A few words about PACWBs

CWB : Binary system made of two stars belonging to the category of OB- or WR-type stars

No compact companion!

Main feature of such a system :
a wind-wind interaction region

Physical conditions : ruled by
the properties of the stellar winds
and by the orbital parameters

**Physics of colliding wind binaries,
see Julian Pittard's talk**

A Particle-Accelerating Colliding-Wind Binary is a CWB with evidence
for the existence of a population of relativistic particles

The background of the slide is a deep space image showing a dense field of stars of various colors (white, yellow, orange, red, blue) against a dark, reddish-brown nebula. A dark, semi-transparent rectangular box is centered in the upper half of the image, containing the text 'The catalogue' in a bold, yellow, sans-serif font.

The catalogue

5th May 2015

VGGRSIII, Heidelberg

The catalogue

Catalogue of about 40 objects :
O-type, WR-type, transition objects

De Becker & Raucq 2013 A&A 558, A28

On-line version : <http://www.astro.ulg.ac.be/~debecker/pacwb/>

The catalogue

Catalogue of about 40 objects :
O-type, WR-type, transition objects

De Becker & Raucq 2013 A&A 558, A28

On-line version : <http://www.astro.ulg.ac.be/~debecker/pacwb/>

Main tracers of particle acceleration

1. Synchrotron radio emission (all but one !)
Spectral index, flux density, variability,
resolved NT source between the stars...
2. Non-thermal X-rays (WR140 , Eta Car)
3. Gamma-rays (Eta Car)

A few questions and facts

5th May 2015

VGGRSIII, Heidelberg

A few questions and facts

Are PACWB restricted to a narrow area of stellar wind parameters ?

Are PACWB restricted to a narrow range of orbital periods ?

Do we need very high energy injection rates into the colliding-wind region to significantly detect NT emission related to relativistic particles?

Is it relevant to seek for hints for particle acceleration especially in systems with strong magnetic fields?

A few questions and facts

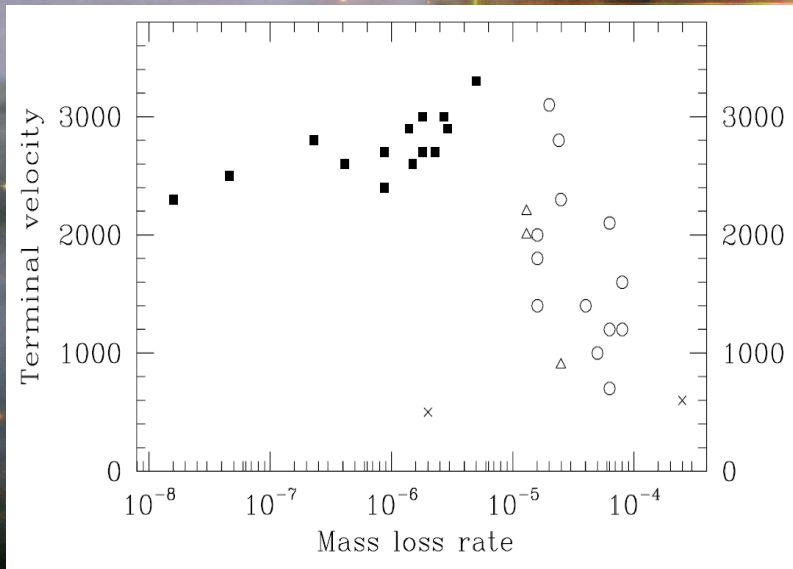

Are PACWB restricted to a narrow area of stellar wind parameters ?

Stellar wind parameters cover a range typical of O-type and WR-type stars

Only one B star, but a transition object with enhanced mass loss

Lack of stars with weak winds

→ large parameter space to investigate, including many spectral types and classes

(De Becker & Raucq 2013)

A few questions and facts

Are PACWB restricted in to narrow range of orbital periods ?

Orbital periods cover a wide range of values, from a few weeks up to many decades !

One puzzling object with a period of ~ 2 days (could be a triple system, with a third star in a wider orbit)

→ close binaries are not favored targets, but any longer period binary is worth investigating !

(De Becker & Raucq 2013)

A few questions and facts

Do we need very high energy injection rates into the colliding-wind region to significantly detect NT emission related to relativistic particles?

Thermal X-rays from CW depend intimately on the amount of power injected in the wind interaction zone

One may consider the particle acceleration process can be favored by a high power injection rate

However : some PACWBs present a significant non-thermal radio emission, but do not show a very bright X-ray excess attributed to the colliding-winds

A few questions and facts

Do we need very high energy injection rates into the colliding-wind region to significantly detect NT emission related to relativistic particles?

HD167971

Bright synchrotron radio emitter
(phase-locked with the 21-year
period)

Thermal X-rays dominated by
CWab, with only a moderate
contribution from CWAB

(De Becker 2015, submitted)

HD93129A

Significant NT radio
emission resolved with the
LBA (Benaglia et al. 2015)

The thermal X-ray spectrum
does not present any hint
for a spectacular emission
from the colliding-winds

(Gagné et al. 2011)

→ a bright thermal X-ray spectrum strongly dominated
by colliding-winds is not a criterion to select a candidate

A few questions and facts

Is it relevant to seek for hints for particle acceleration especially in systems with strong magnetic fields?

The main tracer of particle acceleration requires the presence of a magnetic field
→ one may wonder whether systems with strong magnetic fields may be good candidates !

Spectropolarimetric methods allow to measure surface magnetic field strengths down to 1 - 10 Gauss

However : Attempts to detect magnetic fields in a sample of O-type PACWBs failed to detect it

(Neiner et al. 2015)

A few questions and facts

Is it relevant to seek for hints for particle acceleration especially in systems with strong magnetic fields?

The main tracer of particle acceleration requires the presence of a magnetic field
→ one may wonder whether systems with strong magnetic fields may be good candidates !

Spectropolarimetric methods allow to measure surface magnetic field strengths down to 1 - 10 Gauss

However : Attempts to detect magnetic fields in a sample of O-type PACWBs failed to detect it

(Neiner et al. 2015)

In fact : models suggest that 'local' values of the magnetic field (in the wind-wind interaction region) of the order of a few mG are enough to explain the measured synchrotron radio emission in PACWBs

(Dougherty et al. 2003)

This translates into surface magnetic fields of the order of – or even significantly below – the present upper limits on the measurements

→ the selection of systems with quite strong magnetic fields is not a good criterion to identify new PACWBs

A vibrant, multi-colored nebula (likely the Carina Nebula) with a grid overlay. The nebula features a mix of blue, purple, and orange hues, with numerous bright stars scattered throughout. A semi-transparent dark grey rectangle is centered over the text.

Observation strategies

5th May 2015

VGGRSIII, Heidelberg

Observation strategies

Target selection

1. Categories of potential candidates include all O-type and WR-type objects (even evolved early-B type stars are relevant).
 2. Systems with periods of at least a few weeks deserve to be investigated.
 3. The production of a wealth of thermal X-rays from the colliding-wind region is not a requirement.
 4. The detection of a surface magnetic field at the Gauss-level is not a relevant selection criterion.
- A large fraction of massive star systems deserve to be investigated !

Observation strategies

Tool selection

Mainly : Radio observatories

- repeated observations at cm wavelengths (synchrotron emission is variable, and may not be obvious at all orbital phases)
- measurements at more than one wavelength (spectral index determination)
- potential VLBI campaigns to resolve a NT emission region coincident with the colliding-wind region

But also : High-energy observatories (hard X-rays and Gamma-rays)

- search for an inverse Compton scattering contribution in hard X-rays
- further investigations with Gamma-ray facilities are also relevant

A vibrant, multi-colored nebula (likely the Carina Nebula) with a grid overlay. The nebula features a mix of blue, purple, and orange-red hues, with numerous bright stars scattered throughout. A semi-transparent dark grey rectangle is centered in the upper half of the image, containing the text "Concluding remarks" in a bold, yellow, sans-serif font.

Concluding remarks

5th May 2015

VGGRSIII, Heidelberg

Concluding remarks

So far, no clear selection criterion can be established to restrict significantly the sample of candidates to be investigated
→ many systems could be studied among known massive binaries

Campaigns dedicated to the determination of the multiplicity of massive stars are very important
→ they increase the list of candidates to be investigated

Observation strategies should at first sight favor radio observations
→ such campaigns are in progress, but require a lot of telescope time

The question of the fraction of PACWBs among CWBs is an important issue, and we are still far from the answer

**Thank you
for your attention !**
