by the organ specific promoter, *Lem1,* and encoding enzymes involved in activated oxygen metabolism. The introduced enzymes accumulate in the outer floral organs from anthesis to early kernel development, during which period wheat is most vulnerable to *Fusarium* infection. Mitigating trichothecene toxicity was achieved by introducing genes encoding DON acetyltransferase and a trichothecene efflux pump. Their constitutive co-expression results in a 40-50% reduction in the spread of *Fusarium* infection through the spike. The synergistic effects of the transgenes on enhancing plant structural defenses and decreasing DON levels will be discussed.

P2620. A strong non-specific upstream regulatory region for gene expression in plants

D. V. Belyaev[1,2], G. V. Raldugina[1];
[1]Institute of Plant Physiology, Moscow, Russian Federation, [2]Moscow Institute of Physics and Technology, Dolgoprudny, Russian Federation.

The two versions of the upstream transcription regulatory regions of a peanut gene differing by the presence of an intron were translationally fused to a reporter gene GUS and the resulting cassettes were stably introduced in tobacco by *Agrobacterium*-mediated transformation. The intron-containing construct resulted in plants with the moderate levels of the GUS activity whereas the construct without introns was about 10-fold more active in all plants analysed. The GUS activity measured in leaf extracts of some of the latter plants was about two- to three times higher than the activity usually obtained from the CaMV 35S promoter. These results together with our earlier transient expression experiments on this regulatory region support the hypothesis that the intron in question contains a tissue-specific transcriptional silencer and can be used to genetically engineer peanut in order to control its contamination with aflatoxin and for the other agriculturally important traits. The strong promoter variant may certainly be used for the overexpression of the genes of interest.

P2621. Development of acyanogenic cassava lines by RNAi technology in African elite varieties

K. Jørgensen[1], S. Bak[1], C. Sørensen[1], S. Jensen[1], C. Olsen[2], B. Lindberg Møller[1];
[1]Department of Plant Biology, Plant Biochemistry Laboratory, Frederiksberg C, Denmark, [2]Department of Natural Sciences, Frederiksberg C, Denmark.

Cassava, *Manihot esculenta,* is the most important root crop and the third most important staple food in the Tropics. Major deficits of cassava are low protein content in the tubers, fast post-harvest tuber deterioration and high content of the two cyanogenic glucosides linamarin and lotaustralin. Upon tissue disruption, the cyanogenic glucosides are degraded resulting in release of hydrogen cyanide. No acyanogenic cassava cultivars are known. Use of cassava as a stable food requires processing to remove the cyanide. Proper processing tends to result in loss of protein, minerals, and vitamins.

Cassava is allopolyploid and we have isolated the two *CYP79* paralogs, *CYP79D1* and *CYP79D2*, which encode enzymes catalysing the rate limiting step in cyanogenic glucoside biosynthesis. To block this pathway, RNAi technology has been used with a construct containing a 300 bp fragment of each of the *CYP79* paralogs.

Using RNAi technology we have produced acyanogenic cassava lines from several African elite lines. Analysis of the leaves of transformants revealed lines in which the cyanogenic glucoside content was reduced to less than 1% of wild-type levels.

P2622. Effect of anthocyanins, extracted from berries cultures, on cancer cells

C. Forni[1], A. Lentini[1], M. Nicotra[2], A. Frattarelli[3], G. Vestri[1], C. Damiano[4], S. Beninati[1];
[1]Dipartimento di Biologia, Roma, Italy, [2]Università di Catania, Catania, Italy, [3]Istituto Sperimentale per La Frutticoltura, Roma, Italy, [4]Istituto Sperimentale per la Frutticoltura, Roma, Italy.

Anthocyanins, present in fruits and vegetables, belong to phenolic phytochemicals linked to reducing the risk of cancer.

This work has been undertaken in order to investigate the effect of anthocyanins, produced by berries cultures, on proliferation of B16-F10 melanoma murine cell line.

Anthocyanins were extracted from suspension cultures of strawberry (*Fragaria* x *ananassa* Duch.), raspberry (*Rubus idaeus* L.), and blackberry (*Rubus fruticosus* L.). To increase pigments production, the cultures have been exposed to blue light (400-600 nm) or red light (675 nm); control cultures were exposed to visible light. At the end of the experiments, anthocyanins were extracted and their amounts were determined by spectrophotometer.

The growth of the cultures was enhanced by different lights only in raspberry (blue and red light) and blackberry (blue light), while anthocyanin yield was not affected by the type of light.

The higher inhibition of melanoma cell growth was obtained by treating the cells with anthocyanins extracted from berries cultures exposed to blue light.

Grants from the Regione Lazio (PRAL) and the Ministry of University and Scientific Research (PRIN)

P2623. Medicinal plants used by Traditional Birth Attendants in Kenya

P. K. Daniel, W. M. Musila, J. M. Muema;
National Museums of Kenya, Nairobi, Kenya.

Maternal health provision in Kenya is beyond the reach of most rural women populations.Medicinal plants in Kenya are widely used by TBAs in maternal and child healthcare management. Ethnobotanical surveys were carried out to document medicinal plants used in traditional midwifery in Kamba community of Kenya.The study shows that medicinal plants are widely used by traditional midwives during pregnancy, delivery and during post-natal period. The high use of medicinal plants is mainly due to poor road net network, scarcity of health facilities and unaffordable modern medicine.During the study,430 respondents(TBAs)were interviewed within four districts which form the Kamba community in Eastern province of Kenya.Two hundred plant species were found to be used at one point of the maternity circle or another. Consensus as a quantitative criterion was used in recording field information.Descriptive statistics was used in data analysis.Population reduction criterion was used to determine priority species in need of urgent conservation.Based on this, 14 plant species were found to have become rare due to over exploitation.

P2624. Physiological responses of parsley plants (*Petroselinum crispum*) to Cr^{+3} accumulation

A. Zaker, P. Abrishamchi, M. Lahouti, H. Ejtehadi;
Ferdowsi university, Mashhad, Islamic Republic of Iran.

Cr^{+3} is an essential micronutrient for carbohydrate and lipid metabolism in human and animals. One of the ways for preventing of chromium deficiency and its undesirable effects can be using chromium accumulator plants in daily diets.

For this purpose, parsley (*Petroselinum crispum*) seedlings were grown at hydroponic culture (Hoagland) containing various levels of Cr^{+3} (0.1- 3 mg/l). After 5 weeks, Cr^{+3} accumulation and its effects on growth rate (root and shoot dry weight and length), chlorophyll a and b content and concentrations of Ca^{+2}, K^{+} and Na^{+} in the roots and shoots were studied.

Results showed that parsley growth, chlorophyll content and concentrations of Ca^{+2}, K^{+} and Na^{+} decreased as Cr^{+3} concentrations increased in growing media.

With increasing Cr^{+3} levels in medium, its concentration in the roots and shoots increased significantly, so that in plants grown at tolerance threshold concentration (2 mg/lCr^{+3}), chromium content in the root and shoot was 22 and 6 fold higher than the plants grown at 0.1 mg/lCr^{+3}, respectively. Chromium accumulation in the root was more than the shoots.

P2625. Changes in morphine alkaloid pattern of *papaver somniferum* seeds as a result of thermal degradation

L. Puchinger, D. Leichtfried, R. Paltram;
Institute of Chemical Engineering, Vienna, Austria.

The content of opium alkaloids in *papaver somniferum* seeds varies between 2 and >964 mg/kg for morphine, 0.1 and 79 for codeine and 5 and 30 for thebaine. The level of total opium alkaloids in blue poppy seeds is tentimes the quantity in grey sorts. Containing higher amounts of alkaloids there is no great demand in consequence of their pharmacological-toxicological properties and their possibility of improper use. Only a few grams of this natural product and someone can be suspected of having consumed drugs. Extensive studies were necessary to find out the perfect temperature of 140°C during 45 minutes to reduce the alkaloid content of poppy significantly. In the case of blue poppy seeds morphine decreased from 270 to 180 mg/kg (65 % related to the initial state), codeine from 75 to 44 (60 %) and thebaine from 30 to 9 (30 %). The loss of thebaine can be explained with sublimation process, by morphine and codeine mainly a thermal induced formation of alkaloid condensation products has to be expected. It is a further advantage of thermal treatment of poppy seeds that microorganisms are destroyed and free fatty acids are lowered, thus obtaining a better food quality.

P2626. Aromatic plants for food industry - researches in Ukraine

O. Korablova[1], V. Rabotyagov[2];
[1]National Botanical Garden of NAS of Ukraine, Kiev, Ukraine, [2]Nikita Botanical Garden - NSC, Yalta, Ukraine.

Intensive researches with aromatic plants in Ukraine began in the second part of XX c., and in department of new cultures of National Botanical Garden of NASU - since 1974. The main purpose was to substitute imported spice and used widely in perfumery industry and food enrichment of the cultivated flora medicinal. High price of exotic spice in our country has caused necessity to find spice plants in aboriginal flora of Ukraine or to introduce of them from the South. For the first time in Ukraine were assembled about 120 kinds aromatic plants. The origin most of them is tropics and subtropics. Our studies identified a number of aromatic plants, among them we selected edible plants from Mint Family (Lamiaceae): *Lophanthus, Monarda, Majorana, Salvia, Hyssopus* etc. which cultivated to be used as herbs and as a source of essential oils.

In the several last years most of researches on the aromatic plants were focused on the adaptability of the crop to local conditions.

Studies of the quality essential oil were conducted, to help evaluate the commercial potential of the crop in Ukraine. Essential oil was obtained by water distillation procedure and identification of components by GC.

P2627. Cornelian cherry (*Cornus mas* L.) as alternative species for utilization in diet, landscape architecture and pharmacy

P. Brindza[1], V. Horcin[2], J. Brindza[2], D. Tóth[2], J. Gazo[2], J. Holecyová[2];
[1]Slovak University of Agriculture, Nitra, Slovakia, [2]University, Nitra, Slovakia.

Cornelian cherry belongs among originally widespread species in Europe. It is potential economical valuable fruit species also for cultivation in monocultures. Experimentally were evaluated 250 ecotypes from the Gemer region in Slovakia. The fruit weight was in range 0.6 to 2.7g, fruit length 13.2 to 20.1 mm, proportion of the flesh 77 - 86%, content of vitamin C 16.45 - 78.58 mg/100g, content of organic acids 4.6 - 7.4%, and total amount of sugars 6.6 - 15.1%. Descriptor list for evaluation of genotypes was made on the results base. Experimental data and image documentation were used in processing of the information system for genotypes in *GENOTYP*DATA *Cornus mas* L. evidence. Results confirmed possibility of genotypes detection as well as selection for economical utilization.

P2628. The Effects of Aqueous and Alcoholic Extracts of Walnut's Leaves (*Juglans regia*) on the Blood's Biochemical Factors of Diabetic Rats

M. Behnam-Rassouli[1], **I. Jahansooz**[2], Z. Majidi[1];
[1]Dept. of Biology, School of Sciences, Ferdowsi university of Mashhad, Mashhad, Islamic Republic of Iran, [2]Dept. of chemistry, School of Sciences,, Mashhad, Islamic Republic of Iran.

In this investigation the effects of aqueous and alcoholic extracts administration of walnut's leaves (Juglans rejia) on the serum levels of glucose,urea, triglyceride and cholesterol of diabetic rats were studied

Aqueous and alcoholic extracts of walnut's leaves were prepared by maceration technique and then their lethal doses were measured. From 48 male and female rats, 8 rats considered as control (non diabetic) and the others were made diabetic by subcutaneous injection of 120 mg/kg body weight Alloxan monohydrate.

Diabetic rats were divided into experimental groups 1 (with no treatment), 2 (treated with 0.5 g/kg body weight aqueous extract) and 3 (treated with 0.35 g/kg body weight of alcoholic extract). Blood samples were collected weekly for a period of four weeks and the serum levels of glucose, urea, triglyceride and cholesterol were measured. The results indicate that administration of both extracts may lower the serum levels of glucose and urea and may increase the serum levels of cholesterol and triglyceride.

P2629. Essential oils of some Lamiaceae speces: powerful inhibitors of lipid peroxidation

B. Bozin[1], N. Mimica-Dukic[2], N. Simin[2], G. Anackov[2], R. Igic[2];
[1]Faculty of Medicine, Novi Sad, Serbia and Montenegro, [2]Faculty of Sciences, Novi Sad, Serbia and Montenegro.

With the increasing environmental pressures for industry to use "*clean technology*" and to utilize sustainable sources of materials for manufacturing process, recent researches are concentrated on natural sources of antioxidants such as different plant extracts.

In this study, the effects of essential oils obtained from ten Lamiaceae species (genera *Melissa*, *Mentha*, *Ocimum*, *Origanum*, *Rosmarinus*, *Salvia* and *Thymus*) on Fe^{2+}/ascorbate and Fe^{2+}/H_2O_2 induced lipid peroxidation (LP) in the liposomes was evaluated by TBA-test.

All examined essential oils expressed strong inhibition of LP in both systems of induction. In the Fe^{2+}/ascorbate induced LP all tested essential oils exhibited very strong influence on LP, amongst which highest inhibition was expressed by essential oils of *Mentha longifolia* (94%) and *Origanum vulgare* (85.46%). In the Fe^{2+}/H_2O_2 induced LP the highest LP inhibition was observed with the oils of *Melissa officinalis* (94.59%) and *Salvia nemorosa* (84.69%).The obtained results confirm the standpoint that the plants of the Lamiaceae family are very promising sources of natural antioxidants depending to the essential oils constituents.

P2630. Studies in Basilicum polystachyon (L.) Moench: germination, micropropagation and production of antioxidants, caffeic acid and rosmarinic acid.

D. Chakraborty[1], P. K. Bhattacharyya[1], A. Bandyopadhyay[1], A. Mitra[2], K. Gupta[1];
[1]The University of Burdwan, Burdwan-713 104, WB, India, [2]Natural Product Biotechnology Group, Agricultural & Food Engineering Department, Indian Institute of Technology, Kharagpur 721 302, India.

The germination behavior of *Basilicum polystachyon* Moench, an ethnomedicinal herb, revealed that the seed dormancy could not be removed by physiological and scarification treatments. Treatment with 100ppm GA_3 resulted in 98% germination and it was found to be concentration dependent. Realising its rare occurrence, an efficient regeneration protocol was invented. To develop an *in vitro* regeneration method, the potentiality of various plant parts on Murashige and Skoog's medium (MS) supplemented with 0.5, 2.5, 5, 10µM napthaleneacetic acid (NAA) and 6-benzyladenine (BA) either singly or in all possible combinations was studied. Green compact calli was obtained from the shoot tip explant within two weeks. Optimum concentration for multiple shoot regeneration was 2.5 and10µM NAA and BA in combination producing 14.39±3.07 shoots. Rooting was achieved in half strength MS medium. The plantlets were transferred to the experimental plot after hardening with 99% survivability. *In vitro* flowering of rooted microshoots produced viable non-dormant seeds. Micropropagated plants revealed caffeic acid (0.804 mg/g f wt.) and rosmarinic acid (1.421 mg/g f wt.).

P2631. The Oily Pumpkin (*Cucurbita pepo* var. *styriaca*) as an source for nourishment and biological actively components

Z. Balatova, J. Nozková, J. Brindza, B. Brezinova, J. Popik;
Slovak University of Agriculture in Nitra, Nitra, Slovakia.

In the experiments we have been evaluating a variability of 36 quantitative and qualitative characters on flowers, fruits and seeds of the oily pumpkin (*Cucurbita pepo* var. *styriaca*). We received the pumpkins from a vesture at acreage 30 ha. By the appreciation of the characters the following measures have been designated: seeds weight from fruit in a dry state 0.5 - 257 g, the number of evolved seeds in the fruit 8 - 800 pieces, a seed's width of 6.8 - 12.0 mm, a seed's length of 11.2 - 32.7 mm and a seed's thickness of 1.8 - 32,7 mm. We have found some correlation coefficient of r = 0.41 - 0.59, between the characters fruit length and seeds length, the fruit weight /seeds weight in fresh state with a correlation coefficient of r = 0.69 - 0.87 and the number of seeds in fruit/weight fruit with a correlation coefficient of r =0.61 - 0.79. The important variability was found in the colour of the flesh and in the chemical composition of the flesh, the seeds and the flowers.

P2632. Effect of 40 Vegetable Extracts on Differentiation of 3T3-L1 Preadipocytes into Adipocytes

E. Matsuda[1], Y. Yoshizawa[2], N. Chida[2], N. Watanabe[2], A. Matsubuchi[1], N. Muto[1], S. Kawaii[3], N. Murofushi[2];
[1]Akita Prefectural Institute of Public Health, Akita, Japan, [2]Akita Prefectural University, Akita, Japan, [3]Tokyo Denki University, Saitama, Japan.

Obesity, diabetes, hypercholestemia, and hypertension occur primarily genetically, but they are often triggered by imbalanced lifestyle related to overnutrition. This is the reason the diseases are collectively called "lifestyle related diseases", and as they are risk factors for atherosclerosis, their prevention is of great importance. The strategy is to take measures of primary prevention for lifetime. Diet rich in vegetable and fruit has been recommended to reduce the obesity and the risk of atherosclerosis, but their active components and mechanisms of action have not been fully understood. We examined 40 vegetable extracts for their effects on differentiation of 3T3-L1 preadipocyte cells to adipocytes. As the result, some inhibited lipid accumulation in the cells while the others accelerated it. We identified by HPLC analysis several phenolic compounds, which were partially responsible for the activity. Purification and characterization of other active ingredients are undergoing.

P2633. Citrus Flavonoids and Their Anticancer Activity

S. Kawaii[1], E. Matsuda[2], Y. Yoshizawa[2];
[1]Tokyo Denki University, Saitama, Japan, [2]Akita Prefectural University, Akita, Japan.

Flavonoids are important secondary plant metabolites, and are mainly present in plant tissues in relatively high concentrations as sugar conjugates. Epidemiological studies have indicated that flavonoid consumption is associated with a reduced risk of cancer. The aim of this study was to survey the relationship between anticancer activity and the content of major flavonoid in the edible part of the representative Citrus species and the relatives according to Tanaka’s classification. Various Citrus were subjected to screening for anticancer effect, which was assayed by the differentiating activity against promyelocytic leukemia cells, and to high-performance liquid chromatography analysis of flavonoids. We precisely evaluated the influence of cultivars on flavonoid composition by principal component analysis. The principal component analysis revealed that the distribution of Citrus species belonging to different classes was largely in accordance with Tanaka's classification system.

P2634. The effects of hydro alcolic extract of soya in the histological structure and the level of estradiol and testosterone in male sorie

M. Rahnema, S. Nassiri, H. Ghassempour;
Azad university Zanjan, Zanjan, Islamic Republic of Iran.

Soja is a rich source of phytoestrogen.Therefore,the objective of this project was to determine whethere soja extract can chenge the structure of male reproductive tissue and it can influence on the level of sex hormon. For this purpose,50male sories were selected and divided into 4 groups.3experimental groups were fed with 150 ,100 and 75 mg/kg of hydro alcoholic extraction of soja and control group were fed with the water for 50 days .Blood samples were taken in zero and fiftieth day of experment and the level of sex hormon were measured and repoductive tissue were removed , fixed , processed and stained with H and E staning metod. Histological of servtions were revealed some changein testis. In the testis many spermatcytes at the metaphase stage in 150 mg/kg and 100 mg/kg treated groups and some of these mitotic figures. In conclusion , it seems that soja extract can change the spermatocyte , in low concentration,it may induce proliferation and high concentration, it may lead to cell deat and nucleus fragmentation.The result indicated that level of testosteroneand estradiol was decreased significantly in the group that was fed with 150 mg/kg.

P2635. Changes in soya bean seed under unfavourable conditions

L. M. Prijic[1], M. Srebric[1], B. Vucelic-Radovic[2], M. Barac[2], G. Cvijanovic[1], V. Peric[1], S. Stanojevic[2];
[1]Maize Research Institute Zemun Polje, Belgrade-Zemun, Serbia and Montenegro, [2]Faculty of Agriculture, Belgrade-Zemun, Serbia and Montenegro.

Conservation of plant germplasm is important goal in plant breeding programs and in preservation of biodiversity. Fast germination decline during long-term storage may cause loss of important varieties. Changes in seed were investigated on four soya bean varieties. Two treatments of accelerated ageing method were used to produce the effect of prolonged storage. Standard germination test, cold test and tetrazolium test were conducted to determine the germination and vigour in seed. Soybean seed showed decrease in germination and vigorous seedlings number after AA treatments, especially in seed with lower initial germination. Protein content in soya bean seed with standard quality is 38 - 45 %, thus the seed has short storage life. The change of soluble protein and free amino acid content in the seed of investigated cultivars was determined. SDS-PAGE and densitometric analysis were used to determine the alterations of major soybean protein subunits as a function treatment conditions while the HPLC method was used to detect the change of sucrose content.

P2636. Antiproliferative and Antioxidant Properties of Crabapple Juices

Y. Yoshizawa[1], K. Sakurai[1], S. Kawaii[2], J. Soejima[3], E. Matsuda[1], N. Murofushi[1];
[1]Akita Prefectural University, Akita, Japan, [2]Tokyo Denki University, Saitama, Japan, [3]National Institute of Fruit Tree Science, Morioka, Japan.

Juices prepared from 42 crabapples (*Malus* spp.) were studied attempting to explore their antiproliferative activity. Most of the juices examined showed strong inhibition on proliferation of HL-60 human leukemia cells. The amounts of total phenolics and total anthocyanin, as well as DPPH radical scavenging activity were measured. The antiproliferative effect was more correlated to the amount of polyphenol than that of anthocyanins. Generally speaking, the stronger DPPH radical scavenging activity, the higher antiproliferation on HL-60 was shown. The colors and sizes of fruit and the colors of flower were not strongly correlated to antiproliferative activity, although all of the middle size (1 to 3cm in diameter) fruits examined showed strong HL-60 antiproliferative and DPPH radical scavenging activities. The results suggested a possibility of utilizing crabapple juices as one of the processed foods and beverages contribute to keep good health.

P2637. Forest Tree Seeds: Alternative Source of Human Nutrition.

K. V. Sutaria, B. R. Pandit;
Department of Life Sciences, Bhavnagar, India.

Food the most important, fundamental need, evolved with the existence of the living world. Besides the edible seeds, which are consumed by the living world, forest tree seeds may be a good source of food. These seeds are available in abundance in the forest but are under utilized because of the ignorance of their nutritional status. Thus, 22 forest tree seeds from the Victoria Park (reserved forest) near Bhavnagar (Gujarat) were selected for the study and analysed for their protein, reducing and non-reducing sugars, starch and oil content.

From the estimation for biochemical constituents of seeds, out of 22 species 17 species (9 leguminous and 8 non - leguminous) had fairly good amount of protein. The seeds of 16 (10 leguminous and 6 non-leguminous) species found rich with the good amount of total sugar. Seeds of 14 species (9 leguminous and 5 non-leguminous) species found enriched with starch content. In case of oil content seeds of 10 non-leguminous species and seeds of 2 leguminous species had fairly good percentage of oil.

P2638. Effect of different pathogenic organisms on sugarcane juice quality

B. Fontaniella[1], C. Vicente[2], M. E. Legaz[2];
[1]Rey Juan Carlos University, Móstoles, Madrid, Spain, [2]Complutense University, Madrid, Spain.

Sugarcane diseases caused by pathogenic organisms have often been associated with juice quality changes. In this work, variations in some saccharimetric parameters as % of pol (% of sucrose by polarimetry), brix (soluble solids), reducing sugars, and purity, currently used as juice quality markers were analysed in response to different diseases.

To study Yellow Leaf Syndrome, a disease produced by a phytoplasma, two susceptible sugarcane cv. were chosen: C 120-78 and C 87-51. Results show that YLS infection results in high values of % of pol, brix and purity and low values of reducing compounds, which reflect a high juice quality.

To study leaf scald disease produced by *X. albilineans*, L 55-5 and C 439-52 cv., both susceptible to the disease were chosen. Results show that sugarcane juices from diseased plants presented lower pol, brix and purity values and higher reducing sugars concentration than those obtained from healthy plants.

Smut disease, caused by *U. scitaminea* was study in two cv., My 55-14 (resistant) and Ba 42-231 (susceptible). Not significant differences in saccharimetric parameters were observed between healthy and diseased plants.

P2639. Optimisation of Flavonoid-rich Extracts of *Anthemis tinctoria* and their Applicability in Food Industry

S. Siebenhandl, E. Berghofer, G. Bindeus;
University of Natural Resources and Applied Life Sciences, Vienna, Austria.

Anthemis tinctoria (Compositae) is a herbaceous plant widespread in Europe and formally used as natural dye for cloth.

Among the metabolic products are carotinoids and flavonoids which account for the brilliant yellow colours but as well protect cells and tissues by deactivating singlet oxygen. In this context, it is noteworthy to discuss *Anthemis tinctoria* as potential source for naturally occurring antioxidants in food systems.

The objectives were (1) to define optimum conditions for extraction in respect to antioxidant activity, total yield, total phenolic content and (2) to test the applicability of extracts in food technology.

Optimum extraction conditions were found in the range of 40% to 60% ethanol, possessing antioxidant activity, shown by inhibitory activity in sunflower oil oxidation (Peroxide value) and radical scavenging activity (DPPH° radical). Further research addressed various aspects of extracts obtained in pilot scale as useful food additive (colorant, antioxidant, preservative).

P2640. Identification and Characterization Of A Novel Biodegradable Polymer From Natural Cocos Kernel for its Pharmaceutical Application

S. Madhav, E. Hossain, U. Shankar;
Pharmacy College, Azamgarh, India.

The main aim of our present investigation deals with the isolation and characterization of a stabilizer from *Cocos nucifera* kernel by elemental analysis, UV, IR, NMR and mass spectroscopic studies.
Further, the isolated Cocos polymer was employed for the formulation of magnesium carbonate suspensions, aspirin granules for formulation of tablets and filmability character of the polymer was also assessed. The formulated suspensions were evaluated for its stability. The results revealed that the formulated suspensions showed promising stability. The aspirin tablets were formulated using Cocos polymer solution as binding agent. It was found that the Cocos polymer exerted good bindability. Cocos polymer also showed good filmability, which was confirmed by evaluating the casted films.
Finally, the conclusions were drawn that the novel Cocos stabilizer is polymeric protein in nature and it can be categorized under modern natural biodegradable suspending agent, binding agent and film former.

P2641. Determination of mono- and disaccharides in green coffee and their nutritional significance

K. Derler, M. Murkovic;
University of Technology, 8010 Graz, Austria.

Plants produce a wide range of mono-, oligo- and polymeric carbohydrates for a multitude of physiological and structural purposes, with glucose being the key molecule in living systems. Content and composition of carbohydrates contribute significantly to the nutritional value of foods. In addition, flavour and aroma of foods are particularly determined by carbohydrates and its reaction products during processing, e.g. Maillard reaction and glucose degradation products. Profiling free carbohydrates including several provenances of *Coffea arabica* L. and *C. canephora* L. var. *robusta* were performed by high performance anion exchange chromatography coupled to pulsed electrochemical detection.
In the range of free carbohydrates sucrose dominates the low molecular weight carbohydrate fraction of both species, whereas galactose, glucose and fructose are present in very low amounts.
This work is part of the EU-Project HEATOX investigating the formation of acrylamide in carbohydrate-rich foods.

P2642. *Rhododendron Kotschyi* - Natural Source of Antirheumatic Medicine

R. Popescu, C. E. Gard, M. Dinu;
Faculty of Pharmacy, Bucharest, Romania.

Both *Rhododendron ferrugineum* species growing in western, central and southern Europe and *Rhododendron chrysanthum* species in eastern Asia are frequently used as antirheumatic homeopathic therapy. By using them the side effects of allopathic therapy are avoided.
These two species do not grow in eastern Europe. Instead, *Rhododendron kotschyi* species, on which very little pharmaco-botanical studies have been done, are present in this area.
Our research includes botanical and phramacognostical analysis of *Rhododendron kotschyi* vegetal product (leaves and flower buds) collected from Romania. We used water, ether and alcohol extractive solutions for qualitative determinations. We also did quantitative determinations and comparative analysis of *Rhododendron ferrugineum* and *Rhododendron kotschyi* homeopathic tinctures.
Our finding confirms the similitude of the species taken into study and the possibility of using *Rhododendron kotschyi* as antirheumatic natural medicine.

P2643. Inventory of ether essential oil of aromatic fragrant and spice plants of Armenia and their rational usage

M. S. Musaelian, A. A. Charchoglian;
Institute of Botany of Armenian NAS, Erevan, Armenia.

We present to your consideration the results of inventory of ether essential oil, aromatic fragrant and spice plants of Armenia, which by classification of M.M.Iljin are classified by thried groups. We discovered that 190 species with aromatic plants belong to 45 families: Lamiaceae - 36 species, Apiaceae - 34, Brassicaceae - 21, Asteraceae -19, Fabaceae -10, Rosaceae - 9; Ranunculaceae - 8, Polygonaceae - 7, and the rest from 1 to 4 species belong to other different families. There was made up an index for their usage: spice-aromatic, aromatic-fragrant and spices plants, tea usable, food usable /stuffs/, medicinal plants, medicinal-prophylactic plants as well as used in the perfume and cosmetic industries. There is done the index of ether essential oil and aromatic plants by their therapy activity: in the heart and blood system disease; in the diseases kidney, and bladder; in the disease of gynecology and lactamatic diseases, in the violation of metabolism, in the diseases of nervous system and in external usage.

P2644. Production of Rutin by *in vitro* Cultures of *Calotropis procera.*

S. Ahmad, R. Zafar;
Jamia Hamdard, New Delhi, India.

In vitro production of phytoconstituents is very important tool to ensure high, reliable and reproducible quality. Rutin is the most promising venoactive antioxidant bioflavonoid. Since production of rutin is very much dependant on its extraction from various plant species including *Calotropis procera* which, contains highest amount of rutin in leaves. In the present investigation therefore, an attempt has been made to raise static, cell suspension and transgenic cultures using *Agrobacterium tumefacines* and *A. rhizogenes* in MS and modified MS medium from leaf, stem and root explants as an alternative source for better and regular supply of rutin. The estimation of rutin was carried out by HPTLC method, which was developed and validated by the author and the content of rutin was found increased several folds in transgenic cultures. The highest amount of rutin was found in *A. tumefacines* mediated transformed cultures grown in liquid and semi solid media (MS 1/2) followed by shoots regenerated from leave callus and hairy root cultures. Leaf callus and its cell suspension culture also showed more than 2 and 5 folds increased production of rutin respectively.

P2645. Isolation and determination of fatty acids in oil of seeds and leaves of cotton (var. sahel) and peanut (var. gillane).

B. Delnavaz Hashemloian, a. ataei azimi;
azad islamic university, Saveh, Islamic Republic of Iran.

Cotton (*Gossypium hirsutum*) and peanut (*Arachis hypogaea*) are important source of oil currently used in the food industry. In this research oil of seed and leaf of cotton varSahel and peanut var. Gillan were extracted by choloroform and methanol. After measurment, the extract was prepared for analizis and recognation of fatty acid content by GC-MS. This technique were accompanied by realising of fatty acids by saponification and methylation with sulforic acid-methanol-toluen reagent and then methylated fatty acids were injected to GC-MS instrument. This analysis characteristed that seed oil of cotton var.sahel has a little(<4%) oleic acid and don’t have arashidic. The oilseed of peanut has not lignoseric fatty acid.reminder fatty acids presence with higher content than other in this two plants. Unsaturated fatty acids that are essential for growth in mamals, they are arachidic acid, linoleic acid and linolenic acid. Only linoleic acid is actually required in the diet and in this two plants are very high the other two can be synthesised from detary precursors that in this plants was absence.

P2646. Oral administration of *Hippophae rhamnoides* oil extract increases cardiac endogenous antioxidants and prevents isoproterenol-induced myocardial hypertrophy in rats

G. M. Stoian[1], A. Gruber[1], N. Balta[1], G. Petec[2], I. Georgescu[2], R. Rogojan[2], M. Hoteteu[2], F. Ionescu[3], V. Tamas[3], S. Manea[3];
[1]Faculty of Biology, Bucharest, Romania, [2]National Institute of rehabilitation, Physic Therapy and Balneoclimatology, Bucharest, Romania, [3]Hofigal S.A., Bucharest, Romania.

Isoproterenol (ISO), a nonselective ɓ-adrenergic agonist, induces myocardic hypertrophy by directly acting on ɓ$_1$ and ɓ$_2$ myocardial receptors and by increasing angiotensin II plasma levels. Co-administration of ISO and captopril (an antioxidant) attenuates cardiac hypertrophy. Our study evaluates the cardioprotective effects of a natural antioxidant extract from ***Hippophae rhamnoides*** **oil (HRO)**, in isoproterenol-induced cardiac hypertrophy. Male Wistar rats (160 ± 10 g) were treated during 12 days: (1) ISO group- 0.5 mg kg^{-1} body weight s.c.; (2) HRO group, 50 mg kg^{-1} orally administered; (3) ISO - HRO group; and (4) Control. Endogenous myocardial antioxidants (superoxide dismutase -SOD, catalase, glutathione reductase -GR, glutathione peroxidase -GPx, peroxi-lipids and SH groups) from isolated hearts were analysed. In ISO group was evidenced a significant depletion of myocardial SOD, GR and GPx activities and an increase of SH levels. ISO-induced changes in myocardial SOD, GPx and GSH were significantly prevented by HRO. In conclusion, HRO treatment protects against ISO-induced myocardial hypertrophy by enhancing antioxidants levels.

P2647. Biological active compounds in cyanobacteria and algae

A. Poulíļ ková, D. DŚmalová, M. Strnad;
Faculty of Science, Palacký University, Olomouc, Czech Republic.

During the past 20 years there has been a marked increase in the utilisation of commercial algae products in agriculture, horticulture, pharmacy and medicine, cosmetic industry etc. Recent research has shown that ,,microalgae“ can produced plant growth regulators. Antibacterial and antifungal activities are also well documented for cyanobacteria and algae.

Effective methods of simultaneous cultivation of different algal strains were modified for the purpose of phytohormons screening. Our present project GA CR 522/03/0323 focuses on the optimalization of miniaturized cultures in microtitration plates and assessment of their growth parameters.

Sensitive and specific plant hormone immunoassays were developed in Laboratory of Growth Regulators. Algal suspensions, extracts or medium with their metabolites can be analysed in microtitration plates coated with individual anti-PGR antibodies. ELISAs for zeatin ribside, isopentenyladenosine, benzyladenosine, topolins, indole-3-acetic acid and abscis acid are available. Overproducing strains selected by these methods can be subsequently subjected to detailed analyses by HPLC/ELISA or HPLC/MS.

P2648. Standardization and Immunomodulatory activity of *Mangifera indica* Linn. cultivar Neelam

S. H. Ansari[1], T. Naved[1], J. I. Siddiqui[1], A. A. Ansari[2];
[1]Dept. of Pharmacognosy & Phytochemistry, Faculty of Pharmacy, Jamia Hamdard, New Delhi-110062, India, [2]Dept. of AYUSH, Red Cross Building, Ministry of Health & Family Welfare, New Delhi-110001, India.

Studies have indicated that some of the strongest immune system boosters come from specific healing herbs. A number of these plants are known as adaptogens, which strengthen and normalize the nervous and hormonal systems thereby helping us to adapt to (withstand) the many diverse stresses of modern times. Some also contain antioxidant components which can slow down the cellular aging process and bolster the immune system as well.

Mangifera indica Linn. (Anacardiaceae) is a large evergreen tree of tropical and sub-tropical regions.Ripe mango fruit is considered invigorating, refreshing and fattening. The juice is recommended as a restorative tonic. It is useful in apoplexy.

In the present study, the alcoholic extract of fruit of *Mangifera indica* Linn. has been investigated for its effect on cell mediated and humoral components of the immune system in mice. Administration of test drug produced increase in humoral antibody (HA) titre and delayed type hypersensitivity (DTH) in mice.

Mangifera indica was found out to be a good herbal Immunomodulator and Adaptogen with immunostimulating properties.

P2649. Gathered food plants in Eastern Spain wild, weeds and crypto-crops

C. Obón[1], D. N. Rivera[2], M. Heinrich[3];
[1]Uiversidad Miguel Hernández, Orihuela (Alicante), Spain, [2]Uiversidad de Murcia, Murcia, Spain, [3]University of London, London, United Kingdom.

The “Ensalá del Campo”, “Pastissos d’herbes” and “Camarrotjes” are collective names that in Spanish and Valencian serve to design gathered food plants in the eastern coast of the Iberian Peninsula. These are over one hundred species, with the higher proportion of Compositae, Cruciferae and Liliaceae. Their composition and pharmacological activity have been investigated in the project Local Food - Nutraceuticals.

Although these plants configure a wide repertory of local food recipes, most of the species are widespread in the Mediterranean and examples of similar uses are also recorded in central and eastern Mediterranean countries. The endemic herbs used to give particular flavor to the dishes, such as *Thymus piperella* L. or *T. moroderi* Pau ex Martínez contain relevant active substances.

Ethnobotanical questionnaires have been administered to over two hundred persons in thirty different localities of this area in order to obtain an detailed information on gathered food plant preferences and traditional processing. Over one thousand questionnaires were recovered and introduced in a data base that allows to analyze their contribution to the diet.

P2650. Evaluation of hypericin content (from *Hypericum perforatum*) from mice plasma

B. M. Macri[1], G. Stoian[1], M. Stan[1], I. Mircioiu[2], V. Anuta[3,2], M. L. Flonta[1];
[1]Faculty of Biology, University of Bucharest, Bucharest, Romania,

[3]Faculty of Pharmacy, University of Medicine and Pharmacy Carol Davila, Bucharest, Romania.

Hypericum perforatum extract is used as an antidepressant and a nutritional adjuvant. **Method**: *H. perforatum* extract (Bionorica, Germany) is standardized at 0.4% hypericin content. A HPLC method was used for the detection of hypericin levels from *H. perforatum* extract and from mice plasma. Hypericin was separated by C18 chromatography column (25 cm x 4 mm) using a new mobile phase, ammonium acetate / acetonitrile (4:6; pH = 5). The quantification was performed by using hypericin methanolic external standards (Planta Natural Products, Austria). The method allows the detection of hypericin fluorescence (əex = 315 nm; əem = 590 nm). **Animals**: *H. perforatum* extract was orally administered during one month to 28 mice (1 month and 3 month aged) males and females. **Purpose**: The goals of our study was to identify the age and sex differences of hypericin plasma levels. **Results**: This is the first study on mice in order to determine hypericin plasma levels. Retention time on HPLC column of hypericin is evaluated at 10.85 min for the standard and 12.44 min in plasma mice. Age and sex differences of hypericin plasma levels were observed.

P2651. Nutritional Value of *Asparagus acutifolius* L.

M. Temirkaynak;
Faculty of Agriculture, Antalya, Turkey.

About fourty plant species are used as vegetable in Turkey. In the Mediterranean and regions *Asparagus acutifolius* L. which is one of the perrenial plants and belongs to Liliaceae family, is used traditionaly as vegetable. And this plant is also known as wild asparagus.

There is no study on the nutritional value of this vegetable which is one of the newest vegetable culture of *Asparagus acutifolius L*. The aim of the present study is to determine nutritional values of different organs’s (rhizomes and green asparagus spears) of *Asparagus acutifolius L.L.*

The results of this studies, some botanic characteristitics (plant height, plant weight, root leght and flower size) and nutritional value (N, P, K, Ca, Fe, Na, Mn, Mg, Zn, S and total soluble solid content) were determined in *Asparagus acutifolius L*. We were also determined carbohydrate content and titratable acidity and total ash.

P2652. Traitmill(tm): A Functional Genomic Platform For The Phenotypic Analysis Of Gene Function In Plants.

Y. Hatzfeld, C. Reuzeau, A. Sanz, V. Frankard, W. van Camp, P. Lejeune, P. Hervé, J. de Wolf, R. Peerbolte, W. Broekaert;
CropDesign NV, Gent, Belgium.

The modification of quantitative traits in crops through biotechnology is today highly challenging. To meet this challenge, CropDesign has developed TraitMill, an integrated platform that allows high-throughput and high-resolution testing of the effect of plant-based transgenes on agronomical traits in crop plants. Traitmill currently focuses on rice, which is a good model for other important cereals such as corn and wheat. It involves the following components:

i) A bioinformatics-aided selection of candidate trait improvement,

ii) A collection of promoters validated in rice,
iii) A high-throughput production of transformation vectors,
iv) An industrialized plant transformation system that generates tens of thousands of transgenic plants per year
v) An automated plant handling, imaging and analysis set-up for trait evaluation

Transgenic rice lines showing increased seed yield or increased green biomass have been obtained from TraitMill. Field experiments showed that the plant phenotype observed in Traitmill was often conserved in the field. Thus TraitMill can be used as a good proxy for the validation of transgenes usefull for crop improvement.

P2653. Investigation on the potential utilization of Paulownia wood in Particleboard production

A. Nourbakhsh Habib Abadi, A. Hossienzadeh, A. Kargarfard;
Research Insititute of Forest and Rangelands, Tehran, Islamic Republic of Iran.

A number of factors were responsible for utilization of material in particleboard industry. Species , press time , resin type ,hardner,press temperature, resin content and other factors are important. In this investigation feasibility of Paulownia fortunei wood in particleboards production were prepared at four different Combination of 100%,75%,50%,and 25%(base of paulownia) , three different press time of 4,5,and 6 minutes .

Based on the DIN-68763 standard physical and mechanical properties including Modulus of rupture (MOR),Modulus of elastisity (MOE),and internal bondig (IB), and thickness swelling (after 2 and 24 immersion in water) were tested.

Based on the factorial experimental design at completely random test was analysis and DMRT test was applied.

The results showed that potential utilization of paulownia wood in particleboard production was optimized. For particleboard industry utilization of paulownia is possible.

P2654. Investigation on medium density fiberboard properties produced from eucalyptus microtheca wood

A. Kargarfard[1], A. Hosseinzadeh[2], A. Nourbakhsh[2];
[1]Research Insititute of Forests and Rangelands, Tehran, Islamic Republic of Iran, [2]Research Insititute of Forest and Rangeland, Tehran, Islamic Republic of Iran.

In this investigation, Eucalyptus Microtheca wood for medium density fiberboard (MDF) production and determining of anatomical characteristics, mechanical and physical properties of boards have been studied. variables factors were streaming time in two levels (7.5 and 15 minutes), press temperatures in two levels (165 and 175^{0} c) and press time in three levels (3, 4 and 5 minutes) .

The results of this study indicated that,the highest bending strength (MOR), were observed on MDF boards produced for 7.5 minutes steaming time,and the lowest of MOR belong to boards produced for 15 minutes steaming time.However the maximum and minimum modulus of elasticity (MOE) achived with fibers obtained under same condition ..In all conditions, increasing press time was to improve MOR and MOE of the boards..

The results also showed that the maximum internal bonding (IB), were related to MDF boards produced with fibers obtain under 15 minetes steaming time codition .However increasing of press time didnot affect on IB significantly. Thickness swelling (T.S) after 2 and 24 hours soaking in water of boards had inverse relationship with IB. .

P2655. Varietal differences in bast fiber production in kenaf (*Hibiscus cannabinus* L.)

A. Yamasaki[1], A. Uragami[2], M. Morishita[3];
[1]National Agriculture Research Center for Tohoku Region, Morioka, Japan, [2]National Institute of Vegetable and Tea Science, Tsukuba, Japan, [3]National Agriculture Research Center for Hokkaido Region, Sapporo, Japan.

Kenaf (*Hibiscus cannabinus* L., Malvaceae) is an important fiber crop that originated in southern Africa and is currently widely cultivated in tropical regions. The stalk contains two different fiber types, an outer “bast” and an inner “core”. The fibers are either used separately or together in the manufacture of different products ranging from paper to woven fabrics and industrial absorbents. The cultivation of kenaf is primarily concerned with the bast fiber yields because they are used to produce high-grade fiber. In this study, growth and bast fiber yield of several kenaf varieties was investigated. Nine kenaf varieties were sown on May 19, June 19, and July 19, 2000. Growth was investigated by estimating dry matter production and bast fiber yield under different temperature regimes. Growth was observed to differ markedly among varieties and the percentage of bast fiber in dry matter ranged from 31.4 to 40.4%. The different trends in bast fiber content observed among varieties were independent of time of sowing.

P2656. Antioxidant Activities of Leonotis nepetifolia leaf

S. A. Adesegun[1], H. A. B. Coker[2];
[1]Department of Pharmacognosy, University of Lagos, Lagos, Nigeria, [2]Department of Pharmaceutical Chemistry, University of Lagos, Lagos, Nigeria.

Leonotis nepetiofolia (Linn.) Ait. f (Labiatae) leaf is used in Nigeria to cicatrize wounds and sores (1). The correlation between oxygen free radicals and damage to skin is well documented. The leaf was extracted with 80% ethanol. The anti-oxidative activities, including the radical -scavenging effects, reducing power and Fe^{2+}-chelating ability were studied in vitro. It was found that the anti-oxidative effect of the leaf extract of *L. nepetifolia* was strongly concentration dependent. In general, the anti-oxidative activity increased with increasing extract concentration. From a comparison of the IC_{50} values for each anti-oxidative reactions, it appeared that the leaf extract was more effective in reducing radicals than chelating Fe^{2+} or scavenging Ŭ,Ŭ-diphenyl-ɓ-picrylhydrazyl (DPPH) radicals. However, compared to the commercial antioxidant, the extract showed less scavenging effect on the DPPH radical and reducing power but better Fe^{2+}-chelating ability than Ŭ-tocopherol.

P2657. Histological characterization of Guayacan wood sample obtaned from four different markets in México City.

L. Centeno Betanzos[1], **A. Brechu Franco**[1], C. León Gomez[2], R. Osuna Fernández[1], L. Guillermo[1];
[1]Lab. Desarrollo en Plantas, Facultad de Ciencias, UNAM, Ciudad de Mexico, Mexico, [2]Lab. Xiloteca, Instituto deBiología, UNAM, Ciudad de Mexico, Mexico.

Mexico is one of the countries were medicinal plants are sold as an alternative to attend health problems. However, it’s always a confusing task to identify the species we’re dealing with in the market place. *Guaiacum coulteri* wood and cortex (so called Guayacán) is used for the treatment of type 2 diabetes. The present study focused on characterizing anatomically samples of Guayacán obtained from different markets in Mexico city, as well as comparing these samples with some obtained from the Biology Institute xylarium, UNAM. The wood samples obtained from markets were processed and cut in a microtome for further analysis in the light microscope. The anatomical structure from samples obtained in the market was different from *G. coulteri* samples from the xylarium in respect to porosity clusters, parenchyma bands and heterocellular ratios meanwhile *G. coulteri* shows no clustered porosity, unilateral wingshaped parenchyma and homocellular ratios. Results show that market samples are anatomically different from *G. coulteri* samples. Attention must be payed in respect to quality control in medicinal plants sold in local markets.

P2658. dna fingerprinting of some vigna germplasm by rapd and issr.

H. K. Sarkar, K. Chattopadhyay, M. Ali, N. Mandal, S. Bhattacharyya;
Bidhan Chandra Krishi Viswavidyalaya, Kalyani, India.

Phenotypic and molecular evaluation of *Vigna radiata* and *V. mungo* will help identify accessions potential relevance for *Vigna* improvement programme. 100 germplasm of *Vigna radiata* and *V. mungo* of high yielding, local collections and wild ancestors comprised the experimental materials for DNA fingerprinting using RAPD and ISSR primers. RAPD reactions were done following standard procedure with annealing temperature of 36ºC. Primers comprising of mainly $(GA)_3T$, $(GATA)_4$, $(AG)_3C$, $(TTA)_4TT$, $(AG)_3T$ were used for ISSR reaction adopting annealing temperature according to the T_m of the primers. Extensive inter and moderate intra group variation were detected which may help in cultivar identification, monitoring and aiding gene introgression between germplasm of pulses. Dendogram as revealed by ISSR data correlates better with phenotypic clustering than RAPD data. ISSR markers gave higher polymorphic bands than RAPD markers. PIC as revealed by ISSR primers is greater than that of RAPD primers. *V. mungo* germplasm has narrower genetic base than *V. radiata* germplasm. One decamer RAPD primer gave very high PIC values (0.39) when compared among greengram germplasm.

P2660. Economic Potential Plants in Conservation Areas of the Brazilian Cerrado

S. R. Silva, O. A. Silva, I. L. P. Lima, G. Garritano;
Ibama, Brasilia, Brazil.

This work studed plant species with economic potential. and was carried out in Conservation Areas of the Brazilian Cerrado. The methodology included field collections, bibliographic survey, herbarium survey, morphological analysis and identification of the species. It was found species of following families: Anacardiaceae (*Anacardium humile* St. Hil.), Annonaceae (*Annona coriaceae* Mart.), Apocynaceae (*Aspidosperma tomentosum* Mart.), Asteraceae (*Achyrocline satureoides* (Lam.) DC., Bignoniaceae (*Tabebuia rosea* A. DC.), Dilleniaceae (*Davilla elliptica* St. Hil.), Leguminosae (*Dimorphandra* spp.), Moraceae (*Brosimum gaudichaudii* Trec.) Solanaceae (*Solanum lycocarpum* St. Hil) and Vochysiaceae (*Vochysia rufa* Mart.). Descriptions, figures, synonyms, common names, plant parts used by people and data on species distribuition are showed. Species distribution maps in conservation areas was elaborated. Population structure data for *Dimorphandra mollis* Benth, *D. gardneriana* Tulasne*, Caryocar brasiliense* Camb, *C. coriaceum* Wittm.also are available, which could be applied for species management by small farm communities.

P2661. Biochemical changes in cocoa seed tissue in the course of fermentation

L. Stoll, **H. Kassner**, C. Rohsius;
Biozentrum Klein Flottbek, Hamburg, Germany.

Fresh harvested cocoa seeds are transferred into raw cocoa beans by a plant biotechnological fermentation process. In the course of this fermentation the seed adhering pulp is degraded by microbial action. Within this process lactic acid and acetic acid following ethanol oxidation are produced. Acetic acid penetrates the cocoa seeds and induces proteolysis and aroma precursor formation. The fermentation results in heterogenous raw cocoa beans, which are by visual means classified into slaty, violet, and brown stages. These stages are characterized by considerable changes in biochemical features. The free amino acid content increases with special respect to Ala, Leu, Ileu, the free extractable phenolics are strongly lowered and the enzyme activities, especially the seed phenolase is brought to minimum values. In the transition from slaty to brown seeds the violet stage allows to analyse the way of the post harvest treatment. This means by the complex biochemical features of the violet seed stage in raw cocoa a “processing history” of the traded material can be postulated.

P2662. Photosynthetic light response curves of different pot plants

A. Gogolakova, P. Strba, M. Zima;
The Constantine Philosopher University, Faculty of Natural Science, Department of Botany and Genetics, Nitra, Slovakia.

Plants grown in interior spaces actually come from tropical or arid regions and must adapt to less than ideal conditions in the home or office. Light-response curves give us a wealth of useful information about the photosynthetic mechanisms operating inside the leaves. The net photosynthetic rate (Pn) of intact leaves of experimental pot plants grown in greenhouse was measured by infrared gas analyser in photosynthetic photon flux density (PPFD) from 0 to 1200 $\mu mol.m^{-2}.s^{-1}$ and constant other main conditions. Maximum Pn of *Tradescantia hybrida*, *Primula obconica* and *Radermachera sinica* at 1200 PPFD varied from 5,23 to 8,33 µmol $CO_2.m^{-2}.s^{-1}$, whereas *Campanula carpatica*, *Dendranthema indicum* and *Rosa hybrida* reached higher saturation photosynthetic rate from 14,6 to 22,79 µmol $C0_2\ .m^{-2}.s^{-1}$. Determination of light response curves is important for selection of optimum light conditions for interior plant cultivation and maintenance.

P2663. Fruit maturity and interrlated of temperature and container on longevity of NEEM (*Azadirachta indica*) seeds

M. Rahnama, S. Nassiri;
Azad university Zanjan, Zanjan, Islamic Republic of Iran.

Neem (*Azadirachta indica A.juss*) native to the arid region of Indian subcontinent is a valuable tree because its fast growing rate and many technological importance application.Fruits of neem were collected at different intervals of maturity. Physiologically mature seeds with maximum germination capacity and Longevity were obtained 10 to 12 weeks after flowering (late July to early August) when
some of the fruits turned yellow and started falling on the ground . This period coincided with peak green weight , size and a fully grown embryo enclosed in hard fibrous endocarp . Seeds were stored at 27°C , 17°C and 2°C in sealed polythene bag perforated polythene bags perforated cardboard boxes(seeds wrapped in blotteis). It was found that sealed containers and low temperature 2°C are responsible for rapid deterioration of seeds while well aerated containers inhibited deterioration up to certain extent at room 27°C and 17°C till 6 months.

P2664. Quantitative and qualitative study of peroxidase and polyphenols in Iranian tea (*Camellia sinensis*) during various stages of growth

A. A. Bagheri[1], H. Ebrahimzadeh[2], V. Niknam[2];
[1]Department of Biology,Faculty of Science,University of Tehran, Tehran, Islamic Republic of Iran, [2]University of Tehran, Tehran, Islamic Republic of Iran.

Tea is consumed worldwide and ranks only second to water as a beverage. It is prepared from the dried leaves of *Camellia sinensis.* Tea peoxidase and polyphenols are strong antioxidants and are believed to have beneficial health effects. In this research, leaves of tea were collected three times during growth season and for preparation of crude extract the leaves were homogenized in 0.02 M Tris-HCl buffer (pH 6.8). Quantitative and qualitative alteration of peroxidase during growth stages was determined by spectrophotometry and PAGE system, respectively. The effect of pH, temperature and some chemicals (NaCl, NaN_3, benzyl adenine and chloride of bivalent cations) on peroxidase activity using H_2O_2 as substrate were investigated. The content of polyphenols as the non-enzymic antioxidants was also determined in leaves during several plucking. Peroxidase activity and the content of polyphenols in the first and third harvest were higher than that of the second harvest.

P2665. Physiological responses of sweetpotato *Ipomoea batatas* Lam. under different kinds of irrigation

R. La Rosa[1], N. Pallais[2];
[1]Faculty of Natural Sciences and Mathematic. Federico Villareal University, Lima, Peru, [2]International Potato Center (CIP), Lima, Peru.

Sweetpotato (*Ipomoea batatas* Lam.) can be grown in poor soils with little water. This work was held from February to July in 1995. Objective was to determine physiological responses of sweetpotato when it is subjected to different kinds of irrigation. Cuttings of 17 genotypes were planting in dry sandy soil and irrigated immediately after planting. Treatments were: irrigation at 45 d.a.p., irrigation at 90 d.a.p., without irrigation for all experiment and irrigation every 15 days. A reduction in plant coverage in treatment without irrigation and excessive growth of foliage in treatment irrigated each 15 days was observed in all genotypes, hence water limit growth of foliage. Some genotypes shown high stomata resistance in treatment of irrigation every 15 days, this is because some genotypes are sensible to high soil water content. Leaf water potential is no signified between treatments, inclusive genotypes with high stomata resistance. Dry matter content in roots is no signified between treatments, it means that photosynthesis is not totally affected, but possibly accumulation of water in tissues could be affected.

P2666. Larvicidal and repellancy effect of essential oil of *Cymbopogon winterianus* against mosquitoes and isolation of bioactive compounds

S. Phukan[1], **M. C. Kalita**[2], A. K. Talukdar[3];
[1]Environmental Biotechnology Lab, Department of Biotechnology, Gauhati University, Guwahati-781014, India, [2]Environmental Biotechnology Lab, Department of Biotechnology, Gauhati University,Guwahati-781014, India, [3]Department of Chemistry, Gauhati University,Guwahati-781014, India.

Cymbopogon winterianus is being extensively used as traditional phytopesticide in the North Eastern part of India and many other parts of the globe. Its essential oil was extracted and its bioefficacy against *Aedes aegypti* and *Culex quinquefasciatus* was studied

with the standard procedure recommended by WHO. The calculated LC_{50} was 46.88ppm against *A.aegypti* and 13.27 ppm against *C. quinquefasciatus*. It showed 80% & 30% repellent activity over 3hrs & 4hrs against *C.quinquefasciatus* and 70% & 25% activity over 3hrs & 4hrs against *A.aegypti*. GCMS profile identified 59 compounds (citronellal 26.51%, citronellol 11.38% and geraniol 2.27%).
Of the six fractions (F I-VI) of the oil after fractional distillation, FV exhibited LC_{50} of 12ppm followed by FII with LC_{50} of 13.4 ppm against *A.aegypti* . Against *C.quinquefasciatus* FII showed the lowest LC_{50} (10.10ppm) followed by that of FV (14.03ppm). FI exhibited potency with 60% repellant activity over 4 hrs against *A.aegypti* and 55% against *C. quinquefasciatus* .
The fractions after being subjected to GC analysis were identified as geraniol (FV), limonene(FII) and citronellal(FI) by taking their standard retention time.

P2667. *Rhipidocladum racemiflorum* (Poaceae: Bambusoideae) a natural resource of Mexico with regional economic importance

J. J. Pale-Pale, T. Mejia-Saulés;
Instituto de Ecología, A.C., Xalapa, Mexico.

Although different aspects of Asian bamboos have been studied, mexican bamboos are relatively unknown. Information on the uses of Mexican bamboos is scarce. Bamboo uses were detected in the Monte Blanco locality of Veracrus state. The objective was to document uses of mexican bamboos in Monte Blanco and its economic importance. Methods used were interviews, exploration of natural areas where bamboos grow, identification of bamboo species, etc. Results showed that bamboo use is to elaborate furniture and handicrafts to substitute coffe plantations or in some cases as a complementary activity to increase the family budget. Six bamboo species are used but only one species, *Rhipidocladum racemiflorum*, is native to Mexico. They call it “chiquian” for its thin culm and flexibility. It is used to elaborate chairs as well as delicate decorations for most furniture, handicrafts like lamps, flowerpots, screens, kitchen cupboards etc. It is a cheaper material because it is gathered from its natural habitat. Conclusions are propagate *R. racemiflorum* in Monte Blanco in order to increase income and protect the species habitat, as well as to promote the Monte Blanco furniture.

P2668. Bioactive molecules in *Passiflora* ssp.

F. Guzzo[1], S. Ceoldo[1], **M. Fraccaroli**[1], M. Levi[1], S. Mariotto[2], A. R. Ciampa[2], E. Tedeschi[2], E. Cavalieri[2], M. Menegazzi[2], H. Suzuki[2];
[1]Scientific and Technological Department, University of Verona, Verona, Italy, [2]Department of Neurological and Visual Science, Section of Biological Chemistry, University of Verona, Verona, Italy.

The genus *Passiflora*, with several hundred species many of which of ethnobotanical importance, looks very promising for the identification of bioactive molecules. To this purpose, we are working on: a) development of efficient *in vitro* or *in vivo* propagation methods; b) screening of antioxidant, antimicrobic and antitumour activity in methanol extracts; c) bio-guided identification of the active molecules.
From seeds of about 60 species, mainly collected in the wild, we obtained stable calli for 28 species; 13 of these also regenerated plants. Leaf methanolic extracts of *P. mayarum*, *P. foetida*, *P. nitida*, *P. platyloba* showed inhibitory activity on *E. coli* growth. *P. nitida*, *P. garckei*, *P. palmeri* and *P. subpeltata* showed high antioxidant activity in a microplate DPPH assay. *P. nitida, P. foetida* and *P. palmeri* showed also apoptotic effect on MDA-MB231 tumour cells. The extracts of stems or leaves of other species showed anti-STAT1 (*P. tenuifila and* P. *palmeri),* anti-STAT3 (*P. palmeri and P. nitida*) and anti-STAT6 (*P. palmeri* and *P. coriacea)* activity. Identification of the bioactive molecules is in progress and their production in calli is being explored.

P2669. Acquaintance with biotechnological abilities of Dunaliella alga

M. R. Hadi;
University of Isfahan, Isfahan, Islamic Republic of Iran.

In order to acquaintance with biotechnological abilities of Dunaliella alga for beta-carotene product in Iran, at the first four species of D. viridis, D. parva, D. pseudosalina, and D. salina isolation, purification and exactly identified from salt march of Gave Khoni and then physiological effects of salinity on cells growth, glycerol and beta-carotene contents studied in the purified algae distinguished that species of D. parva, D. pseudosalina, D. salina are able to beta-carotene product and the species of D. salina has the most product amount of beta-carotene . In view of the fact that, Iran has abundant lakes and salt marshes and it has suitable climate for growth of Dunaliella algae and also, it has sun intense light radiation for beta-carotene production, so it seem that the use of Dunaliella species especially D. salina, is possible to culture widely in a numbers of little pool in order to commercial production of beta-carotene.

P2670. Toxicity of *Petiveria alliacea* L. on white fly (*Trialeurodes vaporariorum* West.) in laboratory and greenhouse

R. M. García-Mateos;
Universidad Autónoma Chapingo, Texcoco, Mex., Mexico.

Preparations from *Petiveria alliacea* have been used extensively in traditional medicine and the insecticidal and acaricidal properties have been reported. To determine the toxic effect of *P. alliacea* on *Trialeurodes vaporariorum* the mortality rate and the CL_{50} were evaluated in the laboratory and under greenhouse conditions by preparing three extracts: aqueous, methanolic and dichloromethane. For the laboratory, 50 aleroydidos were placed in petri dishes with a foliole of tomato, that was previously sprayed with solutions. In the laboratory, the extracts mortality rates were higher than under greenhouse conditions. The CL_{50} was higher under greenhouse than laboratory conditions. The CL_{50} for aqueous, methanolic and dichlorometane were 4.6 %, 1.1 % y 0.3 %, respectively, in laboratory, and 16.6 %, 13.3 % y 3.5 %, respectively, under greenhouse conditions. The organic extracts were more toxic than the aqueous extracts in both bioassays against *Trialeurodes vaporariorum* adults. The treatments didn’t interfere with the tomato yield (grams and diameter per fruit), inferring the feasibility of using extracts against *T. vaporariorum* control.

P2671. Hihg levels of variability observed in plants obtained by asexual reproduction of *Agave tequilana* var. azul

R. E. Escobar Guzmán, F. M. X. Zamudio Hernandez, J. Simpson Williamson;
CINVESTAV-Unidad Irapuato, Department of Plant Genetic Engineer, Irapuato-Gto, Mexico.

Agave tequilana Weber, is an important economic crop in Mexico, since it is used to produce tequila. *Agave tequilana* is a diploid (2n=60) with a long life cycle of 8 years. Plants flower only once towards the end of their life and produce seeds with low viability. *Agave tequilana* has been propagated asexually through the production of offsets from rhizomes for more than a century with very little sexual reproduction occurring. Another mechanism of asexual reproduction occurs in the inflorescence producing bulbils, but this method is not used for propagation in commercial plantations. It would be expected that offsets and bulbils of the same plant are genetically homogenous, however AFLP analysis shows differences in AFLP patterns between individuals obtained by both types of asexual reproduction. The genetic variability generated in bulbils is higher than in offsets.
These findings suggest that it may be possible to select individuals with desirable characteristics from asexual populations and raises the question as to how these high levels of variability are produced.

P2672. Genetic diversity on Tunisian pomegranate (Punica granatum l.)

N. Hasnaoui[1], M. Mars[2], M. Trifi[3], J. Ben Chibani[1], M. Marrakchi[3];
[1]Faculty of Pharmacy, Monastir, Tunisia, [2]Ecole d'horticulture, Chott Meryam, Sousse, Tunisia, [3]Faculty of Sciences of Tunis, Tunis, Tunisia.

To study the diversity of pomegranate cultivars, we used phenotypic features of seeds as well as RAPD markers to studying the molecular diversity.
Morphometric analysis of seeds is based on analysis of 7 seed characters followed by statistic analysis. Multivariate analysis are carried out. PCA (Principal Compound Analysis) show distinction of some cultivars. It is the case of cultivar Gabsi 1 (GB1) for example. Group analysis and drawing up dendrogram shows several cultivars clustering.
Besides a PCR-RAPD approach was optimised and used to estimate the genetic relationships among 12 tunisian pomegranate cultivars. Four random primers generated 29 RAPD loci among

them 24 are polymorphic. The resolving power of the four primers ranged between 1.333 and 4.832. A similarity matrix was constructed on the basis of the presence or absence of bands. Among pomegranate cultivars the mean of genetic similarity is 0.516. The polymorphisms in PCR amplification products were subjected to the unweighted pair group method for arithmetic average (UPGMA) and plotted in a phenogram. Cluster analysis identified two main clusters.

P2673. Using pattern, depletion and conservation strategy of the *Triphala* in the village groves of Chittagong region, Bangladesh

M. Miah[1,2], M. Shin[2], M. Rashed[1];
[1]Institute of Forestry & Environmental Sciences, University of Chittagong, Chittagong, Bangladesh, [2]Department of Forest Resources, Kookmin University, Seoul, Republic of Korea.

Triphala is an important combination of three important fruits, i.e., *Emblica officinalis, Terminalia chebula* and *Terminalia bellirica*, which is extensively used as medicine in Bangladesh. Chittagong region in Bangladesh was once rich in *triphala* trees presently subject to the over extraction, lack of proper management, and unawareness. Thus these forest resources are being threatened day by day. The study was conducted to ascertain the present using pattern of the *triphalas*, causes of its depletion and the conservation strategies agreed by the village dwellers. A total of eight major uses of *triphala* trees were recognized. It was revealed that 100% respondents used the *triphala* as fruit tree followed by 75-79% as fuelwood. The present status of growing stock of *triphala* was found in depleted condition particularly in the Muslim dominated area. Induction of social forestry program, proper maintenance and supply of planting materials were found major recommendations by the villagers to retard the depletion of the *triphala* species in the Chittagong region, Bangladesh.

P2674. Study and valuation of Amaranth cultivation in Iran

N. Schahbazian[1], J. Eitzinger[2], I. Alahdadi[3], G. Abbas Akbari[3];
[1]University of Teheran, Abouraihan Campus, Department of Agronomy and Plant Breeding, Tehran, Islamic Republic of Iran, [2]Institute of Meteorology (BOKU-Met), Vienna, Austria, [3]University of Teheran, Abouraihan Campus, Department of Agronomy and Plant Breeding, Teheran, Islamic Republic of Iran.

The aim of the project was to investigate the possibilities and problems of the production of grain-amaranth in Iran (Pakdasht Province of Varamin area) with respect to plant cultivation.

In trials plant densities of 200-300 thousand proved to be favorable, higher densities improved drying of the grain, but can be a shortcoming under drought conditions. Harvesting should be done as late as possible: the longer the growing period from seeding until harvest (approx. end of July) the higher can be the yield. At a growing period of 127-147 days yields averaged 2000 kg/ha. Under optimum conditions, a maximum yield of 4000 kg/ha could be obtained on a fertile soil. Excessive use of fertilizers delay flowering and field grain drying. Pre-conditions for optimized harvesting in a dry-climate-region - genotypes with fast and homogene field grain drying - could be identified.

Various cultivars of the species Amaranthus cruentus and Amaranthus hypochondriacus were tested on about 6 characteristics. A bad drought resistance of Amaranthus hypochondriacus, with an average flowering delay of 15 days, was found. A. cruentus was found to be more adaptable for Iranian agriculture.

P2675. Jojoba: A new crop for Mediterranean Region of Turkey to conserve soil and income for growers

S. Ulger, O. Akdesir, S. Demiral;
Department of Horticulture, Faculty of Agriculture, Akdeniz University, Antalya, Turkey.

Jojoba (*Simmondsia chinensis* L.) is a dwarf, plain looking, evergreen perennial shrub. The Taurus mountains laydown throughout the Mediterranean Coastal of Turkey, and soil erosion takes places at this basins. Since some areas have water shortage and bad soil structure these plants can not easily grow in that areas, but Jojoba is suitable plants for these lands.

Jojoba seeds were sowed in Kumluca-Antalya in 1990. The germinated seeds were transferred to the plastic tubes in 1991, and when their lengths were reached to about 40-50 cm they have planted to the fields in early March in 1991. The plants were fruited in 1997 and 3 female types were found suitable for the region in terms of yield, oil content, resistance to diseases, pests and low temperatures, fruiting uniformity and multi-fruit settings in buds. This promising types were propagated by cuttings.

P2676. Biotechnological strategies for improvement of Annatto colour production

P. Giridhar, R. Parimalan, G. A. Ravishankar;
Plant Cell Biotechnology Department, Central Food Technological Research Institute, Mysore, India.

Bixa orellana Linn (Fam. Bixaceae) is a small tree native to tropical America commonly called as annatto or achiote. Seeds of which give reddish orange color that are commonly used in vegetable oils, drinks, dairy industry, confectionaries and cosmetics. It is the only source of the apocarotenoid bixin (ca.82% of the annatto pigment contains bixin) - a principal coloring constituent of annatto - being produced at the aril portions of the seed. Annatto ranks second in economic importance (next to saffron). Since it is a cross-pollinated one, there is a need to standardize efficient protocols for mass multiplication of elite trees with high yield, enhanced pigment production and disease resistance. Improved silvicultural practices will also yield good returns. The enzyme lycopene cleavage dioxygenase is said to play a key role in the bixin biosynthesis pathway from the precursor lycopene - the richest sink of tomato. Many things are yet to be played upon in this pathway to reveal the natures secret using the tools of today’s biotechnology. The significance of lycopene cleavage dioxygenase will be discussed with reference to *Bixa orellana*.

P2677. Biotechnological intervention for cloning and germplasm preservation of *Pterocarpus marsupium* Roxb.

M. Anis, M. K. Husain, A. Shahzad;
Department of Botany, Aligarh Muslim University, Aligarh, India.

Pterocarpus marsupium Roxb. (Fabaceae), is a multipurpose forest tree of immense medicinal and excellent timber value. The highly heterozygous nature and lack of conventional methods of vegetative propagation warrant application of biotechnological means for cloning and germplasm preservation of elite tree of proven qualities. In this context, a protocol for cloning via multiple shoot formation employing cotyledonary node (CN) explants taken from aseptic seedling was developed. CN were induced to regenerate offshoots in a well known nutrient formulation augmented with various cytokinins viz. TDZ, kinetin and BA. Superiority of TDZ over other cytokinins in inducing multiple shoot buds and their differentiation was observed. Regenerated shoots were proliferated under the influence of BA and IAA. The *in vitro* proliferated and elongated shoots > 4 cm, planted individually on root induction medium. The shoots were rooted nearly to 50-60 percent success to form complete plantlets by adapting two step culture procedure. The root-regenerated shoots showed sustained proliferation and complete plantlets were raised and grown *ex-vitro.*

P2678. Anthraquinone formation in *Senna alata* tissue cultures.

P. Panichayupakaranant, J. Wungsintaweekul, N. Chatsiriwej;
Faculty of Pharmaceutical Sciences, Prince of Songkla University, Hat-Yai, Songkhla, Thailand.

A high performance liquid chromatography was established for the simultaneous quantitative determination of the anthraquinones, including aloe-emodin, rhein, emodin and chrysophanol, produced in *Senna alata*. The root cultures of *Senna alata* were established from the high anthraquinone-yielding *S. alata* roots initiated in liquid B5 medium supplemented with 0.5 mg/l NAA and 1 mg/l kinetin. The obtained root cultures produced higher amount of emodin (0.27 %w/w) and chrysophanol (0.68 %w/w) than that in the leaves and root of the intact plants. Unfortunately, the root cultures have dedifferentiated to be cell cultures after several subcultures with a reduction of emodin and chrysophanol production. Improvement of the medium for an increase of anthraquinone production in the cell cultures exhibited that B5 supplemented with 0.5 mg/l kinetin was suitable for emodin and chrysophanol production. In addition, a declination of emodin and chrysophanol production in the cell cultures was still observed in succeeding subculture.

P2679. Quality evaluation of herbal drugs- A present day need

S. K. Srivastava, A. K. S. Rawat;
National Botanical Research Institute, Lucknow, India.

Commercial production of medicines and other products based on different systems of medicine not only increased many folds in India but world over. Increase in urbanization and population has also increased the tendency of profiteering. A large number of manufacturing units, have entered in the area of herbal drugs and pharmaceuticals. A majority of raw materials employed by these industries are of plant origin, the bulk of which comes from wild sources. The supplies are usually obtained through various trade channels. This has created serious problems with regard to the quality of the raw materials and their desired therapeutic effects. In addition to these, nomenclature of drugs is one of the common factors for creating lot of confusion to the botanical identity of the herbal raw drugs and thus further aggravating the problems of adulteration/substitution in commerce.

Not only morphology can play important role in authentication of herbal drugs but some other parameters like HPTLC; GLC, etc. can also be utilized as marker parameter for drug standardization.

P2680. The effects of hydro alcolic extract of soya in the histological structure and the level of estradiol and testosterone in male sorie

M. A. Rahnema, **M. ,. H. Rahnema**;
Azad university Zanjan, Zanjan, Islamic Republic of Iran.

Soja is a rich source of phytoestrogen.Therefore,the objective of this project was to determine whethere soja extract can chenge the structure of male reproductive tissue and it can influence on the level of sex hormon. For this purpose,50male sories were selected and divided into 4 groups.3experimental groups were fed with 150 ,100 and 75 mg/kg of hydro alcoholic extraction of soja and control group were fed with the water for 50 days .Blood samples were taken in zero and fiftieth day of experment and the level of sex hormon were measured and repoductive tissue were removed , fixed , processed and stained with H and E staning metod. Histological of servtions were revealed some changein testis. In the testis many spermatcytes at the metaphase stage in 150 mg/kg and 100 mg/kg treated groups and some of these mitotic figures. In conclusion , it seems that soja extract can change the spermatocyte , in low concentration,it may induce proliferation and high concentration, it may lead to cell deat and nucleus fragmentation.The result indicated that level of testosteroneand estradiol was decreased significantly in the group that was fed with 150 mg/kg.

P2681. Morphological Diversity in cultivated and wild species of S*esamum*

S. Rajeswari[1], M. Kumar[1], N. M. Ramaswamy[2];
[1]Centre for Plant Breeding and Genetics, Coimbatore, Tamil nadu, India, [2]NMR foundation for Research and Development, Coimbatore, Tamil nadu, India.

Sesame (*Sesamum indicum* L. syn *Sesamum orientale* L.) is one of the oldest oilseed crops and is under cultivation in Asia from ancient times. Oil and protein are important attributes. The genus *Sesamum* comprises 36 species and only limited studies are available on the desirable traits present in different species. Wide diversity is available in the existing germplasm. Our studies in five cultivars (*S. indicum*) *viz*.,CO 1,SVPR 1,TMV 3, TMV 4 and TMV 6 and four wild species *viz*., *S.alatum*, *S.malabaricum*, *S.occidentale* and *S.laciniatum* on growth habits, height, floral morphology, capsule size, colour and seed anatomy indicated the presence of wide variability which can be used for developing high yielding varieties with resistance to phyllody disease. Experimental results and future breeding strategies for sesame will be presented.

P2682. Regeneration potential of Calotropis procera: an important bio-fuel yielding plant of semi-arid regions.

A. Kumari, A. Kumar;
Energy Plantation Demonstration Project Center, Department of Botany, University of Rajasthan, Jaipur, India.

Calotropis procera grows in most arid conditions under temperatures ranging from 45 to 50 degree celcius. It survives by underground thick roots which provide new branches once the aerial portions are completed dried up in the winter season. The Calotropis has great potential to produce biomass under adverse climataic conditions. The yield of the plant can vary from 2.7 dry tonnes to 35 dry tonnes per ha per annum in 3 year rotation cycle. Considering the high temperatures the Calotropis is an ideal plant for the desert regions. It yield several medinally important products also. The biofuel production by this plant has been studied in detail. The time of cutting, length of cutting and the level of cutting under field conditions were evaluated under local region in Vatika and the regeneration potential was studied. The season for harvesting greatly influenced the regeneration potential which was substantially low under winter conditions as compared to spring conditions. The yield of the plant could be doubled by making proper harvesting schedule. Details shall be presented.

P2683. Resource assessment of bio-diesel yielding species Pongamia pinnata and Madhuca indica - a critical factor in large scale cultivation

J. Sarnaik, A. Godbole;
Applied Environmental Research Foundation, Pune, India.

Pongamia pinnata and Madhuca indica are promising indigenous bio-diesel yielding species from India. They could play an important role in meeting ever growing energy requirements of India in a sustainable manner if exhaustive resource assessment of these species is carried out.

Commercial cultivation of these plants specifically for this use is yet to begin in India . Govt of India proposes to cultivate *biodiesel species on* 13 million ha of degraded wastelands of the country. Over 200 districts in 19 States of the country have been identified on the basis of wastelands availability, rural poverty ratio and agro-climatic conditions for taking up such cultivation.

It is important to have realistic yield estimates and economics of production through a series of multi-location yield trials under different agro-climatic conditions, before launching national programme. Present communication has provided the details of such assessment needs and methodologies to be used for such assessment outside the forest or protected areas.

The present paper also deals with the methodology to know the exact availability of the species in wild as well as in community circumstances.

P2684. Eradication of Basidiomicetis and fungus in fruit trees flowers and vegetables.

M. S. Reyes;
AVance Biotechnologies, Chile, Conchali, Santiago, Chile.

Biotens is a biological surfactant and 3TAC is a biological fungicide, made by Avance Biotechnologies, Chile

Attack of chondroterium purpurium(lead disease) on fruit trees appears as silver on its leaves; as fungus obstructs vascular bundles releasing toxines trees die. Due to its vascular position there was no treatment to eradicate the disease. Use of 3 TAC(3 applications to foliage) and Biotens as surfactant allows translocation in wood and elimination of fungus.Result: samples for electronic microscopy pre and post treatment show that regression of disease is related to regression of silver characteristical signs and symptoms, furthermore the fruitnesses attached to trunk fall after second application new sprouts are green and at cut they do not present the characteristic ring of disease. In case of fusarium in tomatoes and carnations in a vascular position, repeats results on trees.

P2685. Micropropagation system of *Curcuma alismatifolia* Gagnep. by using Temporary immersion bioreactor

N. Topoonyanont, **P. Boonmanee**, N. Chailaos;
Faculty of Science, Maejo University, Chiangmai, Thailand.

This particular study involved the duration and feeding frequency of twin-flasks temporary immersion bioreactor in order to improve the micropropagation system of *Curcuma alismatifolia* Gagnep. Retarded shoots of *Curcuma* were cultured on a modified MS (1962) medium supplementary with 0.5 mg/L thidiazuron and 4 mg/L Imazalil. Treatments consisted of 4 different sets of duration and feeding frequency such as 2 1-minute feeding/day; 6 1-minute/day; 2 15-minute/day; and 6 15-minute/day. These treatments were compared with those cultured on solid and liquid media for a 6-week period. The experiments were repeated 2 times. Results showed that 6-time feeding/day for either 1 or 15 minutes gave high number ranging from 1,126.3 to 1,518.3 shoots per container. In the contrary, shoots cultured on the solid medium produced only 241.8 shoots per container with a slight increase in the shoot number being observed in liquid culture. It was also noticed that frequency of feeding provided more effect to the quality of the plant than feeding duration.

P2686. Tropicos: Next Generation - A global resource for taxonomic reference data

C. K. Miller, R. E. Magill;
Missouri Botanical Garden, Saint Louis, MO, United States.

Since 1982 **Tropicos** has been Missouri Botanical Garden's primary data repository for taxonomic information, now including nearly a million names with synonymy, types, references and 2.4 million linked specimens. Web-based **W3Tropicos** debuted in 1997 and now sees over 40,000 queries daily from taxonomists worldwide. **Tropicos:** ***Next Generation (TNG)***, the newest version of MBG's widely used system, implements a feature-rich GUI, web services, a robust, responsive relational data model, and an n-tier system component model. It has been designed to support interfaces both to and from other data sources/systems via web services and out-links using TDWG/GBIF standards. Employing a Services-Oriented Architecture, **TNG** enables load balancing and rapid extension of both processing and network responsiveness. Plans include full data integration from taxon records to on-line flora and identification key systems, digital images of type and other specimens plus digitized literature and other botanical references. Support for direct Internet-based editing by specialists is also planned to leverage the knowledge of the world-wide systematic botany community.

P2687. The systematization and construction of metadata of the Herbarium of the Pontificia Universidad Javeriana - HPUJ

M. Alvear, M. Diazgranados, M. León;
Herbarium Pontificia Universidad Javeriana, Bogotá, Colombia.

The systematization and construction of metadata of biological collections improve precious information and gives virtual access to global resources. A database allows analyzing the information to get estimations about taxonomical, ecological, ethnological and geographical aspects, besides conservation characteristics. During the last three years we were debugging our database, and recently we published online a metadata regarding 12500 botanical registries, corresponding mainly to Andean taxa over 2000 m of altitude (75%). We could run geographical and taxonomical representativeness indexes at different scales and we could evaluate the curatory level of our collection and establish the priorities for the next years. We want to remark that the processes of database systematization and metadata update are meticulous and are continually bound to collection increase. Those activities have been made under the lineaments of a forerunner national program (SIB, Biodiversity Information System), which intend to divulge the information about biodiversity in Colombia, with the collaboration of several institutions with biological collections.

P2688. Web Services for distributed access to species checklists: Spice and Litchi

R. J. White[1], F. A. Bisby[2], A. C. Jones[1], E. J. Donovan[1], Q. Ni[2];
[1]School of Computer Science, Cardiff University, United Kingdom,
[2]School of Plant Sciences, The University of Reading, United Kingdom.

The 'Spice' protocol provides a simple, lightweight, open and easily implemented communications channel, and is available to the biodiversity community for distributed read access to taxonomic and species-checklist databases across the Internet. It is currently used to connect source databases to a central hub and thence to a web-based user interface. It is being implemented on more than 30 databases around the world, each contributing one or more taxonomic sectors to the Dynamic Checklist of the Species 2000 and ITIS Catalogue of Life. The present platform- and programming language-independent HTTP/XML-based system implements a 'Common Data Model' at the species level. Web Services under development provide better support for higher taxa and taxonomic hierarchy browsing, and can link databases with alternative taxonomies and hierarchies. Compatible software implemented so far includes the Spice hub and web interface, a 'Wrapper Development Kit' to ease the task of connecting databases, and the 'Litchi' software to manage conflicting taxonomic concepts.

P2689. Types of Linnaean Plant Names Online

C. E. Jarvis, M. A. Spencer;
Natural History Museum, London, United Kingdom.

The aim of the Linnaean Plant Name Typification Project is the completion of an annotated guide and catalogue to the typification of all valid plant names described by Carl Linnaeus between 1753 and 1776. The core of the Project is its database which holds information on all 9,127 Linnaean names validly published at the ranks of species and variety and including, for the names that have not yet been typified, data on the original specimens and illustrations used by their author. Many of these data are now freely available via the Project website. The site is fully searchable and allows users to obtain information on every individual binomial, including the original place of publication, the type and the author and place of publication of the typification, its current name, and any additional information relevant to its typification or application. Good quality images of type specimens from the George Clifford, Paul Hermann and John Clayton herbaria (all BM) accompany the species records and more images of type specimens and type illustrations are being added as and when they are available.

P2690. Online databases - global resources at the Natural History Museum, London

S. Cafferty, R. Huxley, C. Jarvis;
Natural History Museum, London, UK, London, United Kingdom.

The Natural History Museum is a major repository of natural history collections made throughout the world and over a long period of time. Its earliest botanical collections date from the late 16th century. Conscious of the need to make these collections more widely available, the Museum has undertaken an ambitious programme aimed at increasing the accessibility of its collections. In recent years, the herbaria of Sir Hans Sloane, John Clayton, Paul Hermann and George Clifford, all rich in type specimens, have been been digitised and the images made freely available online, with searchable databases to allow easy retrieval of information.

Currently, the Museum is actively involved in the Mellon Foundation funded African Plants Intiative. This aims to make available online, digitised and databased collections of all the world's African plant type specimens, along with associated library materials. We are also expanding such work and collaborations to include, for example, additional historical collections, cryptogamic plant groups, and Spruce specimens from Latin America.

P2691. TRGP (Taxonomic Repertory of the Genus Peperomia) & PBO (Peperomia Bibliography Online)

G. Mathieu;
Ghent University, Ghent, Belgium.

It will be illustrated that CAT (Computer Aided Taxonomy) does not just means Phylogeny Analysis and Interactive Keys. Taxonomists spend countless hours in gathering & accessing reference data. Tools optimizing these activities save a lot of 'unproductive' time and will, more and more, be part of every botanist's basic toolset...

To study a particular taxonomic group, someone needs at least an up to date list of already published names, including synonymy annotations, references to the protologues and other publications, easy access to the type specimens and information about the distribution of the concerning taxa. Peperomia, with more than 3000 published names, is an interesting case genus. Data and digital images about this genus are online for almost five years now and the project has reached a sufficient stage of maturity. In addition, the TRGP and the PBO are used in several ongoing projects and additional features are added regularly.

Existing repertories can easily be used as building blocks in 'tree of life' projects.

P2692. Extending access and opportunity in a world of varying electronic wealth: a demonstration based on the Web site for the Manual of Grasses for North America

M. E. Barkworth, S. Lim;
Utah State University, Logan, UT, United States.

Web sites can provide access to a wide range of floristic information, but they are of limited value to those without easy Internet access. The *Manual* project is making more information available at its Web site than will appear in the printed volume. As a first step in making the resources more widely accessible, we are re-organizing the site (programs, documents, images, etc.) into a largely self-contained, stand-alone Web site, one that can be saved to a portable hard drive. A script will be written that makes installation of the stand-alone *Manual* a simple procedure. Updates to the file will be provided on a regular basis. This procedure has the potential for expanding access to the project's resources to any botanist with a computer having extra hard disk space (~1GB), a Web browser and a Java Virtual Machine installed on a Linux or MS Windows platform. The files will not be free, but we shall try to minimize the cost. We are also planning to expand the site's scope through collaboration with taxonomists at other locations. Forms will be created for submitting information and resources via the Web or disk. The forms will be included in the stand-alone version of the Web site.

P2693. The Botanical Node within the German GBIF Network

A. Kirchhoff, A. Hahn, W. G. Berendsohn;
Botanic Garden and Botanical Museum Berlin-Dahlem, Berlin, Germany.

The aim of the Global Biodiversity Information Facility (GBIF) is to make the world's biodiversity data freely and universally available via the Internet (www.gbif.org).

The German GBIF node for Botany is coordinated by the Botanic Garden and Botanical Museum Berlin-Dahlem. The partners in the project work towards GBIF's goals by setting up an Internet portal for botanical collections and databases in Germany, integrating existing databases and networks, digitising herbarium collections, and jointly presenting them in a "Virtual Herbarium".

By means of BioCASE network software (protocol, wrapper; see www.biocase.org) and the ABCD (Access to Biological Collection Data) XML standard for data transfer, botanical databases containing about 2.7 million records have already been connected to the GBIF network. They are accessible via the international GBIF portal, as well as via the German GBIF Portal of Botany, which is focussing on German biodiversity and uses an advanced concept-based approach to access the data via taxon names.

P2694. Linking the past to the future: the AlgaTerra Information System

R. Jahn, W. H. Kusber;
Botanischer Garten und Botanisches Museum Berlin-Dahlem, Berlin, Germany.

AlgaTerra is a database, providing information on micro algae (especially diatoms and green algae) on the Internet (www.algaterra.org). The main aim of the AlgaTerra project is clarifying the usage of a name and adding referenced factual data to taxonomic concepts thus making historical knowledge fit for the Internet age and future research. AlgaTerra is an implementation of the "Berlin Taxonomic Information Model" (www.bgbm.org/biodivinf/docs/bgbm-model/) which was supplemented by a module to administer data on nomenclatural types. Illustrated types serve as calibration tool for related taxonomic concepts, which are linked to factual data, such as sequence data, morphology, photographs, ecology, and occurrence. The pilot phase of AlgaTerra (until 2005) was a joint project funded by the German Federal Ministry of Education and Research, merging the research data of five groups (BGBM, Berlin; Lazarus, Ehrenberg Collection, Berlin; Medlin, AWI Institut, Bremerhaven; Friedl, SAG, Göttingen; Reisser, Universität Leipzig).

P2695. The world's first virtual plant study trails as a tool for education, ecotourism, and vegetation research

P. P. But, K. C. Young, H. Lam, H. Y. Yeung, P. Ma, T. K. Woo;
Chinese University of Hong Kong, Hong Kong, Hong Kong Special Administrative Region of China.

With partial support from Quality Education Fund (Hong Kong), we have established three virtual plant study trails. We started by taking serial digital photos of the vegetations along each trail and stitching these photos into a continuous panoramic photo, which is then turned into continuous flashes. These flashes were then loaded on our website <http://hkflora.com/qef/index.php>. Visitors can visit the virtual trails via the internet through a personal computer and scroll along the flashes to view the vegetations as if walking along the trails. When the mouse pointer touches a sensitive zone, the name and other information of the corresponding plant will appear. These virtual plant study trails will serve as useful tools to assist students in fieldwork trainings in botany and to assist guides in leading ecotours. The flashes have also captured the images of the vegetations along the trails at a particular time frame (i.e. 2003-2005 for our three trails) and will serve as *in situ* data of the vegetation at that time. Comparisons with future images of the same trails will demonstrate the vegetation changes that have taken place between two time frames.

P2696. *Taxonomic identification with standarized descriptions*

E. Gibaja[1], M. Delgado[2], W. Fajardo[2], R. Pérez-Pérez[2];
[1]Universidad de Córdoba, Córdoba, Spain, [2]Universidad de Granada, Granada, Spain.

Up to now, many models to represent taxonomic information have been developed, but in spite of representing the same concepts, they don't exactly match. That's the reason because the IUBIS-TDWG is working on the development of a XML-based standard to allow a lossless exchange of information between different authors and different applications. This work describes a system to support the taxonomic identification process and includes the new requirements related to the intercommunication between representation models. That's at this way because is based on the new XML-based standar. The system has been developed following an expert system model and architecture, includes Artificial Intelligence techniques and it can be accessed over the internet. It has passed the verification and validation stage and the achieved experimental results endorse the suitability of these methods.

P2697. *A compararative research about division rules to automatic generation of identification keys*

E. Gibaja[1], F. Waldo[2], R. Pérez-Pérez[2], C. Quesada[2];
[1]Universidad de Córdoba, Córdoba, Spain, [2]Universidad de Granada, Granada, Spain.

The automatic generation of identification keys can be tackled from a entirely computational point of view. Taking into account this approach, a key is equivalent to a decision tree (a graph with tree structure) which is generated from a set of examples, each of them belongs to a particular class (the taxa the key pretends to identify). Nodes will be the identification characters and leaves will be the objectives. The algorithm for generating trees divides the examples using a heuristic division rule which advises about the best character for each step of the key. The final key is different depending on the selected division rule, so we can obtain a great variety of keys from the same data set. This work presents a cuantitative and cualitative research that analices the set of keys obtained applying different division rules over the same dataset. This research has taken into account well known division rules both in the Computer Sciences and Taxonomy area.

P2698. The web page of the vegetal biodiversity for the Douro Region (NE of Portugal)

J. E. Lameiras[1], A. S. Castro[1], A. L. Crespí[1], C. P. Fernandes[1], S. Bernardos[2], F. Amich[3];
[1]Herbarium, Botanical Garden, CETAV, Vila Real, Portugal,
[2]Department of Botany, Unversity of Salamanca, Salamanca, Spain,
[3]Department of Botany, University of Salamanca, Salamanca, Spain.

The elaboration of a dynamic web page about the natural vegetal resources of the Heritage Douro Region is here presented. The analysis carried out, which takes into account the importance of the biodiversity for the sustainable management of the area examined, involved a methodological process based on the correlation of the catalogue of the vascular plants and biophysical parameters. The data derived from this analysis were then used to propose a management for the vegetal resources that leads to sustainable development mechanisms. To ensure the widespread of the information derived from the present study among the scientific community a dynamic web page was elaborated. In this web page databases, georeferenced maps (type of soils, climatology variables, exposition, altitude, ∗), photographs (photographic records per taxon), ecoroutes (routes selected to observe de diversity included in the database files) and information about the vegetal biodiversity (floristic catalogues) are found. The user of this web page will access to the different files included in whole the files of the database simultaneously.

P2699. Developing an Indian Botanic Garden Network for Conservation of Biodiversity

S. Kumar, V. Gupta, S. Ahuja, S. Sharma, P. Pushpangadan;
National Botanical Research Institute, Lucknow, India.

BGCI has launched an international programme Investing in Nature in Argentina, Brazil, China including Hong Kong, India, Indonesia, Japan, Middle East, North America (including Canada and USA) and South-East Asia. Under IIN-India project, an Indian Botanic Garden Network (IBGN) has been established to encourage a greater collaboration and sharing of resources (database) and knowledge among the botanic gardens in India; facilitate exchange of information through website, Newsletter, etc. and to create awareness among public to adopt better garden management practices. This paper discusses various aspects of the first of its kind IBGN database including data standards, methods of data collection, and searchable options on intranet and Internet (www.ibgn.org). IBGN database contains information of botanic garden resources of ca 60 Indian botanical gardens divided into six zones of India effectively representing the breadth of gardens both geographically and administratively**.**

P2700. Flora KwaZulu-Natal: making an electronic regional flora.

H. F. Glen;
KwaZulu-Natal Herbarium, Durban, South Africa.

The main aim of a local flora is to help non-specialists to identify the plants of the area covered. In the case of Kwazulu-Natal (South Africa), this aim can best be achieved by preparing the flora in both electronic and hardcopy forms. Thus the needs of users both with and without access to computers are met. The most effective way of doing this is to generate the electronic form first, and to use both old and new software to generate text for hardcopy from the electronic key files. The electronic version is generated in Lucid3. In this version, all character states used are illustrated, and all taxa included illustrated by (ideally) five or more photographs showing important features. An associated HTML page displays the text of the paper flora for each taxon, and allows space for additional information such as specimen citations and notes on common names, uses etc. The overall plan of the flora is discussed briefly.

P2701. Tela-Botanica: a network for francophone botanists

J. Mathez[1], D. Mathieu[1], J. P. Milcent[1], V. Malécot[2];
[1]Tela Botanica, Montpellier, France, [2]UMR A 462 - Institut National d'Horticulture, Angers, France.

Tela-Botanica is a network of botanist currently including more than 3000 members and around 40 discussion groups. It hosts the synonymic index of the French flora including three overseas départements (Réunion, Guadeloupe and Martinique) (http://www.tela-botanica.org/eflore). This nomenclatural dataset is based on the work of Michel KERGUELEN (1928-1999) and was converted into a database by Benoît BOCK. It was modified following thousands of comments and corrections by members of the network. The third version of the database includes 79930 names for 15799 taxa (a fourth enlarged version is to be launched in 2005). For each name is recorded the correct Latin name, place and date of publication and vernacular names.

Other documents are available on line : a French translation of the International Code for Botanical Nomenclature, a database of French Herbaria (with herbaria missing from Index Herbariorum), a database of publications on botany (25 000 articles), and lists of plant species for 70 départements (out of 96).

The network currently develops, among other things, tools for floristic inventories on PDA, and electronic methods for plant identification.

P2702. Basidiomycetes as the important component of the global biological resources

N. V. Belova;
V.L. Komarov Botanical Institute RAS, St. Petersburg, Russian Federation.

Basidiomycetes include 32 orders and 140 families of agaricoid, aphyllophoroid and gasteroid macromycetes. They are approximately astimated as 30% of known species of fungi. More than 3500 Basidiomycetes species are conserved and maintained in the world culture collections. Tens of edible and biotechnically significant species are cultivated for fruit bodies, natural products and enzymes using various types of wastes. Different drugs, dietary supplements and sanative beverages are prepared using Basidiomycetes. The researches on Biodiversity Conservation *ex situ* increase representation of genetic resources of Basidiomycetes in the culture collections and make them more accessible to users. Nowadays Basidiomycetes are included in the Global Biological Resources as a very important reproducible component, which will have a positive impact on long-term food nutrition, health care and environmental conditions of people life.

P2703. Treatment of synonyms in specimen databases using web resources

M. Delgado, W. Fajardo, E. Gibaja, **R. Perez Perez**;
University of Granada, Granada, Spain.

There is a large amount of information in a herbarium which must be efficiently managed so that it may be studied and knowledge obtained from it. There is therefore an evident need for information systems to fully manage both the information and the very functions of herbariums (Information administration, consultation processes, loan control, management of multimedia information, user administration, Report creation, Issuing of labels, etc.)

Nowadays, the main problem in the specimen databases included in these systems is the existence of synonyms which prevent studies and tasks from being carried out adequately.

In this paper, we shall present a tool which when included in classical herbarium management systems enables the verification of information about taxonomic names by incorporating other sources such as Anthos**,** Species 2000 and GBIF.

The services of tool are managed by means of a Multi-Agent System, i.e. an Input/Output system, which interacts with the web server.

P2704. National Database of DNA Profiles and RDA Integrated Information System (RIIS) of Plant Genetic Resources in R. Korea

E. Cho, K. Ma, J. Lee, J. Kwag, J. Kang, Y. Park;
National Institute of Agricultural Biotechnology, Suwon, Republic of Korea.

Application of biotechnology to genebank accessions for developing high through-put DNA profilinge system was conducted in the Rural Development Administration (RDA) genebank of R. Korea. SSR (Simple Sequence Repeat) markers have been successfully developed in under-utilized crops through enriched method using magnetic beads. Target crops include rice, soybean, barley, wheat, corn, perilla, sesame, apple, pear, job's tear, mungbean and buckwheat. So far, 16,400 accessions of above crops have been profiled using 10 - 20 SSR markers and consequently subjected to a new database of DNA profile. Also the RDA Integrated Information System (RIIS) of plant genetic resources for providing DNA profile and other related data including passport, characterization, evaluation, seed image and geographical location of collection site was developed based on Internet assessable system. Web-based genetic analysis using characterization and DNA profile data is available and compounding survey of specific purpose for accessions is feasible by germplasm users through internet system. More details of RIIS will be introduced with the activities of RDA genebank.

P2705. Digitizing the *Flora Graeca*

R. A. Mills;
Oxford University Library Services, Oxford, United Kingdom.

Oxford holds a wealth of material relating to Sibthorp and Smith's *Flora Graeca*, illustrated by Ferdinand Bauer and often described as 'Oxford's finest botanical treasure' - published 1806-40 and considered the most splendid and expensive Flora ever produced. A new digitization programme, scheduled for completion in 2005, will offer online access to the printed volumes, of which only 25 copies were produced, and to manuscript material hitherto only accessible in Oxford: the original hand-coloured drawings from which the printed engravings were made, unpublished drawings of the *Fauna Graeca* and a unique series of topographical *Mediterranean Scenes,* of great historical and geographical as well as artistic interest. This paper highlights the issues raised by the project, the methodology employed and the metadata captured, and evaluates the lessons learned. The project forms part of the developing *Oxford Digital Library* (www.odl.ox.ac.uk).

P2706. Index Hepaticarum : final publication and a new on-line database

M. J. Price, A. Streiff;
Conservatoire et Jardin botaniques, Chambèsy-Geneva, Switzerland.

Index Hepaticarum (IH), a list of effectively published hepatic names, was started by C.E.B. Bonner at Conservatoire et Jardin botaniques - Geneva (G), in the 1950's. After his death in 1976 the

International Association of Bryologists took over the responsibility for completing the work. Bischler (PC) and Geissler (G) acted as editors for the new project, basing it at G for continuity. *IH* presents all published hepatic names citing the publication and protologue information, and the nomenclatural status for each. *IH* editions from G cover publications from 1 May 1753 to 31 Dec 1973. Names published after 1973 are collated as *IH* supplements by Engel and Crosby. The entry of names for the final section, A-*Jubula*, is now completed (10,000 entries). This work continues with verification of protologues and name validity. Our project database, soon available on-line, contains 30,000 hepatic names, all those published between 1753-1973. The publication of our final edition of *IH* and the debut of our searchable database will complement the work already done on the supplements to *IH*. Collectively this will be an enormous resource for the study of hepatics worldwide.

P2707. New digital life of old palynological collection.

D. A. Britski;
Komarov Botanical Institute of Russian Academy of Science, St.-Petersburg, Russian Federation.

The palynological collection in Komarov Botanical Institute has been started at 1960 when our Palynological Group was established. Collection was permanently increasing in volume and till 1993 it consisted of more than 12000 specimens. In time we faced with some problem of maintenance collection in a good condition. The main were rather short life term of standard pollen grain specimen and impossibility to renovate most unique of them due to lack of herbaria materials. Since the beginning of 90th collection began grow shorter.

To prevent disappearance of the unique specimens and to make them accessible for specialists worldwide we made an attempt to create digital version of the collection.

For these purposes we have developed PostgreSQL database (DB) containing micrographs and morphological data of collections' pollen grains. PHP-powered DB user interface provides search for taxonomic and/or morphological characters.

Currently we are working to organize access to the DB via Internet.

P2708. Managing the Digital Revolution

J. Hutcheon[1], J. Flanagan[2], R. Mills[3], M. Beasley[4], R. Cowan[5];
[1]Royal Botanic Garden, Edinburgh, United Kingdom, [2]Royal Botanic Gardens, Kew, London, United Kingdom, [3]University of Oxford, Oxford, United Kingdom, [4]Natural History Museum, London, United Kingdom, [5]Murdoch University, Murdoch, Australia.

As other speakers in this symposium have made clear, there are many challenges for librarians and information specialists arising from the increasing trend towards digitization of collections as a means of making them available to a world-wide audience. There is great scope for collaboration between organizations holding split or complementary collections to enable better use of available resources and increase the collections' value to researchers, but this often involves international and cross-sectoral working which can be difficult to administer financially. Many decisions need to be made across disparate institutions at the initial planning stage for projects to succeed, in the areas of compiling resources, providing access, preservation and funding. This panel discussion will explore real-world practical solutions being embraced by panel members, and encourage audience participation in identifying user's needs and expectations which should drive future developments in providing virtual access to global resources.

P2709. An Interactive Key to Australian Orchid Genera.

D. L. Jones, K. J. Richards, S. M. Duffy, T. Hopley, M. A. Clements, X. Zhang, J. G. West;
Centre for Plant Biodiversity Research, Canberra, Australia.

The Interactive Key to Australian Orchid Genera is an identification and information system for 190 genera of Australian orchids. Using Lucid software this powerful tool provides an easy to use and simple means of naming an orchid using any information the user has available. A total of 146 characters cover various aspects of the plants morphology as well as ecological and distribution information. The interpretation of the character information is assisted with help notes, colour photos and line drawings.

Included in the key are HTML fact sheets for each genus featuring botanical descriptions, common names, synonyms, geographic and ecological information, as well as natural history notes, distinguishing features, distribution maps and a comprehensive references list. Each genus is illustrated with line drawings and colour photos and for some genera microscopy images are also included.

The Key to Australian Orchid Genera is a complete catalogue of information and an identification tool in one source. It would be a great benefit to a wide range of users from the professional researcher to those with the most basic botanical knowledge.

P2710. Green boon - A computer based multimedia compact disc for medicinal plants of India

P. E. Rajasekharan;
Indian Institute of Horticultural Reasearch, Bangalore, India.

India has always been treasure trove of medicinal herbs. Though we have very old and strong traditional medical system we are unable to capture the world of herbal medicine in the true sense. Green boon is a pioneering effort to bring some parts of our vast knowledge on medicinal plants for your easy reference. It is friendly enough for the casual user who wants to gain some insights in to this wonderful herbal world. This computer based interactive CD is indeed a storehouse of invaluable information. It offers information on medicinal plants at your finger tips. information is available on simple and easy to use format. Package contains quality images of five hundred medicinal and aromatic plants with descriptions and video clippings. Topics like biodiversity, biotechnology, herbal medicines, conservation etc are also explained .A value addition in the form of traditional knowledge related to medicinal plants is also provided. Details of how to cultivate selected medicinal plants are also given. Exhaustive index for easy navigation is also given. This is for the first time an interactive multimedia CD developed for the common man

P2711. Moving botanical illustration into the digital era

N. Simpson;
Independent research, part funded by Queen Elizabeth Scholarship Trust, United Kingdom.

A core component of systematic botany is the description, or re-description, of taxa. The accurate and measured composite plant portraits of botanical illustration form a valuable visual aspect of such description. The advent of electronic publishing and instant online access by an international audience has created new options for botanical illustration work.

This study (July 2003-August 2004) involved an investigation into the use of digital illustration techniques in providing the technological benefits of speed, accuracy, convenience and flexibility, without compromising the artistic values and clarity of traditional botanical artwork.

Results show that correctly designed and constructed digital illustrations can now provide fully realistic, accurate and comprehensive visual plant descriptions. Such digital illustrations are ideal for online or electronic access and their potential, for science and education, is immense.

P2712. The German GBIF Node for Mycology

D. Triebel[1], W. Spiesberger[1], M. Weiss[1], J. Ingenhaag[1], G. Hagedorn[2];
[1]Botanische Staatssammlung München, München, Germany,
[2]Biologische Bundesanstalt für Land- und Forstwirtschaft, Institut für Pflanzenvirologie, Mikrobiologie und biologische Sicherheit, Berlin, Germany.

The international initiative "Global Biodiversity Information Facility" started in 2001. Already two years later the German GBIF Node for Mycology (www.gbif-mycology.de) was installed as service centre for mycological and lichenological biodiversity data in Germany. Its goal is to facilitate the online access to high quality data collections especially from ecologically and commercially important organisms. Meanwhile, the node is administrating a server network, acting as GBIF data provider, transferring data from proprietary databases into applications of the biodiversity component framework "Diversity Workbench" and is giving technical as well as scientific advice to database custodians. The German GBIF Node for Mycology is developing web clients and database wrappers for online access and is building up a sustainable IT infrastructure. Database applications are developed within the concept of the Diversity Workbench (www.diversitycampus.net/Workbench/download.html). The German mycological network originally started with 9 partner institutions and 11 data projects. Currently, 16 databases and information systems are associated.

P2713. Reducing the pain of digitising herbaria and sharing data.

S. D. Grant[1], J. Wall[2], C. K. Frazier[3];
[1]The Natural History Museum, London, United Kingdom, [2]The Royal Botanic Gardens, Kew, London, United Kingdom, [3]University of New Mexico, Albuquerque, NM, United States.

The drive to create digital herbaria has increased, as has the number of systems for doing so (eg the Berlin model, BG-Base, Biota, Biotica, BRAHMS, EMu, Herbar, Specify, Tropicos, and home-grown databases).

There are many complex, high-level standards such as ABCD, Darwin Core, HISPID, Linnean Core and the application of ‘concepts’, many of which concentrate on data exchange and not the actual recording of specimen information.

So starting up virtual herbaria can be difficult and make it seem better to create one’s own system leading to difficulties in reliably sharing datasets with other institutions.

There appears to be a need for:
1) a set of guidelines describing the relationships between specimen data elements between data models;
2) practical examples about field contents;
3) practical guidance on database documentation.

The aim of this poster is to:
1) present a simple diagrammatic representation of specimen data using the historical record approach;
2) propose a workshop which will identify common elements within currently available data models, establish practical guidelines and collate real world examples on how to digitally represent specimens.

P2714. National Database of DNA Profiles and RDA Integrated Information System(RIIS) of Plant Genetic Resources in R. Korea

E. G. Cho;
National Institute of Agricultural Biotechnology, Suwon, Republic of Korea.

Application of biotechnology to genebank accessions for developing high through-put DNA profilinge system was conducted in the Rural Development Administration (RDA) genebank of R. Korea. SSR (Simple Sequence Repeat) markers have been successfully developed in under-utilized crops through enriched method using magnetic beads. Target crops include rice, soybean, barley, wheat, corn, perilla, sesame, apple, pear, job’s tear,mungbean and buckwheat. So far, 16,400 accessions of above crops have been profiled using 10 - 20 SSR markers and consequently subjected to a new database of DNA profile. Also the RDA Integrated Information System (RIIS) of plant genetic resources for providing DNA profile and other related data including passport, characterization, evaluation, seed image and geographical location of collection site was developed based on Internet assessable system. Web-based genetic analysis using characterization and DNA profile data is available and compounding survey of specific purpose for accessions is feasible by germplasm users through internet system. More details of RIIS will be introduced with the activities of RDA genebank.

P2715. The availability of historical photographs - a pragmatic approach

R. Buchner;
Institute of Botany, Vienna, Austria.

Herbaria, museums and other scientific institutions are often housing hundreds and thousands of picture negatives, reprints or colour slides. Unfortunately these pictures are often inaccessible due to several reasons. Sometimes there is no information available on the picture content or is difficult to access, e.g. as hand- or typewritten index cards.

Especially glass plate negatives are very fragile and in different condition states. The gelatine coating is often damaged or is not anymore firmly attached to the glass or even the glass plate is broken.

Despite these damaged objects, digitizing pictures and database storage of all available information will help to make this forgotten resource of information available to the scientific community. Biographies of researchers and photographers or itineraries of expeditions may complete the pictorial information.

A detailed workflow on preservation and digitizing historical images is presented and the output of our project on digitizing of historical images is shown on http://bilder.botanik.univie.ac.at/ .

P2716. Balaton - A Century later of the Borbás’ Monography

I. L. Szabo[1], **P. Szeglet**[1], K. Csermak[1], A. T. Szabo[2], P. Pomogyi[3], Z. Domotorffy[4];
[1]Georgikon Faculty, Keszthely, Hungary, [2]Veszprem University Faculty of Teacher's Training, Veszprem, Hungary, [3]West-Transdanubian Water Authority Department Kis-Balaton, Keszthely, Hungary, [4]DigiScience Ltd., Pilisborosjeno, Hungary.

This study presents a comparative analysis of the researches done 100 years ago and today in connection with Lake Balaton.

Balaton proved to be the most intensively investigated lake at the beginning of the 20th century as a result of the “Issues of the scientific researches of Lake Balaton” program. The volume about the plants and phytogeography was composed by Vince Borbás and today it is regarded as a literary masterpiece, a basic botanical and phytogeographical discovery. Actual characteristics of the lake are significantly determined by the urbanisation, eutrophication and the recent years of drought. The previous minerogen and organogen succession has been replaced by ruderalisation. The lake bed sedimentation is very strong. There are spreading invasive neophytes impairing the archeophytes. The condition of the reed stands is grave. The above-mentioned phenomena and processes are represented and digitally demonstrated by the census and mapping of plant species and habitats in 2004.

P2717. The first ethnobotanical field book on internet: stirpium nomenclator pannonicus of St. Beythe (1583), Carolus Clusius (1583, 1584), D. Zwittinger (1711) and F. Wolkinger et al. (1992)

F. Wolkinger[1], I. Szabo[2], A. T. Szabo[3];
[1]Institut für Pflanzenphysiologie der Universität, Graz, Austria, [2]Department of Botany, Georgikon Faculty, University of Veszprém, Keszthely, Hungary, [3]University of Veszprém, Institute of Biology, Department of Botany, Veszprém, Hungary.

Stirpium nomenclator pannonicus is the first printed book on field ethnobotany edited by Carolus Clusius and Stephanus Beythe in 1583 in Güssing/Nemetujwar and reprinted later repetedly as a document of early integration of Pannonian life sciences in European herbalism. Clusius was an early “Pan-European” botanist connected to the history of botany in Austria, Belgium, Croatia, England, France, Germany, Hungary, Italy, Slovakia, Slovenia, Spain, Switzerland, and especially The Netherlands. An Internet version of this valuable botanical filed work is presented here, mirroring electronically the common botanical knowledge registered in 16th century Pannonia. The E-version analyse critically all the previous editions, making available worldwide a lasting document of European Herbalism and that of plant diversity explored and used by different ethnic groups of Pannonia about 420 years ago.

P2718. Present status of Atlas Florae Europaeae

P. Uotila, L. Junikka, A. Kurtto, T. Lahti;
Botanical Museum, Finnish Museum of Natural History, University of Helsinki, Helsinki, Finland.

Atlas Florae Europaeae (AFE) is a program for mapping the vascular plant flora of Europe on the grid basis. It was launched in 1965, and thus far 13 volumes have been published, containing 3 556 maps of 3 276 species and 1 151 subspecies, and they cover more than 20% of the European vascular plant flora. The mapping work is performed by collaborators in all the European countries. New software, “Atlas Florae Europaeae Data Editor”, has been developed to provide the mapping data electronically. From vol. 13 onwards a new grid was adopted. It is based on UTM and MGRS and extends over land and sea in a regular pattern. Total number of cells with land in Europe is 4 750. The old data has been converted into the new grid, and at present the AFE database comprises ca. 785 660 distribution records. The new grid is also used by several faunistic mapping projects in Europe and because of its regular pattern it is relatively easy to make co-ordinate converting programs from national grid systems to the new European grid. Besides printed Atlas volumes, the maps are shown online on the AFE web pages which facilitate updates of old maps, and the data itself has been used in various research projects.

P2719. Hungarian botanical monographs in the electronic age

L. Gerely[1], G. Borbély[2], L. Vörös[3], A. Borhidi[4];
[1]Biological Institute, University of Pécs, Pecs, Hungary, [2]Biological Institute, University of Debrecen, Debrecen, Hungary, [3]Biological and

Limnological Institute of the Hungarian Academy of Science, Tihany, Hungary, [4]Institute of Ecology & Botany, Hungarian Academy of Sciences, Vácrátót, Hungary.

The following Central-European monographs written by authors of the Hungarian Taxonomical and Geobotanical School: are presented: Jávorka S., 1925, *Hungarian Flora*; Soó R., 1927, *Die geobotanische Monographie von Kolozsvár*; Jávorka S., Csapody V., 1929-1934/ 1975, *Iconographia florae Hungariae*; Nyárády E.Gy., Soó R., 1941-1944, *Flora von Kolozsvár*; Soó R., *The Phylogenetic System of Plants*; Soó R. 1964 - 1980, *Synopsis Systematico-geobotanica-Hungariae*; Borhidi A., O. Muñiz 1983: *Catálogo de Plantas Cubanas Amenazadas o Extinguidas;* Borhidi A., 1991: *Phytogeography and Vegetation Ecology of Cuba*. Borhidi A., 1995: *Phylogenic System of the Flowering Plants;* Borhidi A., 1996: *Critical revision of the Hungarian Plant Communities*; Borhidi A., Sánta A, (ed.) 1999: *Red Data book of the Hungarian Plant Communities I-II;* Borhidi A., 2002: *The Green Dress of Gaia;* Borhidi A., 2003: *Plant Communities of Hungary*. The E-presentation of a monograph is structured on the web (http://bint-biotar.vein.hu Collecta Clusiana, IBC-2005) as follows: Author selection; Title selection; Subject selection (Table of content); Text (doc/html/jpg); Comments; Miscellanea (PP Presentations).

P2720. Paul Kitaibel's descriptiones et icones plantarum rariorum hungariae (1802-1812) 2004 - and the electronic age

J. Géczi;
-, Budapest, Hungary.

Paul Kitaibel's (1757-1817) descriptions and pictures of the rarest plants of Hungary (*Descriptiones et icones plantarum rariorum Hungariae*) are a magnificent early result of botanical iconography and plant taxonomy of the Carpathian Basin. The work was sponsored by Francis Waldstein and edited in Vienna between 1802-1812, in three folio volumes (28 booklets) following the model of N. J. Jacquin's work, *Icones plantarium rariorum*. The unfinished series of *Descriptiones et icones* contains 280 hand coloured and scientifically perfect plant pictures. Only about 200 copies have been produced from this first Austro-Hungarian botanical iconography, with only 40 copies distributed in Hungary. Thirty copies were posted to England, but they all perished during the shipment; an additional 53 copies were confiscated by French authorities. Copies are also in Austria and in other countries, as well. The reprint of *Descriptiones* was published in Hungary in 2004, with sample pages of the iconography made available on the internet. The poster provides information about history of the work, together with its cultural and botanical values.

P2721. Sharing pictorial information via internet - a project based (mainly) on open source

J. Schachner, R. Buchner;
Institute of Botany, Vienna, Austria.

Sharing information combining visual and text based data is one of the most important skills in modern research. These informations are often maintained by large databases which are accessible via the Internet.
Despite professional databases like Oracle there are Open Source solutions which may help scientific institutions or communities to setup low-cost but powerful database solutions for the web.
Besides a low-budget system a user-friendly interface, a fast and manageable database administration system and a popular programming language is required for our purposes. A real classic combination is a Linux Server (SUSE, Debian, Red Hat, ?) incl. an Apache Web Server, a MySQL database and PHP (PHP: Hypertext Preprocessor - a recursive acronym) for the dynamic web interface. The challenge is now to combine input as well as text and graphical information both as visual and printed output. Design and workflow are shown in detail.
Check out our solution at http://www.paldat.org/ .

P2722. Bibliographies and botany

R. A. Cowan[1], **A. S. George**[2];
[1]Library / School of Biological Sciences & Biotechnology, Murdoch, WA, Australia, [2]Murdoch University, Murdoch, WA, Australia.

Bibliographies in any field may appear to be redundant in this era of the internet. Information professionals particularly the reference librarian or special subject librarians realize the importance of bibliographies in their daily encounters with clients. Has the internet changed the composition of a quality bibliography? Does the botanical information on the internet act as a surrogate?
Taxonomic Literature second edition (TL-2) has become a standard and is a benchmark bibliography. Sadly, a great proportion of the literature for 'cryptogams' sensu Linnaeus is not included, leaving a major lacuna in the bibliographic tools for botanists working with these organisms. With the inspiration of TL-2 and the experience gained from building these databases we have embarked on a companion to TL-2, Taxonomic Literature Cryptogamia (TLC). TLC will be a descriptive bibliography based on primary sources, available in print and electronic media.

P2723. Testing databases of herbarium collections as a source of biodiversity studies

L. Baena Cobos[1], W. Fajardo Contreras[2], C. Morales Torres[1], R. Pérez Pérez[2], C. Quesada Ochoa[1], T. Vizoso Paz[1];
[1]Herbarium of the University of Granada, Granada, Spain, [2]Department of Computer Sciences and Artificial Intelligence, Granada, Spain.

Up to now numerous programmes and projects which promote and facilitate the processing of data of botanical collections have been made. We have developed our own computer system in the Herbarium of the University of Granada as the consequence of an interdisciplinary work between botanists and computer scientists. This system not only offers the computerization of our herbarium data and to take part in international iniciatives such as GBIF, it also includes a series of Intelligent Agents which allow the evaluation of different parameters (geographical distribution, altitudinal distribution, ecology, phenology, etc) and biodiversity rates (*alfa*, *beta* and *gamma*) directly and accurately. We present this tool: BIOMEN (*Biological Management System Executed over Network*) in our poster and the results obtained through its application in the family *Cruciferae* Juss. of the province of Granada (Spain) represented in our collection.

P2724. Data capture and mapping priorities for herbarium specimens: putting conservation concerns at the top of the agenda

K. Harman[1], J. Moat[1], E. Nic Lughadha[1], J. Dransfield[1], R. Magill[2], B. Thiers[3], A. Paton[1];
[1]Royal Botanic Gardens, Kew, Richmond, United Kingdom, [2]Missouri Botanical Garden, St. Louis, MO, United States, [3]New York Botanic Garden, Bronx, NY, United States.

Only about 3% of plant species have had their conservation status assessed following current IUCN criteria. To meet the targets of the Global Strategy for Plant Conservation (all known species to have preliminary conservation assessments by 2010) the rate of production needs to be increased massively. Analysing specimen data within a GIS can rapidly produce preliminary assessments and help address this need. We correlated conservation status of selected plant species with the number of herbarium specimens at three major plant diversity institutes. We found the repeated trend that the majority of threatened species had few specimens, and species with few specimens represented the majority of all species. The implications of this are that by databasing a relatively small percentage of the world's herbarium specimens, targeting those species represented by fewer specimens in key collections representative of the region concerned, we can obtain a preliminary assessment for the great majority of threatened plant species globally.

P2725. Biodiversity pattern and beyond: integrating herbarium-based informatics with phylogenetic and environmental data

S. A. Bickford[1], **J. G. West**[1], S. W. Laffan[2];
[1]Centre for Plant Biodiversity Research, CSIRO Plant Industry, Canberra, Australia, [2]School of Biological, Earth and Environmental Sciences, University of New South Wales, Sydney, Australia.

Australia's Virtual Herbarium, a collaborative national specimen digitisation and web-based dissemination project, is providing unprecedented opportunities to map patterns of the distribution of taxa and collective measures of diversity of the Australian flora. Through case studies we illustrate its potential, when integrated with phylogenetic and environmental data in geographical analytical frameworks, for conservation planning, macro-ecology and evolutionary biology. Conservation planning requires taxonomically correct, geographically representative information on species distributions. Analyses of the environmental distribution of herbarium records is providing insight into collection bias and the scale at which diversity patterns can be reliably resolved to inform conservation policy. Analyses of the geographic and environmental distribution of monophyletic clades, that explicitly examine spatial scale and non-stationarity of patterns, are providing exciting opportunities to assess the relative roles of the contemporary environment and historical evolutionary processes in the distribution of gradients of diversity.

P2726. The role of herbaria and flora in preserving local plant-use information: the case of the Ethiopian national herbarium and flora

M. Giday[1], Z. Asfaw[2], Z. Woldu[2];
[1]Institute of Pathobiology, Addis Ababa, Ethiopia, [2]National Herbarium, Addis Ababa, Ethiopia.

The aim of this study was to compile and analyse information on local use of plants based on data obtained from labels of specimens stored at the National Herbarium and Flora volumes of Ethiopia. For the study, two families were considered: Fabaceae and Euphorbiaceae. Analysis of the data recovered from the specimen labels of the two families yielded a total of 116 locally useful plant species in Ethiopia. Medicinal use claimed the highest proportion of plants (52%). The study also revealed *Acacia nilotca, Croton macrostachyus* and *Ricinus communis* as having the highest use diversities. Further analysis of the herbarium data belonging to Euphorbiaceae demonstrated an increasing trend, with time, in the incorporation of plant-use information by collectors on specimen labels although much of the records were found incomplete to be considered sufficiently useful. The study also revealed that the bigger extent of use information given on herbarium labels regarding the two families was not incorporated in the relevant Flora volumes. All this justifies the need for carrying out proper ethnobotanical investigations or targeted collections in the country.

P2727. Modelling species palaeo- distribution patterns in BDWorld - implications for predicting the impact of global climate change

P. W. Brewer[1], N. Caithness[1], F. A. Bisby[1], P. J. Valdes[2], T. Sutton[1], C. Yesson[1], A. Culham[1], J. S. Pahwa[3], A. C. Jones[3], R. J. White[3];
[1]Centre for Plant Diversity and Systematics, Reading, United Kingdom, [2]Bristol University, Bristol, United Kingdom, [3]Cardiff University, Cardiff, United Kingdom.

Using state of the art climate model data covering the past 22 thousand years and present day specimen locality collections, we model the possible palaeo- distributions of a number of plant species. By direct comparison with pollen distribution records from the Global Pollen Database, the relationship between the actual palaeo- distribution and the modelled potential distribution in various time periods is analysed. Whilst there have been many previous attempts to model species distributions in present climatic conditions, the relevance of similar predictions for the future have yet to be fully verified. By using independent distribution data for the past in the form of fossil pollen, the relevance of static distribution modelling tools in temporal distribution modelling is therefore assessed for the first time. This high-throughout modelling procedure has been made possible through the BDWorld project utilising distributed GRID computing technologies.

P2728. BiodiversityWorld: A problem-solving environment for global biodiversity.

N. Caithness[1], F. A. Bisby[1], W. A. Gray[2], R. J. White[2], A. C. Jones[2], T. Sutton[1], P. W. Brewer[1], C. Yesson[1], S. Bhagwat[3], J. S. Pahwa[2];
[1]The University of Reading, Reading, United Kingdom, [2]Cardiff University, Cardiff, United Kingdom, [3]The Natural History Museum, London, United Kingdom.

The goals of the BDWorld project are to create an extensible framework for supporting distributed GRID computing in biodiversity research, with seamless access to remote data and analytical tools. From the users' perspective the system consists of a graphical work-flow manager that provides access to a rich set of remote data resources and analytical tools. From the system perspective there is a layered architecture with replaceable communications protocols, a workflow designer, a workflow enactment engine, a metadata repository for semantic mediation and reasoning, a resource locator, a resource matcher, and a suite of wrappers or proxies for the remote resources. We present an overview of the system architecture and development, and demonstrate examples of its use in three exemplar study areas: (i) biodiversity richness analysis, (ii) bioclimatic modelling and climate change scenarios, and (iii) phylogenetic and biogeography analyses.

P2729. Identification key for the cypress family (Cupressaceae)

C. Schulz, P. Knopf, T. Stützel;
Special Botany, Ruhr-University, Bochum, Germany.

The identification of Cupressaceae taxa, except for some local and easily distinguishable taxa, is difficult even for specialists. One reason for this is the lack of a complete key including all Cupressaceae taxa, another reason is that diagnoses and descriptions are spread over several hundred publications which are sometimes difficult to access. Based on morphological studies of about ¾ of the species and a careful compilation of the most important descriptions of Cupressaceae, a first interactive identification key for the entire Cypress family (Cupressaceae) could be set up. The key comprises any of the 30 genera, 134 species, 7 subspecies, 38 varieties, 1 form and thus all 180 taxa. The conventional key uses mainly features of adult leaves, female cones and other characters which are all relatively easy to be used. The key was puplished as a conventional key and digital key with more than 1000 detail-illustrations and a lot of additional information about common names, synonyms and features.

P2729. The natural habitates for edemic, rare and threatened species from the Abruptul Prahovean Reserve (Bucegi Massif, Southern Carpathians)

C. D. Bita-Nicolae;
Institute of Biology, Bucharest, Bucharest, Romania.

Abruptul Prahovean is a natural reserve of the Bucegi Massif (Merridional Carpathians), on the southen slope of Caraiman and on the Jepi valley.There is an area of strict protection extempt from grazing in this reserve. It has been constituted since 1955. In this area we emphasize the importance of a 45 endemic, rare and threatened plant species (Cormophytes) in the regional context. According to their statut in the Carpathians area the species are also included in Romanian Red Lists. However, there are many studies in this protected area but in this paper we selected this list of endemic, rare and threatened species and described them and their habitat types. More over, we selected the codes for them in accordance with the database from the EMERALD software; the habitat classification is based on "A classification of Palearctic habitats", Habitats Directives - 92/43/EEC and of Romanian Law 462/2001 Annex 2. Consequently, we used EUNIS code for habitats, related to phytosociological associations, as described in Romanian phytosociological literature.

P2730. Iranian medicinal plants monographs

F. Naghibi, S. Kamkar, A. Ghorbani, M. Mosaddegh;
Traditional Medicine & Materia Medica, Tehran, Islamic Republic of Iran.

In the computer and information age, using new technologies for storage, retrieval and analysis of information is vital. Objectives of this work were documentation of published and unpublished literature on medicinal plants of Iran, to facilitate information exchange between scientific communities by digitalizing the monographs and to harmonize the information on medicinal plant and use of herbal medicine. Each monograph contains detailed information on botanical family and scientific name, vernacular name, botanical description including photos, habit and habitats, distribution maps. Detailed ethnobotanical information, medicinal uses, chemical composition and compounds, pharmacology and dosage have been included. A computer program has been developed to restore this information. This information is provided for 100 species up to now. These species belong to 39 families. This work is still in progress to cover all the medicinal plants used in Iranian Traditional and folk medicine.

Make your plants VIPs

.... grow them in a Percival!

At Percival we know the needs of real VIPs and make sure that your **V**ery **I**mportant **P**lants will get just the environment they need.

With over 50 years of experience as a dedicated manufacturer of plant biology chambers Percival offers over 50 different models to suit every conceivable application. Whether you want it large or small, hot or cold, dry or humid, or just plain stress-free call the experts at Percival and put your VIPs where they belong.

Just choose one of many models:

- Arabidopsis Chambers
- Plant Tissue Culture Chambers
- Seed Germination Chambers
- Dew Chambers
- Snow Chambers
- Chambers for plant/insect interactions
- Economic multi-purpose Plant Biology Chambers for algae, fungi etc.
- E-30LED with LED modules
- Reach-in Plant Growth Chambers
- Walk-In Rooms for Arabidopsis and Plant Tissue Culture
- Walk-In Plant Growth Chambers

Do you already have a specific project? Need more information?
