Practical informations I

- Instructor: Marc Van Droogenbroeck
- Assistant: Renaud Vandeghen
- Slides: http://orbi.uliege.be
- Evaluation
 - personal project (split in several sub-tasks): 3 students, evaluated in December.

The project is compulsory!

If a sub-task is not done, then the student gets a note of 0 for the sub-task AND following sub-tasks.

No possibility to resubmit in August!

- written exam (also compulsory!), closed book, during the exam session.
- 3 [*August only*] written examination.

Onter the second sec

- **①** January: 2/3 for the project, 1/3 for the exam
- **2** August/September: 1/2 for the project, 1/2 for the exam

▶ Hands on computer vision \Rightarrow "practice" computer vision

Table: Two representations of RGB color values (8 bit per color channel).

Acquisition: three sensors

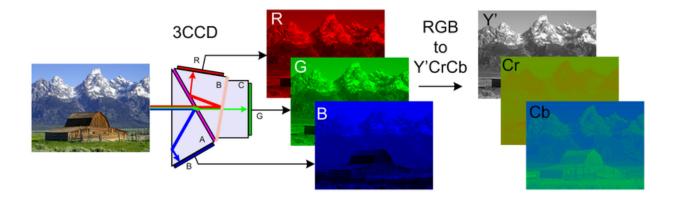

Figure: Acquisition of a $Y C_b C_R$ signal [Wikipedia]

There are variations, such as the Y U V colorspace, mainly developed for compression:

- **1** information concentrated in the Y channel \Rightarrow better compression.
- 2 better decorrelation between channels.

A Bayer filter mosaic is a color filter array for arranging RGB color filters on a square grid of photo sensors.

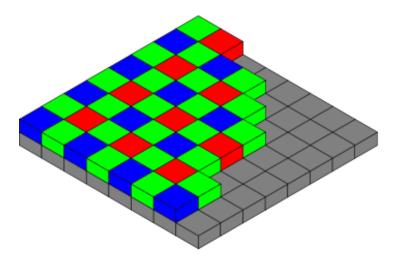

Figure: The Bayer arrangement of color filters on the pixel array of an image sensor.

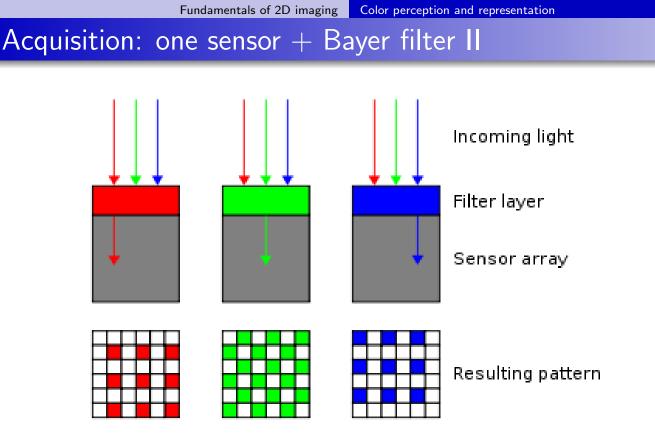

Figure: Profile/cross-section of sensor.

- Most mono-sensor cameras use the Bayer pattern, except for professional 3CCD cameras (three sensor planes + prism to split the incoming light)
- ▶ The filter pattern is 50% green, 25% red and 25% blue. Why?
- We only have one value per pixel. Other values are re-built by interpolation, but they might not even exist... !
- For compression or processing,
 - 1 sensor plane ⇒ normally only one byte to process. Possible if the processing occurs in the sensor, not anymore if the interpolated image is forwarded.
 - 3 sensor planes ⇒ 3 planes to process or to compress.
 Expected compression rate: more or less the same as for a grayscale image.
- It might be wiser, for processing, to have a black-and-white (or a monochromatic, such as red) camera, instead of a color camera.

Bayer filter: practical considerations

Sampling grid and frame organization

- Each sample located on a grid is named a *pixel* (which stands for *picture element*).
- There are two common sampling grids and they induce certain types of connectivity (defined the *number of neighbors*).

| Squar | Hexagonal grid | |
|----------------|----------------|----------------|
| • • | • • • • | |
| • • | • • • • • | |
| •• | • • • • | |
| | | |
| 4-connectivity | 8-connectivity | 6-connectivity |
| | | |

Table: Types of grid and associated connectivities.

Fundamentals of 2D imaging Data representations

Data structure for dealing with images

- Typical data structure for representing images: matrices (or 2D tables), vectors, trees, lists, piles, ...
- For matrices, there are several ways to organize the memory:
 - 1 channel (for example, luminance):
 - upper left corner coordinate correspond to the (0,0) location in the matrix.
 - one byte per pixel
 - 3 channels, such RGB images. We have two options:
 - store 3 matrices separately (according to the 1 channel storage scheme)
 - Interprete store the RGB values consecutively (intermixed) for each pixel. For example, if $R_1G_1B_1$ and $R_2G_2B_2$ are the color values of two consecutive pixels, then we could store the values as $R_1G_1B_1R_2G_2B_2$ in a single matrix.

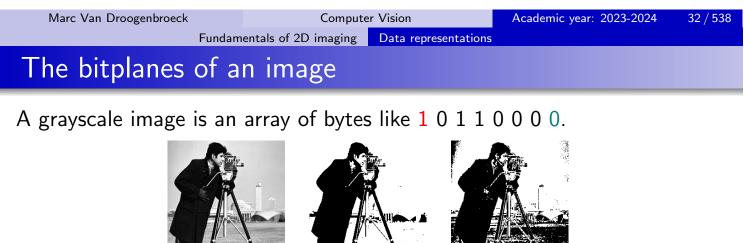

Table: Image and its 8 bitplanes starting with the Most Significant Bitplane (MSB) to the Least Significant Bit (LSB). Marc Van Droogenbr

Typology of images and videos

- 2D. This types refers to a "classic" image and is usually expressed as a 2D array of values. It might represent the luminance, a color, depth, etc.
- 3D. 3D images are obtained with devices that produce 3D images (that is with x, y, z coordinates). Medical imaging devices produce this type of images.
- 2D+t. *t* refers to time. Therefore, 2D + t denotes a video composed over successive 2D images, indexed by *t*.
- 3D+t. 3D+t images are in fact animated 3D images. A typical example is that of animated 3D graphical objects, like that produced by simulations.

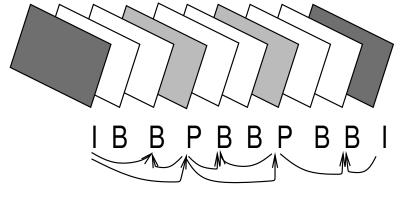

Compression ratios: ITU-R 601 (ex CCIR 601)

- $\blacktriangleright YC_bC_r$
- 4:4:4 (720/720/720) = 270 [Mb/s]
- ▶ 4:2:2 (720/360/360) = 180 [Mb/s]

Two main principles:

- remove some redundancies inside the frame (intraframe coding)
- remove some redundancies between frames (interframe coding)

MPEG-2 levels and profiles

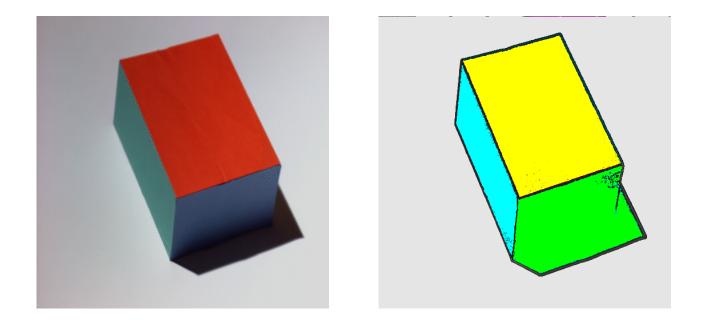

| Profile | Simple | Main | SNR | Spatial | High |
|--------------------------------------|--------|------|-----|---------|------|
| Low level (235 x 288 x 30Hz) | | Х | Х | | |
| Main level (720 x 576 x 30Hz) | Х | Х | Х | | Х |
| High-1440 level (1440 × 1152 × 60Hz) | | Х | | Х | Х |
| High level (1920 x 1152 x 60Hz) | | Х | | | Х |

A 50 Hz video stream of size 720 \times 576 (PAL) corresponds to 270 [Mb/s] uncompressed

- Lossless compression: $\approx 100 [Mb/s]$
- Lossy compression (but intraframe only): $\approx 27 [Mb/s]$
- Lossy compression (including interframe coding): MPEG-2 format
 ~ 5 [Mb/s] or less

Image segmentation

Several successive stages:

- Selection of a Region of Interest (ROI). Processing is limited to that area.
- Detection of edges (contours).
- Identification and classification of characters.

Marc Van Droogenbroeck

Computer Vision

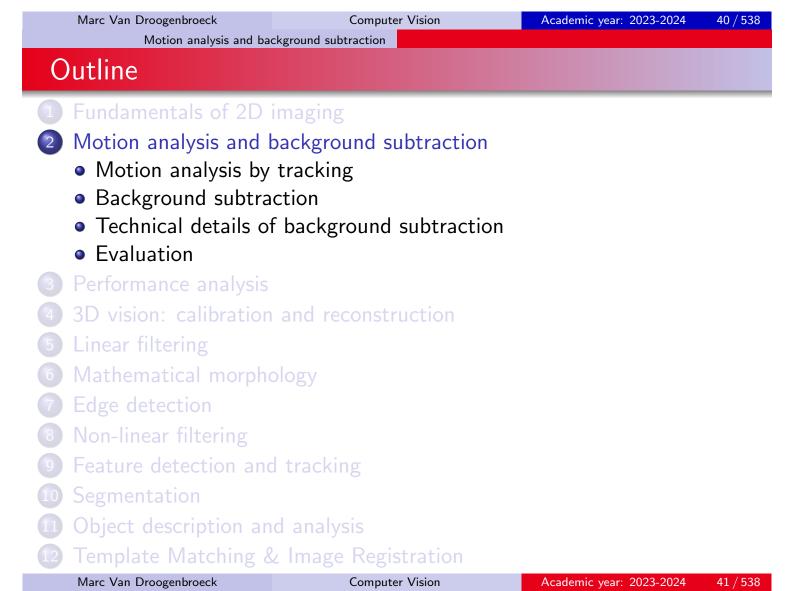

Academic year: 2023-2024

39 / 538

Example of classification task: classify handwritten digits

- Goal: learn to recognize handwritten digits (by machine learning)
- Dataset: the MNIST (Mixed National Institute of Standards and Technology) database of handwritten digits has
 - a training set of 60,000 examples.
 - a *test/validation set* of 10,000 examples.
 - normalization: the digits have been size-normalized and centered in a fixed-size image.

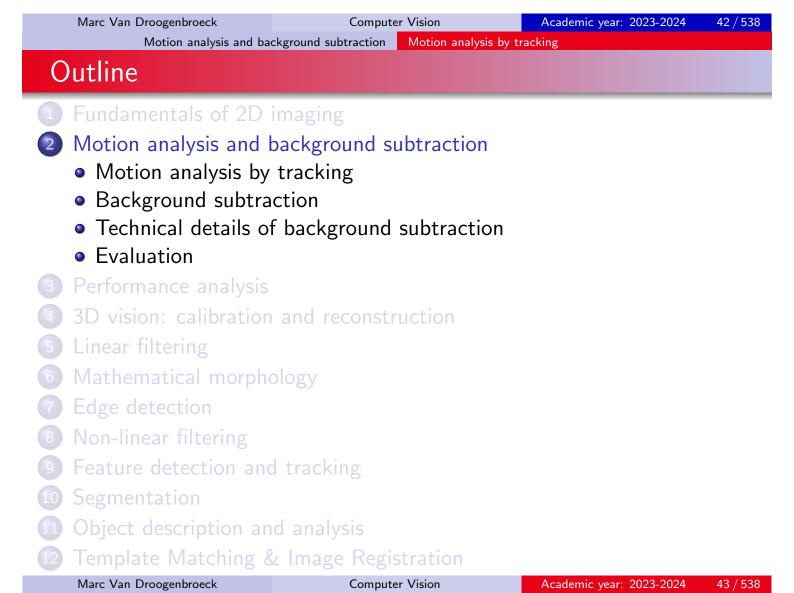

Detection of motion

There are basically two "pure" approaches for motion analysis/detection in a video sequence:

• Motion analysis by *tracking* (= *motion estimation* based techniques):

- detects some particular points in a video frame.
- find the corresponding points/objects in the next frame.
- based on a model, interpret the trajectories of the points/objects (usually at the object level).
- 2 Motion detection by background subtraction:
 - build a reference frame or model with no foreground in it.
 - compare a next frame to the reference.
 - update the reference.

Motion analysis by tracking: principles

There are several techniques but, usually, they involve the following steps:

- detect features in successive frames.
- 2 make some correspondences between the features detected in consecutive frames
- Solution based on a model, regroup some features to facilitate the tracking of objects.

Feature detection

Some known feature detectors:

- Harris's corner detector
- Scale Invariant Feature Transform (SIFT)
- Speeded Up Robust Features from an image (SURF)
- Features from Accelerated Segment Test (FAST)
- …

Original image

Features detected by SURF

Feature correspondence

Difficulties for feature correspondence

Typical questions/difficulties for tracking approaches (targeting *motion estimation*):

- How to filter the features? (remove some useless features)
- How do we regroup features?
 - we need a *model*. But this introduces a **bias towards the model**.
- How do we ensure continuity over time?
- What happens when occlusions occur?
- How to solve ambiguities (one feature in one image is identical to several in the next frame)?

…

Background subtraction

Common tasks:

- ► background subtraction ⇒ segmentation
- ► change detection \Rightarrow generate alarms (and reduce rate of false alarms!) Plethora of methods (2023):
 - 'motion detection' on IEEE Xplore: 34,620 papers
 - 'background subtraction video' on IEEE Xplore: 3,750 papers

Different spatial contexts:

- pixel-based (pixelwise)
- region-based
- tracking (spatio-temporal neighborhood)

Marc Van DroogenbroeckComputer VisionAcademic year: 2023-202454 / 538Motion analysis and background subtractionTechnical details of background subtraction

Techniques for background subtraction

Objective of pixel-based background subtraction techniques

Separate the *foreground* (pixels "in motion") from the *background* ("static" pixels).

Implementation perspective

A video sequence is like a data cube whose dimension is only fixed in 2 dimensions.

► The data cube extends with time.

Challenges for building a background subtraction algorithm:

- need to find a way to accumulate knowledge of increasing size inside of a constant sized memory block.
- 2 this knowledge should be updated regularly to deal with changes.

Techniques for background subtraction

Objective of pixel-based background subtraction techniques

Separate the *foreground* (pixels "in motion") from the *background* ("static" pixels).

Implementation perspective

A video sequence is like a data cube whose dimension is only fixed in 2 dimensions.

The data cube extends with time.

Challenges for building a background subtraction algorithm:

- 1 need to find a way to accumulate knowledge of increasing size inside of a constant sized memory block.
- 2 this knowledge should be updated regularly to deal with changes.

Marc Van Droogenbroeck Computer Vision Academic year: 2023-2024 55 / 538 Motion analysis and background subtraction Technical details of background subtraction Implementation of background subtraction in 3 steps

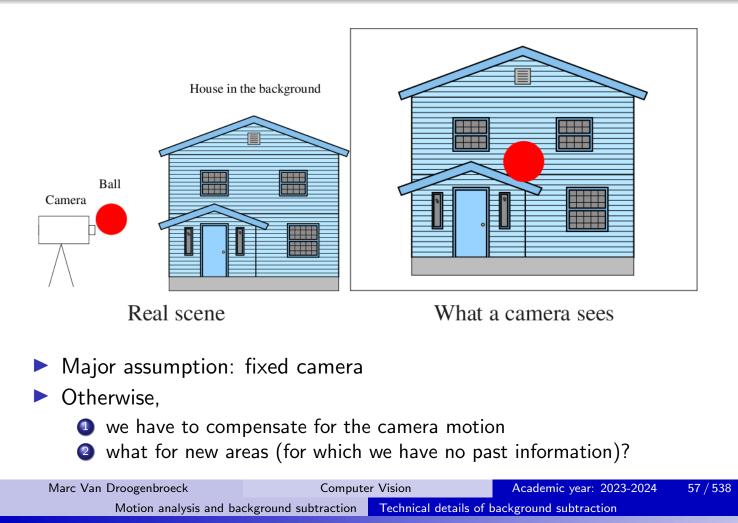

Steps

[1. Initialization] build a *reference frame* or a *statistical model* for the background.

- [2. Subtraction or segmentation] compare the current frame to the reference frame or model, and "subtract" the frame to get a binary image indicating pixels who have changed.
- [3. Updating] update the reference frame or model.

When we develop a technique, we have to detail these three steps!

Principles

Reference frame or a model?

One frame in the sequence

Built reference frame

Figure: Building a reference frame (or an unimodal model).

Building a reference frame from a video sequence is the *task* of background estimation/background generation.

For real-time processing, we need a reference frame as soon as possible.

Elementary method (reference frame)

Naive approach for the step of segmentation (static background)

Foreground is detected, pixel by pixel, as the difference between the current frame and a static reference image (background). Let p be a pixel location. p belongs to the background if

$$|I_t(p) - B(p)| \le \text{threshold}$$
 (7)

where

- ▶ $I_t(p)$ is the current pixel value (at time t),
- \triangleright B(p) is the reference background value for that pixel.

Problems:

- ▶ How do we *choose* the reference image?
- ► The reference image should *change over time*.
- What is the best threshold?

Choices for a better reference image

Simple techniques (for the step of updating)

- One "good" image is chosen (usually a frame empty of foreground objects).
- Exponentially updated reference image (blending)

$$B_t(p) = \alpha I_t(p) + (1 - \alpha) B_{t-1}(p)$$
(8)

Typical value for α : 0.05 (in that case, $B_t = 0.05 I_t + 0.95 B_{t-1}$)

Median of the last N frames (for each pixel separately).

Initialization

- ullet \Rightarrow fill in the first reference image or initialize the model
- difficulty: problem with the presence of *ghosts*.

Segmentation

- \Rightarrow rules + parameters ...
- difficulties:
 - homogeneous rule for the whole image?
 - how to set the values of the parameters?

Updating

- \Rightarrow we need strategies
- difficulty: how to adapt the scene dynamics?

There are two main strategies for the updating

Blind update (the most common)

update the reference image or the model for all pixels, regardless of the segmentation result (that is if the pixel is a foreground or a background pixel)

does it make sense?

onservative update

only update when the pixel belongs to the background

what if the segmentation was wrong (deadlock)?

Marc Van DroogenbroeckComputer VisionAcademic year: 2023-202463 / 538Motion analysis and background subtractionTechnical details of background subtraction63 / 538There are two main strategies for the updating

Blind update (the most common)

update the reference image or the model for all pixels, regardless of the segmentation result (that is if the pixel is a foreground or a background pixel)

does it make sense?

Conservative update

only update when the pixel belongs to the background

what if the segmentation was wrong (deadlock)?

The background is modeled as a probability density function to be estimated

- One Gaussian distribution per pixel
- Mixture of Gaussians for each pixel
- Kernel-based estimation of the probability density function

[Model]

For each pixel, the probability density function of observed values is modeled by a **single** Gaussian.

Let v be an observed value for a pixel p:

$$\mathsf{pdf}(\mathbf{v}) \sim G(\mu, \, \sigma) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(\mathbf{v}-\mu)^2}{2\sigma^2}} \tag{9}$$

Once the model is built (here it means that we need to estimate the mean and variance), we evaluate the distance to the mean.

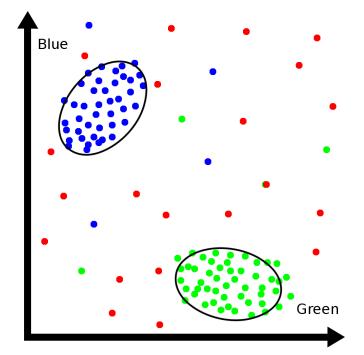

[Segmentation step]

$$|v_t - \mu| \le \text{parameter} \times \sigma$$
 (10)

then the pixel p belongs to the background.

Mixture of Gaussians Model

Motivation: the probability density function of the background is multi-modal

[Stauffer, 1999, 2000] [Power, 2002] [Zivkovic, 2006]

For each pixel:

$$pdf(v) \sim \sum_{i=1}^{N} \alpha_i G(\mu_i, \sigma_i)$$
 (11)

Typical values for n: 3 or 5

Fundamental assumptions

- The background has a low variance.
- The background is more frequently visible than the foreground.

Motion analysis and background subtraction Technical details of background subtraction

Kernel Density Estimation (KDE) methods

For each pixel:

$$pdf(v) \sim \sum_{i=1}^{N} \alpha_i K_{\sigma}(v - v_i)$$
 (12)

where $\{v_i\}_{i=1,...,N}$ are the *N* last values observed (samples) for that pixel, and $K_{\sigma}()$ is a kernel probability function centered at v_i .

Decision rule

The pixel belongs to the background if $pdf(v) \leq threshold$.

[Elgammal, 2000] [Zivkovic, 2006]

Typical values $pdf(v) \sim \sum_{i=1}^{N} \alpha_i K_{\sigma}(v - v_i)$ with

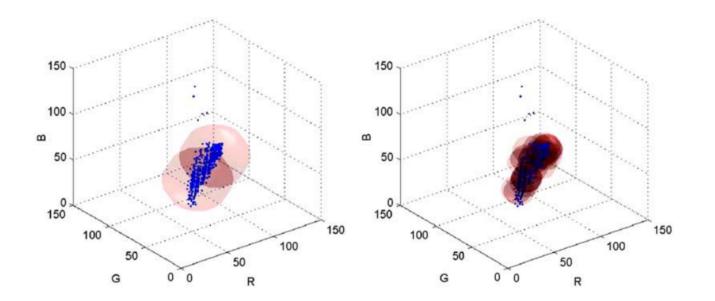

• Number of samples:
$$N = 100$$

• Weight:
$$\alpha_i = \alpha = \frac{1}{N}$$

Spreading factor:
$$\sigma = Variance(v_i)$$

Probability density function chosen to be Gaussian:
 K_σ(v - v_i) = G(v_i, σ²)

GMM techniques vs KDE techniques

- Codebook
- Principal Components Analysis (PCA)
- Relaxation techniques (mainly post-processing of binary segmentation maps)
- Local Binary Patterns
- ViBe: no model, all based on samples
- Deep learning based methods

More details about ViBe: design rules

The design of ViBe was motivated by:

- information at the pixel level should be preferred to aggregated features (for speed and efficiency).
- *collect samples*, rather than build a statistical model:
 - sample values have been observed in the past.
 - no bias towards a model.
- Image: minimize the number of collected samples.
- Ino "planned obsolescence" notion for samples.
 - don't use the commonly (and exclusively) adopted substitution rule that consists to replace oldest samples first or to reduce their associated weight.
 - all samples are equally valid.
- **o** foresee a mechanism to ensure *spatial consistency*.
- keep the *decision* process *simple*.

 Requirements while designing ViBe
 ViBe

- No pre- or post-processing!
- 2 Be real-time.
- A unique set of parameters.
- Working as soon as you get the second frame.

Keys of a background subtraction technique

- **Model**. What is a good model for the background?
- How to classify pixels in the background/foreground? Need for a classification criterion.
- **I** How to **update** the model?
- Initialization?

- Model each background pixel with a set of samples (non-parametric method), instead of with an explicit pixel model. Each background pixel x is modeled by a collection of N background sample values: $M(x) = \{v_1, v_2, \ldots, v_N\}$
 - Avoid the difficult task of estimating the probability density function.
 - No statistical notion. Assume a binary image, what is the meaning of the mean? It is even a value that might never be observed ...
 - How could a model consider values of its immediate neighborhood?

Pixel classification

- A pixel belongs to the background if there are at least two matches: #{S_R(v(x)) ∩ {v₁, v₂, ..., v_N}} ≥ #min
- \blacktriangleright N = 20 and $\#_{min} = 2$

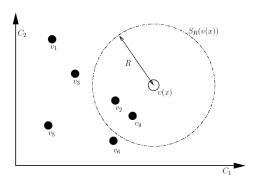

Fig. 1. Comparison of a pixel value with a set of samples in a two dimensional Euclidean color space (C_1, C_2) . To classify v(x), we count the number of samples of $\mathcal{M}(x)$ intersecting the sphere of radius R centered on v(x).

Principles:

Conservative update: update the model only if a pixel value is considered as a background. If it is foreground, do not update at all.

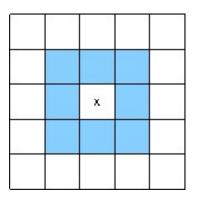

Mechanisms:

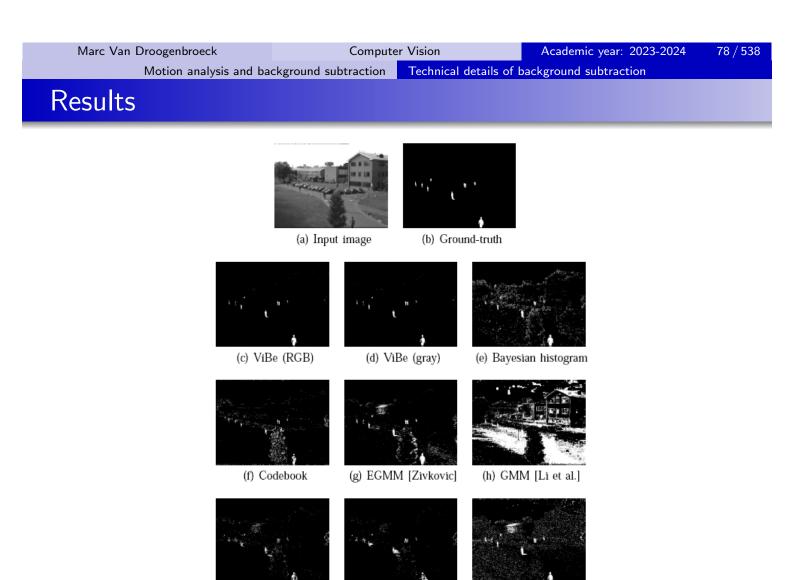

- The background model of a pixel is updated randomly! One sample in the model is chosen randomly and replaced. The lifetime of the replaced value is ignored.
- 2 Random time subsampling. Not every model is updated. Which one is decided randomly (typically 1 out of 16, on average).
- Sandomly select a neighbor and modify the model of it with the value of the local pixel and according to the 1 and 2 mechanisms (spatial diffusion).

Model Initialization

From a single frame, populate the pixel models with values found in the spatial neighborhood of each pixel.

- Values randomly taken in their neighborhood
- Values chosen in the close 8-connected neighborhood

What do we want to evaluate?

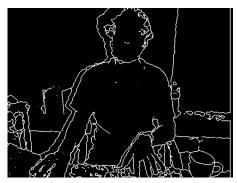

Segmentation

Edge detection

It is challenging...

Background subtraction

The process of evaluation might involve:

- The definition of a *methodology* that comprises *experiments* (note that it is important to be explicit on experimental conditions).
- Criteria or scores.
- **Reference data**:
 - unlabeled data, which is collected "in the wild".
 - labeled or annotated data, sometimes named as ground truth data.

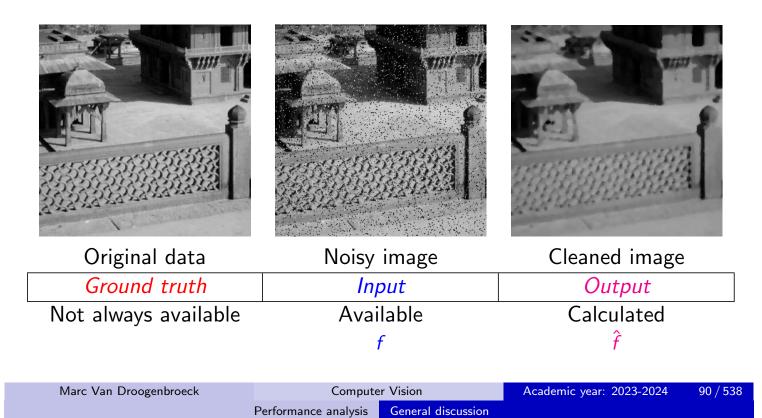

Typology of evaluation methods:

- Subjective. The evaluation process involves a representative group of human viewers.
 - [+] takes the *user's experience* into account.
 - [-] is time-consuming (→ expensive), provides subjective evaluation scores, depends on the experimental setup.
- **2 Objective**. Based on objective measurements.

Objective quality measures and distortion measures I

Let f be the input image (whose size is $N \times N$) and \hat{f} be the image after some processing.

Objective quality measures and distortion measures II

Definition (Mean Square Error)

$$MSE = \frac{1}{NM} \sum_{j=0}^{N-1} \sum_{k=0}^{M-1} \left(f(j,k) - \hat{f}(j,k) \right)^2$$
(13)

Definitions (Signal to noise ratios)

[Signal to Noise Ratio]

$$SNR = \frac{\sum_{j=0}^{N-1} \sum_{k=0}^{M-1} (f(j,k))^2}{\sum_{j=0}^{N-1} \sum_{k=0}^{M-1} (f(j,k) - \hat{f}(j,k))^2}$$
(14)

[Peak Signal to Noise Ratio]

$$PSNR = \frac{NM \times 255^2}{\sum_{j=0}^{N-1} \sum_{k=0}^{M-1} \left(f(j,k) - \hat{f}(j,k) \right)^2}$$
(15)

Marc Van Droogenbroeck

Computer Vision

On the importance of ground truth data

Depending of the availability of ground truth, we have:

- Standalone evaluation.
 When a reference is not available.
- Relative evaluation.
 When ground truth data is available for comparison.

Properties of "good" ground truth data

- representative for the application.
- ② different conditions for the acquisition (large variety of samples, always directly related to the application).
- (a) correctly annotated (\rightarrow there is some agreement on the quality of the reference).

Depending of the availability of ground truth, we have:

- Standalone evaluation.
 When a reference is not available.
- Relative evaluation.

When ground truth data is available for comparison.

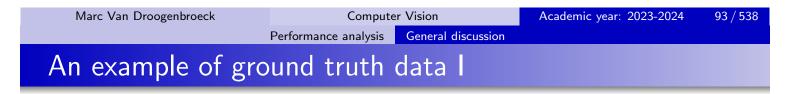

Properties of "good" ground truth data

- representative for the application.
- Ifferent conditions for the acquisition (large variety of samples, always directly related to the application).
- Source correctly annotated (\rightarrow there is some agreement on the quality of the reference).

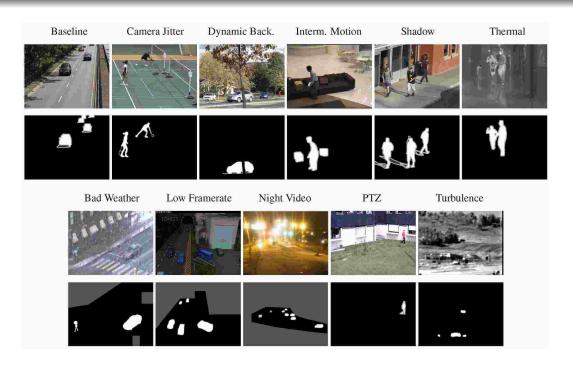

Difficulties specific to ground truth data

Annotation process

- the "annotation" process (which consists to build the ground truth data) is complex and sometimes debatable. Two[']"flavors":
 - synthetic data (which comes with synthetic annotations)
 - real data with manually annotated data.
- the annotation process is partly subjective.

ChangeDetection.NET (CDNET) dataset: a dataset for testing background subtraction algorithms

An example of ground truth data II

Main characteristics:

- 11 categories: about 5 videos per category
- long video sequences
- thousands of annotated images (ground truth data)
 - 5 labels: static (≡ background), shadow, non-ROI, unknown, and moving (≡ foreground)
- 7 performance metrics are computed
- ranking per video, category, and globally

|------------------------|---|-----------|--------------------------|----------|
| | Performance analysis General discussion | | | |
| Evaluation tasks | | | | |

We can distinguish 3 main reasons for evaluation:

- Optimization/analysis of a solution. For example, we have different parameter sets, then
 what are the best parameters?
- Comparison between algorithms
 Is algorithm A better than algorithm B?

Ranking. Which one is the best?

Ideally, evaluation tools should be different for these tasks. In practice, there is a confusion.

A framework for developing evaluation criteria

Terminology from the *classification theory*.

Definition (Classification)

In machine learning and statistics, classification is the process of identifying the *category/class of a new observation*, on the basis of a training set of data containing observations (or instances) whose category membership is known.

The categories are named "classes".

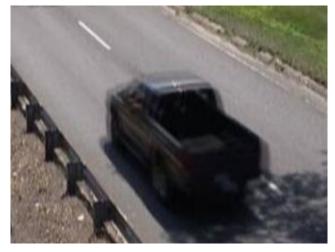

Example (In background subtraction, there are two classes:)

- Foreground
- Background

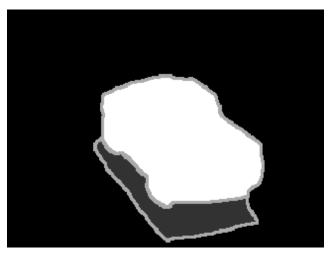

But there could be more: shadows, sky, road, etc.

The notion of positive and negative

Let us consider a two-class problem and denote the "negative" and "positive" classes by c^- and c^+ , respectively. In background subtraction, background \equiv negative and foreground \equiv positive .

Original image

Binary segmentation map

Figure: Background subtraction identifies pixels belonging to the foreground (positive class c^+ , white pixels) and pixels belonging to the background (negative class c^- , black pixels).

A classifier estimates the class of each new sample (pixel in the case of background subtraction).

There are two notions of classes:

[true class or ground truth] it is denoted by $y \in \{c^-, c^+\}$. [estimated class] the class estimated by the classifier is denoted by $\widehat{y} \in \{c^-, c^+\}$

Other notions:

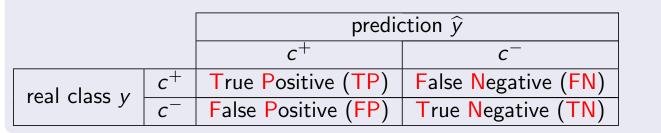

•
$$\pi^- = p(y = c^-)$$
 and $\pi^+ = p(y = c^+)$ are the priors.

▶ the rates of negative and positive predictions, denoted by
\$\overline{\alpha^-} = p(\overline{y} = c^-)\$ and \$\overline{\alpha^+} = p(\overline{y} = c^+)\$ respectively (not to be confused with the priors!).

Confusion matrix

Definition (Confusion matrix)

There are four possibilities, described by the confusion matrix:

Remarks:

- ► There are four quantities: TP, FN, FP, TN.
- It is easy to extend a confusion matrix to more than two classes.
- How do we build metrics/performance indicators?

| Marc Van Droogenbroeck | Computer Vision | | Academic year: 2023-2024 | 101 / 538 |
|------------------------|--|--|--------------------------|-----------|
| | Performance analysis Evaluation criteria and | | nd metrics | |
| Evaluation metrics | 5 | | | |

Definitions (Conditional probabilities)

They involve the true class:

True Positive Rate, also named **sensitivity** or **recall**, is defined as

$$\mathsf{TPR} = p\left(\widehat{y} = c^+ | y = c^+\right) = \frac{\mathsf{TP}}{\mathsf{TP} + \mathsf{FN}} \tag{16}$$

True Negative Rate (also named specificity) is

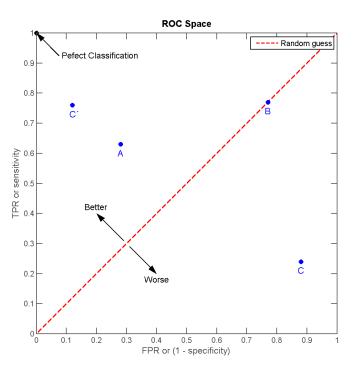

$$\mathsf{TNR} = p\left(\widehat{y} = c^{-}|y = c^{-}\right) = \frac{\mathsf{TN}}{\mathsf{TN} + \mathsf{FP}} \tag{17}$$

These quantities are linked to the

- False Positive Rate $FPR = (1 TNR) = \frac{FP}{FP+TN}$
- False Negative Rate FNR = (1 TPR)

Receiver Operating Characteristic (ROC) evaluation space

Definition (Receiver Operating Characteristic (ROC)) The (FPR, TPR) pair defines the ROC evaluation space.

| | 1. A. | , | | | | | | | |

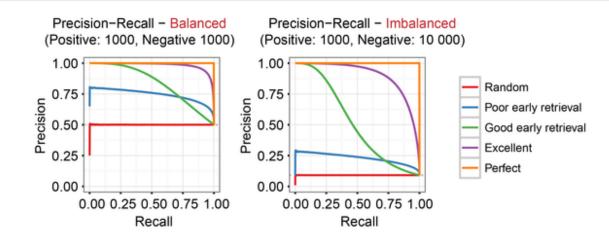

Precision/recall evaluation space

Definition (Precision)

$$\mathsf{P} = p\left(y = c^{+}|\widehat{y} = c^{+}\right) = \frac{\mathsf{TP}}{\mathsf{TP} + \mathsf{FP}} \tag{18}$$

Definitions (Recall $[\equiv TPR]$)

$$\mathsf{R} = p\left(\widehat{y} = c^{+}|y = c^{+}\right) = \frac{\mathsf{TP}}{\mathsf{TP} + \mathsf{FN}}$$
(19)

Marc Van Droogenbroeck

Performance analysis Evaluation criteria and metrics

Particularities of the ROC and Precision/Recall space

- Unachievable zone in the PR space, but only the upper part of the ROC curve makes sense.
- In the ROC space, the diagonal represents the random classifiers.

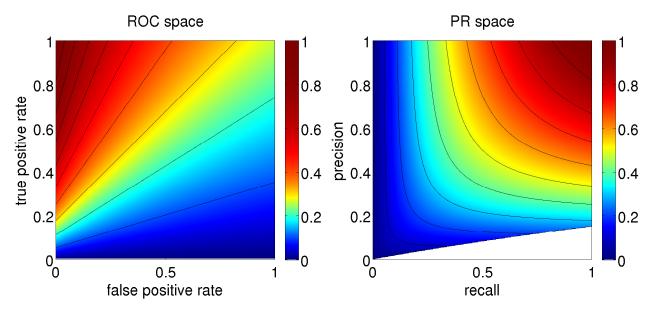

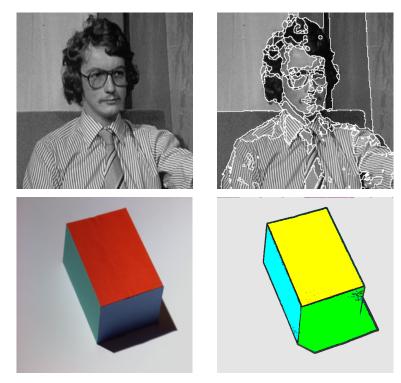

Figure: Isoperformance lines for the F metric ($F = 2\frac{P \times R}{P+R} = \frac{2TP}{2TP+FP+FN}$).

Illustrations

Evaluation of segmentation quality I

Problem statement

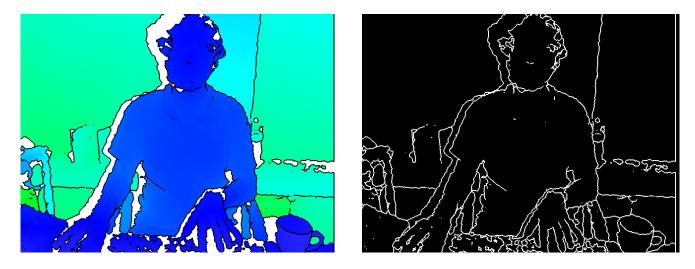

Practice:

- Does not nicely fit into the framework of classification
- Some difficulties:
 - *individual* object segmentation quality vs *overall* segmentation quality evaluation
 - subjectivity for defining the ground truth
- Two major classes of metrics for standalone segmentation quality evaluation
 - intra-object homogeneity
 - inter-object disparity
- Metrics for relative segmentation quality evaluation
 - spatial accuracy
 - temporal accuracy

Evaluation of edge detection I

Problem statement

Practice:

- Some evaluation methods rely on the classification theory.
- Use of the Precision/Recall evaluation space.
- The *F* score is a trade-off (harmonic mean between P and R): $F = \frac{2}{\frac{1}{P} + \frac{1}{R}} = 2\frac{P \times R}{P + R}$

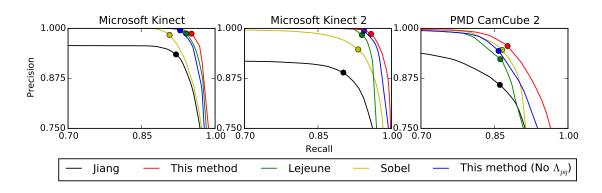

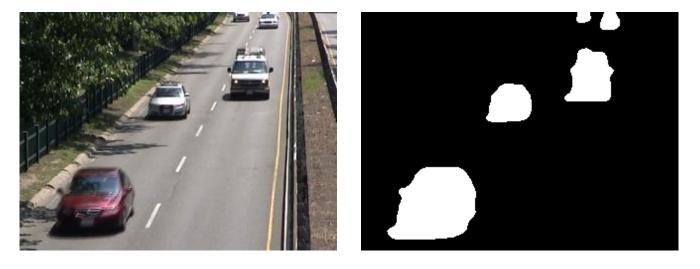

Figure: Maximum Precision and Recall curve obtained by varying the parameter set. Circles indicate where the F measure is maximal.

Evaluation of background subtraction I

Problem statement

Practice:

- Many dataset with ground truth available.
- Background subtraction is often considered as a classification task.
- Many algorithms available \Rightarrow most people try to *rank* algorithms.
- Many metrics. No agreement over the best one (if it exists). Therefore, an algorithm is evaluated with respect to multiple metrics.
- It is still hard to evaluate the dynamic (≡ over time) behavior. Usually, there is one score for the whole video sequence.
- The role of priors is underestimated or just ignored.

Performance analysis Illustrations

Problems with the ChangeDetection dataset I

Reminder: main characteristics

- 11 categories: about 5 videos per category
- Iong video sequences
- thousands of annotated images (ground truth data)
 - 5 labels: static (≡ background), shadow, non-ROI, unknown, and moving (≡ foreground)
- ▶ 7 performance metrics are computed
- ranking per video, category, and globally

Are there problems?

- About the content:
 - Some categories are irrelevant for most targeted applications.
 - Some hand-made annotations are debatable. For example, how do you handle ghosts or static objects? How do you define the shadow?
- About the methodology:
 - All the data is available ⇒ *it is possible to* fine tune all the parameters.
 - Parameters of methods are supposed to be the same for all videos. How do we treat methods that adaptively tune parameters?
 - Problem with the ranking methodology.
 - The averaging process for the metrics (per category and globally) is incorrect.
 - No source code available for some methods ⇒ some results are impossible to check.
 - Some metrics are redundant

| | 3D vision: calibration and reconstruction Camera calibration: the pinhole model |

Two common tasks in 3D vision I

Camera calibration

- Definition. Camera calibration is defined as the technique of estimating the characteristics of a camera.
 - Goal. Determine an accurate relationship between (X, Y, Z), a 3D point in the real world, and (x, y), its corresponding 2D projection in the image acquired by a calibrated camera.

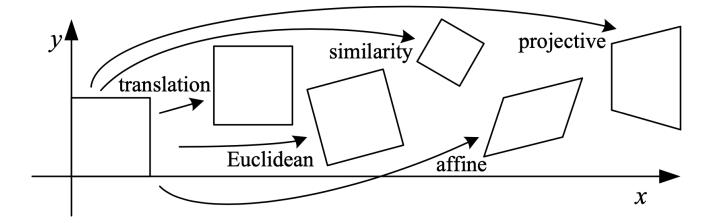

Two common tasks in 3D vision II

3D reconstruction

Definition. 3D reconstruction is the process of capturing the shape and appearance of real objects.

Building a mathematical model for cameras I

A camera projects a 3D world onto a 2D image. \Rightarrow this is the concept of *projection*.

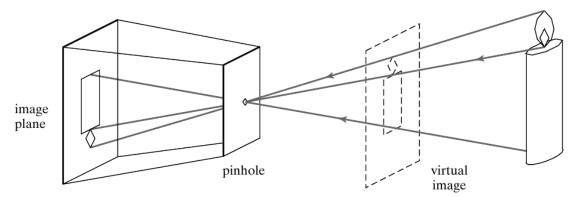

Remarks:

- when we apply a *transformation*, some characteristics are preserved. For example, when you translate an object, its dimensions and angles are preserved.
- translations and rotations (which can be expressed as the product of a matrix on the (X, Y, Z)^T real world coordinates) preserves distances, angles, etc. These leads to so-called Euclidean transformations.
- But what is preserved in general?
 - distances? angles? parallelism? alignment of pixel (\equiv lines)?

The real problem if that we have some ambiguities when we project an 3D object to a 2D plane.

One of the simplest model (and most common): *pinhole camera* (central projection)

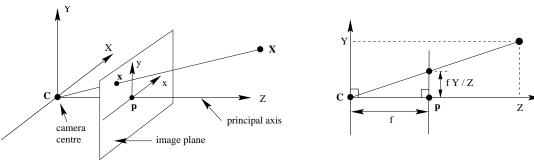

What is preserved?

- distances? angles? "parallelism"? No.
- alignment of pixel (\equiv lines)? Yes

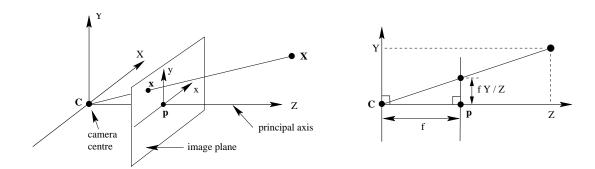

Pinhole camera model

All the light rays converge to a unique point (*camera center*) before arriving on the sensor plane.

- Vocabulary terms:
 - camera center: center of the central projection.
 - *image plane*: plane of the sensor.
 - *principal axis*: line passing through the camera center and orthogonal to the image plane.
 - *principal* point: intersection between the principal axis and the image plane.
 - f is called the focal length.

If $\mathbf{X} = (X, Y, Z)^T$ is a point in space¹ and $\mathbf{x} = (x, y)^T$ is its projection on the image plane, then *similar triangles* gives

$$\frac{x}{f} = \frac{X}{Z}$$
 and $\frac{y}{f} = \frac{Y}{Z}$ (20)

<u>Ambiguity</u>: although f is fixed for a camera, we cannot derive the absolute values of X and Y from the measured pair of values (x, y). \Rightarrow a convenient representation is that of homogeneous coordinates

¹We use capital/uppercase letters to denote coordinates in the real world. Marc Van Droogenbroeck Computer Vision Academic year: 2023-2024

Homogeneous coordinates I

Homogeneous coordinates

Idea: new representation, by adding a trailing 1: (x, y, 1)

$$(x, y) \equiv (x, y, 1) \tag{21}$$

By definition, we assume that

$$(x, y) \equiv (\lambda x, \lambda y, \lambda)$$
(22)

so that all pixels with varying λ are equivalent. In other words, in homogeneous coordinates, a point may be expressed by an infinite number of homogeneous coordinates.

Note: this is similar to how we define rational numbers, that have many different equivalent representations:

$$\frac{1}{3} = \frac{2}{6} = \frac{13}{39}$$
Marc Van Droogenbroeck
Computer Vision
Academic year: 2023-2024
125 / 52
3D vision: calibration and reconstruction
Camera calibration: the pinhole model
(23)

Homogeneous coordinates II

Properties:

- (x, y, 0) is not equivalent to (x, y). It is a special point.
- ▶ A point of \mathbb{R}^n is represented by a vector of size n + 1. Example:

$$\mathbf{x} = (x_1, x_2, x_3)^T \in \mathbb{R}^3 \mapsto \left(\frac{x_1}{x_3}, \frac{x_2}{x_3}\right)^T \in \mathbb{R}^2$$

A line in a plane is represented by the following equation ax + by + c = 0. With homogeneous coordinates, this becomes:

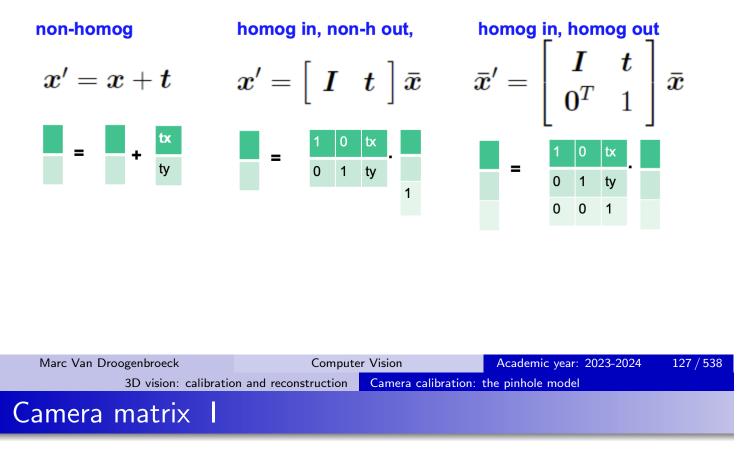

$$\mathbf{I}=(a, b, c)^{7}$$

- A point belongs to a line if and only if $\mathbf{x}^T \mathbf{I} = 0$.
- Intersection between two lines: x = I × I' where × is the product between vectors.

538

Simple example to show the interest of homogeneous coordinates

Let us consider translations.

With the help of homogeneous coordinates, the relationships of a pinhole camera model can be expressed in a *convenient* matrix form:

$$\lambda \begin{bmatrix} x \\ y \\ 1 \end{bmatrix} = \begin{bmatrix} f & 0 & 0 & 0 \\ 0 & f & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix} \begin{bmatrix} X \\ Y \\ Z \\ 1 \end{bmatrix}$$
(24)

where λ is equal to the depth Z.

Remember that we don't know the depth Z from the observation in the place image (depth ambiguity).

$$\begin{pmatrix} X \\ Y \\ Z \\ 1 \end{pmatrix} \mapsto \lambda \begin{bmatrix} x \\ y \\ 1 \end{bmatrix} = \begin{bmatrix} f & 0 & 0 & 0 \\ 0 & f & 0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix} \begin{pmatrix} X \\ Y \\ Z \\ 1 \end{pmatrix} = P\mathbf{X}$$

Marc Van Droogenbroeck

Camera matrix II

P is a camera (projection) matrix

For convenience, P is decomposed as follows:

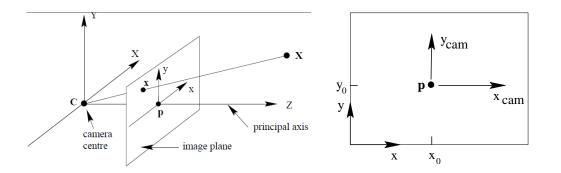

$$P = \begin{bmatrix} f & 0 & 0 \\ 0 & f & 0 \\ 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} 1 & 0 & 0 & | & 0 \\ 0 & 1 & 0 & | & 0 \\ 0 & 0 & 1 & | & 0 \end{bmatrix}$$
(25)
$$= K [I_{3 \times 3} | \mathbf{0}_{3 \times 1}]$$
(26)

• K = diag(f, f, 1) is the calibration matrix.

(1) The central point might not be at (0, 0) in the image plane

 \Rightarrow two additional parameters in the calibration matrix

If (x₀, y₀)^T are the coordinates of the principal point, the projection becomes:

$$(X, Y, Z)^T \mapsto \left(f\frac{X}{Z} + x_0, f\frac{Y}{Z} + y_0\right)^T$$
 (27)

Marc Van Droogenbroeck

Generalization of the pinhole camera model II

The matrix form is

$$\lambda \begin{bmatrix} x + x_0 \\ y + y_0 \\ 1 \end{bmatrix} = \begin{bmatrix} f & 0 & x_0 & 0 \\ 0 & f & y_0 & 0 \\ 0 & 0 & 1 & 0 \end{bmatrix} \begin{pmatrix} X \\ Y \\ Z \\ 1 \end{pmatrix}$$
(28)

The matrix K becomes

$$\mathbf{K} = \begin{bmatrix} f & x_0 \\ & f & y_0 \\ & & 1 \end{bmatrix}$$
(29)

(2) Non rectangular light-elements on the sensor

 \rightarrow *skew* parameter *s*

(3) Non squared elements

This modifies the aspect ratio $\rightarrow \alpha_x$ and α_y .

Finally,

$$\mathbf{K} = \begin{bmatrix} \alpha_{\mathbf{x}} & \mathbf{s} & \mathbf{x}_{\mathbf{0}} \\ & \alpha_{\mathbf{y}} & \mathbf{y}_{\mathbf{0}} \\ & & 1 \end{bmatrix}$$
(30)

132 / 538

Intrinsic parameters

Intrinsic parameters

In a refined camera model,

$$\mathbf{K} = \begin{bmatrix} \alpha_x & \mathbf{s} & \mathbf{x}_0 \\ & \alpha_y & \mathbf{y}_0 \\ & & 1 \end{bmatrix}$$
(31)

This matrix has 5 parameters. These parameters are called *intrinsic parameters*.

They characterize a camera and should be estimated for each camera separately. But once they are known, there is no need to estimated them again!

Definition

A camera is said to be *calibrated* if

$$\mathbf{K} = \begin{bmatrix} \alpha_x & \mathbf{s} & \mathbf{x}_0 \\ & \alpha_y & \mathbf{y}_0 \\ & & 1 \end{bmatrix}$$

is known.

In general:

$$\blacktriangleright \ \alpha_{x} \simeq \alpha_{y}$$

$$\blacktriangleright$$
 $s \simeq 0$

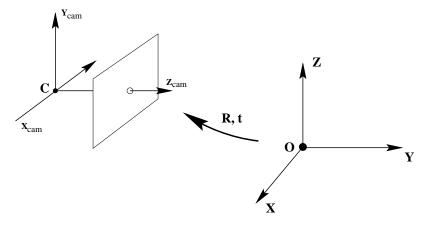

> x_0 and y_0 close to 0 pixel (typically a few pixels maximum).

But we have a problem: we don't know where the center of camera is located in the real world. So there is no way to measure $(X, Y, Z, 1)^T$.

Towards extrinsic parameters

Points in the 3D world need to be expressed in a system coordinate different from that of the camera (which is not known).

Both coordinate systems are related by a rotation and a translation:

| Marc Van Droogenbroeck | Compute | er Vision | Academic year: 2023-2024 | 135 / 538 |
|---------------------------------|---|-----------|--------------------------|-----------|
| 3D vision: calibratic | on and reconstruction Camera calibration: t | | the pinhole model | |
| Towards extrinsic parameters II | | | | |

For a translation:

$$\begin{bmatrix} X_{c} \\ Y_{c} \\ Z_{c} \\ 1 \end{bmatrix} = \begin{bmatrix} X_{0} - t_{1} \\ Y_{0} - t_{2} \\ Z_{0} - t_{3} \\ 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 & 0 & -t_{1} \\ 0 & 1 & 0 & -t_{2} \\ 0 & 0 & 1 & -t_{3} \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} X_{0} \\ Y_{0} \\ I \end{bmatrix}$$
(32)
$$= \begin{bmatrix} I & -t \\ 0 & 1 \end{bmatrix} \begin{bmatrix} X_{0} \\ Y_{0} \\ Z_{0} \\ 1 \end{bmatrix}$$
(33)

More generally (translation + rotation):

$$\begin{bmatrix} X_c \\ Y_c \\ Z_c \\ 1 \end{bmatrix} = \begin{bmatrix} \underline{\mathbf{R}}^T & \mathbf{0} \\ \mathbf{0} & \mathbf{1} \end{bmatrix} \begin{bmatrix} \underline{\mathbf{I}} & -t \\ \mathbf{0} & \mathbf{1} \end{bmatrix} \begin{bmatrix} X_0 \\ Y_0 \\ Z_0 \\ 1 \end{bmatrix}$$
(34)

Marc Van Droogenbroeck

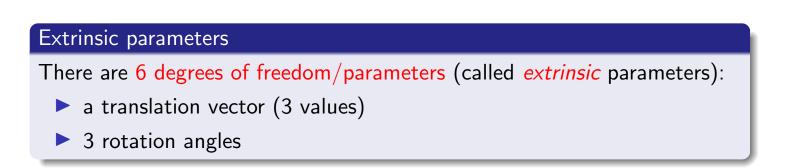

Computer Vision

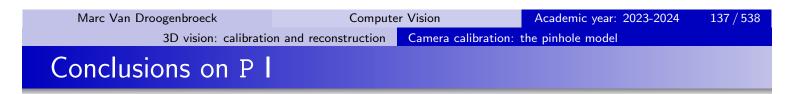

Towards *extrinsic* parameters III

In conclusion:

$$\mathbf{X}_{\mathbf{c}} = \begin{bmatrix} \underline{\mathbf{R}}^{\mathsf{T}} & -\underline{\mathbf{R}}^{\mathsf{T}} t \\ 0 & 1 \end{bmatrix} \mathbf{X}_{\mathbf{0}}$$
(35)

where **R** is a rotation matrix and t a translation vector. This is not a projection, but an Euclidean transform between coordinate systems.

Pinhole camera model:

$$\lambda \mathbf{x} = \mathbf{K} \left[\mathbf{I}_{\mathbf{3} \times \mathbf{3}} | \mathbf{0}_{\mathbf{3} \times \mathbf{1}} \right] \mathbf{X}_{\mathbf{c}}$$
(36)

Link between the coordinate system of the camera and an arbitrary coordinate system:

$$\mathbf{X}_{\mathbf{c}} = \begin{bmatrix} \underline{\mathbf{R}}^{\mathsf{T}} & -\underline{\mathbf{R}}^{\mathsf{T}} t \\ 0 & 1 \end{bmatrix} \mathbf{X}$$
(37)

By combination:

$$\lambda \mathbf{x} = KR^{T} \left[\mathbf{I} \right| - t \right] \mathbf{X} = P \mathbf{X}$$
(38)

where $P = KR^T [I| - t]$.

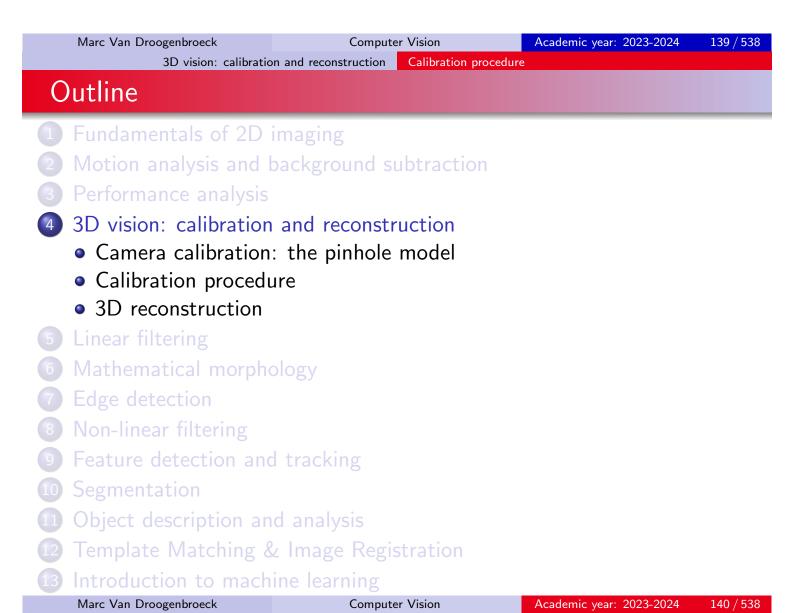

Conclusions on P II

Definition

A camera represented with a camera matrix of the form $P = KR^T [I| - t]$ is called **normalized camera**.

P is a 3×4 matrix, which is subject to scale ambiguity. Therefore, P has 11 degrees of freedom (unknown parameters):

- 5 intrinsic parameters (*related to camera itself*; the manufacturer can computed them and give them to the user who buys the camera).
- 6 extrinsic parameters (*related to* the choice of an external *coordinate system*).

Calibration procedure I

How do we find the parameters of P?

- ▶ We need correspondences between some 3D positions on their location on the projected 2D image $X_i \leftrightarrow x_i = (x_i, y_i, z_i)$.
- As a result

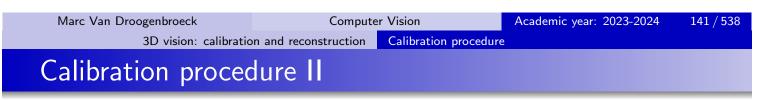

$$\mathbf{x}_i = \mathbf{P}\mathbf{X}_i \Rightarrow \mathbf{x}_i \times \mathbf{P}\mathbf{X}_i = \mathbf{0}$$

Let \mathbf{P}^{j} be the vector with the *j*th line of P,

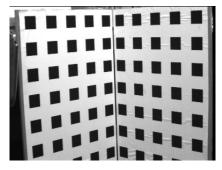

$$\begin{bmatrix} \mathbf{0}^{\mathsf{T}} & -z_i \mathbf{X}_i^{\mathsf{T}} & y_i \mathbf{X}_i^{\mathsf{T}} \\ z_i \mathbf{X}_i^{\mathsf{T}} & \mathbf{0}^{\mathsf{T}} & -x_i \mathbf{X}_i^{\mathsf{T}} \\ -y_i \mathbf{X}_i^{\mathsf{T}} & x_i \mathbf{X}_i^{\mathsf{T}} & \mathbf{0}^{\mathsf{T}} \end{bmatrix} \begin{pmatrix} \mathbf{P}^1 \\ \mathbf{P}^2 \\ \mathbf{P}^3 \end{pmatrix} = \mathbf{0}$$

Two of these equations are linearly independent. But how many correspondences do we need to solve this linear systems?

At least 6

- In practice, we have an over-determined system of linear equations Ap = 0 if there is no noise. But, due to noise, we use an optimization procedure, such as the minimum square optimization
- Use of a precise and well-known 3D calibration pattern

| 3 |) reconstruction |

► 3D reconstruction of the scene

Reconstruction involves several aspects:

- dense reconstruction (we have to find the depth for every pixels of the scene)
- non-dense reconstruction
- detection of features. Usually, these are special points of objects (corners, centers, etc)
- the scene content might be moving

Feature detection and motion are often related to each other!

|------------------------|-----------------------|-------------------|--------------------------|-----------|
| 3D vision: calibratic | on and reconstruction | 3D reconstruction | | |
| 3D reconstruction | | | | |

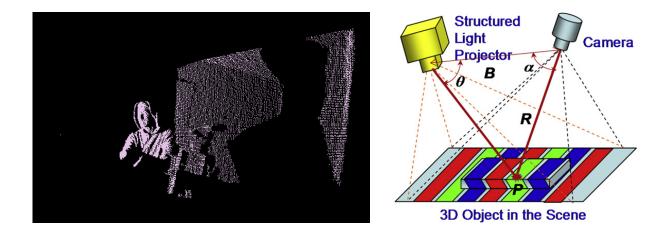

There are several ways to reconstruct the 3D geometry of a scene (typology of methods)

- Direct methods:
 - depth cameras (also named range or 3D cameras)
 - stereoscopic vision or multiview camera systems
- Indirect methods (more or less out of fashion due the existence of 3D cameras):
 - "depth from motion"
 - "depth from focus"
 - "depth from shadow"
 - ...

Depth cameras I

There are two *acquisition* technologies for depth-cameras, also called range- or 3D-cameras:

[1] estimation of the deformations of a pattern sent on the scene (*structured light*).

First generation of the Kinects

3D vision: calibration and reconstruction 3D reconstruction

Depth cameras III

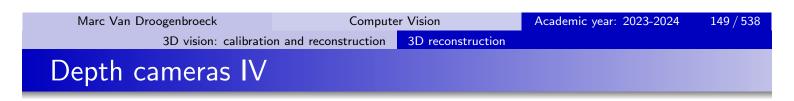

[2] *measurements* by *time-of-flight* (ToF). Time to travel forth and back between the source led (camera) and the sensor (camera).

If d is the distance to a point in the scene and t is the time for the signal to travel from and back to the sensors, then

$$d = \frac{c}{2t}$$

where $c = 3 \times 10^8 \ m/s$ is the speed of light.

Mesa Imaging, Kinect (second generation), PMD cameras

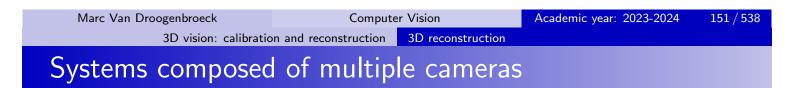

150 / 538

3D vision: calibration and reconstruction 3D reconstruction

Illustration of a depth map acquired with a range camera

Two informations are provided by a range camera: *depth* and *intensity*

Three elements interact:

- calibration
- possible motion of the cameras
- 3D structure of the scene

Theorem

Assume a series of images taken with an uncalibrated moving camera for which we have establish correspondences between pairs of points, then it is only possible to reconstruct the 3D scene up to a projective transform.

In the following, we only consider fixed cameras.

Steps to reconstruct a scene from multiple cameras (*stereoscopic* system)

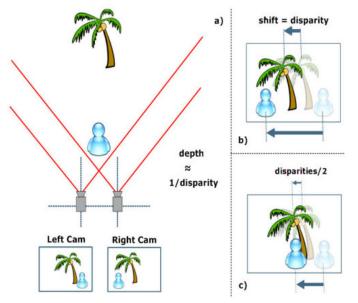

Generally, we have to find correspondences between points of the views of two color cameras.

There are several possibilities:

- cameras are aligned (mechanically of numerically, after a transformation) \rightarrow computation of the disparity map.
- 2 cameras are not aligned \rightarrow corresponding points in the two camera planes are related to each other via the fundamental matrix. The fundamental matrix imposes a constraint; it is not sufficient to reconstruct a scene (calibration is needed, etc). This is studied under the name of epipolar geometry.
- **3** all the points are in the same plane \rightarrow this constraint (knowledge) facilitates the correspondence finding between two views. The transformation is named an homography.

If cameras are aligned, the disparity is the inverse of depth.

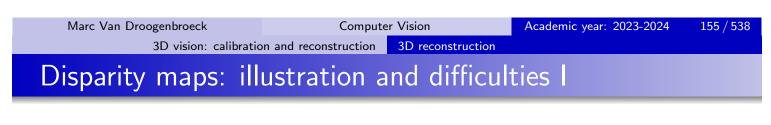

3D vision: calibration and reconstruction 3D reconstruction

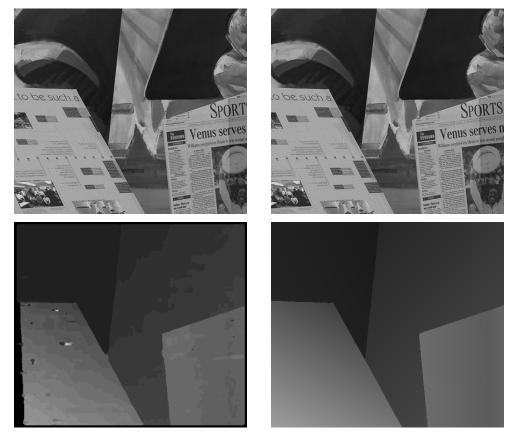

Computation of a disparity (depth) map

If two cameras only differ in the horizontal direction, the horizontal difference between two locations provides an information about the depth.

Attention:

- cameras and alignments are not perfect!
- disparity only estimates Z!

Marc Van Droogenbroeck

Computer Vision

Academic year: 2023-2024

156 / 538

Disparity maps: illustration and difficulties II

left view

right view

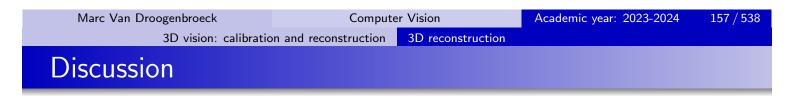

disparity

contours

The computation is disparity is difficult:

- close to borders (diffraction effects)
- in texture-less zones

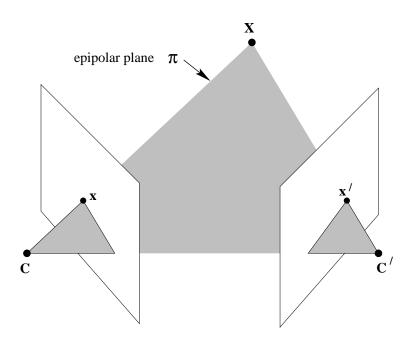

Advantages (+) or drawbacks (-) of a reconstruction (\equiv depth computation) by the technique of disparity maps:

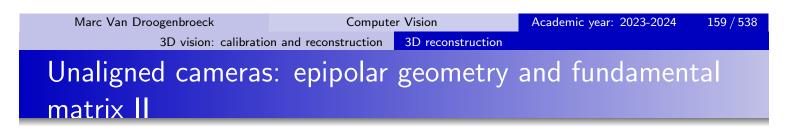

- (+) the process is simple. One only has to estimate the distance between two corresponding points along a line.
- (-) cameras must be aligned,
 - either mechanically,
 - or by software. This usually involves re-sampling the image, leading to precision losses.

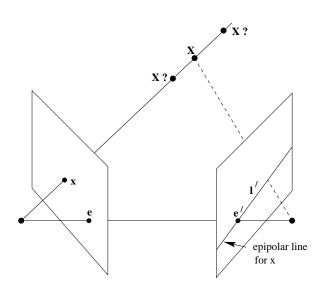

We need an alternative when the cameras are not aligned.

Unaligned cameras: epipolar geometry and fundamental matrix I

C and C' are the center of the two cameras.

The use of a second camera is supposed to help determining the location of a point X along the projection line of the other camera.

Major challenges I

<u>Objective</u>: find a way to use the correspondences between points in a pair of views to be able to find (X, Y, Z) for every point in the scene.

- Calibration:
 - each camera has its own calibration matrix:
 - solution: find the intrinsic and extrinsic parameters
 - when there are two cameras
 - <u>solution</u>: there exists a way to build the relationship between the projections in the camera planes that is expressed by the *fundamental* matrix or the *essential* matrix.
- Camera placement:
 - fixed: the manufacturer can calibrate the camera.
 - *changing or unknown*: one can isolate the intrinsic parameters, but this requires a calibration procedure.
- Object structures: they might lead to ambiguities (holes, shadows, etc).

| Marc Van Droogenbroeck | Computer Vision | | Academic year: 2023-2024 | 161 / 538 |
|---|-----------------|-------------------|--------------------------|-----------|
| 3D vision: calibration and reconstruction | | 3D reconstruction | | |
| Major challenges I | I | | | |

• <u>"realistic" solution</u>: do some prior assumptions about the objects. It is impossible to solve all the ambiguities, even with an infinite number of cameras.

162 / 538

3D vision: calibration and reconstruction 3D reconstruction

Towards the *fundamental* matrix

Consider a point X in space. It is viewed by the two cameras as:

$$\lambda_1 \mathbf{x}_1 = \mathbf{P}_1 \mathbf{X} = [\mathbf{A}_1 | \mathbf{b}_1] \mathbf{X}$$
(39)

$$\lambda_2 \mathbf{x}_2 = \mathbf{P}_2 \mathbf{X} = [\mathbf{A}_2 | \mathbf{b}_2] \mathbf{X}$$
(40)

We find X, Y, Z with the help of the equations of the first camera:

$$\lambda_1 \mathbf{x}_1 = \mathbf{P}_1 \mathbf{X} = [\mathbf{A}_1 | b_1] \mathbf{X} = \mathbf{A}_1 \begin{bmatrix} X \\ Y \\ Z \end{bmatrix} + b_1$$
(41)

therefore,

$$\begin{bmatrix} X \\ Y \\ Z \end{bmatrix} = A_1^{-1} (\lambda_1 \mathbf{x}_1 - b_1)$$
(42)

By substitution, in the second equation, we get

$$\lambda_2 \mathbf{x}_2 = \mathbf{A}_2 \mathbf{A}_1^{-1} (\lambda_1 \mathbf{x}_1 - b_1) + b_2 = \lambda_1 \mathbf{A}_{12} \mathbf{x}_1 + (-\mathbf{A}_{12} b_1 + b_2)$$
(43)

Consequently, \mathbf{x}_1 and \mathbf{x}_2 are *linearly independent*.

|---|----|-------------------|--------------------------|-----------|
| 3D vision: calibration and reconstruction | | 3D reconstruction | | |
| Fundamental matr | ix | | | |

Epipolar constraint

$$\begin{bmatrix} x'\\y'\\1 \end{bmatrix}^{T} \mathbf{F} \begin{bmatrix} x\\y\\1 \end{bmatrix} = 0$$
(44)

- \blacktriangleright The **fundamental matrix** F is a 3 \times 3 matrix that constraints the values of the coordinates in the image planes of two cameras.
- ▶ $\mathbf{x}' \mathbf{F} \mathbf{x} = 0$ for all the corresponding pairs $\mathbf{x} \leftrightarrow \mathbf{x}'$.

Characteristics:

- 7 degrees of freedom (rank 2 matrix)
- the determinant is null
- it is defined up to a scaling factor

Link between the fundamental matrix and the calibration matrices of the cameras I

We can derive the fundamental matrix, starting from the two camera models. Assume that:

- we are able to isolate the intrinsic and extrinsic parameters of both cameras.
- 2 the absolute 3D coordinate systems is placed on the internal coordinate of one camera. Then, we have

$$P = K[I|0]$$
 and $P' = K'[R|t]$ (45)

Then, it can be shown that the fundamental matrix is given by

$$\mathbf{F} = \mathbf{K}^{\prime - T}[t]_{\times} \mathbf{R} \mathbf{K}^{-1} = \mathbf{K}^{\prime - T} \mathbf{R}[\mathbf{R}^{T} t]_{\times} \mathbf{K}^{-1}$$
(46)

where

$$[a]_{\times} = \begin{bmatrix} 0 & -a_3 & a_2 \\ a_3 & 0 & -a_1 \\ -a_2 & a_1 & 0 \end{bmatrix}$$
(47)

If the intrinsic parameters are known, the coordinates can be normalized to remove the effect of the intrinsic parameters (according to transformation such as $\hat{u} = K^{-1}u$ and $\hat{u'} = K'^{-1}u'$, leading to

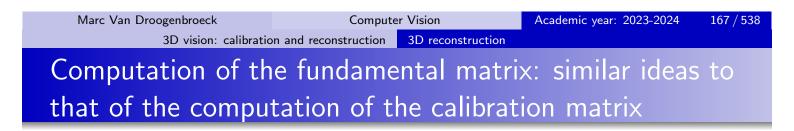

$$P = [I|0] \quad \text{and} \quad P' = [R|t] \tag{48}$$

Link between the fundamental matrix and the calibration matrices of the cameras III

The fundamental matrix simplifies, which results in the *essential* matrix.

$$\mathbf{E} = [t]_{\times} \mathbf{R} = \mathbf{R} [\mathbf{R}^{\mathsf{T}} t]_{\times}$$
(49)

The major advantage of this matrix is that only the extrinsic parameters play a role (the essential matrix has 5 degrees of freedom).

- We have to find a number of pairwise correspondences $\mathbf{x}_i \leftrightarrow \mathbf{x}'_i$ (minimum of 4)
- We build a system of linear equations by means of $\mathbf{x}_i' \mathbf{F} \mathbf{x}_i = 0$
- The resolution of the system leads to F

There exist several algorithms to proceed to the determination of F.

Remember that, if the fundamental matrix links the points between two planes, it does not suffice to reconstruct a scene.

Reconstruction of a 3D: steps I

- Find correspondences between pairs of points in the two views
- 2 Calculate the fundamental/essential matrix
- So Find the camera parameters, with the help of the essential matrix:

$$P = [I|\mathbf{0}]$$
 $P' = [[\mathbf{e}']_{\times}F|\mathbf{e}']$

where

$$[\mathbf{a}]_{ imes} = \left[egin{array}{cccc} 0 & -a_3 & a_2 \ a_3 & 0 & -a_1 \ -a_2 & a_1 & 0 \end{array}
ight]$$

 $\mathbf{F}^{T}\mathbf{e}'=\mathbf{0}$

and

• For each pixel $\mathbf{x}_i \leftrightarrow \mathbf{x}'_i$, triangulate \mathbf{X}_i :

$$\mathbf{P}\mathbf{X}_i \times \mathbf{x}_i = 0$$
 et $\mathbf{P}'\mathbf{X}_i \times \mathbf{x}'_i = 0$

We have 4 equations for 3 unknowns.

Attention! Remember that this reconstruction is valid up to a projective transform.

|------------------------|--|--|--------------------------|-----------|
| | | | | |
| Linear filtering | | | | |

- Fourier transform and filtering operation
- The notion of "ideal" filter
- Categories of ideal filters
- Typical filters:
 - Low-pass filters
 - High-pass filters
 - Gabor filters

Let us take f(x, y) as the values of a single channel image (for example, the grayscale component):

- (x, y) are the coordinates
- f(x, y) is the single-valued image of the pixel located at (x, y)

Definition ((Continuous) Fourier transform)

The (continuous) Fourier transform $\mathcal{F}(u, v)$ of f(x, y) is defined by

$$\mathcal{F}(\boldsymbol{u},\boldsymbol{v}) = \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} f(\boldsymbol{x},\boldsymbol{y}) e^{-2\pi j (\boldsymbol{u}\boldsymbol{x} + \boldsymbol{v}\boldsymbol{y})} d\boldsymbol{x} d\boldsymbol{y}$$
(50)

Example

The Fourier transform is a complex image (it has a real component and an imaginary component). Often, we are interested in the amplitude.

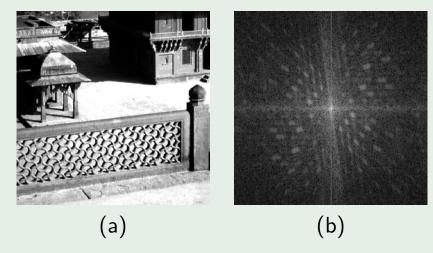

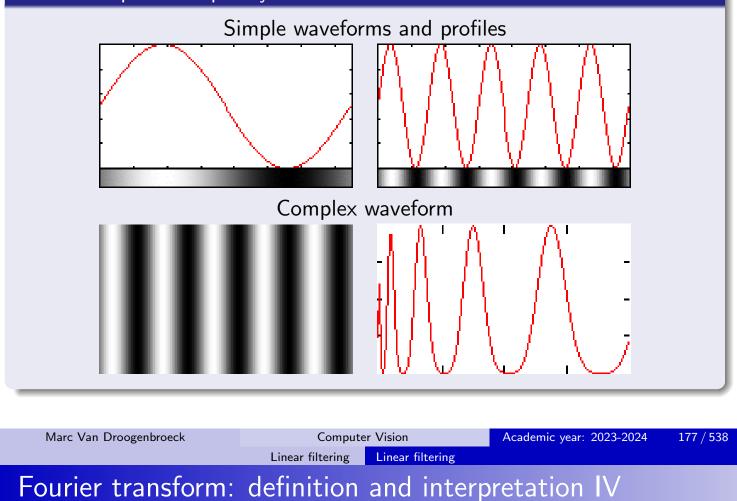

Figure: (a) original image and (b) *centered* Fourier transform of its amplitude.

Fourier transform: definition and interpretation III

Linear filtering

Linear filtering

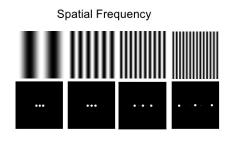

What is a spatial frequency?

The Fourier transform is a representation of f(x, y) in terms of spatial frequencies:

How the Image information is stored in the Fourier Transform

How the Image information is stored in the Fourier Transform

Orientation

Computer Vision

Fourier transform: definition and interpretation V

Linear filtering

Definition ((Continuous) *inverse* Fourier transform)

The inverse (continuous) Fourier transform is defined by

$$f(x,y) = \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} \mathcal{F}(u,v) e^{2\pi j(ux+vy)} du dv$$
(51)

Linear filtering

There is a one-to-one relationship between a f(x, y) and $\mathcal{F}(u, v)$:

$$f(x, y) \rightleftharpoons \mathcal{F}(u, v) \tag{52}$$

Definition (Filtering)

Applying a filter $\mathcal{H}(u, v)$ corresponds to modify the Fourier coefficient of some frequencies

$$\mathcal{F}(\boldsymbol{u},\boldsymbol{v}) \longrightarrow \mathcal{F}(\boldsymbol{u},\boldsymbol{v})\mathcal{H}(\boldsymbol{u},\boldsymbol{v})$$
 (53)

| Marc Van Droogenbroeck | Computer Vision | | Academic year: 2023-2024 | 179 / 538 |
|--------------------------|-----------------------------------|--|--------------------------|-----------|
| | Linear filtering Linear filtering | | _ | |
| Notion of "ideal" filter | | | | |

A filter is said to be "ideal" if every transform coefficient is multiplied by 0 or 1.

Definition (Ideal filter)

An *ideal* filter is such that its transfer function is given by

$$\forall (u, v), \mathcal{H}(\underline{u}, v) = 0 \text{ or } 1.$$
(54)

The notion of ideal filter is closely related to that of *idempotence*. The idempotence for a filter is to be understood such that, for an image f(x, y),

$$\mathcal{F}(\boldsymbol{u},\boldsymbol{v})\mathcal{H}(\boldsymbol{u},\boldsymbol{v}) = \mathcal{F}(\boldsymbol{u},\boldsymbol{v})\mathcal{H}(\boldsymbol{u},\boldsymbol{v})\mathcal{H}(\boldsymbol{u},\boldsymbol{v})$$
(55)

For one-dimensional signals (such as the image function along an image line):

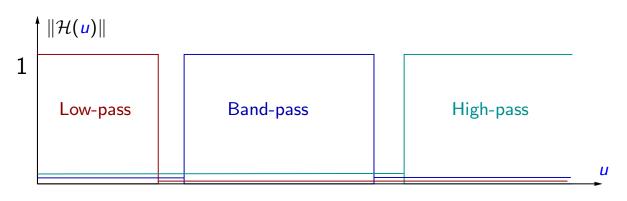

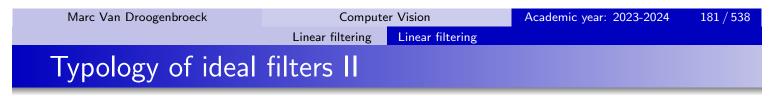

Figure: One-dimensional filters.

There are three types of circular ideal filters:

Low-pass filters:

$$\mathcal{H}(\boldsymbol{u},\boldsymbol{v}) = \begin{cases} 1 & \sqrt{\boldsymbol{u}^2 + \boldsymbol{v}^2} \le R_0 \\ 0 & \sqrt{\boldsymbol{u}^2 + \boldsymbol{v}^2} > R_0 \end{cases}$$
(56)

(a) Original image

(b) Low-pass filtered image

Typology of ideal filters III

High-pass filters:

$$\mathcal{H}(\boldsymbol{u}, \boldsymbol{v}) = \begin{cases} 1 & \sqrt{\boldsymbol{u}^2 + \boldsymbol{v}^2} \ge R_0 \\ 0 & \sqrt{\boldsymbol{u}^2 + \boldsymbol{v}^2} < R_0 \end{cases}$$
(57)

Linear filtering

Band-pass filters. There are equivalent to the complementary of a low-pass filter and a high-pass filter:

Linear filtering

$$\mathcal{H}(\boldsymbol{u},\boldsymbol{v}) = \begin{cases} 1 & R_0 \leq \sqrt{\boldsymbol{u}^2 + \boldsymbol{v}^2} \leq R_1 \\ 0 & \text{otherwise} \end{cases}$$
(58)

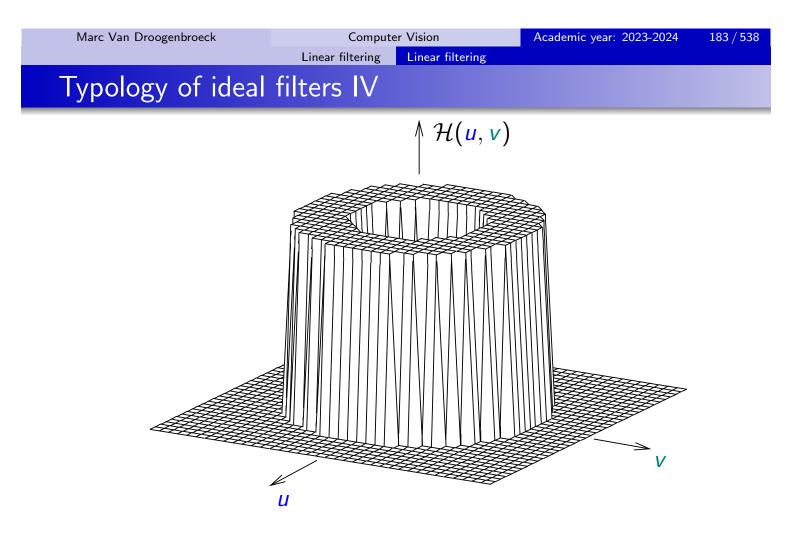

Figure: Transfer function of pass-band filters.

184 / 538

Effects of filtering

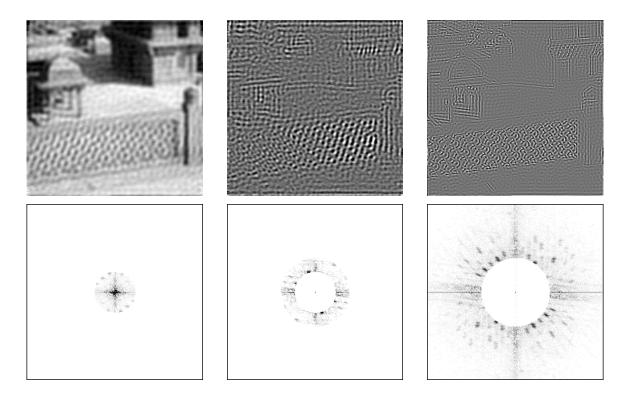

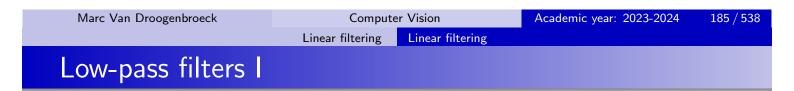

Figure: Fourier spectra of images filtered by three types of circular filters.

A typical low-pass filter is the Butterworth filter (of order n) defined as

$$\mathcal{H}(\boldsymbol{u},\boldsymbol{v}) = \frac{1}{1 + \left(\frac{\sqrt{\boldsymbol{u}^2 + \boldsymbol{v}^2}}{R_0}\right)^{2n}}.$$
(59)

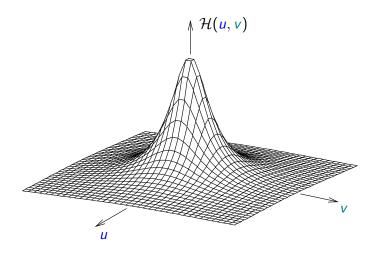

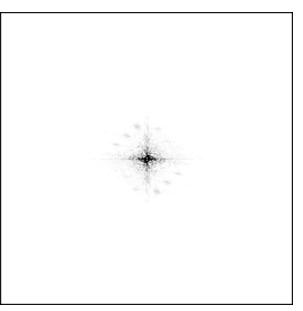

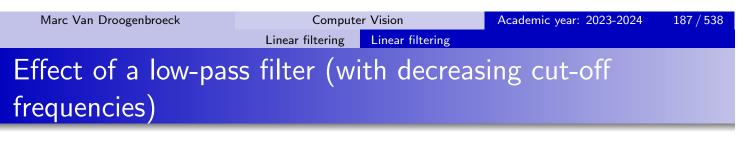

Figure: Transfer function of a low-pass Butterworth filter (with n = 1).

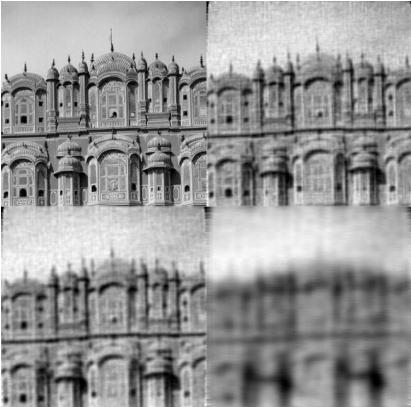

Low-pass filters II

(a) Input image (b) Spectrum of the filtered image Figure: Effects of an order 1 Butterworth filter (cut-off frequency: $f_c = 30$).

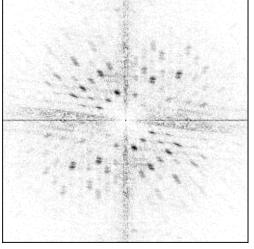

High-pass filters I

$$\mathcal{H}(\boldsymbol{u},\boldsymbol{v}) = \frac{1}{1 + \left(\frac{R_0}{\sqrt{\boldsymbol{u}^2 + \boldsymbol{v}^2}}\right)^{2n}}$$
(60)

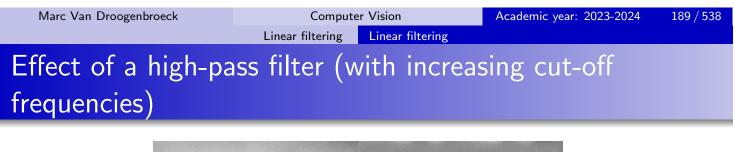

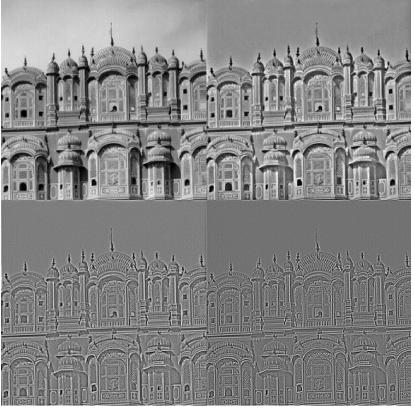

(a) Filtered image

(b) Spectrum of (a)

Figure: Effects of an order 1 Butterworth filter 1 (cut-off frequency: $f_c = 50$).

190 / 538

Gabor filters I

Definition

Gabor filters belong to a particular class of linear filters. There are directed filters with a Gaussian-shaped impulse function:

Linear filtering

Linear filtering

$$h(x,y) = g(x',y')e^{2\pi j(Ux+Vy)}$$
(61)

- ► (x', y') = (x cos φ + y sin φ, -x sin φ + y cos φ), these are the (x, y) coordinates rotated by an angle φ, and
- $g(x',y') = \frac{1}{2\pi\sigma^2} e^{(-(x'/\lambda)^2 + y'^2)/2\sigma^2}$.

The corresponding Fourier transform is given by

$$\mathcal{H}(\boldsymbol{u},\boldsymbol{v}) = e^{-2\pi^2 \sigma^2 [(\boldsymbol{u}' - \boldsymbol{U}')^2 \lambda^2 + (\boldsymbol{v}' - \boldsymbol{V}')^2]}$$
(62)

- $(u', v') = (u \cos \phi + v \sin \phi, -u \sin \phi + v \cos \phi)$, and
- (U', V') is obtained by rotating (U, V) with the same angle ϕ .

Gabor filters III

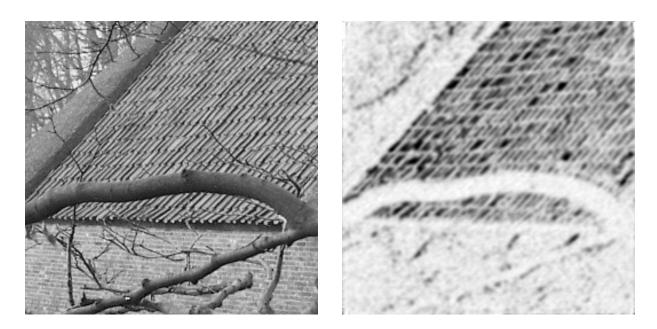

Figure: Input image and filtered image (with an filter oriented at 135°).

There are mainly 4 techniques to implement a Gaussian filter:

• Convolution with a restricted Gaussian kernel. One often chooses $N_0 = 3\sigma$ or 5σ

$$g_{1D}[n] = \begin{cases} \frac{1}{\sqrt{2\sigma}} e^{-(n^2/2\sigma^2)} & |n| \le N_0 \\ 0 & |n| > N_0 \end{cases}$$
(63)

2 Iterative convolution with a uniform kernel:

$$g_{1D}[n] \simeq u[n] \otimes u[n] \otimes u[n]$$
(64)

where

$$u[n] = \begin{cases} \frac{1}{(2N_0+1)} & |n| \le N_0 \\ 0 & |n| > N_0 \end{cases}$$
(65)

- Multiplication in the Fourier domain.
- Implementation as a recursive filter.

Reminders of the set theory I

Sets will be denoted with capital letters, such as A, B, \ldots , and elements of these sets by lowercase letters a, b, \ldots

Set equality

Two sets are *equal* if they contain the same elements:

 $X = Y \Leftrightarrow (x \in X \Rightarrow x \in Y \text{ and } x \in Y \Rightarrow x \in X)$. The empty set is denoted as \emptyset .

Inclusion

X is a *subset* of Y (that is, X is included in Y) if all the elements of X also belong to Y: $X \subseteq Y \Leftrightarrow (x \in X \Rightarrow x \in Y)$.

Intersection

The *intersection* between X and Y is the set composed of the elements that belong to both sets:

 $X \cap Y = \{x \text{ such that } x \in X \text{ and } x \in Y\}.$

Union

The *union* between two sets is the set that gathers all the elements that belong to at least one set:

 $X \cup Y = \{x \text{ such that } x \in X \text{ or } x \in Y\}.$

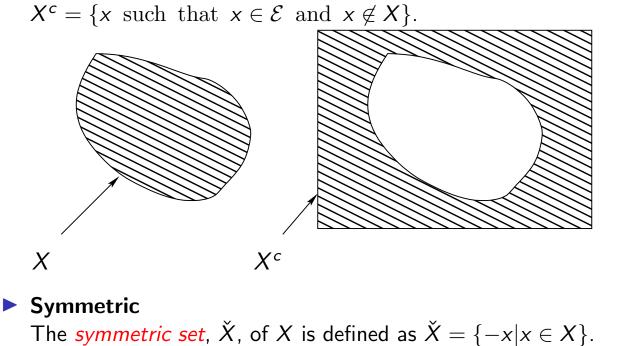

Difference

The set difference between X and Y, denoted by X - Y or $X \setminus Y$ is the set that contains the elements of X that are not in Y : $X - Y = \{x | x \in X \text{ and } x \notin Y\}.$

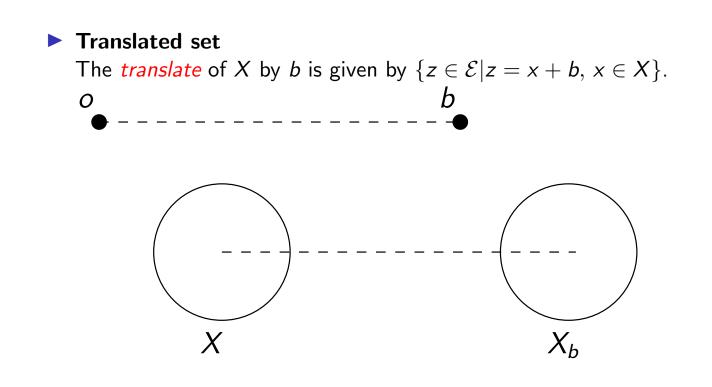

Reminders of the set theory III

Complementary

Assume that X is a subset of a \mathcal{E} space, the *complementary set* of X with respect to \mathcal{E} is the set, denoted X^c , given by

Basic morphological operators I

Erosion

Definition (*Morphological erosion*)

$$X \ominus B = \{z \in \mathcal{E} | B_z \subseteq X\}.$$

(66)

(67)

The following algebraic expression is equivalent to the previous definition:

Definition (Alternative definition for the morphological erosion)

$$X \ominus B = \bigcap_{b \in B} X_{-b}.$$

B is named "**structuring element**".

Basic morphological operators II

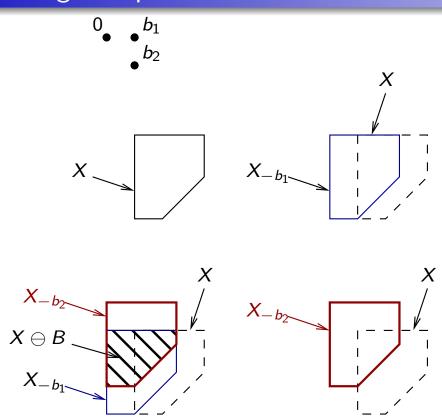

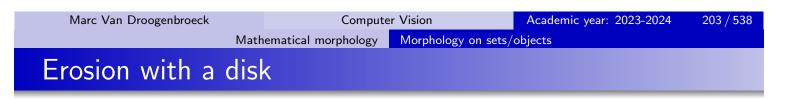

Figure: Algebraic interpretation of the erosion.

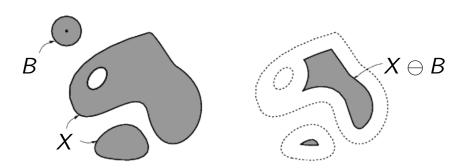

Figure: Erosion of X with a disk B. The origin of the structuring element is drawn at the center of the disk (with a black dot).

Computer Vision

Dilation I

Definition (Dilation)

From an algebraic perspective, the *dilation* (*dilatation* in French!), is the union of translated version of X:

$$X \oplus B = \bigcup_{b \in B} X_b = \bigcup_{x \in X} B_x = \{x + b | x \in X, b \in B\}.$$
 (68)

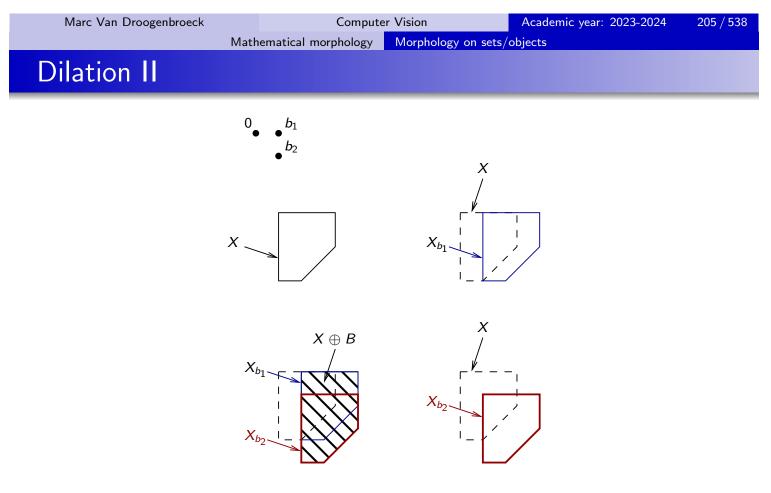

Figure: Illustration of the algebraic interpretation of the dilation operator.

Dilation III

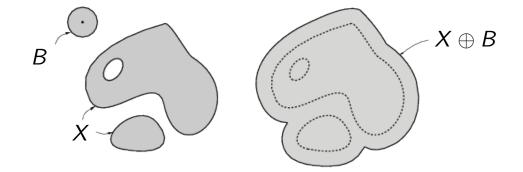

Figure: Dilation of X with a disk B.

Duality

Erosion and dilation are two dual operators with respect to complementation:

$$X \ominus \check{B} = (X^c \oplus B)^c \tag{69}$$

$$X \ominus B = (X^c \oplus \check{B})^c \tag{70}$$

Erosion and dilation obey the principles of "ideal" morphological operators:

- erosion and dilation are invariant to translations: $X_z \ominus B = (X \ominus B)_z$. Likewise, $X_z \oplus B = (X \oplus B)_z$;
- erosion and dilation are compatible with scaling: $\lambda X \ominus \lambda B = \lambda (X \ominus B)$ and $\lambda X \oplus \lambda B = \lambda (X \oplus B)$;
- erosion and dilation are local operators (if B is bounded);
- it can be shown that erosion and dilation are continuous transforms.

Algebraic properties

- erosion and dilation are *increasing* operators: if $X \subseteq Y$, then $(X \ominus B) \subseteq (Y \ominus B)$ and $(X \oplus B) \subseteq (Y \oplus B)$;
- ② if the structuring element contains the origin, then the erosion is *anti-extensive* and the dilation is *extensive*, that is $X \ominus B \subseteq X$ and $X \subseteq X \oplus B$.

Definition (Opening)

The *opening* results from cascading an erosion and a dilation with the same structuring element:

$$X \circ B = (X \ominus B) \oplus B$$

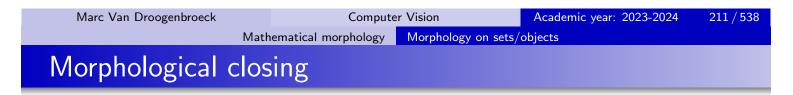

(71)

Interpretation of openings (alternative definition)

The interpretation of the opening operator (which can be seen as an alternative definition) is based on

$$X \circ B = \bigcup \{ B_z | z \in \mathcal{E} \text{ and } B_z \subseteq X \}$$
 (72)

In other words, the opening of a set by structuring element B is the set of all the elements of X that are covered by a translated copy of B when it moves inside of X.

Definition (Closing)

A *closing* is obtained by cascading a dilation and an erosion with a unique structuring element:

$$X \bullet B = (X \oplus B) \ominus B \tag{73}$$

Opening and closing are dual operators with respect to set complementation: indeed,

$$(X \circ B)^c = X^c \bullet \check{B} \tag{74}$$

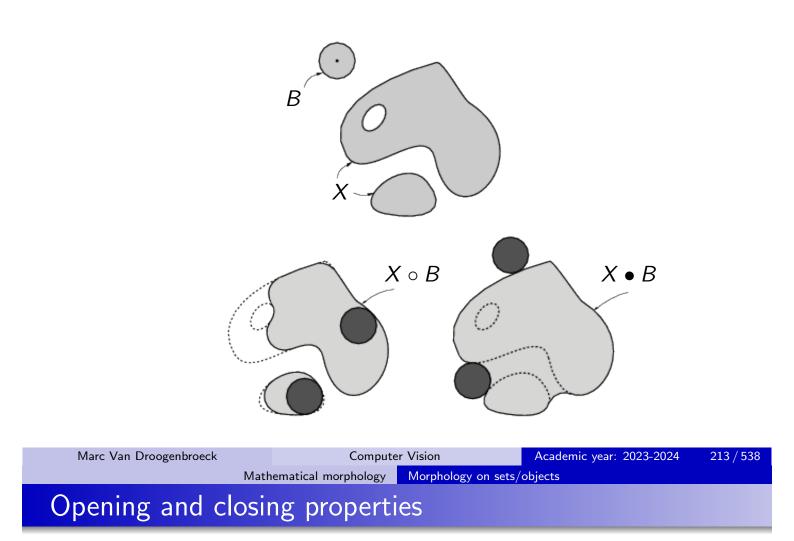

and

$$(X \bullet B)^c = X^c \circ \check{B} \tag{75}$$

212 / 538

Mathematical morphology Morphology on sets/objects

Opening and closing of X with a disk B

By construction, the opening and closing follow the "ideal" principles of morphological operators.

The most important algebraic properties of $X \circ B$ and $X \bullet B$ are

• opening and closing are *increasing*. If $X \subseteq Y$, then

$$(X \circ B) \subseteq (Y \circ B) \text{ and } (X \bullet B) \subseteq (Y \bullet B)$$
 (76)

opening is anti-extensive, and closing is extensive (no condition related on the origin here!)

$$X \circ B \subseteq X, \quad X \subseteq X \bullet B \tag{77}$$

opening and closing are *idempotent* operators (projective operators).
 This means that

$$(A \circ B) \circ B = A \circ B$$
 and $(A \bullet B) \bullet B = A \bullet B$ (78)

Marc Van Droogenbroeck

General properties I

Dilation is commutative and associative

$$X \oplus B = B \oplus X \tag{79}$$

$$(X \oplus Y) \oplus C = X \oplus (Y \oplus C) \tag{80}$$

Dilation distributes the union

$$(\bigcup_{j} X_{j}) \oplus B = \bigcup_{j} (X_{j} \oplus B)$$
(81)

The erosion distributes the intersection

$$(\bigcap_{j} X_{j}) \ominus B = \bigcap_{j} (X_{j} \ominus B)$$
(82)

| Marc Van Droogenbroeck | Comput | er Vision | Academic year: 2023-2024 | 215 / 538 |
|------------------------|-------------------------|---------------------|--------------------------|-----------|
| | Mathematical morphology | Morphology on sets/ | objects | |
| General propert | ties II | | | |

$$X \ominus (B \oplus C) = (X \ominus B) \ominus C \tag{83}$$

The opening and closing are not related to the exact location of the origin (so they do not depend on the location of the origin when defining B). Let z ∈ E

$$X \circ B_z = X \circ B \tag{84}$$

$$X \bullet B_z = X \bullet B \tag{85}$$

A practical problem: dealing with borders

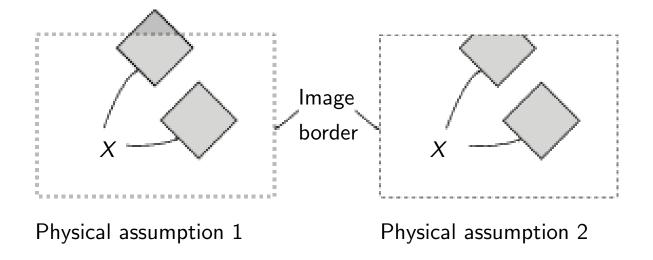

Figure: Two possible physical assumptions for borders.

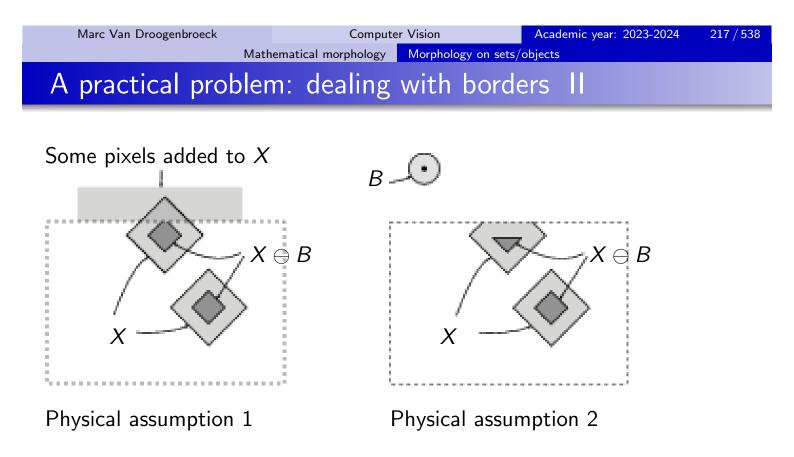

Figure: Comparison of the effects of two physical assumptions on the computation of the erosion of X.

Neighboring transforms

| Definition | |
|--|------|
| The Hit or Miss transform $X \Uparrow (B, C)$ is defined as | |
| $X \Uparrow (B, C) = \{x B_x \subseteq X, \ C_x \subseteq X^c\}$ | (86) |

If $C = \emptyset$ the transform reduces to an erosion of X by B.

Geodesic dilation

A geodesic dilation is always based on two sets (images).

Mathematical morphology

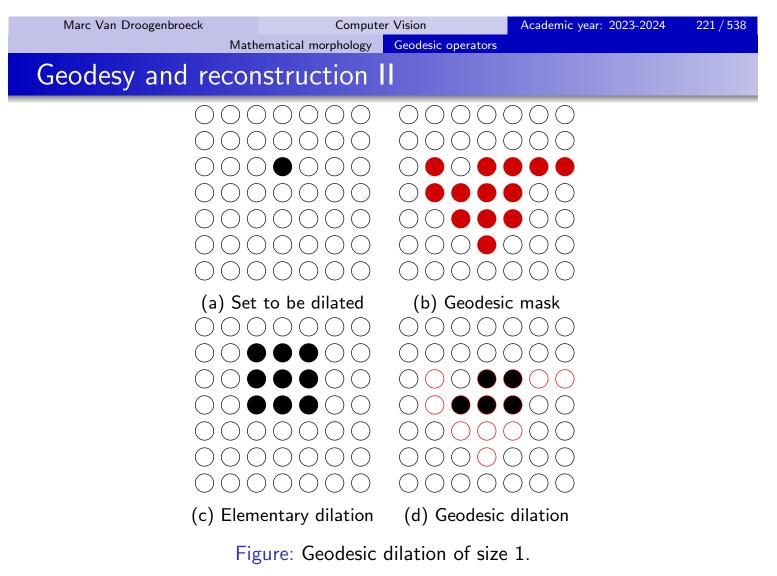

Definition

The *geodesic dilation of size* 1 of X conditionally to Y, denoted $D_Y^{(1)}(X)$, is defined as the intersection of the dilation of X and Y:

$$\forall X \subseteq Y, \ D_Y^{(1)}(X) = (X \oplus B) \cap Y$$
(87)

Geodesic operators

where *B* is usually chosen according to the frame connectivity (a 3×3 square for a 8-connected grid).

Definition

The *reconstruction* of X conditionally to Y is the geodesic dilation of X until idempotence. Let i be the iteration during which idempotence is reached, then the reconstruction of X is given by

Mathematical morphology Geodesic operators

$$R_Y(X) = D_Y^{(i)}(X)$$
 with $D_Y^{(i+1)}(X) = D_Y^{(i)}(X)$. (89)

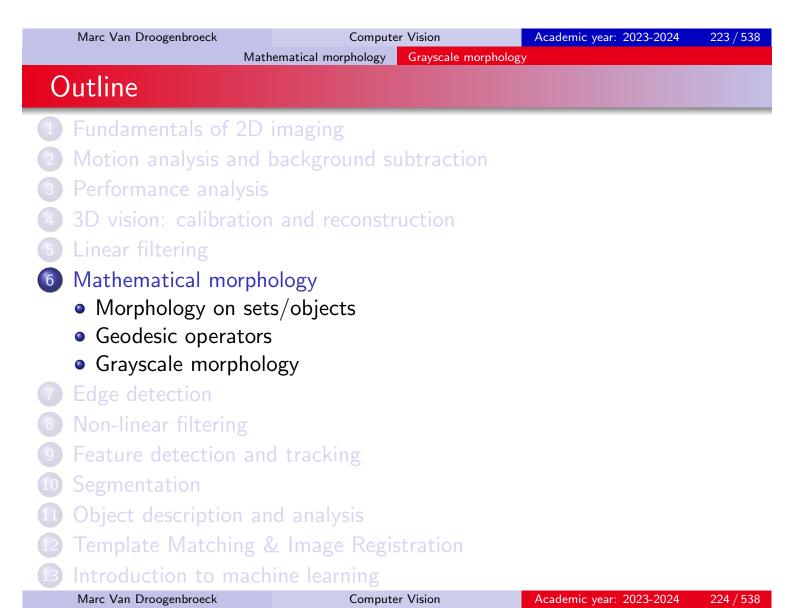

(c) Reconstructed blobs

Figure: Blob extraction by marking and reconstruction.

(b) Marking blobs

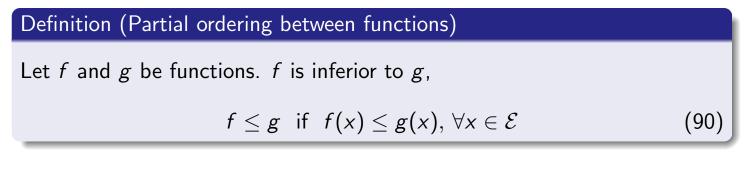

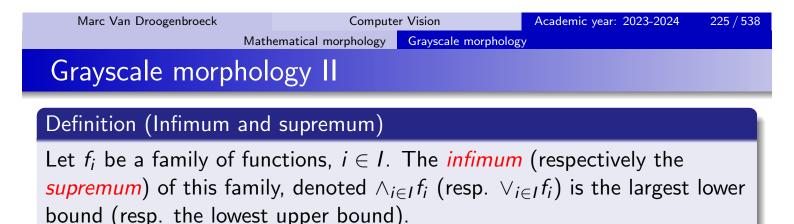

Grayscale morphology I

Notion of a function

Let \mathcal{G} be the range of possible grayscale values. An image is represented by a function $f : \mathcal{E} \to \mathcal{G}$, which projects a location of a value of \mathcal{G} . In practice, an image is not defined over the entire space \mathcal{E} , but on a limited portion of it, a compact D.

We need to define an order between functions.

In the practical case of a finite family *I*, the supremum and the infimum correspond to the maximum and the minimum respectively. In that case,

$$\forall x \in \mathcal{E}, \begin{cases} (f \lor g)(x) = \max(f(x), g(x))\\ (f \land g)(x) = \min(f(x), g(x)) \end{cases}$$
(91)

Definition (Translate of a function)

The translate of a function f by b, denoted by f_b , is defined as

$$\forall x \in \mathcal{E}, \quad f_b(x) = f(x-b).$$

Marc Van Droogenbroeck

(92)

Additional definitions related to operators I

Definition (Idempotence)

An operator ψ is *idempotent* if, for each function, a further application of it does not change the final result. That is, if

$$\forall f, \ \psi(\psi(f)) = \psi(f) \tag{93}$$

Definition (Extensivity)

An operator is extensive if the result of applying the operator is larger that the original function

$$orall f, \ f \leq \psi(f)$$

An operator is *anti-extensive* if the result of applying the operator is lower that the original function

$$orall f, \ f \geq \psi(f)$$

Definition (Increasingness)

An increasing operator is such that it does not modify the ordering between functions:

$$\forall f, g, \ f \leq g \Rightarrow \psi(f) \leq \psi(g) \tag{96}$$

By extension, an operator ψ_1 is lower that an operator ψ_2 if, for every function f, $\psi_1(f)$ is lower to $\psi_2(f)$:

$$\psi_1 \le \psi_2 \Leftrightarrow \forall f, \ \psi_1(f) \le \psi_2(f)$$
 (97)

(94)

(95)

Erosion and dilation

Definition (Grayscale dilation and erosion)

Let *B* be the domain of definition of a structuring element. The *grayscale dilation* and *erosion* (with a flat structuring element) are defined, respectively as,

$$f \oplus B = \bigvee_{b \in B} f_b(x) \tag{98}$$

$$f \ominus B = \bigwedge_{b \in B} f_{-b}(x) \tag{99}$$

| $f \oplus B(x) = \max$ | | 30 | 30 | 30 | 24 | 22 | 23 | 25 | 25 | 25 | |

Typical questions:

- best algorithms? (note that there is some redundancy between neighboring pixels)
- how do we handle borders?

Algorithms

- Based on the decomposition of the structuring element:
 - $f \ominus (H \oplus V) = (f \ominus H) \ominus V$
 - $f \ominus (B \oplus B) = (f \ominus B) \ominus \partial(B)$
- Appropriate structure for storing and propagating the local min and max
 - queues
 - histogram

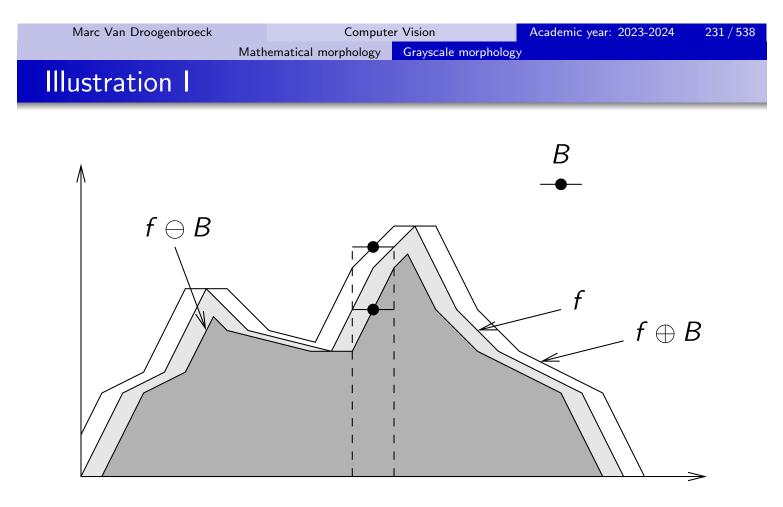

Figure: Erosion and dilation of a function.

Illustration II

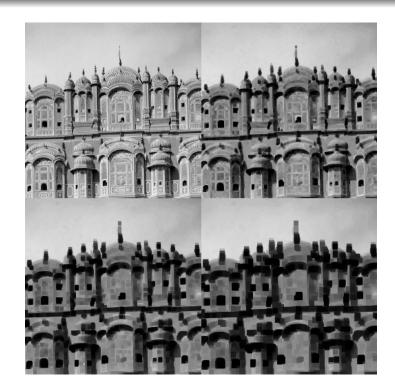

Figure: Erosions with squares of increasing sizes.

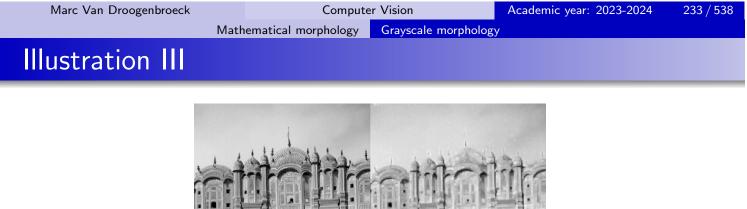

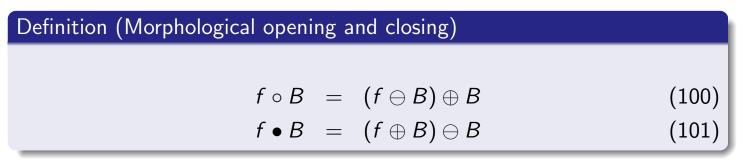

Figure: Dilations with squares of increasing sizes.

Morphological opening and closing

The opening $f \circ B$ is obtained by cascading an erosion followed by a dilation. The closing $f \bullet B$ is the result of a dilation followed by an erosion.

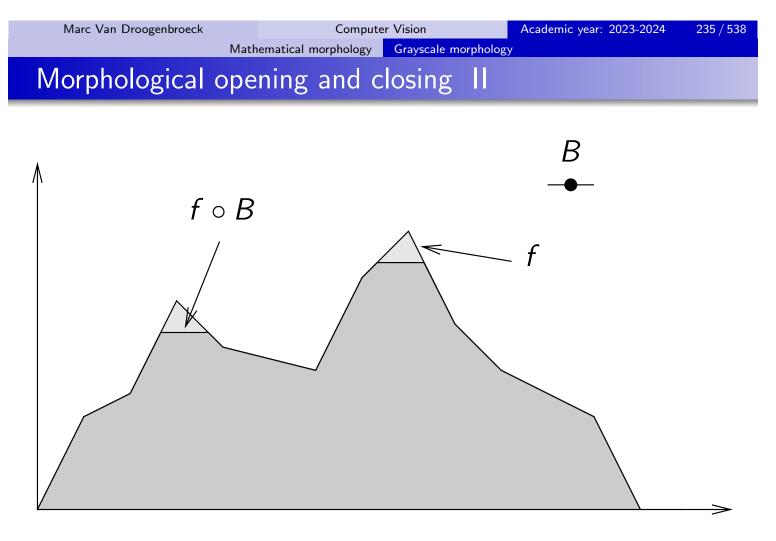

Figure: Opening of a function.

Computer Vision

Mathematical morphology Grayscale morphology

Properties of grayscale morphological operators

Erosion and dilation are increasing operators

$$f \le g \Rightarrow \begin{cases} f \ominus B \le g \ominus B \\ f \oplus B \le g \oplus B \end{cases}$$
(102)

Erosion distributes the infimum and dilation distributes the supremum

$$(f \wedge g) \ominus B = (f \ominus B) \wedge (g \ominus B)$$
 (103)

$$(f \lor g) \oplus B = (f \oplus B) \lor (g \oplus B)$$
 (104)

Opening and closing are idempotent operators

 $(f \circ B) \circ B = f \circ B$ (105)

$$(f \bullet B) \bullet B = f \bullet B \tag{106}$$

Opening and closing are anti-extensive and extensive operators respectively

$$f \circ B \leq f$$
 (107)

$$f \leq f \bullet B \tag{108}$$

For derivate operators, we have to address two problems simultaneously:

- **1** find the best **approximate** for the derivate.
- **2** avoid an excessive amplification of the noise.

These are two apparent contradictory requirements \Rightarrow *trade-offs*

Linear operators II

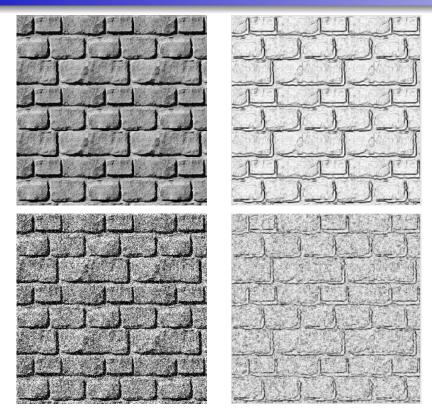

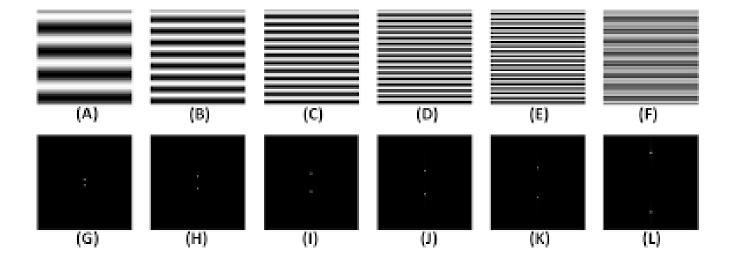

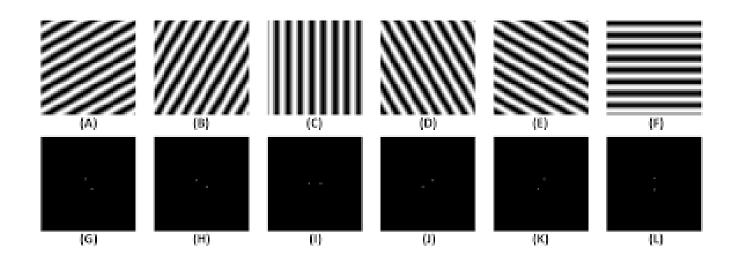

Figure: Images (left-hand side) and gradient images (right-hand side)

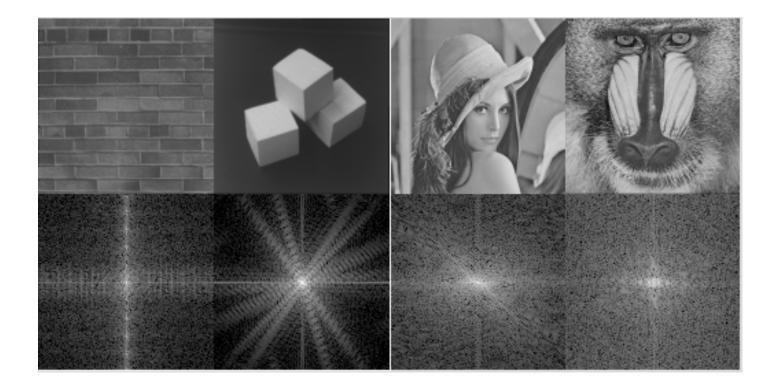

Fourier transform (quick reminder) II

Edge detection Linear operators

First derivate operator I

Let us consider the *partial* derivate of a function f(x, y) with respect to x. Its Fourier transform $\mathcal{F}(u, v)$ becomes

$$\frac{\partial}{\partial x}f(x,y) \rightleftharpoons 2\pi j u \mathcal{F}(u,v) \tag{110}$$

In other words, deriving with respect to x consists of multiplying the Fourier transform of f(x, y) by the following transfer function $\mathcal{H}_x(u, v) = 2\pi j u$, or of filtering f(x, y) with the following impulse function:

$$h_{x}(x,y) = \int_{-\infty}^{+\infty} \int_{-\infty}^{+\infty} (2\pi j u) e^{2\pi j (xu+yv)} du dv$$
(111)

If we adopt a *vectorial notation* of the derivate, we define the *gradient* ∇f of image f by

$$\nabla f = \frac{\partial f}{\partial x} \overrightarrow{e_x} + \frac{\partial f}{\partial y} \overrightarrow{e_y} = (h_x \otimes f) \overrightarrow{e_x} + (h_y \otimes f) \overrightarrow{e_y}$$
(112)

Definition (Gradient amplitude)

$$|\nabla f| = \sqrt{(h_x \otimes f)^2 + (h_y \otimes f)^2}$$
(113)

The amplitude of the gradient is sometimes approximated by

$$|
abla f| \simeq |h_x \otimes f| + |h_y \otimes f|$$
 (114)

which introduces a still acceptable error (in most cases) of 41%! But we still have to find a way to calculate $h_x \otimes f$ and $h_y \otimes f$...

Definition (Gradient orientation) $\varphi_{\nabla f} = \tan^{-1} \left(\frac{h_y \otimes f}{h_x \otimes f} \right)$ (115)

Second derivate operator

Definition (Laplacian $\nabla^2 f$)

The Laplacian is the scalar defined as

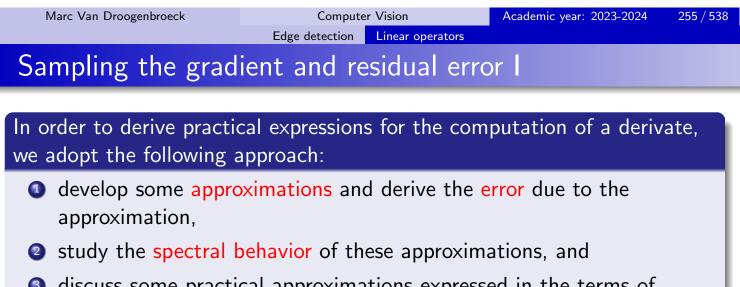

$$\nabla^2 f = \frac{\partial^2 f}{\partial x^2} + \frac{\partial^2 f}{\partial y^2} = (h_{xx} \otimes f) + (h_{yy} \otimes f)$$
(116)

As the first derivate, it can be shown that in the Fourier domain, the Laplacian consists to apply the following filter

$$\nabla^2 f \cong \left((2\pi j \boldsymbol{u})^2 + (2\pi j \boldsymbol{v})^2 \right) \mathcal{F}(\boldsymbol{u}, \boldsymbol{v})$$
(117)

$$\Rightarrow -4\pi^2(u^2+v^2)\mathcal{F}(u,v) \qquad (118)$$

As can be seen, high frequencies tend to be amplified. Is this suitable?

I discuss some practical approximations expressed in the terms of convolution masks.

Sampling the gradient and residual error II

Centered approximations (along a single axis!, for example a line of the image)?

First derivate: an approximation is

$$f'_{a}(x) = \frac{f(x+h) - f(x-h)}{2h} = \frac{(+1)f(x+h) + (-1)f(x-h)}{2h}$$
(119)

where h is the distance between two samples and index a denotes that it is an approximation. Note that this approximation consists to filter f(x) by the following "multiplicative" mask

$$\frac{1}{2h} \left[\begin{array}{ccc} -1 & 0 & +1 \end{array} \right] \tag{120}$$

or the convolution mask

$$\frac{1}{2h} \left[\begin{array}{cc} +1 & 0 & -1 \end{array} \right] \tag{121}$$

| Marc Van Droogenbroeck | Compute | er Vision | Academic year: 2023-2024 | 257 / 538 | |
|--|----------------|------------------|--------------------------|-----------|--|
| | Edge detection | Linear operators | | | |
| Sampling the gradient and residual error III | | | | | |

Second derivate: one possible approximation is

$$f_a''(x) = \frac{f(x+h) - 2f(x) + f(x-h)}{h^2}$$
(122)

Sampling the gradient and residual error IV

We make use of the following representation of a function.

Theorem (Taylor series)

The Taylor series of a real valued function f(z) that is infinitely differentiable at a real number a is the following power series

$$f(z) = f(a) + \frac{f'(a)}{1!}(z-a) + \frac{f''(a)}{2!}(z-a)^2 + \dots$$
(123)

Then, we substitute:

- Iocation a by location x
- location z by either x + h or x h

Computation of the residual error. Let's consider the following Taylor series

$$f(x+h) = f(x) + h f'(x) + \frac{h^2}{2} f''(x) + \ldots + \frac{h^n}{n!} f^{(n)}(x) + \ldots \quad (124)$$

$$f(x-h) = f(x) - h f'(x) + \frac{h^2}{2} f''(x) + \ldots + (-1)^n \frac{h^n}{n!} f^{(n)}(x) + \ldots$$

First derivate. By subtraction, member by member, these two equalities, one obtains

$$f(x+h)-f(x-h) = 2h f'(x) + \frac{2}{3!}h^3 f^{(3)}(x) + \ldots = 2h f'(x) + O(h^3)$$
(125)

After re-ordering,

$$f'(x) = \frac{f(x+h) - f(x-h)}{2h} + O(h^2)$$
(126)

Marc Van Droogenbroeck

Sampling the gradient and residual error VI

Second derivate.

$$f(x+h) = f(x)+h f'(x) + \frac{h^2}{2} f''(x) + \ldots + \frac{h^n}{n!} f^{(n)}(x) + \ldots \quad (127)$$

$$f(x-h) = f(x)-hf'(x) + \frac{h^2}{2}f''(x) + \ldots + (-1)^n \frac{h^n}{n!}f^{(n)}(x) + (128)$$

Like for the first derivate, we use the Taylor extension by add them this time,

$$f(x+h)+f(x-h) = 2f(x) + h^2 f''(x) + \frac{2}{4!}h^4 f^{(4)}(x) + \dots$$
(129)

As a result:

$$f''(x) = \frac{f(x+h) - 2f(x) + f(x-h)}{h^2} + O(h^2)$$
(130)

The $f_a''(x)$ approximation is also of the second order in h.

Synthesis of expressions with a pre-defined error.

Another approximation, of order $O(h^4)$, can be built. It corresponds to

$$f'_{a}(x) = \frac{-f(x+2h) + 8f(x+h) - 8f(x-h) + f(x-2h)}{12h}$$
(131)

262 / 538

Spectral behavior of discrete gradient operators I

Consider the one-dimensional continuous function f(x) and the following first derivate:

$$f'_{a}(x) = \frac{f(x+h) - f(x-h)}{2h}$$
(132)

Its Fourier is given by

$$\frac{f(x+h) - f(x-h)}{2h} \rightleftharpoons \frac{e^{2\pi j u h} - e^{-2\pi j u h}}{2h} \mathcal{F}(u)$$
(133)

which is, given that $sin(a) = \frac{e^{ja} - e^{-ja}}{2j} \Leftrightarrow e^{2\pi juh} - e^{-2\pi juh} = 2j sin(2\pi hu)$,

$$\frac{f(x+h)-f(x-h)}{2h} \rightleftharpoons (2\pi j u) \frac{\sin(2\pi h u)}{2\pi h u} \mathcal{F}(u)$$
(134)

where the $(2\pi j u)$ factor corresponds to the ideal (continuous) expression of the first derivate.

Let us now consider the approximation of the second derivate

$$f_a''(x) = \frac{f(x+h) - 2f(x) + f(x-h)}{h^2}$$
(135)

Its Fourier transform is given by

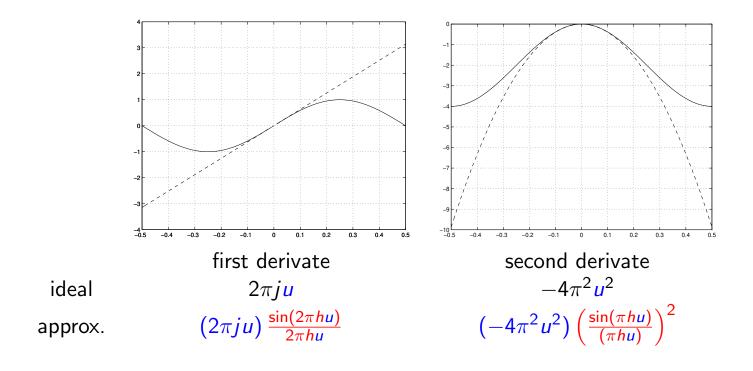

$$\frac{f(x+h)-2f(x)+f(x-h)}{h^2} \rightleftharpoons (-4\pi^2 u^2) \left(\frac{\sin(\pi h u)}{(\pi h u)}\right)^2 \mathcal{F}(u) \quad (136)$$

Edge detection Linea

Linear operators

Spectral behavior of discrete gradient operators III

Figure: Spectral behavior of the derivate approximations (for h = 1).

| Marc Van Droogenbroeck | Computer Vision | Academic year: 2023-2024 | 265 / 538 | | |
|---|----------------------------|--------------------------|-----------|--|--|
| | Edge detection Linear oper | rators | | | |
| Practical expressions of gradient operators and | | | | | |
| convolution/multip | olication masks I | | | | |

Practical expression are based on the notion of convolution masks

$$\left[\begin{array}{cc} +1 & -1 \end{array}\right] \tag{137}$$

corresponds to the following non-centered approximation of the first derivate:

$$\frac{(-1) \times f(x,y) + (+1) \times f(x+h,y)}{h}$$

$$(138)$$

This "convolution mask" has an important drawback. Because it is not centered, the result is shifted by half a pixel. One usually prefers to use a centered (larger) convolution mask such as

$$\left[\begin{array}{ccc} +1 & 0 & -1 \end{array}\right] \tag{139}$$

Marc Van Droogenbroeck

Practical expressions of gradient operators and convolution/multiplication masks II

In the y (vertical) direction, this becomes

$$\begin{bmatrix} +1\\0\\-1 \end{bmatrix}$$
(140)

But then, it is also possible to use a diagonal derivate:

$$\begin{bmatrix} +1 & . & . \\ . & 0 & . \\ . & . & -1 \end{bmatrix}$$
(141)

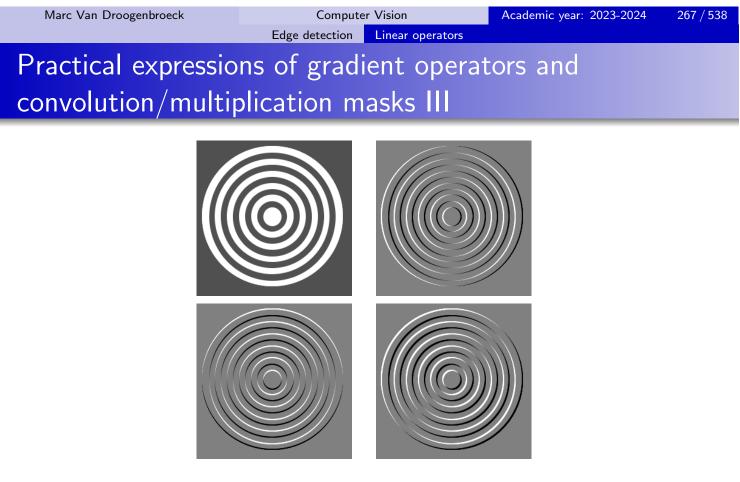

Figure: (a) original image, (b) after the application of a horizontal mask, (c) after the application of a vertical mask, and (d) mask oriented at 135° .

Computer Vision

The use of (centered) convolution masks still has some drawbacks:

Border effects.

Solutions:

- (i) put a *default* value *outside* the image;
- (ii) *mirroring extension*: copy inside values starting from the border;
- (iii) *periodization* of the image –pixels locate on the left are copied on the right of the image,
- (iv) copy border values to fill an artificial added border.

► The range (dynamic) of the possible values is modified.

It might be needed to apply a normalization factor.

Detecting lines

Challenge: detect lines in an image

Towards the Hough transform

- Difficulty: matching a set of points arranged as a line
- Idea: instead of considering the family of points (x, y) that belong to a line y = ax + b, consider the two parameters
 - the slope parameter a (but a is unbounded for vertical lines)
 - 2 the intercept parameter b (that is for x = 0)

With the Hough transform, we consider the (r, θ) pair where

- the parameter r represents the distance between the line and the origin,
- while θ is the angle of the vector from the origin to the line closest point

Edge detection Hough's transform

Definition of the Hough transform II

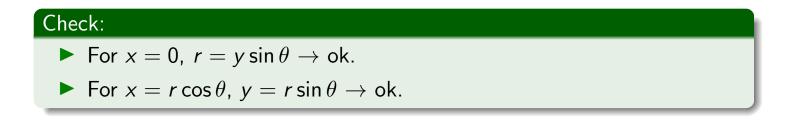

We have several ways to characterize a line:

- Slope *a* and *b*, such that y = ax + b.
- 2 The two parameters (r, θ) , with $\theta \in [0, 2\pi[$ and $r \ge 0$.

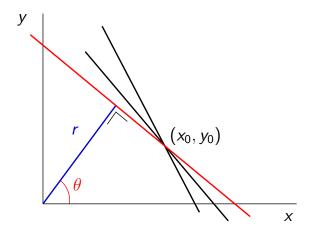

Link between these characterizations:

The equation of the line becomes

$$y = \left(-\frac{\cos\theta}{\sin\theta}\right)x + \left(\frac{r}{\sin\theta}\right)$$
(147)

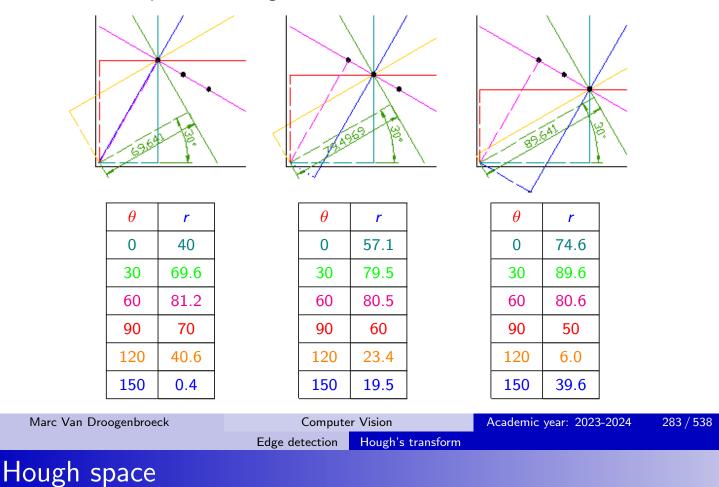

By re-arranging terms of $y = \left(-\frac{\cos\theta}{\sin\theta}\right)x + \left(\frac{r}{\sin\theta}\right)$, we get that, for an arbitrary point on the image plane with coordinates, e.g., (x_0, y_0) , the family of lines passing through it are given by

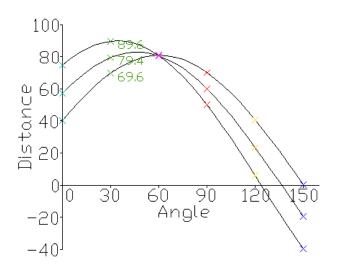

$$r = x_0 \cos \theta + y_0 \sin \theta \tag{148}$$

Marc Van Droogenbroeck

Example

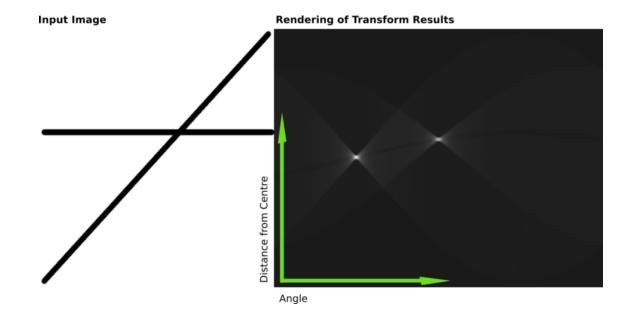

For three points (x_0, y_0) , we explore the Hough space. That is, we compute r for a given set of orientations θ :

Thus, the problem of detecting colinear points can be converted to the problem of finding concurrent curves.

Hough space

 Marc Van Droogenbroeck
 Computer Vision
 Academic year: 2023-2024
 285 / 538

 Edge detection
 Hough's transform

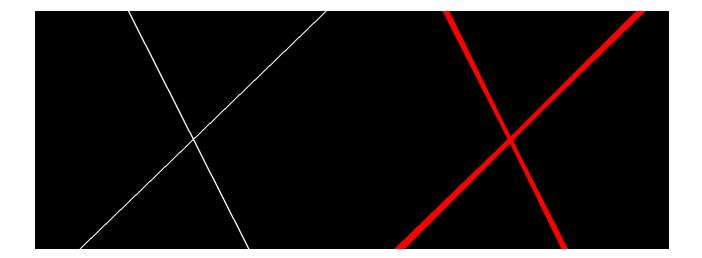

Algorithm

- Detect edges in the original image.
- Select only some pixels corresponding to "strong edges" for which there is enough evidence that they belong to lines.
- If a comparison of the Hough space:
 If a comparison of the Hough space:
 - For example, we take each θ in $[0^0, 360^0]$ with a step of 1^0 .
 - 2 We calculate the corresponding r by $r = x_0 \cos \theta + y_0 \sin \theta$.
 - So If Hough (r, θ) is one bin of the Hough space, then we do

$$\mathsf{Hough}(\mathbf{r}, \mathbf{\theta}) \longleftarrow \mathsf{Hough}(\mathbf{r}, \mathbf{\theta}) + 1 \tag{149}$$

- Threshold the accumulator function $Hough(r, \theta)$ to select bins that correspond to lines in the original image.
- **•** Draw the corresponding lines in the original image.

 - Alternate sequential filters
 - Morphological filter

Introduction to rank filters

| f(x) | 25 | 27 | 30 | 24 | 17 | 15 | 22 | 23 | 25 | 18 | 20 |
|-------------------------|----|----|----|----|----|----|----|----|----|----|----|
| f(x-1) | ? | 25 | 27 | 30 | 24 | 17 | 15 | 22 | 23 | 25 | 18 |
| f(x) | 25 | 27 | 30 | 24 | 17 | 15 | 22 | 23 | 25 | 18 | 20 |
| f(x+1) | 27 | 30 | 24 | 17 | 15 | 22 | 23 | 25 | 18 | 20 | ? |
| $f \ominus B(x) = \min$ | | 25 | 24 | 17 | 15 | 15 | 15 | 22 | 18 | 18 | |
| $f \oplus B(x) = \max$ | | 30 | 30 | 30 | 24 | 22 | 23 | 25 | 25 | 25 | |

We could also order the values:

| f(x) | 25 | 27 | 30 | 24 | 17 | 15 | 22 | 23 | 25 | 18 | 20 |
|-------------------------|----|----|----|----|----|----|----|----|----|----|----|
| 1 | | 25 | 24 | 17 | 15 | 15 | 15 | 22 | 18 | 18 | 18 |
| 2 | 25 | 27 | 27 | 24 | 17 | 17 | 22 | 23 | 23 | 20 | 20 |
| 3 | 27 | 30 | 30 | 30 | 24 | 22 | 23 | 25 | 25 | 25 | |
| $f \ominus B(x) = \min$ | | 25 | 24 | 17 | 15 | 15 | 15 | 22 | 18 | 18 | |
| $f \oplus B(x) = \max$ | | 30 | 30 | 30 | 24 | 22 | 23 | 25 | 25 | 25 | |

Let $k \in \mathbb{N}$ be a threshold.

Definition (*Rank filter*)

The operator or k-order rank filter, denoted as $\rho_{B,k}(f)(x)$, defined with respect to the B structuring element, is

$$\rho_{B,k}(f)(x) = \bigvee \{t \in \mathcal{G} | \sum_{b \in B} [f(x+b) \ge t] \ge k\}$$
(150)

The simplest interpretation is that $\rho_{B,k}(f)(x)$ is the *k*-est value when all the f(x + b) values are ranked in decreasing (increasing) order. Rank filters are ordered. Let $\sharp(B)$, be the surface of *B*, then

$$\rho_{B,\sharp(B)}(f)(x) \le \rho_{B,\sharp(B)-1}(f)(x) \le \ldots \le \rho_{B,1}(f)(x)$$
(151)

Median filter I

If *n* is odd, the $k = \frac{1}{2}(\sharp(B) + 1)$ choice leads to the definition of a self-dual operator, that is a filter that produces the same result as if applied on the dual function. This operator, denoted med_B, is the *median filter*.

| f(x) | 25 | 27 | 30 | 24 | 17 | 15 | 22 | 23 | 25 | 18 | 20 |
|-------------------------|----|----|----|----|----|----|----|----|----|----|----|
| 1 | | 25 | 24 | 17 | 15 | 15 | 15 | 22 | 18 | 18 | 18 |
| med _B | 25 | 27 | 27 | 24 | 17 | 17 | 22 | 23 | 23 | 20 | 20 |
| 3 | 27 | 30 | 30 | 30 | 24 | 22 | 23 | 25 | 25 | 25 | |
| $f \ominus B(x) = \min$ | | 25 | 24 | 17 | 15 | 15 | 15 | 22 | 18 | 18 | |
| $f \oplus B(x) = \max$ | | 30 | 30 | 30 | 24 | 22 | 23 | 25 | 25 | 25 | |

Marc Van Droogenbroeck

Computer Vision Non-linear filtering

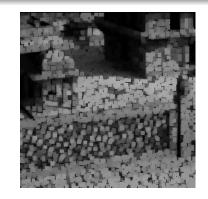

(a) Original image f + noise

(c) Low-pass Butterworth ($f_c = 50$)

Academic year: 2023-2024

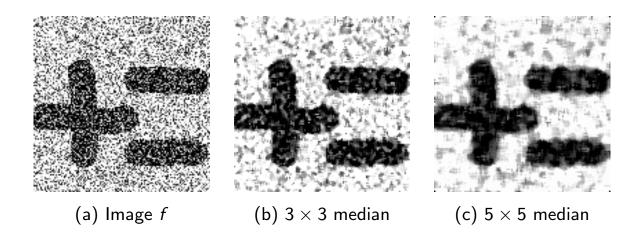

(b) Opening with a 5×5 square

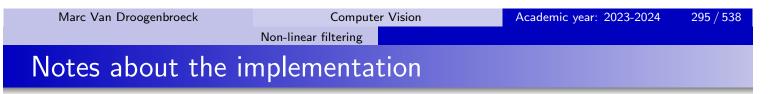

(d) Median with a 5 imes 5 square

293 / 538

Effect of the size of the median filter

The median filter is not idempotent. Successive applications can result in *oscillations* (theoretically if the domain of the function is infinite)

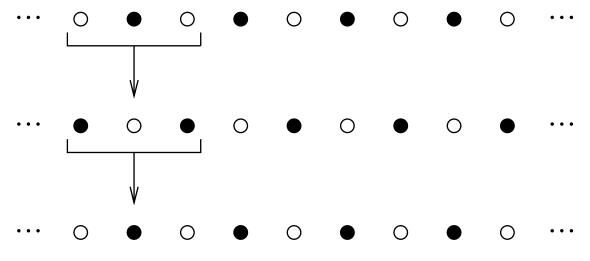

Figure: Repeated application of a median filter.

Also,

$$\mathsf{med}_{5\times 5}(f) \neq \mathsf{med}_{1\times 5}(\mathsf{med}_{5\times 1}(f)) \tag{152}$$

but it is an acceptable approximation!

Morphological filters

Definition (Algebraic filter)

 ψ

By definition, a filter is an *algebraic filter* if and only if the operator is increasing and idempotent:

is an algebraic filter
$$\Leftrightarrow \forall f, g \begin{cases} f \leq g \Rightarrow \psi(f) \leq \psi(g) \\ \psi(\psi(f)) = \psi(f) \end{cases}$$
 (153)

Definition (Algebraic opening)

An algebraic opening is an operator that is increasing, idempotent, and anti-extensive. Formally,

$$\forall f, g, f \leq g \Rightarrow \psi(f) \leq \psi(g)$$
 (154)

$$\forall f, \, \psi(\psi(f)) = \psi(f) \tag{155}$$

$$\forall f, \, \psi(f) \le f \tag{156}$$

An *algebraic closing* is defined similarly, except that the operator is *extensive*.

| | Non-linear filtering | | | |
| How to build a filt | er? | | | |

By combining know filters!

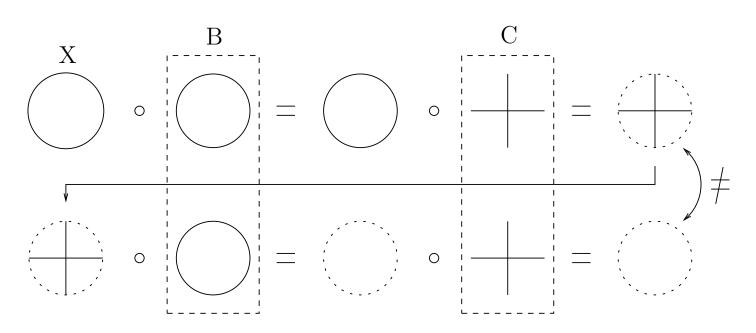

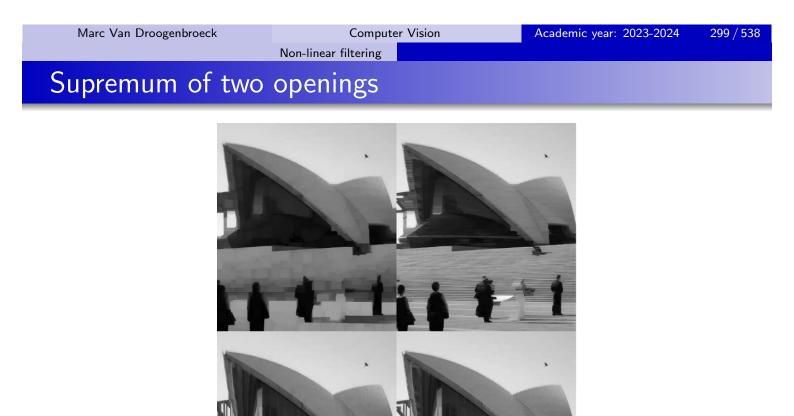

Figure: The composition (cascading) of two openings is not an opening.

How to build a filter? II

New filters can be built starting from openings, denoted α_i , and closings, denoted ϕ_i . The rules to follow are:

- the supremum of openings is an opening: $(\bigvee_i \alpha_i)$ is an opening;
- 2 the infimum of closings is a closing: $(\bigwedge_i \phi_i)$ is a closing.

Openings: $\gamma_{mH \oplus nV}(f)$, $\gamma_{mH}(f)$, $\gamma_{nV}(f)$, and $\gamma_{mH}(f) \lor \gamma_{nV}(f)$

Marc Van Droogenbroeck

Computer Vision

Academic year: 2023-2024

300 / 538

Let ψ_1 and ψ_2 be two filters such that $\psi_1 \ge I \ge \psi_2$ (for example, ψ_1 is a closing and ψ_2 an opening).

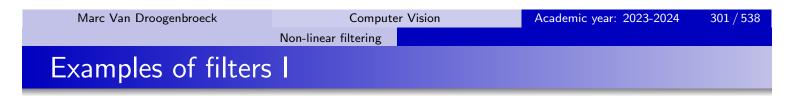

Theorem (*Structural theorem*)

Let ψ_1 and ψ_2 be two filters such that $\psi_1 \ge I \ge \psi_2$, then

 $\psi_1 \ge \psi_1 \psi_2 \psi_1 \ge (\psi_2 \psi_1 \lor \psi_1 \psi_2) \ge (\psi_2 \psi_1 \land \psi_1 \psi_2) \ge \psi_2 \psi_1 \psi_2 \ge \psi_2$ (157)

 $\psi_1\psi_2, \,\psi_2\psi_1, \,\psi_1\psi_2\psi_1, \,\psi_2\psi_1\psi_2 \,\,are \,\,all \,\,filers$ (158)

Note that there is no ordering between $\psi_1\psi_2$ and $\psi_2\psi_1$.

Alternate Sequential Filters (ASF)

Let γ_i (ϕ_i) be an opening (resp. a closing) of size *i* and *I* be the identity operator (i.e. I(f) = f).

We assume that there is the following order:

$$\forall i, j \in \mathbb{N}, \ i \leq j, \ \gamma_j \leq \gamma_i \leq I \leq \phi_i \leq \phi_j, \tag{159}$$

For each index *i*, we define these operators:

$$m_{i} = \gamma_{i}\phi_{i}, \quad r_{i} = \phi_{i}\gamma_{i}\phi_{i},$$
$$n_{i} = \phi_{i}\gamma_{i}, \quad s_{i} = \gamma_{i}\phi_{i}\gamma_{i}.$$

Examples of filters II

Definition (Alternate Sequential Filters (ASF))

For each index $i \in \mathbb{N}$, the following operators are the alternate sequential filters of index i

$$M_i = m_i m_{i-1} \dots m_2 m_1$$
 $R_i = r_i r_{i-1} \dots r_2 r_1$ (160)

$$N_i = n_i n_{i-1} \dots n_2 n_1$$
 $S_i = s_i s_{i-1} \dots s_2 s_1$ (161)

Theorem (Absorption law)

$$i \leq j \Rightarrow M_j M_i = M_j \text{ but } M_i M_j \leq M_j$$
 (162)

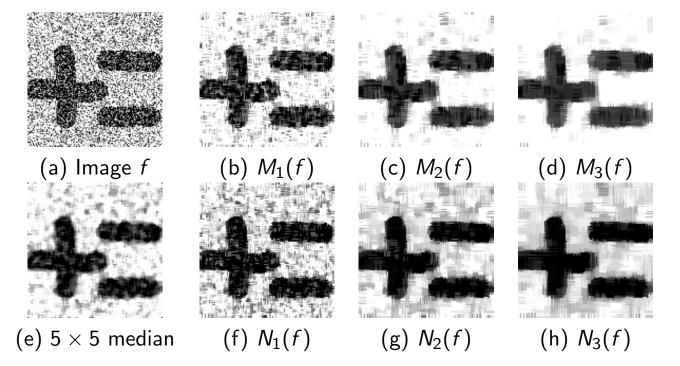

Figure: Use of alternate sequential filters to remove some noise.

The morphological center is a typical example of toggle mapping.

Definition (Morphological center)

Let ψ_i be a family of operators. The *morphological center* β of a function f with respect to the ψ_i family is defined, for each location x of the domain of f as follows:

$$\beta(f)(x) = (f(x) \lor (\bigwedge_{i} \psi_{i}(x))) \land (\bigvee_{i} \psi_{i}(x))$$
(163)

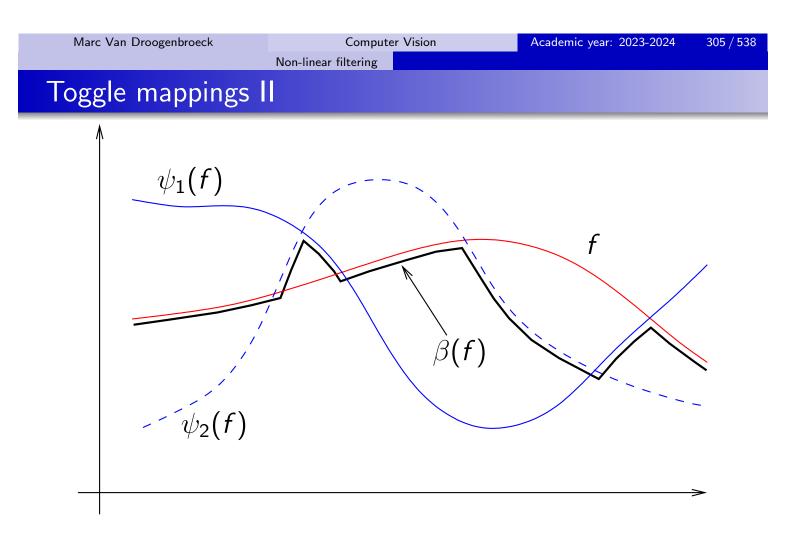

Figure: Morphological center of a one-dimensional signal.

- Features are edges, corners, etc.
 Most of them are based on derivatives.
- The choice of features is application-dependent!
- For tracking:
 - We need matching measures and metrics to find the best matching locations between frames.
 - Features need to be "strong": resilient to illumination changes, to local deformations, etc.

Principle:

- first apply a Gaussian filter (with the purpose of reducing noise).
- compute the Laplacian of the filtered image.
- detect the locations of zero-crossings in the image.

Parameters:

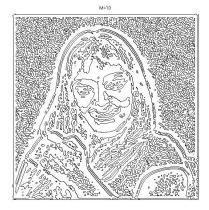

variance of the Gaussian filter

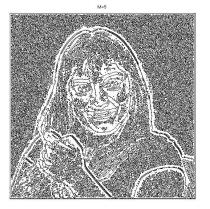

Result:

- collection of images with features detected at different scales.
- not suitable for tracking.

Historical example: the Laplacian of Gaussians II

Steps: select a set of robust features in the reference frame (or sub-frame/Region of Interest [ROI]) 2 compute the same set of features in the target image establish the relationship between the two sets of features. Many strategies are possible: global optimization local optimization RANSAC algorithm

- Template Matching & Image Registration
 - Introduction to machine learning

Approach

- There is an object, characterized by some quantities put in a vector X, that cannot be observed directly.
- We assume that we can trust a dynamic model of the state that allows us to predict how it evolves over time.
- Periodically, we observe the scene and produce a measure Y, that is a function of the state of the system.
- ▶ With this observation, we correct our estimate of the system state.

- Wait for a new image.
- **Predict** the current state of the tracked object.
- **③** Use that prediction to delineate a region of interest.
- Extract the tracked object in the new image.
- Our previous step and use it to correct the estimate of the object state.

Independence assumptions

- The system state and the observation are considered as random vectors.
- We limit the model to a Markov model. If X_i defines the object state in frame i, then

$$p(X_i|X_{i-1}, X_{i-2}, \ldots) = p(X_i|X_{i-1})$$
 (168)

In other words, only the immediate past matters.

The measurement only depends on the current state (no memory):

$$p(\mathbf{Y}_i|\mathbf{X}_i,\ldots) = p(\mathbf{Y}_i|\mathbf{X}_i)$$
(169)

- The dynamic model is linear.
- Errors in the modeling of state variables are considered as additive Gaussian noise.
- 3 The measurement process is linear.
- Noise on the measurement is characterized by an additive Gaussian noise.

Prediction and correction

Prediction

Multiply the state by a matrix D, and add Gaussian noise:

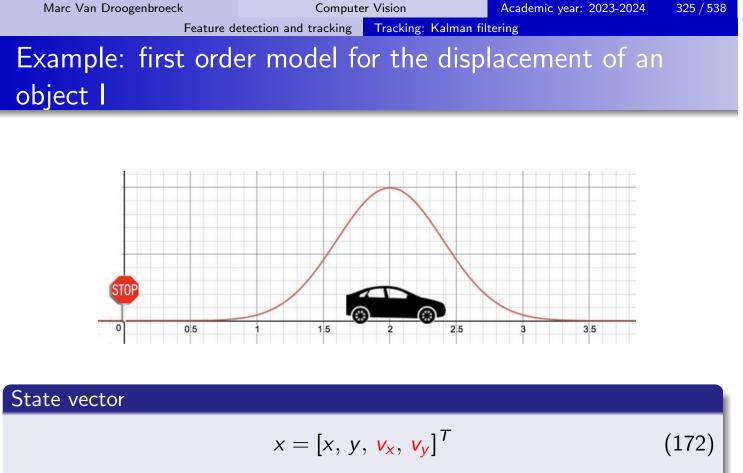

$$x_t \sim p(X_t | X_{t-\Delta t}) = \mathcal{N}(D_t x_{t-\Delta t}; \Sigma_{Dt})$$
 (170)

where Σ_{Dt} is the covariance matrix.

Measurement

Multiply the state by a matrix M, and add Gaussian noise:

$$y_t \sim p(Y_t|X_t) = \mathcal{N}(M_t x_t; \Sigma_{Mt})$$
(171)

where (v_x, v_y) are the components of the speed vector.

Example: first order model for the displacement of an object II

Model

We have that

$$x(t + \Delta t) = x(t) + v_x(t)\Delta t$$
(173)

$$\begin{bmatrix} x(t+\Delta t) \\ y(t+\Delta t) \end{bmatrix} = \begin{bmatrix} 1 & 0 & \Delta t & 0 \\ 0 & 1 & 0 & \Delta t \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ v_{x}(t) \\ v_{y}(t) \end{bmatrix}$$
(174)

Matrix of the dynamic system (state-transition model):

| | [1 | 0 | Δt | 0] | |
|------------|----|---|------------|------------|-------|
| <i>D</i> = | 0 | 1 | 0 | Δt | (175) |
| $D \equiv$ | 0 | 0 | 1 | 0 | (175) |
| | 0 | 0 | 0 | 1 | |

Measurement

$$y = [x, y]^{T}$$
(176)
Observation matrix: $M = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix}$

A linear, recursive estimator

Compute: x_t given $x_{t-\Delta t}$ and y_t

Dynamic and measurement models:

$$x_t \sim \mathcal{N}(D_t x_{t-\Delta t}; \mathbf{\Sigma}_{Dt})$$
 (177)

$$y_t \sim \mathcal{N}(M_t x_t; \Sigma_{Mt})$$
 (178)

Starting assumptions: \overline{x}_0^- and Σ_0^- are known.

Under these assumptions (linear dynamics, linear measurement function, Gaussian noise), the Kalman filter is the optimal recursive estimator.

Prediction

Predicted state estimate Predicted estimate covariance

$\overline{\mathbf{x}}_{t}^{-} = D_{t} \overline{\mathbf{x}}_{t-\Delta t}^{+}$ $\Sigma_{t}^{-} = \Sigma_{Dt} + D_{t} \Sigma_{t-\Delta t}^{+} D_{t}^{T}$

Correction/update

Measurement residual Residual covariance Optimal Kalman gain Updated state estimate Updated estimate covariance

 $r_{t} = y_{t} - M_{t}\overline{x}_{t}^{-}$ $R_{t} = M_{t}\Sigma_{t}^{-}M_{t}^{T} + \Sigma_{Mt}$ $K_{t} = \Sigma_{t}^{-}M_{t}^{T}(R_{t})^{-1}$ $\overline{x}_{t}^{+} = \overline{x}_{t}^{-} + K_{t}r_{t}$ $\Sigma_{t}^{+} = (I - K_{t}M_{t})\Sigma_{t}^{-}$

330 / 538

- We are not using future measurements to refine past state estimate. Solution: forwards-backwards Kalman filtering.
- Non-linear dynamic and measurement models. Solutions:
 - Extended Kalman Filter (EKF): local linearization representation.
 - Unscented Kalman filter: non-linear propagation of the mean and covariance using the unscented transform.

Missing measurements. Skip the correction step.

Multiple measurements. Choose the closest measurement.

Multiple measurements and multiple targets. Find the best global target assignment by computing a distance matrix.

The choice of the (generally probabilistic) distance metric is crucial in this data association problem.

| | | | |

Problem statement I

Definition (Segmentation)

Generally, the problem of segmentation consists in finding a set of non-overlapping regions R_1, \ldots, R_n such that

$$\mathcal{E} = \bigcup_{i=1}^{n} R_{n} \quad \text{and} \quad \forall i \neq j, \ R_{i} \cap R_{j} = \emptyset$$
 (179)

Definition (Alternative definition)

More formally, the segmentation process is an operator ϕ on an image I that outputs, for example, a binary image $\phi(I)$ that differentiates regions by selecting their borders.

An alternative consists to attribute a different label to each pixel of different regions (this is called *scene labeling*).

Problem statement II

Segmented image

Labelled image

Segmentation is a spatial process

As any similar operator, segmentation can be local or global:

- for *local* segmentation techniques, the results for one given pixel does not impact the segmentation result outside a close neighborhood.
- for global techniques, changing one pixel value can impact the whole result.

A first typology of segmentation techniques and comparisons

| Family of | input | local/global | markers |

 Segmentation
 Segmentation by thresholding
 Segmentation
 Segmentation

Rationale

There are two classes of pixels:

- **background** pixels
- **foreground** pixels

[Note that background and foreground do not refer to motion in this case!]. Sometimes, there is a "*don't know*" class

Assumptions to solve the segmentation problem:

• the probability density functions of the two content types are different.

one threshold or two thresholds (Otsu's method) are sufficient.

Segmentation by thresholding III

Computer Vision

Images can be seen as topographic surfaces

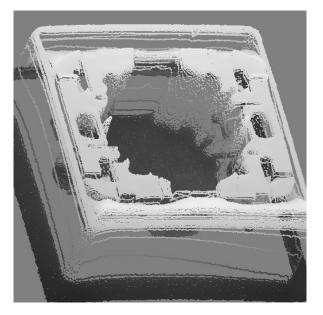

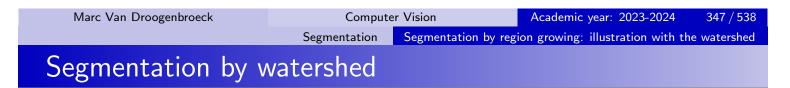

Figure: An image (left-hand side) and a view of its corresponding topographic surface (right-hand side).

In the terms of a topographic surface, a catchment basin C(M) is associated to every minimum M.

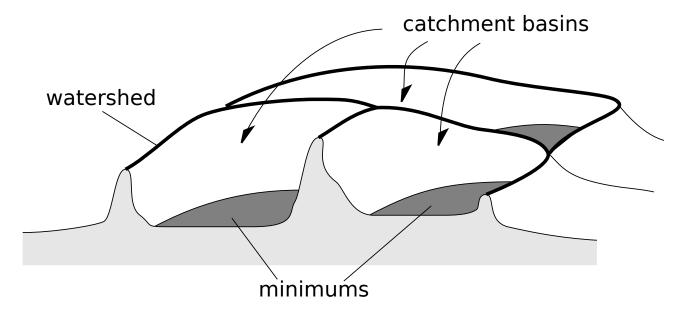

Figure: Minimums, catchment basins, and watershed.

Segmentation

Segmentation by region growing: illustration with the watershed

Image: Comparison of the segmentation

Image: Comparison of the segmentation

Image: Comparison of the segmentation of the segmentation

Image: Comparison of the segmentation

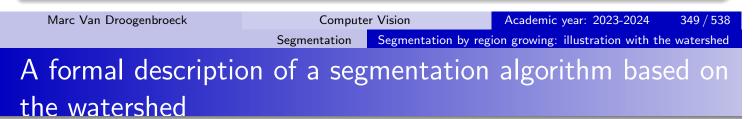

Image: Comparison of the segmentation of the segmentation

Image: Comparison of the segmentation

Image: Comparison of the segmentation of the segmentation

Steps:

- identify valleys (minimums)
- 2 proceed to flooding
- construct dams between neighboring catchment basins

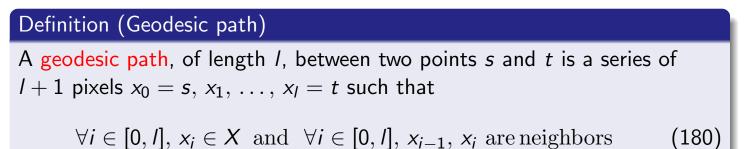

Approach: proceed level by level

- An horizontal "slice" is binary image. Therefore, we first study the case of binary images.
- definition of geodesic path and distance.
- description of an algorithm that handles a stack of thresholded images.

Geodesic path

Let X be a binary image.

Note that this definition applies to images defined on digital grids.

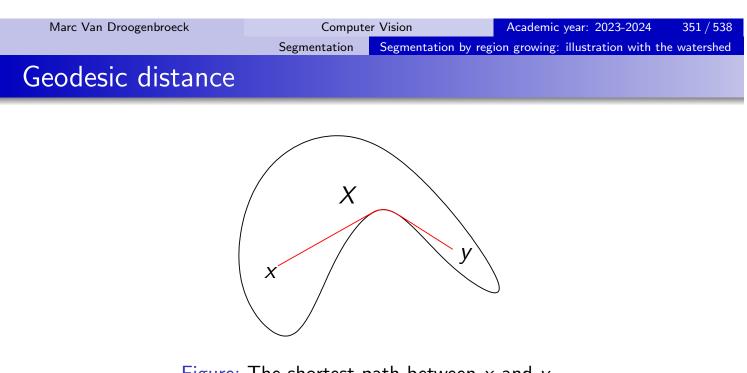

Figure: The shortest path between *x* and *y*.

Definition (Geodesic distance)

The geodesic distance between two points s and t is the length of the shortest geodesic path linking s to t; the distance is infinite if such a path does not exist.

Marc Van Droogenbroeck

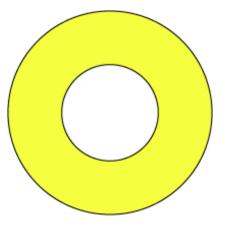

Computer Vision

Questions:

• is the geodesic *distance* between x and y *unique*?

Segmentation

Is the geodesic path between x and y unique?

Algorithm for the construction of the geodesic skeleton by growing the zone of influence

Notations:

The zone of influence of a set Z_i , is denoted by $ZI(domain = X, center = Z_i)$ and its frontier by $FR(domain = X, center = Z_i)$. The skeleton by zone of influence (SZI) is obtained via the following algorithm:

- first, one delineates the Z_i zones of each region;
- for remaining pixels, an iterative process is performed until stability is reached: if a pixel has a neighbor with an index *i*, then this pixel gets the same index; pixels with none or two different indices in their neighborhood are left unchanged;
- after all the iterations, all the pixels (except pixels at the interface) are allocated to one region of the starting regions Z_i.

Example

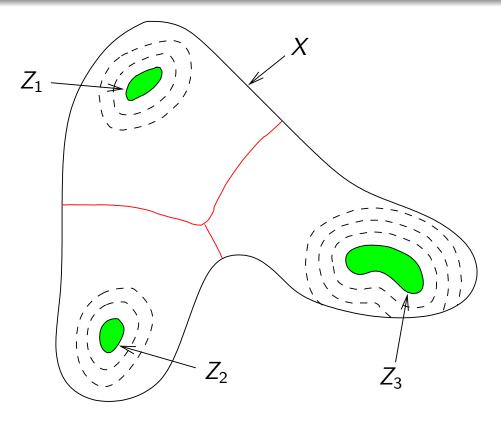

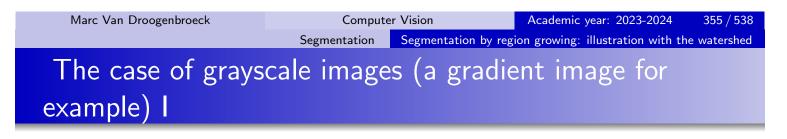

Figure: Geodesic skeleton.

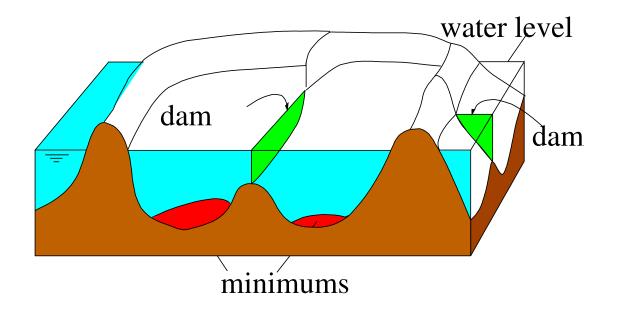

Figure: A dam is elevated between two neighboring catchment basins.

The case of grayscale images (a gradient image for example) II

Notations:

- ► f is the image.
- ▶ h_{min} and h_{max} are the limits of the range values of f on the function support (typically, $h_{min} = 0$ and $h_{max} = 255$).
- T_h(f) = {x ∈ dom f : f(x) ≤ h} is a set obtained by thresholding f with h. For h growing, we have a stack of decreasing sets.
- M_i are the minimums and $\mathcal{C}(M_i)$ are the catchment basins.

Let $C_h(M_i)$ be the subset of the M_i basin filled at "time" (or "height") h. Then

$$\mathcal{C}_h(M_i) = \mathcal{C}(M_i) \cap T_h(f) \tag{181}$$

In this expression, $C(M_i)$ is unknown.

Initialization:

C_{h min}(M) = T_{h min}(f); the initialization considers that all the local minimums are valid catchment basin originators.

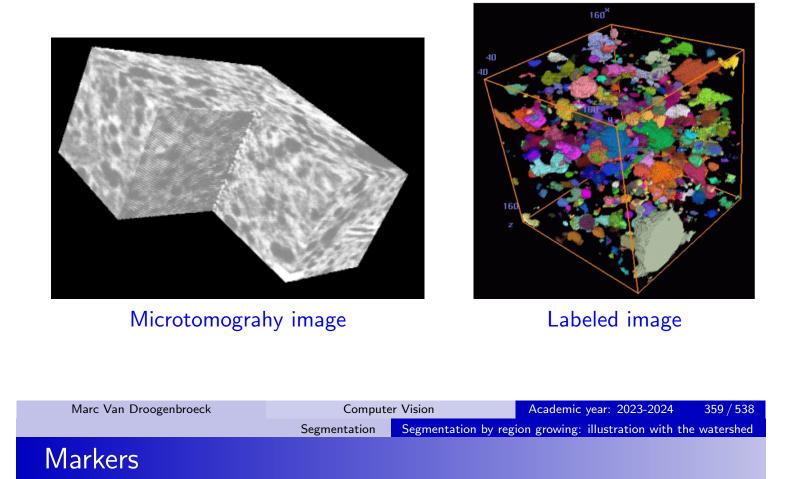

Construction

$$\forall h \in [h_{min} + 1, h_{max}] : \mathcal{C}_h(M) = ZI_h \cup Min_h$$
(182)

with

- ► ZI_h = influence zone (with domain $T_h(f)$);
- Min_h is the set of all the points of T_h(f) that have no label after the growing process of influence zones. They correspond to minimums that are introduced at level h.

Illustration: detection of pores in gypsum

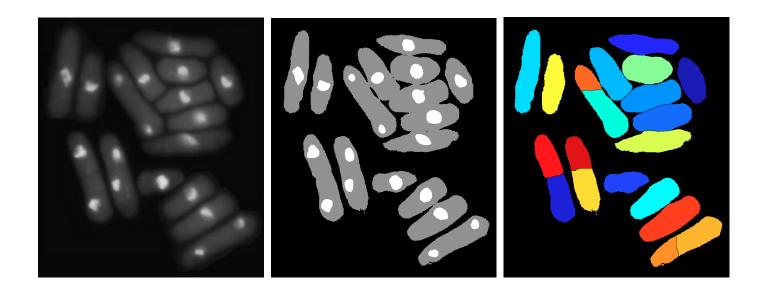

Marking is a process that allows to select only some of the local minimums.

Watershed has the following advantages with respect to other techniques (such as thresholding):

- the possibility to be applicable to any sort of input image (original image, gradient, etc).
- the flexibility to put some markers to select only a few local minimums. With markers, the amount of regions is exactly equal to the number of markers put in the image.

- Definition?
- Statistical characterization of textures
 - Local mean
 - Local standard deviation
 - Local histogram
 - Co-occurrence matrix of a grayscale image
- Geometrical characterization of textures
 - Spectral approach
 - Texture and energy

The major question related to texture are:

- texture analysis. The purpose is to characterize a texture by a set of parameters called "texture descriptors".
- texture recognition.
- image segmentation.

Definition (Tentative definition)

A texture is a signal than can be *extended naturally* outside of its domain.

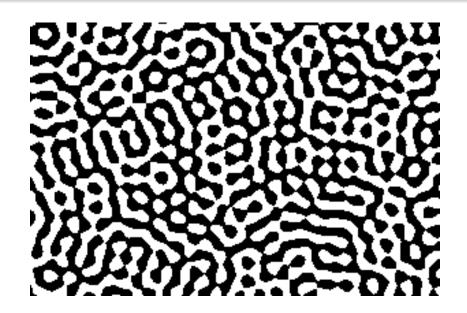

Figure: One possible texture (according to Lantuéjoul).

Object description and analysis

Texture analysis

Examples of "real" textures

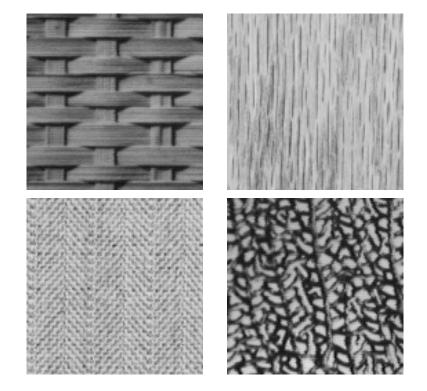

Figure: Example of an image with two textures.

Statistical descriptors of textures

Simple descriptors:

- mean
- variance

But, there is a problem

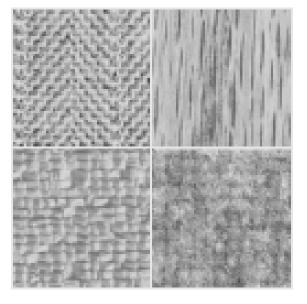

Figure: Textures with identical means and variances.

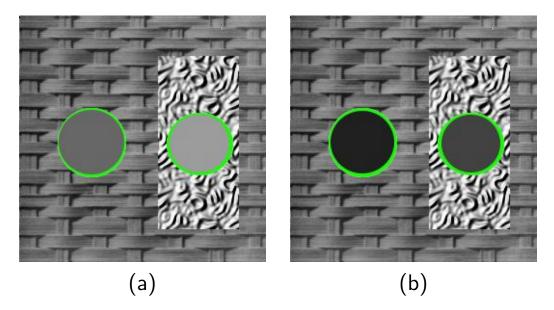

Figure: Illustration of texture statistics computed over a circle. (a) grayscale mean (103 and 156 respectively) (b) standard deviation (32 and 66 respectively).

Local statistics

Definition (Local mean)

The local mean over a spatial window W is defined as

$$\mu_{f} = \frac{1}{\sharp(\mathsf{W})} \sum_{(x,y)\in\mathsf{W}} f(x,y)$$
(183)

where $\sharp(W)$ is the cardinality of W.

Definition (Local standard deviation)

The standard deviation over a spatial window W is defined as

$$\sigma_f = \sqrt{\frac{\sum_{(x,y)\in \mathsf{W}} \left[f(x,y) - \mu_f\right]^2}{\sharp(\mathsf{W})}}$$
(184)

Definition (Histogram)

The *histogram* of an image is the curve that displays the frequency of each grayscale level.

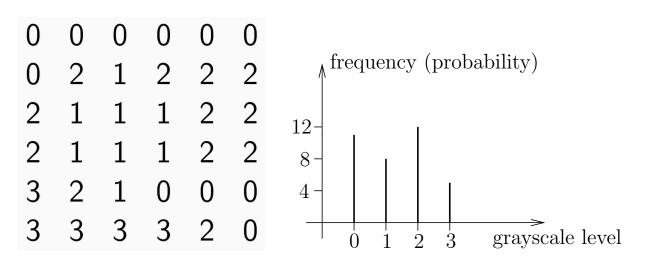

Figure: Non normalized histogram of an image.

Object description and analysis Texture analysis

Global and local histograms II

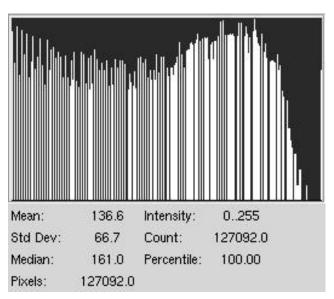

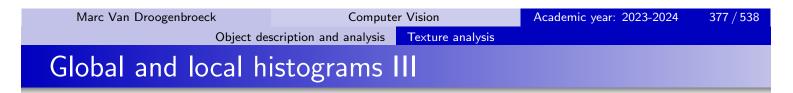

Figure: An image and its global histogram (here W accounts for the whole image domain).

Definition (Local histogram)

With a smaller window W, it is possible to define a local (normalized) histogram p(l) as

$$p(I) = \frac{\#\{(x, y) \in W \mid f(x, y) = I\}}{\#(W)}$$
(185)

378 / 538

Mean

$$\mu_L = \sum_{l=0}^{L-1} l \, p(l) \tag{186}$$

where L denotes the number of possible grayscale levels inside the W window.

Standard deviation

$$\sigma_L = \sqrt{\sum_{l=0}^{L-1} (l - \mu_L)^2 p(l)}$$
(187)

Obliquity

$$S_{s} = \frac{1}{\sigma_{L}^{3}} \sum_{l=0}^{L-1} (l - \mu_{L})^{3} p(l)$$
(188)

"Kurtosis"

$$S_k = \frac{1}{\sigma^4} \sum_{l=0}^{L-1} (l - \mu_L)^4 \, p(l) - 3 \tag{189}$$

| | | | | |

Co-occurrence matrix of a grayscale image I

Definition (Co-occurrence matrix)

A co-occurrence matrix is defined by means of a geometrical relationship R between two pixel locations (x_1, y_1) and (x_2, y_2) . An example of such a geometrical relationship is

$$x_2 = x_1 + 1 \tag{190}$$

$$y_2 = y_1$$
 (191)

for which (x_2, y_2) is at the right of (x_1, y_1) .

The co-occurrence matrix $C_R(i, j)$ is squared, with the $L \times L$ dimensions, where L is the range of all possible grayscale values inside of B. Indices of the co-occurrence matrix then indicates the amount of grayscale level value pairs as defined by R.

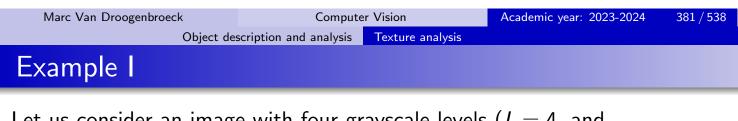

Object description and analysis

Construction of the $C_R(i,j)$ **matrix**:

- **1** Matrix initialization: $\forall i, j \in [0, L[: C_R(i, j) = 0.$
- 2 Filling the matrix. If the relationship/condition R between two pixels (x_1, y_1) and (x_2, y_2) is followed/met, then

 $C_R(f(x_1, y_1), f(x_2, y_2)) \leftarrow C_R(f(x_1, y_1), f(x_2, y_2)) + 1$

Texture analysis

Let us consider an image with four grayscale levels (L = 4, and l = 0, 1, 2, 3):

$$f(x,y) = \begin{array}{ccccc} 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 1 \\ 0 & 2 & 2 & 3 \\ 2 & 2 & 3 & 3 \end{array}$$
(192)

$$P_{0^{0},d}(i,j) = \#\{(x_{1},y_{1}), (x_{2},y_{2}) \in B \mid y_{1} = y_{2}, |x_{2} - x_{1}| = d, \\ f(x_{1},y_{1}) = i \text{ and } f(x_{2},y_{2}) = j\}$$
(193)

The $P_{0^0,1}$ and $P_{90^0,1}$ matrices are 4 \times 4 matrices respectively given by

$$P_{0^{0},1} = \begin{bmatrix} 6 & 2 & 1 & 0 \\ 2 & 2 & 0 & 0 \\ 1 & 0 & 4 & 2 \\ 0 & 0 & 2 & 2 \end{bmatrix} \qquad P_{90^{0},1} = \begin{bmatrix} 6 & 1 & 2 & 0 \\ 1 & 2 & 1 & 1 \\ 2 & 1 & 2 & 1 \\ 0 & 1 & 1 & 2 \end{bmatrix}$$
(194)

Example II

About the use of co-occurrence matrices:

[+] Rich information about the texture

 [-] Explosion of the number of features in the case of small textures

Use of the Fourier transform

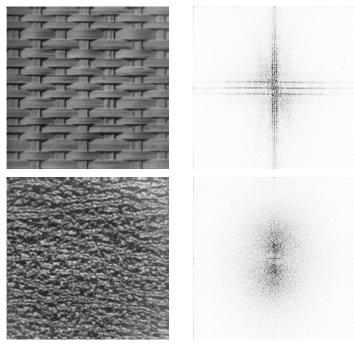

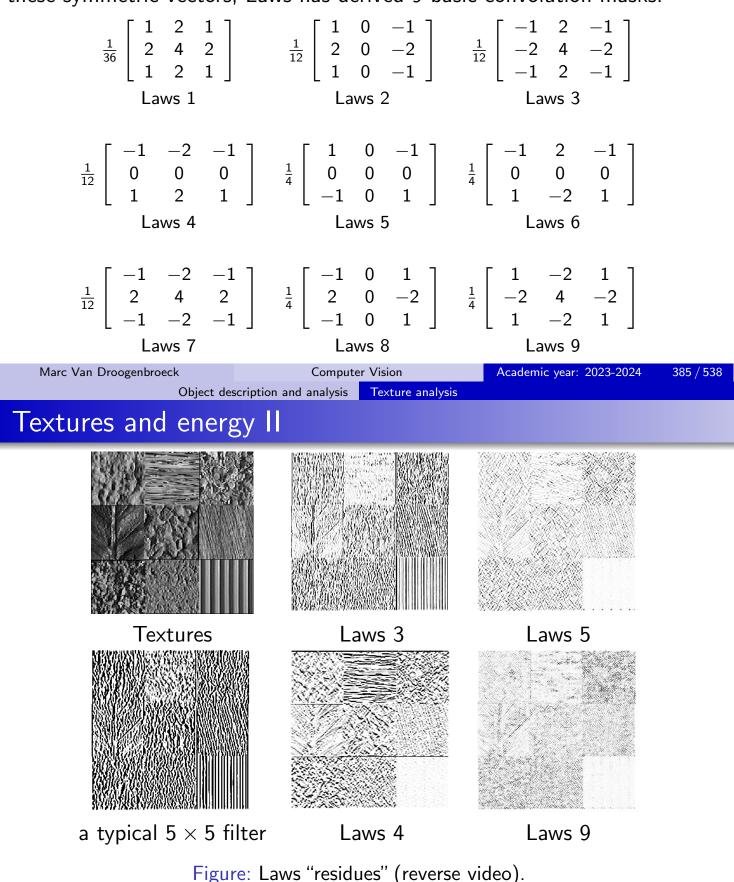

Figure: Spectral characterization of a texture. Right-hand images are the modules of the Fourier transforms (inverse video).

Textures and energy I

Measures are derived from three simple vectors: (1) $L_3 = (1, 2, 1)$ that computes the *mean*, (2) $E_3 = (-1, 0, 1)$ that detects edges, and (3) $S_3 = (-1, 2, -1)$ which corresponds to the second derivate. By convolving these symmetric vectors, Laws has derived 9 basic convolution masks:

Some shape descriptors see the object as:

a binary function

$$f(x,y) = \begin{cases} 1 & \text{if } (x,y) \text{ belongs to the object} \\ 0 & \text{otherwise} \end{cases}$$
(195)

a series of points in the complex 2D space

$$s[n] = x[n] + jy[n] \tag{196}$$

s[n] is a one-dimensional discrete collection of complex numbers.

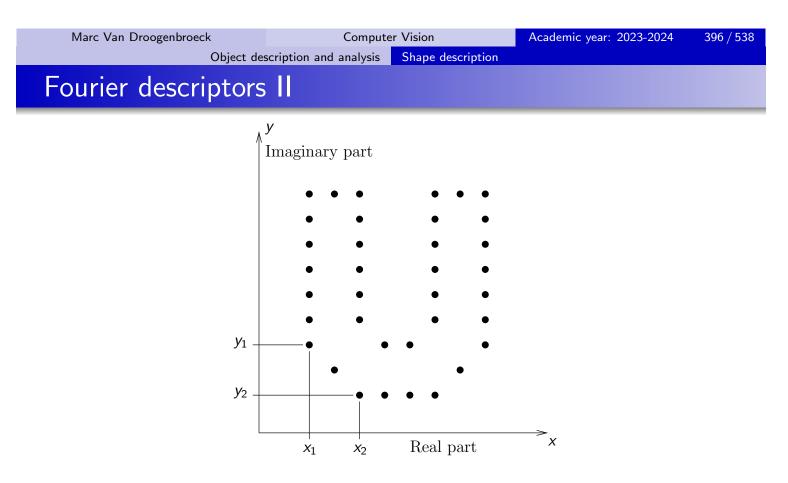

Figure: Representation of a shape as a series of points in the complex 2D space.

Fourier descriptors III

Definition (Fourier descriptor)

The discrete Fourier transform of s[n] is defined as

$$S[u] = \frac{1}{N} \sum_{n=0}^{N-1} s[n] e^{-2\pi j u n/N}$$
(197)

The S[u] coefficients are the Fourier descriptors of the shape.

Approximations.

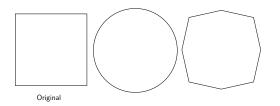

Figure: Original shape and approximations with a selection of Fourier descriptors.

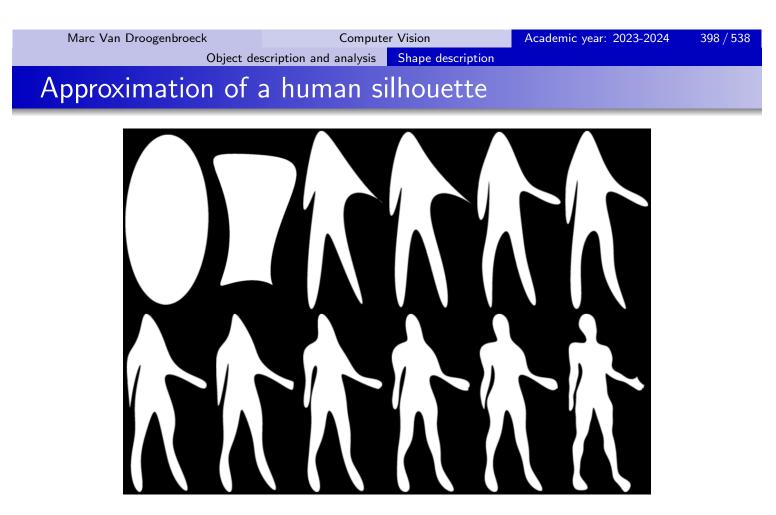

Figure: Approximations of a human silhouette by an increasing number of Fourier descriptors.

The quadtree as a shape descriptor

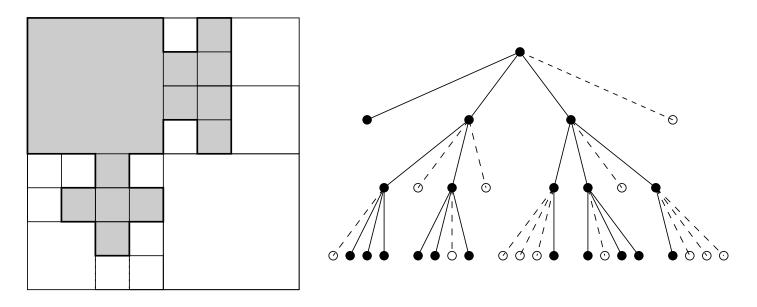

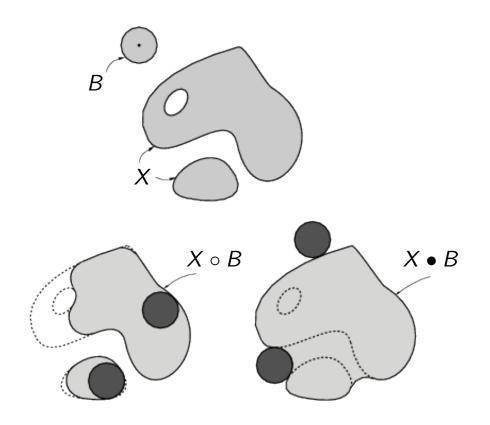

Figure: Quadtree decomposition and quadtree representation.

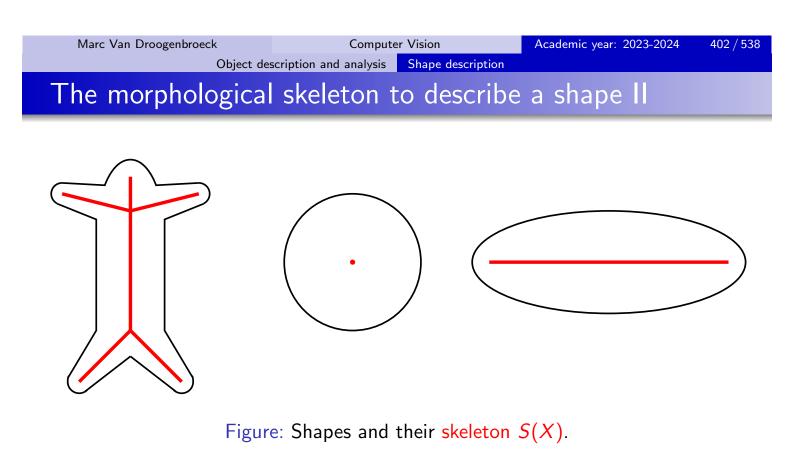

The morphological skeleton to describe a shape I

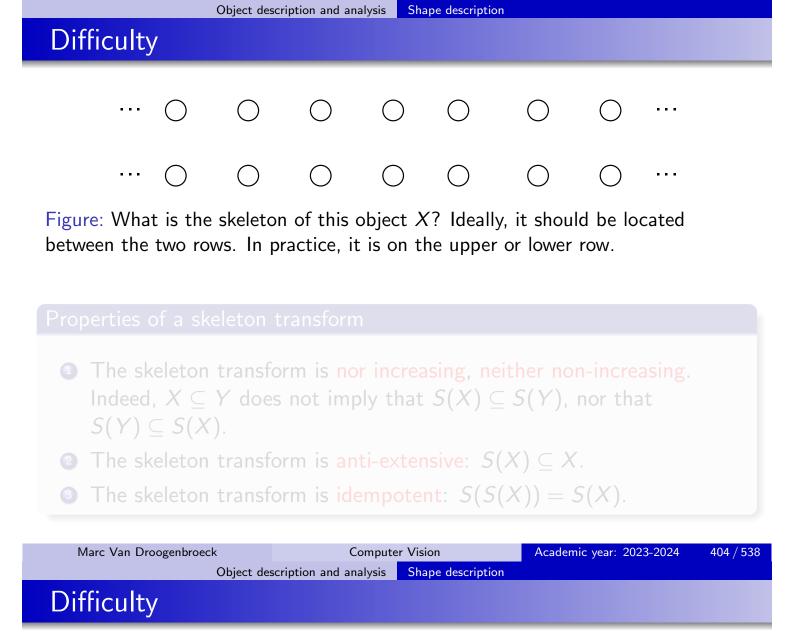

First attempts to define the skeleton

- Consider a continuous set X and its frontier ∂X; an element x of the object X belongs to the skeleton of X, denoted by S(X), if there exists a disk centered on x, included in X, that touches ∂X at least twice (maximal balls with two contact points).
- ► Locus of the center of all the maximal balls *B* contained in *X*.

These definitions are not fully equivalent, but they have the same topological closure in \mathbb{R}^2 .

Skeletons are sensitive to noise on the object.

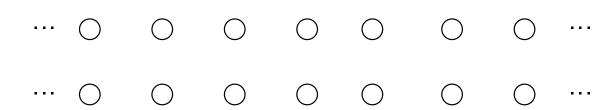

Figure: What is the skeleton of this object X? Ideally, it should be located between the two rows. In practice, it is on the upper or lower row.

Properties of a skeleton transform

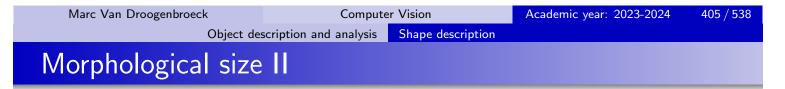

- The skeleton transform is nor increasing, neither non-increasing. Indeed, $X \subseteq Y$ does not imply that $S(X) \subseteq S(Y)$, nor that $S(Y) \subseteq S(X)$.
- 2 The skeleton transform is anti-extensive: $S(X) \subseteq X$.
- The skeleton transform is idempotent: S(S(X)) = S(X).

Definition (Continuous object size)

Let B be a continuous set whose size is arbitrary set to 1. Then, we can define a scale space of continuous sets by

$$rB = \{rb|b \in B\} \ r \ge 0 \tag{198}$$

where r is a continuous parameter.

Definition

The *dilation* (*dilatation* in French!) of X by B is defined as

$$X \oplus B = \{x + b | x \in X, b \in B\}$$
(199)

Definition (Discrete object size)

Let *B* be a discrete, convex, finite, set of \mathbb{Z}^2 , whose size is arbitrary set to 1. Then, we build a family of homethetic versions of *B*, for n = 0, 1, ..., by

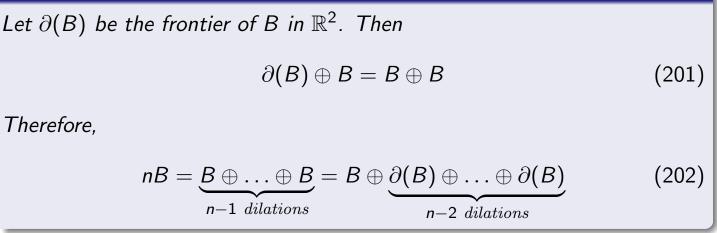

$$nB = \underbrace{B \oplus \ldots \oplus B}_{n-1 \text{ dilations}}$$
(200)

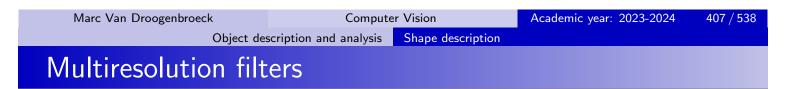

In this expression, nB is obtained as a cascade of (n-1) successive dilations. By convention, for n = 0, $0B = \{(0,0)\}$. Note that $nB \oplus mB = (n+m) \oplus B$ for every n, m.

Computer Vision

Morphological size III

Theorem

Definition

We define the multiresolution opening and closing respectively as

$$X \circ nB = (X \ominus nB) \oplus nB \tag{203}$$

$$X \bullet nB = (X \oplus nB) \ominus nB$$
 (204)

Since $(X \ominus B) \ominus C = X \ominus (B \oplus C)$ and $(X \oplus B) \oplus C = X \oplus (B \oplus C)$, $X \circ nB = [(X \ominus B) \ominus B \dots \ominus B] \oplus B \oplus B \dots \oplus B$ (205)

n erosions

n dilations

By definition,

$$X \circ nB = \bigcup_{(nB)_z \subseteq X} (nB)_z$$
(206)

Formal definition of the skeleton I

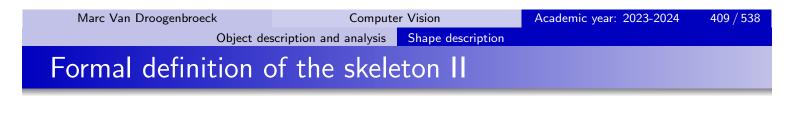

Definition (Skeleton [Lantuéjoul])

The skeleton of a set X is the union of a family of subsets S_n , each of them being the set of references to translates of nB included in X, except all the references of translates of (n + 1)B contained in X. Formally, we have

$$S_n(X) = (X \ominus nB) \setminus ([X \ominus nB] \circ B), \ n = 0, 1, \dots, N$$
(207)

$$S(X) = \bigcup_{n=0}^{N} S_n(X)$$
(208)

where B is a 2×2 wide pixels set for a square digital grid or an hexagon for an hexagonal grid.

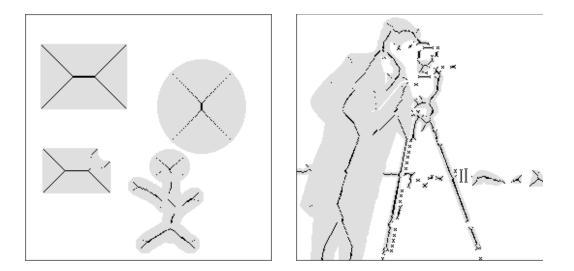

Figure: Some skeletons obtained with Lantuéjoul's formula.

Inverse skeleton

We define

$$\pi(X) = [[[S_N(X) \oplus B] \cup S_{N-1}(X)] \oplus B \cup S_{N-2}(X)...] \oplus B \cup S_0(X)$$
(209)

It can be shown that

$$\pi(X) = \bigcup_{n=0}^{N} [S_n(X) \oplus nB] = X$$
(210)

 \Rightarrow it is possible to reconstruct the shape perfectly based on the skeleton

Definition (Distance function)

The distance function of a set $X \subseteq \mathcal{E}$, denoted by $\phi(X)$, is defined as

$$[\phi(X)](h) = d(X^c, h) \tag{211}$$

with the convention that $d(\emptyset, h) = +\infty$ for $h \in \mathcal{E}$.

Computer Vision

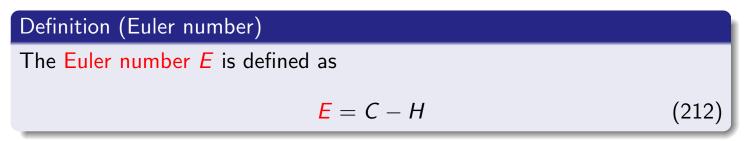

416 / 538

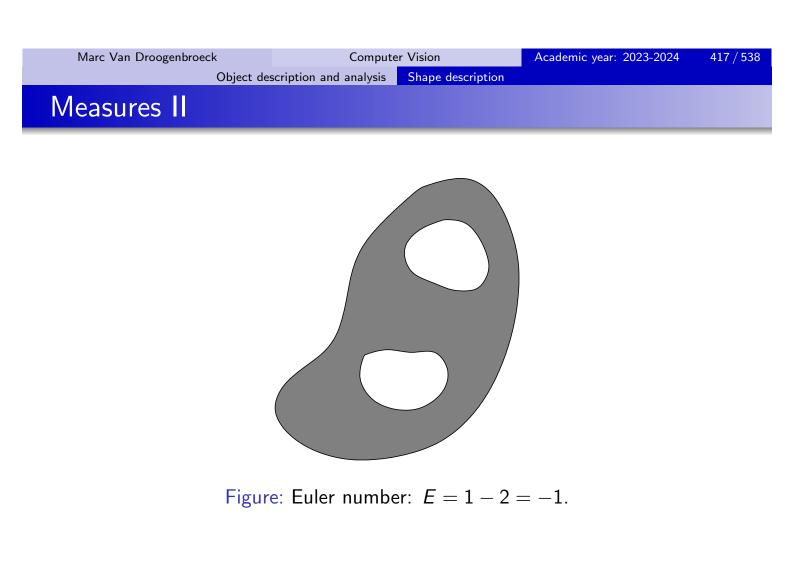

Measures I

There are three fundamental measures

- Perimeter
- 2 Area
- Euler-Poincarré number

There is a relationship between the number of connected components C and the number of holes H.

Measures III

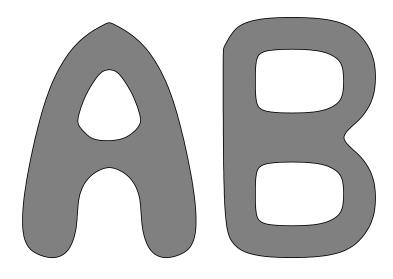

Figure: Two letters with a different Euler number.

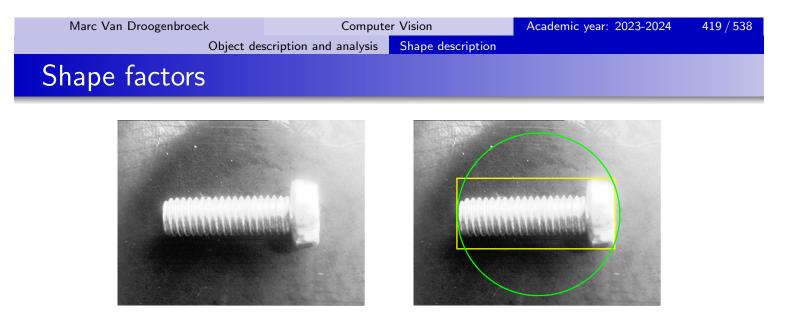

Figure: An object X and two reference sets (circumscribing disk/ellipse and smallest rectangular bounding box R).

| Shape factor name | Expression |
|-------------------|--------------------------------------|
| compactdness | $\frac{P(X)^2}{4\pi A(X)}$ |
| rectangularity | $\frac{A(X)}{A(R)}$ |
| circularity | $\frac{4A(X)}{\pi D_{max}^2}$ |
| anisometry | D _{max} D _{min} |

Moments

Moments are surfacic measures, used for example in character recognition. Remember that we can see an object as a binary function

$$f(x, y) = \begin{cases} 1 & \text{if } (x, y) \text{ belongs to the object} \\ 0 & \text{otherwise} \end{cases}$$
(213)

Definition (Moment of order p + q)

The p + q moment of a function f(x, y) is defined as

$$m_{pq} = \sum_{x} \sum_{y} x^{p} y^{q} f(x, y)$$
(214)

All these moments can be centered:

$$\mu_{pq} = \sum_{x} \sum_{y} (x - m_{10})^{p} (y - m_{01})^{q} f(x, y)$$
(215)

and they can be normalized:

$$\eta_{pq} = \frac{\mu_{pq}}{\mu_{00}^{\frac{p+3}{2}}}$$
(216)

Granulometry is an approach to compute a size distribution of grains in binary images, using a series of opening operations.

Consider a ball nB whose radius is given by n, then we define a granulometric curve by

$$\psi(n) = A(X \circ nB) \tag{217}$$

where A() denotes the area.

Abrupt changes is this curve are interesting for detecting typical sizes.

Definition (Pattern spectrum)

The Pattern Spectrum (PS) is defined as

$$\mathsf{PS}(n) = -\frac{A(X \circ nB)}{dn}$$

Marc Van Droogenbroeck

(218)

422 / 538

Morphological measures and granulometry II

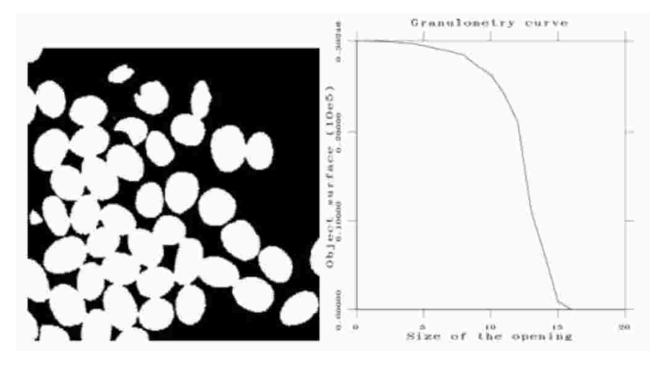

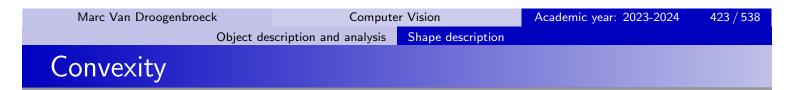

Figure: A binary object and a corresponding granulometric curve.

Definition (Convexity)

A set $X \subseteq \mathcal{E}$ is convex if $rx + (1 - r)y \in X$ for every $x, y \in X$ where $r \in [0, 1].$

In other words, a line joining two arbitrary points of X has to be entirely included in X.

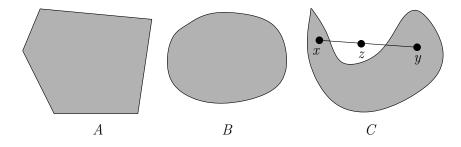

Figure: A, B are convex; C is not convex.

Convex envelope I

The notion of convexity leads to that of convex envelope

Definition (Convex envelope)

The convex envelope of a set $X \subseteq \mathcal{E}$, denoted by co(X), is the intersection of all the convex sets comprising X.

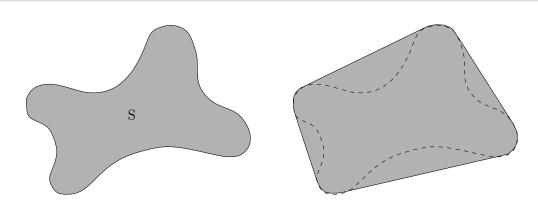

Figure: A set X and its convex envelope.

| Marc Van Droogenbroeck | Computer Vision | | Academic year: 2023-2024 | 425 / 538 |
|---------------------------------|-----------------|-------------------|--------------------------|-----------|
| Object description and analysis | | Shape description | | |
| Convex envelope II | | | | |

TheoremFor
$$X, Y \subseteq \mathcal{E}$$
, $co(X \oplus Y) = co(X) \oplus co(Y)$ (219)

Definition (Convexity shape factor)

The convexity shape factor is defined as

$$C = \frac{A(X)}{A(co(X))} \tag{220}$$

Template matching - Example

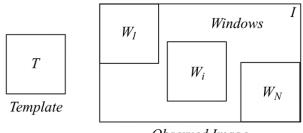

Template matching - Definition

Definition

Template matching is the process of either finding any instance of a template image T within another image I or finding which ones of the templates T_1, T_2, \ldots, T_N correspond in some way to another image I.

We search how to transform or warp a template (resp. image) to make it similar to a reference image (resp. template).

The template is also called the pattern or the model.

Figure: Find where the template T is located in the observed image I.

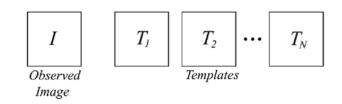

Figure: Find the template T_k which correspond to the observed image I.

Image registration or alignment - Example

Image registration or alignment - Definition

Definition

Image registration is the process of spatially aligning two images of a scene/object so that corresponding points assume the same coordinates.

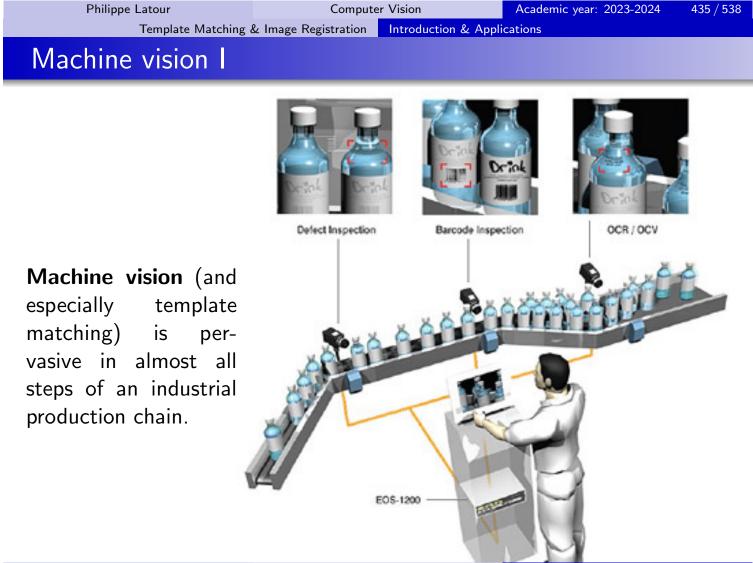

Given two images taken, for example,

- at different times.
- from different devices
- or different point of view;
- the goal is to determine a reasonable transformation of the images
- such that a transformed version of the first image is similar to the second one.

 Template Matching & Image Registration
 Introduction & Applications

Template matching vs. Image registration

- Template matching and image registration processes have essentially the same goal:
 - They compare two (or more) images, and
 - look for a transformation/warping of one (or both) image(s),
 - in order to match/align the images (to make them fit).

They differ by the way users consider the images;

• In template matching, one of the image is special (the template) and is often (not always) smaller in size.

The other image represents/spans the *work space* where we would like to *locate* the template.

 In image registration both images play a similar role. They are both embedded in a global *work space* where we would like to find their relative *position*.

Table of content

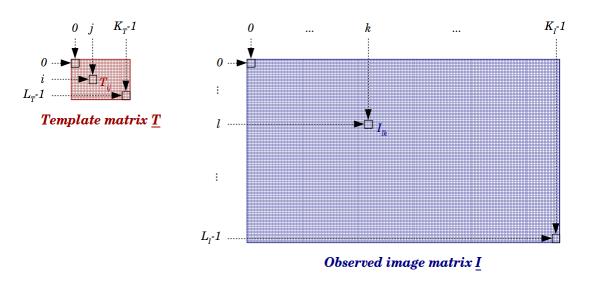

Introduction & Applications.

- Some solutions and their corresponding approach.
 - Naive solution & Block diagram.
 - Pixel based approach.
 - Feature based approach.
 - Comparisons.
- Template matching & image registration components.
- Implementation speed-up.

Naive solution I

We consider:

- ▶ the image I with L_I lines and K_I columns, represented by the matrix $\underline{I} = (I_{lk})$ where $I \in [0, L_I[, k \in [0, K_I[,$
- ▶ the template **T** with L_T lines and K_T columns, represented by the matrix $\underline{T} = (T_{ij})$ where $i \in [0, L_T[, j \in [0, K_T[.$

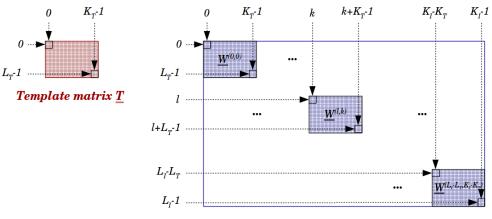

We define all the admissible (sub-)windows $W^{(l,k)}$ completely included within the image I and of the same size as the template **T** by the following sub-matrices $\underline{W}^{(l,k)}$:

$$W_{ij}^{(l,k)} = \begin{cases} I_{l+i,k+j} & \text{for } i \in [0, L_T - 1], \ j \in [0, K_T - 1] \\ 0 & \text{otherwise} \end{cases}$$
(221)

where $I \in [0, L_I - L_T]$ and $k \in [0, K_I - K_T]$ are the indices, in the image I, of the upper left pixel of $W^{(I,k)}$.

Observed image matrix I

Naive solution III

Compute the Euclidean distance

$$\operatorname{dist}\left(\underline{T},\underline{W}^{(l,k)}\right) = \sum_{i=0}^{L_T - 1} \sum_{j=0}^{K_T - 1} \left[T_{ij} - W_{ij}^{(l,k)}\right]^2$$
(222)

then create the distance map **D**, represented by the matrix \underline{D} :

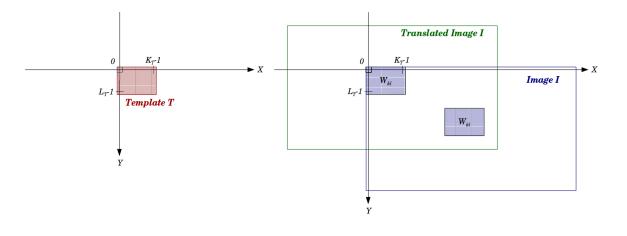

$$D_{\lfloor \frac{K_T}{2} \rfloor + k, \lfloor \frac{L_T}{2} \rfloor + l} = \begin{cases} \operatorname{dist}\left(\underline{T}, \underline{W}^{(l,k)}\right) & \text{for } l \in [0, L_l - L_T], \ k \in [0, K_l - K_T] \\ 0 & \text{otherwise} \end{cases}$$
(223)

and find the position of the minimum in these map.

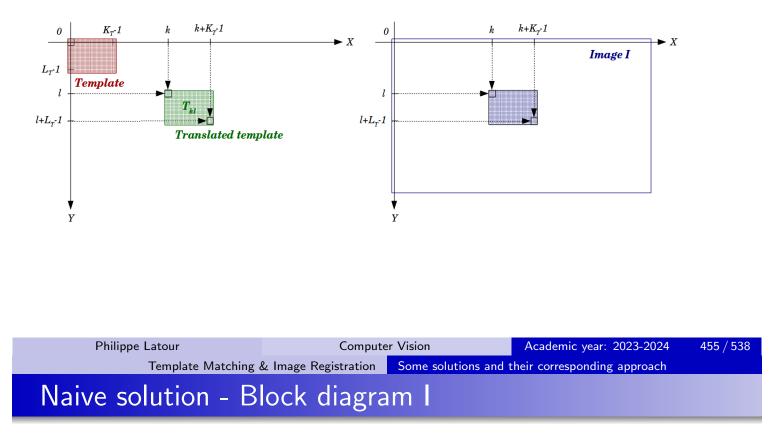

Previously, in the naive solution, we matched the template T to a part of the translated version of the image (the sub-image function $W_{k,l}(x,y) = l(x+k,y+l)$).

In pixel coordinates, this may be illustrated by:

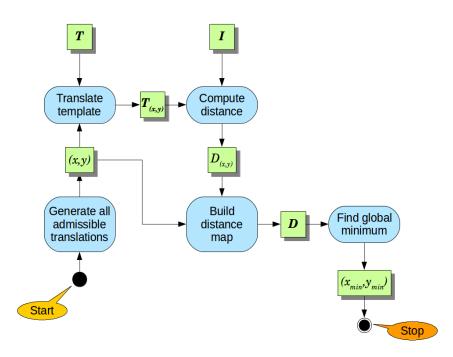

Naive solution in pixel coordinates - Template translation

It is equivalent to match a translated template to the original image:

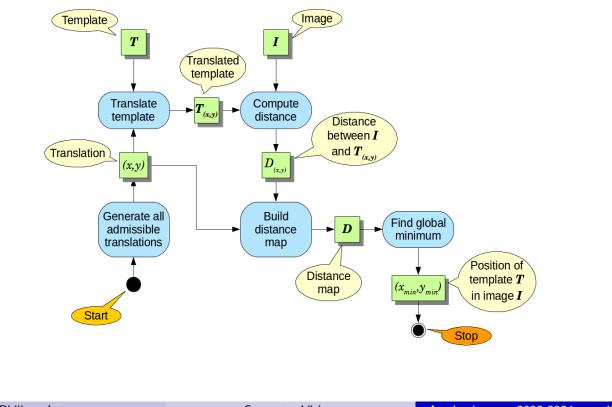

The block diagram of this pixel based (naive) solution is:

Naive solution - Block diagram II

The block diagram of this pixel based (naive) solution is:

 Template Matching & Image Registration
 Some solutions and their corresponding approach

 Pixel-based ... ?

Question?

Which "elements" are we going to match in the reference and template images ?

All pixels of an image/template:

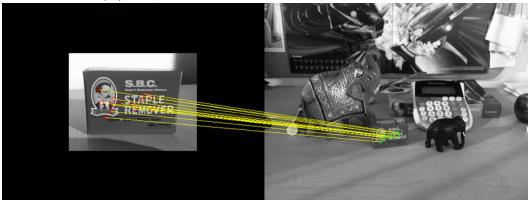

- For all warped templates, compare all pairs of corresponding pixels (\equiv located at the same place in the images and the warped template).
- Then compute a global score based on the individuals comparisons.
- And choose the warping for which the score is maximum/minimum

... or Feature-based ?

Question?

Which "elements" are we going to match in the reference and template images ?

"Interesting" points of an image/template:

- First search for the feature points in the image/template,
- Then find the best matching between feature points in the image and the template
- And finally compute the warping based on the best feature points matching

Introduction & Applications.

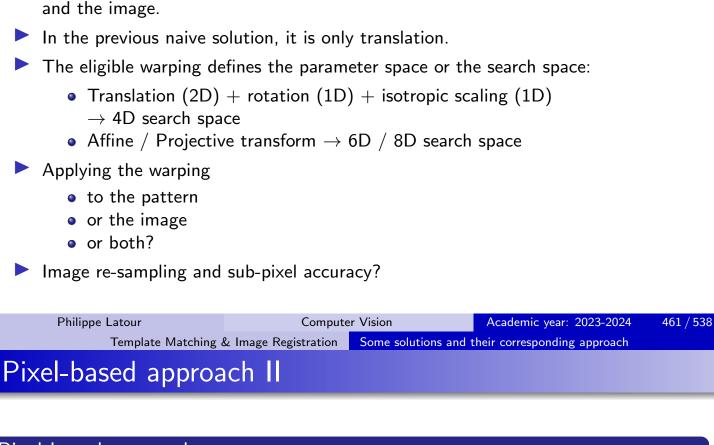

- Some solutions and their corresponding approach.
 - Naive solution & Block diagram.
 - Pixel based approach.
 - Feature based approach.
 - Comparisons.
- Template matching & image registration components.
- Implementation speed-up.

Pixel-based approach I

Pixel-based approach

Shift or warp the images relatively to each other, then look at how much the pixels agree and find the warping parameters for which the agreement is maximum.

So, we first need to decide which kind of warping is eligible between the template

Pixel-based approach

Shift or warp the images relatively to each other, then look at how much the pixels agree and find the warping parameters for which the agreement is maximum.

- Then a suitable similarity or dissimilarity measure must be chosen to compare the images
- In the previous naive solution, it is the Euclidean distance.
- The similarity or dissimilarity measure depend on the image characteristics to which it is necessary to be invariant. The insensitivity properties guide the choice of a score/distance measure.
 - Lighting conditions (linear gain and offset)
 - Noise
 - "Small" rotation or scaling
 - Thinning
 - $\bullet \rightarrow$ Define the similarity/dissimilarity measure

Pixel-based approach III

Pixel-based approach

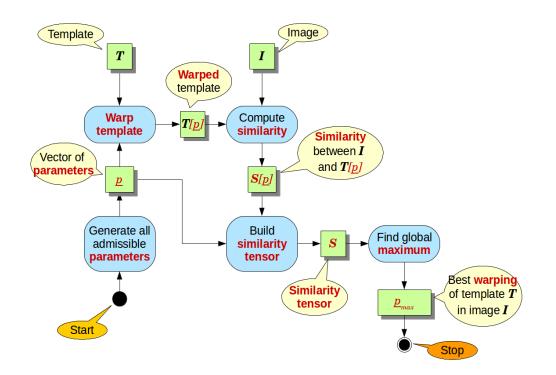

Shift or warp the images relatively to each other, then look at how much the pixels agree and find the warping parameters for which the agreement is maximum.

- In the previous naive solution, we try all possible alignment (an exhaustive search).
 But this solution is often impractical and hierarchical coarse-to-fine techniques based on image pyramids are often used.
 The search technique must be devised:

 Exhaustive search
 Coarse to fine hierarchical refinement.
 - Steepest descent
 - Conjugate gradient
 - Quasi-Newton method
 - Levenberg-Marquardt
 - Simulated annealing

- Implementation speed-up.

Feature-based approach

Feature-based approach

In both images, extract feature points and compute their descriptor vector. Then, match the corresponding feature points and compute the image warping that transforms at best (maximum agreement) each feature points into its corresponding one.

Let's consider two images of the same (or similar/related) scene/object taken

- at different moment, or
- from a different point of view, or
- with different sensor (parameters).

|---------------------|----------------------|----------------------|------------------------------|-----------|
| Template Matching a | & Image Registration | Some solutions and t | their corresponding approach | |

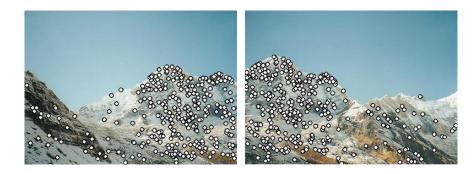

Feature points definition I

Feature-based approach

In both images, extract feature points and compute their descriptor vector. Then, match the corresponding feature points and compute the image warping that transforms at best (maximum agreement) each feature points into its corresponding one.

Feature points in each image carry critical information about (local) scene structure.

- Also called critical points, interest points, key points, extremal points, anchor points, landmarks, control points, tie points.
- For instance corners, vertices, junctions, edges, dark/light blob center, unique patches, moments, ...

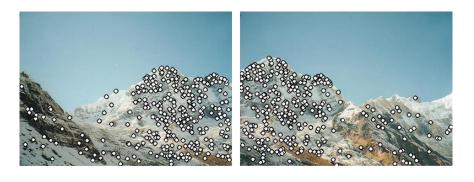

Feature points definition II

Feature-based approach

In both images, extract feature points and compute their descriptor vector. Then, match the corresponding feature points and compute the image warping that transforms at best (maximum agreement) each feature points into its corresponding one.

Feature points are/should be:

- Independent of noise, blurring, contrast, lightning conditions.
- Dependent or Independent of geometric changes (rotation, scaling, affine) transform).
- Widely used in image analysis (not only for image registration).

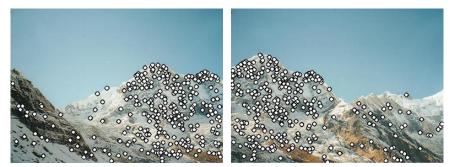

Feature points definition III

Feature-based approach

In both images, extract feature points and compute their descriptor vector. Then, match the corresponding feature points and compute the image warping that transforms at best (maximum agreement) each feature points into its corresponding one.

- Defining and computing a "featureness" function
 - Invariant to some image variation (translation, rotation, scaling, brightness, contrast, ...)
 - For instance; central moments, pixel intensity variances, gradient module, LoG/DoG, entropy, Harris cornerness, ...
- And keeping only the most-significant maxima/minima/zeroes of the "featureness" function.

Philippe Latour

Academic year: 2023-2024

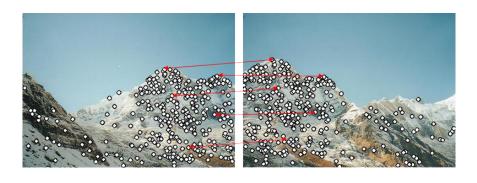

Feature points representation & matching I

Feature-based approach

In both images, extract feature points and compute their descriptor vector. Then, match the corresponding feature points and compute the image warping that transforms at best (maximum agreement) each feature points into its corresponding one.

Represent each feature point by a descriptor vector

- Vector of characteristic values describing the feature point in an unique and discriminatory way.
- Position, gradient, image moment, scale, orientation, Histogram Of Gradients (HOG), Local Binary Pattern (LPB), ...

| Philippe Latour Computer V | | r Vision | Academic year: 2023-2024 | 471 / 538 |
|--|--|----------------------|-----------------------------|-----------|
| Template Matching & Image Registration | | Some solutions and t | heir corresponding approach | |
| | | | | |

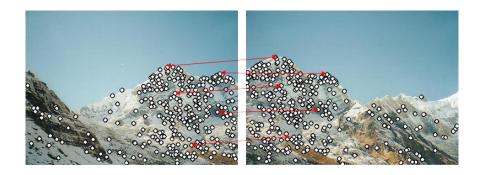

Feature points representation & matching II

Feature-based approach

In both images, extract feature points and compute their descriptor vector. Then, match the corresponding feature points and compute the image warping that transforms at best (maximum agreement) each feature points into its corresponding one.

Find/match the corresponding feature points in both images:

Compare the descriptor vectors to find the best correspondence between feature points in each images.

Feature points transformation

Feature-based approach

In both images, extract feature points and compute their descriptor vector. Then, match the corresponding feature points and compute the image warping that transforms at best (maximum agreement) each feature points into its corresponding one.

Compute the transformation/warping such that the feature points in the left image fit their corresponding point in the right image.

- Define which kind of warping is admissible; rigid global warping (homography) or elastic/local warping.
- Use robust fitting methods:
 - RANSAC,
 - Hough Transform,
 - ICP (Iterative Closest Point)

Given two corresponding sequences of measurement {a_i | i = 1, · · · , n} and {b_i | i = 1, · · · , n}, we will represent them by the following (column) vectors:

•
$$\underline{A} = (a_i)_{i=1,\cdots,n} \in \mathbb{R}^n$$

•
$$\underline{B} = (b_i)_{i=1,\cdots,n} \in \mathbb{R}^n$$

- <u>A</u> and <u>B</u> might represent measurements from two objects or phenomena. Here, in our case, we assume they represent images and a_i and b_i are the intensities of the corresponding pixels in the images.
- The similarity (dissimilarity) between them is a measure that quantifies the dependency (independency) between the sequences.
- In the naive solution, we used the Euclidean distance (the square L2 norm).

Pearson correlation coefficient

Definition

The Pearson correlation coefficient of two vectors \underline{A} and \underline{B} is:

$$r(\underline{A},\underline{B}) = \frac{covar(\underline{A},\underline{B})}{\sqrt{var(\underline{A})var(\underline{B})}}$$
(224)

With the usual notations:

$$\mu_{A} = \frac{1}{n} \sum_{i=1}^{n} a_{i} \qquad \text{var} (\underline{A}) = \sigma_{A}^{2} = \frac{1}{n} \sum_{i=1}^{n} (a_{i} - \mu_{A})^{2} = \frac{1}{n} \sum_{i=1}^{n} a_{i}^{2} - \mu_{A}^{2}$$

$$\mu_{B} = \frac{1}{n} \sum_{i=1}^{n} b_{i} \qquad \text{var} (\underline{B}) = \sigma_{B}^{2} = \frac{1}{n} \sum_{i=1}^{n} (b_{i} - \mu_{B})^{2} = \frac{1}{n} \sum_{i=1}^{n} b_{i}^{2} - \mu_{B}^{2}$$

$$\text{covar} (\underline{A}, \underline{B}) = \frac{1}{n} \sum_{i=1}^{n} (a_{i} - \mu_{A}) (b_{i} - \mu_{B}) = \frac{1}{n} \sum_{i=1}^{n} a_{i} b_{i} - \mu_{A} \mu_{B}$$
We may write:

We may write:

$$r\left(\underline{A},\underline{B}\right) = \frac{\frac{1}{n}\sum_{i=1}^{n} (a_i - \mu_A) (b_i - \mu_B)}{\sqrt{\frac{1}{n}\sum_{i=1}^{n} (a_i - \mu_A)^2} \sqrt{\frac{1}{n}\sum_{i=1}^{n} (b_i - \mu_B)^2}}$$
$$r\left(\underline{A},\underline{B}\right) = \frac{\frac{1}{n}\sum_{i=1}^{n} a_i b_i - \mu_A \mu_B}{\sqrt{\frac{1}{n}\sum_{i=1}^{n} a_i^2 - \mu_A^2} \sqrt{\frac{1}{n}\sum_{i=1}^{n} b_i^2 - \mu_B^2}}$$

The Pearson coefficient $r(\underline{A}, \underline{B})$ is then easily computed with one pass on the images \underline{A} and *B*. Philippe Latour Computer Vision Academic year: 2023-2024 483 / 538

Template Matching & Image Registration Template matching & image registration components

Pearson correlation coefficient properties I

If we introduce the reduced or normalized vectors:

$$\underline{\tilde{A}} = \frac{1}{\sigma_A} (\underline{A} - \mu_A \underline{1}) \text{ and } \underline{\tilde{B}} = \frac{1}{\sigma_B} (\underline{B} - \mu_B \underline{1})$$

We have the following relation:

Theorem

$$r(\underline{A},\underline{B}) = \frac{1}{n} \underline{\tilde{A}}^{T} \underline{\tilde{B}} = r(\underline{\tilde{A}},\underline{\tilde{B}})$$
(225)

Which is obvious from

$$r\left(\underline{A},\underline{B}\right) = \frac{1}{n} \sum_{i=1}^{n} \left(\frac{a_{i} - \mu_{A}}{\sigma_{A}}\right) \left(\frac{b_{i} - \mu_{B}}{\sigma_{B}}\right) = \frac{1}{n} \underline{\tilde{A}}^{T} \underline{\tilde{B}} = r\left(\underline{\tilde{A}},\underline{\tilde{B}}\right)$$

Philippe Latour

Template Matching & Image Registration Template matching & image registration components

Pearson correlation coefficient properties II

The Pearson coefficient doesn't depend on the image's gain and offset.

Theorem (Invariance to affine transformation of pixel values)

For any values $\alpha, \beta, \gamma, \delta$ such that $\alpha \neq 0$ and $\gamma \neq 0$, we have:

$$r\left(\alpha\underline{A} + \beta\underline{1}, \gamma\underline{B} + \delta\underline{1}\right) = sign\left(\alpha\gamma\right)r\left(\underline{A},\underline{B}\right)$$

This result comes immediately from

$$(\alpha \underline{A} + \beta \underline{1}) = \frac{1}{|\alpha| \sigma_{A}} \left[(\alpha \underline{A} + \beta \underline{1}) - (\alpha \mu_{A} + \beta) \underline{1} \right] = \frac{\operatorname{sign}(\alpha)}{\sigma_{A}} \left(\underline{A} - \mu_{A} \underline{1} \right) = \operatorname{sign}(\alpha) \underline{\tilde{A}}$$

Then

$$r\left(\alpha\underline{A} + \beta\underline{1}, \gamma\underline{B} + \delta\underline{1}\right) = r\left((\alpha\underline{\widetilde{A} + \beta}\underline{1}), (\gamma\underline{\widetilde{B} + \delta}\underline{1})\right)$$

$$r\left(\alpha\underline{A} + \beta\underline{1}, \gamma\underline{B} + \delta\underline{1}\right) = r\left(sign\left(\alpha\right)\underline{\tilde{A}}, sign\left(\gamma\right)\underline{\tilde{B}}\right) = sign\left(\alpha\gamma\right)r\left(\underline{A},\underline{B}\right)$$

 Pearson correlation coefficient properties
 III

Due to the usual properties of variance and covariance;

Theorem

The range of values of $r(\underline{A},\underline{B})$ is [-1,+1]:

r = +1 if and only if $\underline{B} = \alpha \underline{A} + \beta \underline{1}$ with $\alpha > 0$. It is a perfect direct matching between \underline{A} and \underline{B} .

r = -1 if and only if $\underline{B} = \alpha \underline{A} + \beta \underline{1}$ with $\alpha < 0$. It is a perfect inverse matching between \underline{A} and \underline{B} .

r = 0 if and only if there is no linear correlation between <u>A</u> and <u>B</u>.

Pearson correlation coefficient map

(a) A template T.

(b) An image *I* containing the template T.

(c) The correlation image C[T, I] with intensity at a pixel showing the correlation coefficient between the template and the window centered at the pixel in the image.

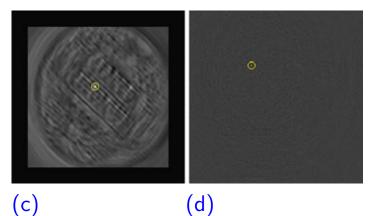

(d) The real part of image $C_{p}[T, I]$, showing the phase correlation result with the location of the spike encircled.

(a)

 \blacktriangleright The Spearman rank correlation or Spearman's Rho (ρ) between vectors $\underline{A} = (a_i)_{i=1,\dots,n}$ and $\underline{B} = (b_i)_{i=1,\dots,n}$ is given by

$$\rho = 1 - \frac{6\sum_{i=1}^{n} \left[R(a_i) - R(b_i)\right]^2}{n(n^2 - 1)}$$
(226)

where $R(a_i)$ and $R(b_i)$ represent ranks of a_i and b_i in images <u>A</u> and В.

Remark: to eliminate possible ties among discrete intensities in images, the images are smoothed with a Gaussian of a small standard deviation, such as 1 pixel, to produce unique floating-point intensities. Spearman rank correlation or Spearman's rho II

Comparison with the Pearson correlation coefficient:

- ρ is less sensitive to outliers and, thus, less sensitive to impulse noise and occlusion.
- ρ is less sensitive to nonlinear intensity difference between images than Pearson correlation coefficient.
- Spearman's ρ consistently produced a higher discrimination power than Pearson correlation coefficient.
- Computationally, ρ is much slower than r primarily due to the need for ordering intensities in I and J .

- ▶ If a_i and b_i , for i = 0, ..., n, show intensities of corresponding pixels in <u>A</u> and <u>B</u>, then for $i \neq j$, two possibilities exist:
 - Either concordance : $sign(a_j a_i) = sign(b_j b_i)$
 - Or discordance : $sign(a_j a_i) = -sign(b_j b_i)$
- Assuming that out of the C_n^2 possible combinations, N_c pairs are concordant and N_d pairs are discordant, Kendall's τ is defined by:

$$\tau = \frac{N_c - N_d}{\frac{n(n-1)}{2}} \tag{227}$$

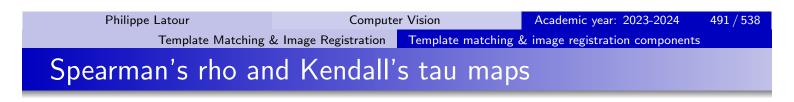

If bivariate (<u>A</u>, <u>B</u>) is normally distributed, Kendall's \(\tau\) is related to Pearson correlation coefficient r by:

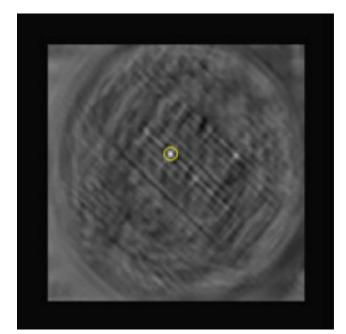

$$r = \sin\left(\frac{\pi\tau}{2}\right) \tag{228}$$

Kendall's tau II

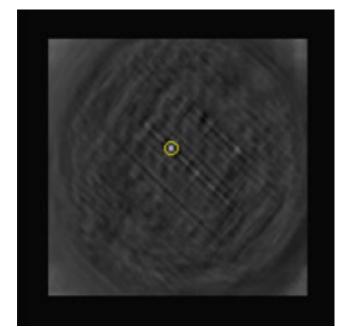

Comparison with other similarity measures:

- Pearson correlation coefficient can more finely distinguish images that represent different scenes than Kendall's τ .
- Conversely, Kendall's τ can more finely distinguish similar images from each other when compared to Pearson correlation coefficient.
- Spearman's ρ and Kendall's τ have the same discrimination power when comparing images of different scenes.
- Kendall's τ is one of the costliest similarity measures.

Spearman's Rho

Kendall's Tau

 Template Matching & Image Registration
 Template matching & image registration components

Corner-based detectors I

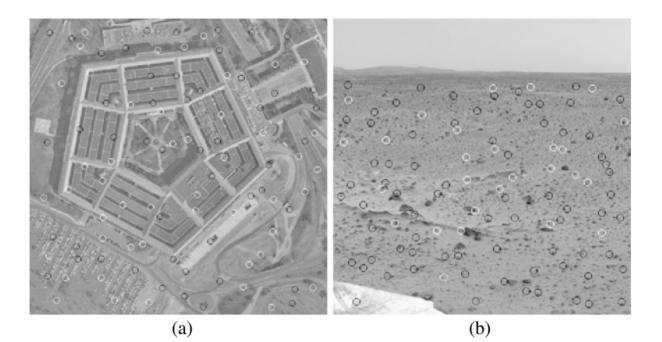

- The angle between the line connecting pixel (x, y) to the *i*th pixel on the smallest circle and the x-axis is θ_i, and the intensity at the *i*th pixel is I₁(θ_i)
- ▶ If $\tilde{I}_j(\theta_i)$ represents the normalized intensity at θ_i in the *j*th circle, then

$$C(x, y) = \sum_{i=1}^{n} \prod_{j=1}^{m} \tilde{I}_{j}(\theta_{i})$$
(229)

is used to measure the strength of a vertex or a junction at (x, y).

- In the following formula, if m = 2 (2 circles), C(x, y) is the Pearson coefficient of the two vectors $\tilde{l}_1(\theta_i)$ and $\tilde{l}_2(\theta_i)$.
- Pixel (x, y) is then considered a **corner** if C(x, y) is locally maximum.

Corner-based detectors II

 Philippe Latour
 Computer Vision
 Academic year: 2023-2024
 497 / 538

 Template Matching & Image Registration
 Template matching & image registration components

Laplacian-based detectors I

- A number of detectors use either the Laplacian of Gaussian (LoG) or the difference of Gaussians (DoG) to detect points in an image.
- For the following development, we consider a "continuous" image

$$I: \Omega \subset \mathbb{R}^2 \to \mathbb{R}: (x, y) \in \Omega \to I(x, y), \qquad (230)$$

and we define a scaled version of this image

$$L(x, y; \sigma) = g(x, y; \sigma) \otimes I(x, y), \qquad (231)$$

where $g(x, y; \sigma) = \frac{1}{2\pi\sigma^2} \exp\left(-\frac{x^2+y^2}{2\sigma^2}\right)$ is the Gaussian kernel of variance σ^2 .

• The Laplacian of Gaussian $LoG = \triangle L(x, y; \sigma)$ is defined as

$$\triangle L(x, y; \sigma) = \triangle [G(x, y; \sigma) \otimes I(x, y)] = [\triangle g(x, y; \sigma)] \otimes I(x, y).$$
(232)

Laplacian-based detectors II

So, we compute the Laplacian of the Gaussian

$$\triangle g(x,y;\sigma) = \frac{x^2 + y^2 - 2\sigma^2}{2\pi\sigma^6} \exp\left(-\frac{x^2 + y^2}{2\sigma^2}\right) \qquad (233)$$

and its partial derivative relatively to σ

$$\frac{\partial}{\partial\sigma}g(x,y;\sigma) = \frac{x^2 + y^2 - 2\sigma^2}{2\pi\sigma^5} \exp\left(-\frac{x^2 + y^2}{2\sigma^2}\right).$$
 (234)

Then, we deduce

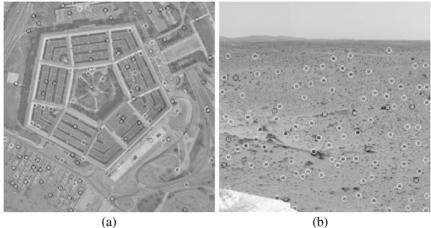

$$\sigma \triangle L(x, y; \sigma) = \frac{\partial}{\partial \sigma} L(x, y; \sigma) \simeq \frac{\left[L(x, y; k\sigma) - L(x, y; \sigma)\right]}{k\sigma - \sigma} \quad (235)$$

and the DoG operator is an approximation to the LoG operator

$$L(x, y; k\sigma) - L(x, y; \sigma) = (k-1)\sigma^2 \triangle L(x, y; \sigma).$$
(236)

- Local extrema of LoG or its approximation DoG detect centers of bright or dark blobs in an image.
 - They are less influenced by noise than points representing corners and junctions
 - They are stable and discriminative for image matching.
- SIFT (Scale Invariant Feature Transform) used the difference of Gaussians (DoG) to find points in an image.

Correlation and Fourier Transform I

The 2D Discrete Fourier Transform (2D-DFT) enable the fast computation of the cross-correlation of images.

Definition

A discrete image of *L* lines and *K* columns is first represented by: the matrix of its pixel values $\underline{l} = (l_{lk})$ where $l = 0, \dots, L-1$ and $k = 0, \dots, K-1$, and then, we extend the image by defining $a_{lk} = 0$ when $l \notin [0, L-1]$ or $k \notin [0, K-1]$

Definition (2D-DFT on a grid of L lines by K columns)

The 2D-DFT of \underline{I} is the matrix

$$\underline{\mathcal{I}} = \mathcal{F}[\underline{l}] = (\alpha_{uv})$$

where $u = 0, \cdots, L-1$ and $v = 0, \cdots, K-1$, and

$$\alpha_{uv} = \sum_{l=0}^{L-1} \sum_{k=0}^{K-1} I_{lk} e^{-j2\pi \left(\frac{lu}{L} + \frac{kv}{K}\right)} = \sum_{l,k \in \mathbb{Z}} I_{lk} e^{-j2\pi \left(\frac{lu}{L} + \frac{kv}{K}\right)}$$

And the inverse formulas are

$$I_{lk} = \frac{1}{LK} \sum_{u=0}^{L-1} \sum_{v=0}^{K-1} \alpha_{uv} e^{j2\pi \left(\frac{lu}{L} + \frac{kv}{K}\right)}$$

504 / 538

Template Matching & Image Registration Implementation speed-up

Correlation and Fourier Transform III

In the previous definition, we extend the range of values of u and v and obtain a periodic "infinite" array, thanks to the following relation:

$$\alpha_{u+L,v+K} = \sum_{I,k\in\mathbb{Z}} I_{Ik} e^{-j2\pi \left(\frac{I(u+L)}{L} + \frac{k(v+K)}{K}\right)}$$

$$\alpha_{u+L,v+K} = \sum_{l,k\in\mathbb{Z}} I_{lk} e^{-j2\pi \left(\frac{lu}{L} + \frac{kv}{K}\right)} \underbrace{e^{-j2\pi (l+k)}}_{e^{-j2\pi (l+k)}} = \alpha_{uv}$$

So, we define α_{uv} for all integral values of u and v by $\alpha_{u+nL,v+mK} = \alpha_{uv}$.

Definition

The cross-correlation of two "extended" images \underline{I} (initially L_I lines by K_I columns) and \underline{T} (initially L_T lines by K_T columns) is

$$\Gamma(\underline{I},\underline{T}) = \underline{C} = (c_{lk})$$

where

$$c_{lk} = \sum_{n=0}^{L_l - 1} \sum_{m=0}^{K_l - 1} I_{nm} T_{n+l,m+k} = \sum_{n,m \in \mathbb{Z}} I_{nm} T_{n+l,m+k}$$

with $c_{lk} \neq 0$ if $l \in \{-L_l + 1, \dots, L_T - 1\}$ and $k \in -\{K_l + 1, \dots, K_T - 1\}$, and $L_C = L_l + L_T - 1$ and $K_C = K_l + K_T - 1$.

506 / 538

Correlation and Fourier Transform V

The 2D-DFT of the cross-correlation of these two images is

$$\gamma_{uv} = \sum_{l,k\in\mathbb{Z}} c_{lk} e^{-j2\pi \left(\frac{lu}{l_C} + \frac{kv}{K_C}\right)}$$

$$\gamma_{uv} = \sum_{l,k\in\mathbb{Z}} \left[\sum_{n,m\in\mathbb{Z}} I_{nm} T_{n+l,m+k}\right] e^{-j2\pi \left(\frac{lu}{l_C} + \frac{kv}{K_C}\right)}$$

$$\gamma_{uv} = \sum_{n,m\in\mathbb{Z}} I_{nm} \sum_{l,k\in\mathbb{Z}} T_{n+l,m+k} e^{-j2\pi \left(\frac{lu}{l_C} + \frac{kv}{K_C}\right)}$$

$$\gamma_{uv} = \sum_{n,m\in\mathbb{Z}} I_{nm} \sum_{l',k'\in\mathbb{Z}} T_{l'k'} e^{-j2\pi \left(\frac{(l'-n)u}{l_C} + \frac{(k'-m)v}{K_C}\right)}$$

$$\gamma_{uv} = \left(\sum_{n,m\in\mathbb{Z}} I_{nm} e^{+j2\pi \left(\frac{nu}{l_C} + \frac{mv}{K_C}\right)}\right) \left(\sum_{l',k'\in\mathbb{Z}} T_{l'k'} e^{-j2\pi \left(\frac{l'u}{l_C} + \frac{k'v}{K_C}\right)}\right)$$

$$\gamma_{uv} = \alpha_{uv}^* \beta_{uv}$$

The best-matching template window in the image is located at the peak of the cross-correlation

$$\underline{C}[\underline{T},\underline{I}] = \frac{1}{n}\Gamma(\underline{T},\underline{I}) = \frac{1}{n}\mathcal{F}^{-1}\left\{\mathcal{F}\left\{\underline{T}\right\}^*\mathcal{F}\left\{\underline{I}\right\}\right\}$$
(237)

- This is different from the Pearson correlation coefficient, where each sub-window of the image <u>I</u> is first normalized before being correlated.
- Phase correlation: the information about the displacement of one image with respect to another is included in the phase component of the cross-power spectrum of the images:

$$\underline{C_{p}}\left[\underline{T},\underline{I}\right] = \mathcal{F}^{-1} \left\{ \frac{\mathcal{F}\left\{\underline{T}\right\}^{*} \mathcal{F}\left\{\underline{I}\right\}}{\|\mathcal{F}\left\{\underline{T}\right\}^{*} \mathcal{F}\left\{\underline{I}\right\}\|} \right\}$$
(238)

Template Matching & Image Registration Implementation speed-up

Multiresolution - Coarse-to-fine approach

- Compute image and pattern down-scaled pyramids.
- Proceed to a full search of the most reduced (coarser) pattern within the most reduced image.
- Find a number of possible candidates at the coarsest scale by an exhaustive search.
- For each candidates at a given scale:
 - Upscale the image and the candidate and look for the best matching pattern location in a neighborhood of the candidate.
 - Reduce the number of candidates
 - If the finer scale has not yet been reached, proceed to the next scale level

Hybrid approach: feature extraction in one image only

- Search for some feature points in the template.
- Consider very simple feature points as
 - the local maxima of the gradient,
 - regularly spaced patches.
- Scan the warping parameter space following a given strategy:
 - Transform the feature points of the template following the current eligible warping parameters.
 - Superimpose the warped feature points (of the template) on the observed image.
 - At each warped feature points location in the observed image, check if a compatible feature point exists in the observed image and measure its similarity/dissimilarity score.
 - Compute a global measure of similarity/dissimilarity by adding all the individual scores of the feature points.
 - Find the optimum of this measure on the search space.
- "Detect and track" instead of "detect and match".

Machine learning techniques

Machine learning (ML) techniques² aim is to

- build a decision rule automatically.
- speed up the decisions.
- be able to generalize to unseen objects. Really?!

Computational cost:

- The model is learned only once.
- The model is used many times.
- [Q] Which operation should be the fastest?

²We consider only "supervised" machine learning techniques.

| Introduction | to machine learning | Introduction to mach | ine learning (ML) | |
| Machine learning t | echniques | | | |

Examples of techniques are:

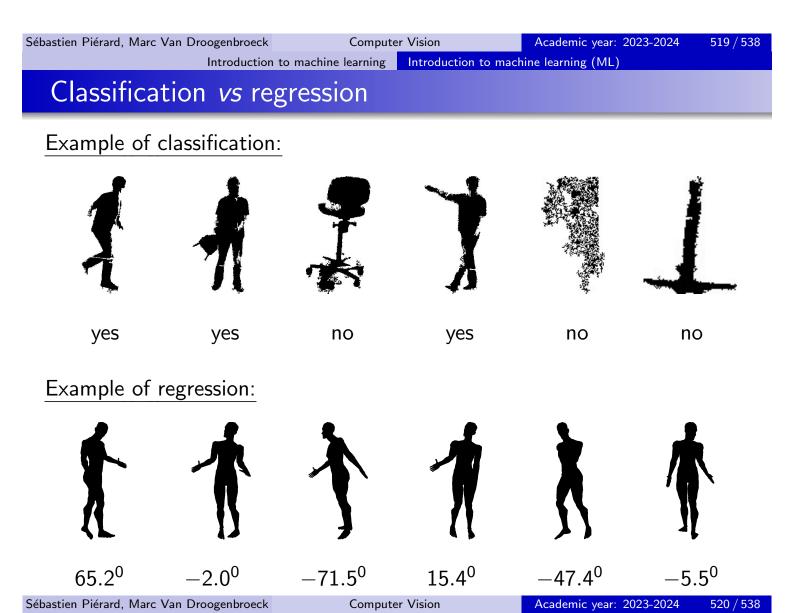

- Naive Bayes classifier
- Nearest neighbor
- Artificial neuronal networks (\rightarrow deep learning)
- Support Vector Machines (SVM) [CV95]
- Random forests (*ExtRaTrees* [GEW06])

A good reference book on this topic is [HTF09].

Families of machine learning methods

For supervised learning, we have labeled (annotated) training data.

Applications I

ML techniques have proven to be successful for many purposes:

- detecting people in images [DT05];
- recognizing people [BHP05];
- analyzing people's behavior [SFC⁺11];
- detecting faces with software embedded in cameras [VJ04];

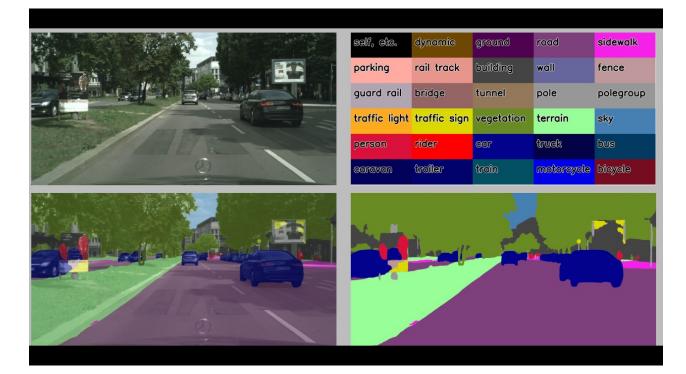

[image source: Shotton2011RealTime]

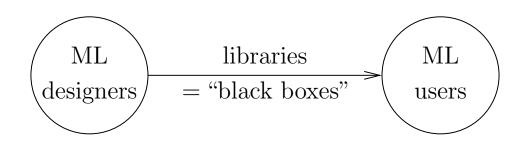

Applications II

- semantic segmentation
- etc

In practice ...

There exists many machine learning libraries. For example,

- scikit-learn (Python)
- libSVM (Matlab, Java, Python, etc)
- Regression trees (C/Matlab)
- Java-ML (Java)
- Shark (C++)

▶ ...

More specifically for deep learning,

Caffe2, TensorFlow, Theano, Torch, Keras, CNTK (Python)

How does it work? What is learned?

Example of learning database:

| | <i>x</i> ₁ | <i>x</i> ₂ | <i>x</i> 3 | <i>x</i> 4 | <i>x</i> 5 | y |
|----------|-----------------------|-----------------------|------------|------------|------------|---|
| sample 1 | 7.99 | 6.77 | 9.75 | 1.58 | 1.00 | 0 |
| sample 2 | 2.24 | 9.51 | 1.14 | 8.00 | 7.66 | 0 |
| sample 3 | 2.18 | 2.83 | 2.96 | 5.14 | 9.73 | 0 |
| sample 4 | 8.44 | 7.39 | 4.57 | 4.94 | 2.70 | 1 |
| sample 5 | 9.55 | 5.92 | 2.52 | 0.46 | 1.53 | 1 |
| sample 6 | 3.32 | 9.13 | 0.50 | 5.07 | 8.22 | 2 |

 $MODEL \equiv y(x_1, x_2, x_3, x_4, x_5) = ?$

- y is the output variable (the class)
- Samples are described by *attributes* (or *features*) x_1, x_2, \ldots
- The same number of attributes should be used for all samples.
- The meaning of an attribute should not depend on the sample.

Introduction to machine learning Understanding classification

The intrinsic difficulty of machine learning

The theoretical rule to minimize the error rate is

$$y\left(\overrightarrow{x}\right) = \underset{y_i \in \{0,1,\ldots\}}{\arg \max} \left(p(y = y_i | \overrightarrow{x}) \right)$$
(239)

Let ρ be the probability density function (pdf) of all objects in the attributes space, and ρ_i be the pdf of the objects belonging to class y_i . Using Bayes' rule (that is p(A|B)p(B) = p(B|A)p(A)):

$$p(y = y_i | \overrightarrow{x}) = \frac{\rho_i \left[\overrightarrow{x} \right] p(y = y_i)}{\rho \left[\overrightarrow{x} \right]}$$
(240)

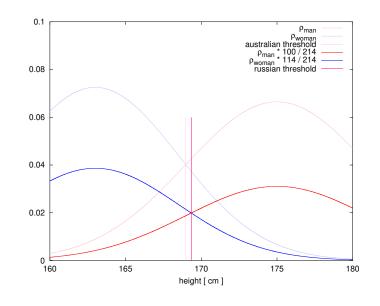

Therefore,

$$y\left(\overrightarrow{x}\right) = \operatorname*{arg\,max}_{y_i \in \{0,1,\ldots\}} \left(\rho_i\left[\overrightarrow{x}\right] p(y=y_i)\right)$$
(241)

The intrinsic difficulty is that it is very difficult to estimate ρ_i from the learning database because the space is not densely sampled.

Let us assume that we have to recognize men and women based on a single attribute: the height. In Australia, there are 100 women for 100 men. But in Russia, there are 114 women for 100 men.

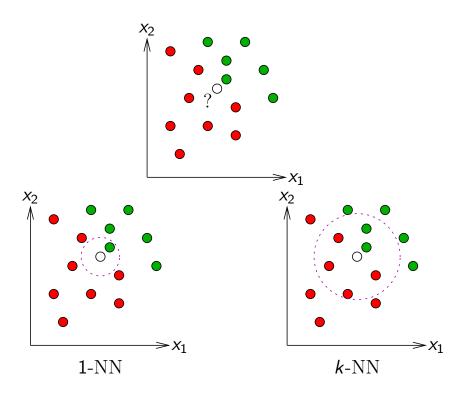

y = (height < 169.34)? "woman" : "man" ;

Sébastien Piérard, Marc Van Droogenbroeck

Computer Vision

Example of classifier: the nearest neighbors (NN) I

Let us consider a problem in 2 dimensions (2 attributes x_1, x_2):

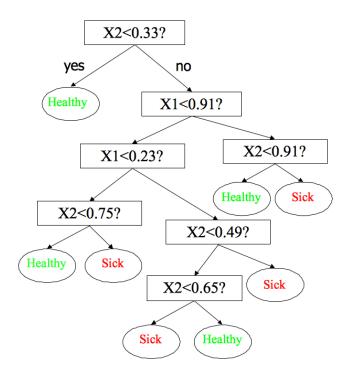

Advantages:

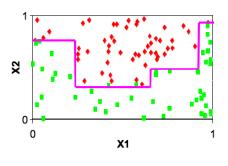

- The size of the neighborhood is automatically chosen depending on k.
- The model is the learning set (or a pruned version of it).

Drawbacks

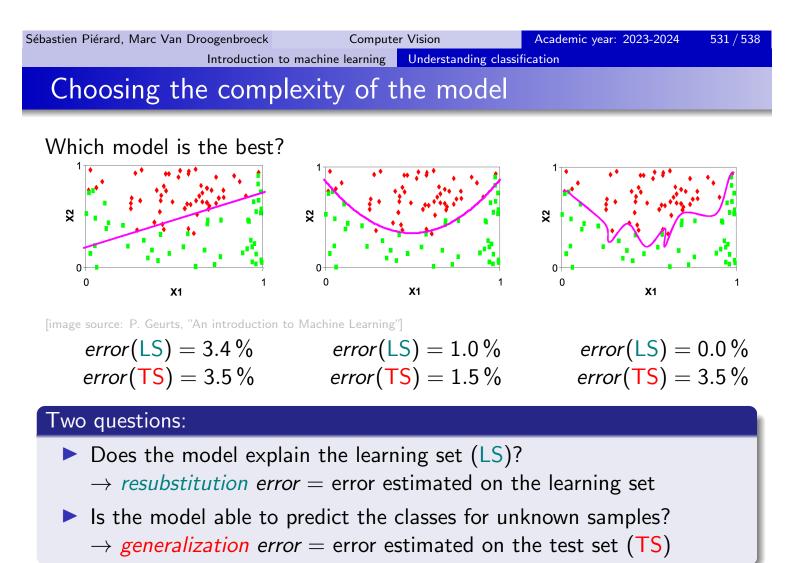

- The time needed to take a decision is $\mathcal{O}(n)$, where *n* is the learning set size.
- Which distance measure should we select? There exists an infinity of possible choices! [DD09]

Example of classifier: the decision trees

ML = automatic + generalization + preprocessing

Machine learning techniques are

- powerful methods.
- a complement to traditional methods.
- essential in computer science.
- adequate for real time computation.
- "easy" to use (not to engineer, nor to optimize ³).

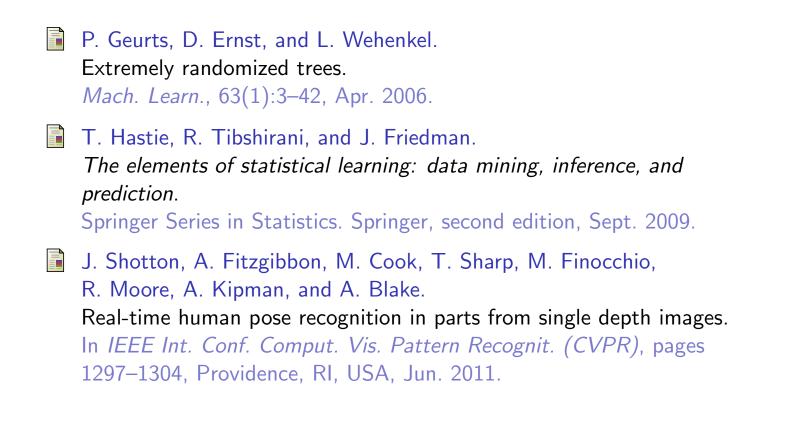

³This is why researchers are still working on machine learning methods.
