In order to assess the amount of habitat available for Monastria in future climate we used two climatic models for 2050 and 2070, derived from climate surfaces IPCC – HadGEM2-ES and MIROC5 (http://www.worldclim.org, IPCC 2007). For each model applied to pooled data sets, we used two outputs (RCP 4.5 and 8.5), representing roughly a pessimistic and optimistic greenhouse scenario according to CO2 emissions. We already know from previous studies that the Monastria with apterous females is unable to move between remnants of primary forest by using inhospitable matrix (grasslands, diverse plantations) or "secondary" forests where it is never found. We then searched the extent of forest remnants that are capable to host Monastria now and in the projected future climates. Our results point for a critical situation in which a maximum of 4% of the present distribution area will fit Monastria's habitat requirements in the near future. This calls attention to the need for considering the most frequent case of dispersal-limited species in relation to habitat connectivity when evaluating the potential effect of climate

P-2214-19

Agent-Based Modeling of Reasonable Consumption for Grassland Ecosystem Supply Service in Inner Mongolia, China

H. Yan (1) ; P. L. (2) ; L. Zhen, (3)
(1) IGSNRR,CAS, Beijing, China; (2) IGSNRR, Beijing, China; (3) IGSNRR, CAS, Beijing, China

Sustainable ecosystem service is of vital importance to the survival and development of human society. How to balance the conflicts between the ecosystem protection and the ecological consumption of local residents has been a serious challenge today especially in ecologically vulnerable area. In order to find out reasonable consumption approaches of the grassland ecosystem supply service and explore the sustainable land management strategies for the local social-ecosystem, taking Hulun Buir, Inner Mongolia Autonomous Region as the case study region, based on the agents' behaviors rules derived from households survey, a Agent-Based Model (ABM) has been developed in this study for simulating the ecosystem consumption pressure under different grassland management scenarios. This model links the supply and consumption of grassland ecosystem service by calculating ecosystem NPP supply and households NPP consumption. The model includes three sub-models: Individual growth status sub-model, Households' land-use decision sub-model, and Ecosystem service consumption pressure sub-model. In accordance with the multi-objective land management practices in case study area, four land management scenarios were modeling in this study, (1) business as usual, (2) aiming at increasing household's living level, (3) aiming at ecosystem protection and (4) aiming at balancing the ecosystem protection and living level improvement. The result indicate that reasonable ecosystem service consumption mode is possible in the research region, under which the indicators including ecosystem pressure, NPP supply, forage consumption of livestock, households incomes and herders' living level could reach a reasonable and sustainable level, This reasonable consumption mode is an improvement of traditional grazing mode, which could stimulate herders to control the livestock marketing rate by rational ecological compensation measurements, so as to ensures the NPP consumption is close to but never beyond the threshold.

2215 - Tropical degraded forests response to global change: current knowledge and cross-cutting research challenges for monitoring and processes understanding

Tropical Forest Degradation in the context of climate change: increasing role and research challenges

P. Sist (1) ; J. Chave (2) ; E. Rutishauser (3)
(1) Cirad, Montpellier, France; (2) CNRS, Laboratoire evolution et diversité biologique (edb), umr 5174, Toulouse, France; (3) CarboFor-Expert, Genève, Switzerland

While developed countries in temperate regions faced their forest transition about 100 years ago or more, "tropical forest rich" nations still largely depend on forest resources or land clearing for their development. Hence, tropical forests are retreating at an alarming rate from advancing cash crops, such as oil palm, soybean, or cattle ranching. Beside tropical deforestation, tropical forest degradation resulting mostly from human-induced causes (e.g. predatory or illegal logging, non-timber forest product extraction, fuel wood extraction) significantly contributes to greenhouse gas emissions and loss of biodiversity. If deforestation is an obvious ecosystem change, forest degradation is more difficult to discern and quantify. Degraded forests have become a major component of today's tropical landscapes, representing up to 50 % of all tropical forests. For example, almost half of standing primary tropical forests, up to 400 million ha, are designated by national forest services for timber production. The portion of tropical forests managed for timber extraction, hereafter referred to as "managed forests", will therefore play key roles in the trade-off between provision of goods and maintenance of carbon stocks, biodiversity, and other services. However, so far, most of our understanding of tropical forest arise from studies carried out in old-growth undisturbed forests, or secondary forests (i.e. regrowth forests) while the ecology of degraded forests at the regional and continental scale remains poorly studied and their role to mitigate climate change still very poorly known. However, understanding the functions played by degraded forests in providing goods and environmental services in the context of climate change is crucial. We will first discuss the complex concept of forest degradation in the tropics and then define degraded forests. We will show their importance in providing timber while maintaining high levels of biodiversity and carbon stocks. We will further demonstrate that implementation of sustainable forest management can promote long term provision of ecosystem services. Finally, the potential of tropical degraded forests in mitigating climate change will be discussed along with future research challenges on this issue.

K-2215-02

R&D efforts, coordination, and needs towards operational forest monitoring systems in the context of an increasing Earth observation data availability

B. Mora (1)
(1) GOFC-GOLD LC Project Office, Wageningen, Netherlands

Deforestation is the second largest source of anthropogenic greenhouse gas emissions to the atmosphere, accounting for 15% to 20% of the total emissions. To meet the challenge of climate change in the Agriculture, Forestry and Other Land Use (AFOLU) sector, the United Nations Framework Convention on Climate Change (UNFCCC) has been developing the Reducing Emissions from Deforestation and Forest Degradation (REDD+) mechanism. The UNFCCC recommends the use of remote sensing for forest monitoring in the frame of REDD+. Forest degradation can be monitored by remote sensing technologies using direct methods like forest gap detection, or indirect methods using logging roads as a proxy. International initiatives such as the Global Observation for Forest Cover and Land Dynamics (GOFC-GOLD) and the Global Forest Observations Initiative (GFOI) of the Group on Earth Observations (GEO) foster sustainable availability of Earth observation data to support national forest monitoring and reporting activities compliant with the good practice guidance of the Intergovernmental Panel on Climate Change (IPCC). GOFC-GOLD and GFOI also provide guidance to countries to develop forest monitoring systems, with the REDD Sourcebook and the Method and Guidance Document, respectively. These international initiatives foster also coordinated research and development (R&D) activities encouraging joint projects between research institutions, in collaboration with space agencies.

The launch of Landsat-8 in 2014 ensures the continuity of Landsat missions with an increased ability to collect data compared to the 1980's (about 14 times more images). Joint to the American effort, Europe will increase further Earth observations capabilities with the advent of the Sentinel satellite constellations. Sentinel 1A was launched in 2014 with a Synthetic Aperture Radar C-band sensor. The launch of the Sentinel-2A carrying a superspectral optical sensor is scheduled for June 2015. Sentinel-2A will allow a coverage of the land surface every 10 days. Once Sentinel-2B will be launched, the Sentinel-2 satellites combined with Landsat-8 will allow a revisit time period of 3-4 days. Other national and international satellite missions will also will provide or provide already additional imagery, either in the radar and optical domain (e.g., CBERS-4, SPOT series,

Pleiades, ALOS-2). The increased amount of observations will facilitate the use of time series analysis methods for the monitoring of tropical forests. Such methods are still at the R&D stage however some studies have started to show their potential capabilities to detect deforestation, forest degradation, but also forest regrowth. Challenges still remain to make such methods operational such as data set accessibility, data source interoperability (optical and radar), increase of the robustness, use of recommended practices, and standards. Such R&D efforts can serve other international policy discussions and agreements beyond those from the UNFCCC. The monitoring of habitats and their fragmentation for instance are listed among the Biodiversity Aichi Targets proposed by the United Nations Convention on Biological Diversity (UNCBD).

This presentation will present some foreseeable forest monitoring methods including degradation to become operational in tropical regions within the next decade, in the context of an increasing availability of Earth Observation data. We will present also international efforts to coordinate research, promote robust forest monitoring methods and standards. Finally we will discuss the current knowledge gaps and R&D needs to be met to achieve the objectives of some international policy negotiations and agreements.

K-2215-03

Tropical forests, Earth Observation and REDD+: requirements, research and progress in supporting developing countries

FM. Seifert (1)
(1) European Space Agency, Earth observation programme, ESA-ESRIN, Frascati, Italy

Tropical forests represent about 45 % of the world forests, are home to over 2/3 of terrestrial living species and play a major role in climate regulation. In 2005, official discussions initiated at the United Framework Convention on Climate Change (UNFCCC) established a process to analyze how reducing greenhouse gas emissions from deforestation and degradation (REDD) in developing countries could contribute to the ultimate goal of the Convention. A basic underpinning requirement is the systematic long-term observation of forests and other land cover characteristics and changes on national and global levels. The European Copernicus programme will guarantee these long term observations by the Sentinel satellites for the next decades. In response to this need several international activities have been established like the REDD working group within the "Global Observation of Forest and Land Cover Dynamics" (GOFC-GOLD) and the "Global Forest Observation Initiative" (GFOI) of GEO. Both initiatives foster a continuous interaction mechanism with the UNFCCC to provide technical contributions to the negotiations and for national-level capacity development for monitoring emphasizing the important role of satellite remote sensing in this context.

The presentation will elaborate the state of play of REDD+ in the political context and discuss the approach and experiences of the Earth Observation and carbon monitoring community with the REDD political discussions. It addresses the research community with open scientific questions to improve methodologies to support REDD early actions and readiness mechanisms for building national REDD monitoring systems. Critical issues on monitoring forest degradation, accuracy assessments, biomass burning and the role of evolving technologies will be discussed.

O-2215-01

Assessment of forest degradation in the Amazon using multi-sensors techniques: the case of Paragominas (Brazil)

V. Gond (1) ; C. Bourgoin (1) ; L. Blanc (1) ; N. Baghdadi (2) ; J. Oszwald (3) ; P. Sist (4)
(1) CIRAD, ES, Montpellier, France; (2) IRSTEA, Umr tetis, Montpellier, France; (3) Université Rennes-2, Umr letg, Rennes, France; (4) Cirad, Montpellier, France

The Amazonian pioneer front region is a mosaic of different forests types and agricultural landscapes resulting from the colonization of the region through forest conversion into pasture and agricultural lands. Fearnside and Guimaraes (1996) showed that 47% of the deforested area is rapidly abandoned. It also appears that logged forests surface is equivalent to deforested areas (Asner et al., 2005).

Consequently a degradation gradient exists from low-impacted logged forests (depending of the logging intensity) to young secondary (regrowth) forests. To obtain more accurate estimation of carbon stocks, it is important today to take into account the degraded forest gradient including all degraded forest stages between mature intact forests and non-forest areas. The first main challenge is to identify and to characterize the various stages.

The identification of forest degradation is still a complex and expansive problem even if it has been focused until now only on logged tropical rainforest (Asner, 2009; Gond and Guitet, 2009; Desclées et al., 2006; Asner et al., 2005; Souza et al., 2003). In parallel estimation of biomass loss in the degraded forest is little-studied. Within temperate and boreal forests some estimation are made by Solberg et al., (2013). The combination of optical remotely sensed data (Landsat-8), radar (Terra-Sar-X) and Lidar (IceSat) have to be studied to analyze the potential of the multi-sensors techniques to characterize the tropical rainforest degradation (Betbeder et al., 2014).

The study presents the first results obtained during the field work at Paragominas (Pará, Brazil) on different forest degradation intensities (Bérenguer et al., 2014). This field database is then compared with multi-sensors remote sensing to better understand multiple interactions and to establish a forest degradation typology.

O-2215-02

The Challenges of Monitoring Forest Degradation: A Case Study from Central India

R. Defries (1) ; M. Agarwala, (2)
(1) Columbia University, Ecology, Evolution, and Enviromental Biology, New York, NY, United States of America; (2) Columbia University, Ecology, evolution, and environmental biology, New York, United States of America

Forest degradation, as distinct from deforestation, results in loss of forest biomass within forested ecosystems. Implications for climate include reductions in carbon storage and the reduced ability of forests to provide hydrological services that buffer against climate change. Many factors contribute to anthropogenically-driven forest degradation, including local dependence on forest resources for fodder, fuelwood and other products as well as fire and commercial timber extraction. Monitoring forest degradation with remote sensing is more complex than monitoring deforestation and calls for the use of data from non-optical sensors. An example from central India, where local livelihoods are highly dependent on forests, illustrates the use of optical and radar data to monitor changes in forest biomass associated with human use. Loss of biomass is associated with human use surrounding villages. Reductions in degradation in this context depend on providing livelihood options that reduce dependence on forest resources. The utility of operational systems for monitoring progress towards that goal depends on the involvement of NGOs and other institutions working with local communities. Expanding degradation monitoring over large areas needs to account for the heterogeneity of forest types and varying pressures on forests in different settings.

O-2215-03

Development of EO based national forest cover monitoring systems in the Congo Basin

C. Sannier (1) ; LV. Fichet, (1)
(1) SIRS SAS, Villeneuve d'Ascq, France

Deforestation is currently known to account for up to 20% of global greenhouse gas (GHG) emissions. Therefore, a significant decrease in deforestation can have a direct positive impact on reducing GHG emissions. Initiatives such as the Reduction of Emissions from Deforestation and Degradation (REDD), Low Emission Development Strategies (LEDS) or Zero Deforestation (ZD) aim to provide incentives to reduce deforestation. The Congo Basin represents the

second largest forest area in the world after the Amazon. Deforestation in Congo Basin countries is generally expected to be low. The assessment of forest cover and forest cover change area is essential for the initiatives mentioned above to determine what is referred to as activity data in the Intergovernmental Panel on Climate Change (IPCC) 2006 guidelines on the Agriculture, Forestry and Other Land Use (AFOLU) sector.

Producing estimates of deforestation in tropical countries in relation to greenhouse gas (GHG) emissions often relies on the use of satellite remote sensing in the absence of National Forest Inventories (NFI). A probability sample combined with an appropriate response design can provide forest cover and forest cover change area estimates and their associated uncertainties in the form of confidence intervals at a set probability threshold as required in the IPCC 2006 guidelines and for reporting to the United Nations Framework Convention on Climate Change (UNFCCC). However, wall-to-wall mapping is often required by countries to provide an exhaustive assessment of their forest resources and as input to land use plans for management purposes, but implementing a wall-to-wall approach is expensive requiring specialized equipment and staff. The recent release of the Global Forest Change mapping products could provide an alternative for tropical countries wishing to develop their own wall-to-wall forest monitoring mapping products.

A model assisted regression (MAR) estimator was applied nationally in Gabon and for selected regions in Cameroon and CAR using the combination of both reference data obtained from a probability sample and nationally produced forest cover and forest cover change maps and produced from the Global Forest Change data. The resulting area estimate is potentially more accurate than the direct expansion estimate and provides an estimate of the precision of the estimate which is not available from the map statistics alone.

Results show that the method presented provides a reliable means of producing forest cover and forest cover change area statistics and confirm the low level of deforestation expected in Congo basin countries. It also confirms the high level of forest cover in Gabon with more than 88% of the country covered by forest covering an area of just over 23.5 million hectares. In Cameroon and CAR, forest represents about 72% of the area of the regions selected with a total of over 5 million hectares.

Forest cover estimates for national level maps lead to coefficients of variation less that 0.3% at national level in Gabon and between 1.4 and 1.8% at regional level in Cameroon and CAR thus reducing significantly the level of uncertainty for forest cover area estimates compared with reference data alone.

Deforestation rates are generally low, with less than 0.4% between 1990 and 2000 in Gabon. In CAR, the deforestation rate is about 1.5% between 1990 and 2000 and 0.8% between 2000 and 2010. However, the deforestation in Gabon is not statistically different from 0 between 2000 and 2010. The same is observed for the Centre region of Cameroon. This is because the changes detected are very small and as a result the coefficients of variations of change estimates are greater.

Overall, results based on the global forest change data are not as accurate and precise and substantial post-processing and calibration are required to obtain results of similar quality than that of the national maps. However, it is considered that the level of effort necessary would be considerably less than that for producing the national maps.

Will tropical forests face slow down with ongoing climate changes?

B. Hérault (1) ; M. Aubry-Kientz (2) ; V. Rossi (3) ; F. Wagner (4)

(1) Cirad, UMR EcoFoG, Kourou, French Guiana; (2) Université des Antilles et de la Guyane, Umr ecofog, Kourou, French Guiana; (3) Cirad, Ur b&sef, Yaounde, Cameroon; (4) National Institute for Space Research, Remote sensing division, São José dos Campos, Brazil

In the context of climate changes, identifying and then predicting the impacts of climatic drivers on tropical forest dynamics is becoming a matter of urgency. We used a coupled model of tropical tree growth and mortality, calibrated with forest dynamic data from the 20 year study site of Paracou, French Guiana, in order to introduce and test a set of climatic variables. Three major climatic drivers of the tropical forest dynamics were identified through the variable selection procedure: drought, water saturation and temperature. Drought decreased annual growth and mortality rates, high precipitation increased mortality rates and high temperature decreased growth. Interactions between key functional traits, stature and climatic variables were investigated, showing best resistance to drought for trees with high wood density and for trees with small current diameters. We then used SELVA, an individual-based model to run forest dynamic simulations for the next century using predictions from the IPCC 5AR with 3 different scenarios corresponding to 3 relative concentration pathways. Basal area, above-ground fresh biomass, quadratic diameter, growth and mortality rates exhibited decreasing values as long as the scenario became pessimistic. Temperature is the strongest driver highlighting a drop of 40% in average forest growth for the RCP8.5. Our results highlights the potential slow-down danger that tropical forests will face during the next century.

2215-POSTER PRESENTATIONS

P-2215-01

Amazonia, a tropical forest in transition: from natural biogenic conditions to land use change, large scale biomass burning and urbanization

P. Artaxo (1) ; H. Barbosa, (1) ; JF. Brito, (1) ; S. Carbone, (1) ; E. Sena, (1) ; L. Rizzo, (2)

(1) University of São Paulo, Applied Physics Department, Sao Paulo, Brazil; (2) Federal University of São Paulo, UNIFESP , Department of earth and exact sciences, Diadema, Brazil

Amazonia is a large tropical forest in transition, with strong pressures for agriculture expansion, climate change, urbanization and others. Deforestation rate has decreased dramatically, from 27,700 km² in 2004 to 4,700 km² in 2013, being responsible for a strong reduction in greenhouse gas emissions on the order of 70%. Agricultural expansion and climate variability have become important agents of disturbance in the Amazon basin. Recent studies have demonstrated considerable resilience of Amazonian forests to moderate annual drought, but they also show that interactions between deforestation, fire and drought potentially lead to losses of carbon storage and changes in regional precipitation patterns and river discharge. Although the basin-wide impacts of land use and drought may not yet surpass the magnitude of natural variability of hydrologic and biogeochemical cycles, there are some signs of a transition to a disturbance-dominated regime. These signs include changing energy and water cycles in the southern and eastern portions of the Amazon basin.

Feedbacks in Amazonia are very strong between ecosystem functioning, trace gases and aerosol emissions, cloud cover, precipitation, radiation balance and other key issues. In the wet season, a large portion of the Amazon region constitutes one of the most pristine continental areas, with very low concentrations of atmospheric trace gases and aerosol particles. However, land use change modifies the biosphere-atmosphere interactions in such a way that key processes that maintain the functioning of Amazonia are substantially altered. This study presents long term aerosol and trace gases observations at a preserved forest site in Central Amazonia, with observations from 2008 to 2013. Amazonian aerosols were characterized in detail, including aerosol size distributions, aerosol light absorption and scattering, optical depth and aerosol inorganic and organic composition, among others properties. Trace gases analyzed includes volatile organic compounds (VOCs), O3, CO2, CH4, N2O and CO. The central Amazonia region showed very low aerosol concentrations (PM2.5 of 1.3±0.7 μgm-3 and 3.4±2.0 μgm-3 in the wet and dry seasons, respectively), with a median particle number concentration of a low 220 cm-3 in the wet season. Aerosol composition shows organic aerosol accounting to 81% to the PM1 aerosol loading. Aerosol light scattering and absorption coefficients were very low during the wet season, increasing by a factor of 5, approximately, in the dry season due to long range transport of biomass burning aerosols reaching the forest site in the dry season.

Remote sensing observations from six AERONET sites and from MODIS from 1999 to 2013, provides a regional and temporal overview of changes in Amazonian atmosphere. Aerosol Optical Depth (AOD) at 550 nm of less than 0.1 is characteristic of natural conditions over Amazonia. At the arc of deforestation region, AOD values greater than 4 were frequently observed in the dry season. Combined analysis of MODIS and CERES showed that the mean direct radiative forcing of aerosols at the top of the atmosphere (TOA) during the biomass burning season was a high -5.6 ± 1.7 Wm-2, averaged over whole Amazon Basin. For high AOD (larger than 1) the maximum daily direct aerosol radiative forcing at the TOA was as high as -20 Wm-2 locally. This change in the radiation balance caused increases in the diffuse radiation flux, with an increase of Net Ecosystem Exchange (NEE) of 18-29% for high values of AOD. Recently the GoAmazon project is analyzing the impacts of urbanization on atmospheric properties, and preliminary results shows important changes in ozone formation, secondary organic aerosol production and cloud properties.

From this analysis, it is clear that land use change in Amazonia shows alterations of many atmospheric properties, and these changes are affecting the functioning of the Amazonian ecosystem in significant ways. The potential impacts on global carbon cycle and on the hydrological cycle are large.

P-2215-02

Climatic implications of rainforest transformations in Nigeria: quantitative and qualitative approaches

S. Ayanlade (1)

(1) Obafemi Awolowo University, Ile-Ife, Nigeria, Dept. of Geography,, Ile-Ife, Osun, France

This study examines forest transformation in the rainforest of Nigeria, focusing on the drivers of forest change, the climatic and societal implications on the local people. Both quantitative and qualitative approaches were used. Remote sensing was used to perform quantitative analysis while social methods were used as qualitative approached to evaluate the spatial and temporal rate of deforestation. A time series of Landsat data was used over the period from 1984 to 2011. Remote sensing change detection methods were used to assess forest transformation in rainforest reserves in the study area. Two forest reserves, Okomu and Sakponba/Urhonigbe, were examined to have detail case studies of intensified deforestation within forest reserves. The implications of these changes on local climate around the forest reserves were assessed. Social survey data, questionnaires and interviews, were used to assess societal implications of forest transformation on local people in the study area. Ancillary data such as population data, road network data, and climate data were used to assess the drivers of forest transformation and their implications. Correlation analysis was performed to assess the relationship between deforestation and population, road network, and surface temperature (ST) around the forest reserves. The results show that Okomu forest reserve nearly 50% of its area cover while Sakponba/Urhonigbe forest reserves loss about 90%. There are good relationship between deforestation and distance from road (R2= 0.52), also between population and deforestation with a correlation (R2) of 0.48. There appears to be a significant relationship between change forest cover and surface temperature with R2= 0.46. Thus, the major finding of this study is that a major cause of deforestation in the rainforest is a result of increased accessibility created by road network. Forest reserve with high rate of road accessibility has high rate of deforestation compared to the forest reserve with less road network. The results from this study also show that increased population appears to be driving people to access these forest areas, that the relationship between population and deforestation relatively significant. The major implication of deforestation on local climate is that ST tends to increase as the rate of deforestation increases. Area with high forest cover tends to experience low ST while area with high rate of deforestation appears to have high ST. The results from social survey show that the drivers of forest transformation in the rainforest of Nigeria are multifaceted. Such drivers include the influence of human activities such as communal and commercial logging, which are enhanced by high and rapidly increasing population, and accessibility to forest reserves through road transportation network. Corruption, lack of political will and unenforced environmental laws are other major drivers, though these are not easily understood in the study area because of lack of accurate data about them. This study is important to both governments and local people to see the need for better forest conservation.

P-2215-03

Predicting the combined impacts of climate change and selective logging in timber production forests of Central Africa

F. Claeys (1) ; F. Mortier (1) ; DY. Ouédraogo (2) ; L. François (3) ; S. Gourlet-Fleury (1) ; B. Hérault (4) ; R. Gaspard (4) ; A. Fayolle (2) ; N. Picard (5)

(1) Centre for International Cooperation in Agricultural Research for Development (CIRAD), Tropical Forest Goods and Ecosystem Services (BSEF), Montpellier, France; (2) University of Liège, Biosystems engineering (biose), Gembloux, Belgium; (3) University of Liège, Unit for modelling of climate and biogeochemical cycles (umccb), Liège, Belgium; (4) Guyanese Forest Ecology (ECOFOG), Kourou, France; (5) Centre for International Cooperation in Agricultural Research for Development (CIRAD), Tropical forest goods and ecosystem services (bsef), Yaounde, Cameroon

In the design and the implementation of current rules of Sustainable Forest Management (SFM), still too little account is taken of the sensitivity of tropical forests to climate change. In the Congo Basin, forests cover 220 million hectares and represent an economic sector of utmost importance for the rural development as well as for national and regional climate strategies. Hence, these forests constitute a major challenge for both adaptation and mitigation.

A prerequisite to ensure the relevance and the effectiveness of SFM recommendations in this region is to elucidate the influence on forest dynamics of both climate change and harvesting pressure. This influence will likely consist of major shifts in structure and floristic composition. By opening the stands and increasing light availability, selective logging fosters the development of light demanding species. Some of these species, particularly the pioneers, are thought to be particularly drought sensitive so that global warming could strongly impact logged forests. The study of forest-climate-logging relationships needs therefore species-level predictions. However, the high diversity of tropical forests, in pair with the scarcity of data, hinders the correct fitting of species-specific models.

To investigate the combined effects of climate and harvesting influence on Central African forests, we conducted long-term simulations of forest dynamics under several scenarios of climate change and timber harvesting. Climate scenarios were based on outputs from simulations of the atmospheric model ARPEGE-Climate of the French National Centre for Meteorological Research (CNRM), performed within the Coupled Model Intercomparison Project Phase 5 (CMIP5) and under several Representative Concentration Pathway (RCP) scenarios of the International Panel on Climate Change (IPCC). We also used outputs fields such as soil water and potential evapotranspiration from the model CARbon Assimilation In the Biosphere (CARAIB) of University of Liège obtained under the same climatic scenarios. Logging scenarios were implemented by considering a wide range of felling intensities.

To carry out this work, we developed an innovative method based on a Mixture of inhomogeneous matrix models (MIMM) that permits to test and simulate the influence of timber harvesting and climate change on forest dynamics. While insuring a satisfactory fitting of vital parameters, such a methodology allowed us to reflect the diversity of tree ecological patterns, notably in response to climate variables. To do this, we simultaneously clustered species into groups according to species-specific ecological responses and identified group-specific explicative environmental and climate variables. To infer and validate model outputs, we used the M'Baïki site, in the Central African Republic (CAR), a unique experimental site that has been monitored for 30 years through a collaborative partnership with various French and CAR institutional and research organizations.

Our methodology is a novel tool to accurately predict long-term ecological consequences in Congo Basin forests under both constraints of climate change and selective logging. One of the main immediate applications would be to check if classical SFM strategies, such as Reduced Impact Logging (RIL), Improved Forest Management (IFM) or post-logging sylviculture, are still valid when the ecological complexity and the climate sensitivity of tropical forests are duly taken into account. As an envisaged development, a coupling with a logging company model could allow to predict climate change impact on the economics of forest-based sectors, including tax revenues and socio-economic local benefits. More generally, our work could contribute to the improvement of climate-smart policies for Central African forests, a critical issue in the current context of deployment of the mechanism of Reducing emissions from deforestation and forest degradation and the role of conservation, sustainable management of forests and enhancement of forest carbon stocks in developing countries (REDD+).

The AmazonFACE research program: assessing the effects of increasing atmospheric CO2 on the ecology and resilience of the Amazon forest

D. Lapola (1) ; CAN. Quesada (2) ; RJ. Norby, (3) ; AC. Araújo (4) ; T. Domingues (5) ; I. Hartley (6) ; B. Kruijt (7) ; K. Lewin (8) ; P. Meir (9) ; A. Rammig (10) ; A. Walker (11) ; J. Ometto (12)

(1) Universidade Estadual Paulista, Rio Claro, Brazil; (2) Instituto Nacional de Pesquisas da Amazônia, Manaus, Brazil; (3) Oak Ridge National Laboratory, Environmental sciences division and climate change sciences institute, Oak Ridge, TN, United States of America; (4) Empresa Brasileira de Pesquisa Agropecuária, Belem, Brazil; (5) Universidade de São Paulo, Ribeirao Preto, Brazil; (6) University of Exeter, Geography, College of Life and Environmental Sciences, Exeter, United Kingdom; (7) Alterra, wageningen UR, Wageningen, Netherlands; (8) Brookhaven National Laboratory, Long Island, United States of America; (9) University of Edinburgh, School of geosciences, Edinburgh, United Kingdom; (10) Potsdam Institut fuer Klimaforshung, Potsdam, Germany; (11) Oak Ridge National Laboratory, Oak Ridge, United States of America; (12) National Institute for Space Research (INPE), Earth system science centre, Sao Jose dos Campos, Brazil

Despite being suggested, for nearly 20 years now, as a process of utter importance for the resilience of the Amazon forest and maintenance of the global carbon cycle, the existence, magnitude and duration of a supposed "CO2 fertilization" effect in tropical forests remains largely undetermined. Reducing this uncertainty is critical to the future of the Amazon region as well as for global assessments of ecosystem vulnerability to climate change. In this presentation we will introduce the AmazonFACE (Free-Air CO2 Enrichment) research program, an experiment of unprecedented scope and importance in a primary, old-growth forest of the Amazon basin near Manaus, Brazil - the first of this kind in a tropical forest. The experiment will simulate an atmospheric CO2 composition of the future in order to help answer the question: "How will rising atmospheric CO2 affect the resilience of the Amazon forest, the biodiversity it harbors, and the ecosystem services it provides in light of projected climatic changes?" Amazon-FACE is divided in three phases: (I) pre-experimental ecological characterization of the research site (Jun.2014-Nov.2015); (II) pilot experiment comprised of two 30-m diameter plots, being one maintained with atmospheric [CO2] at +200ppmv and the other with ambient CO2 concentration (Dec.2015-Nov.2017); (III) fully-replicated long-term experiment comprised of four pairs of FACE plots maintained at ambient or elevated CO2 concentrations for 10 years (Dec.2017-Nov.2027). The forest inside these plots will be scientifically scrutinized from the top-most canopy leaves to the deepest roots in terms of carbon metabolism and cycling, water use, nutrient cycling, forest community composition, and interactions with environmental stressors. A multi-disciplinary team of scientists namely from Brazil, USA and Europe will employ state-of-the-art tools from deep in the soil to above the forest canopy. The resulting data sets will be valuable resources for a broad community of scientists, especially for ecosystem and climate modelers.

P-2215-05

Evidence of Ecological Resilience Clusters to climate typology in the Amazon Rainforest: a methodological proposal

L. Martorano (1) ; L. Lisboa, (2) ; R. Muniz, (2) ; E. Sotta, (3) ; NES. Beltrão (4)

(1) s/nº, Agrometeorology/modelling, Belem, Brazil; (2) ESALQ, Piracicaba, Brazil; (3) Embrapa, Amapá, Brazil; (4) UEPA, Belém, Brazil

Resilience is usually defined as the capacity of an ecosystem to absorb disturbance without shifting to an alternative state and losing function and services. This concept encompasses three distinct processes: resistance, the magnitude of disturbance and the speed of return to the original structure, which are fundamentally different but rarely distinguished. Successfully increasing the resilience of natural systems may therefore have important implications for human welfare in global climate change scenarios. Forest areas contribute in maintaining the moisture due to evapotranspiration exchanges. Severe droughts and periods with diverse anthropogenic pressures are threatening the ecological resilience in the Amazon region. This research intended to identify the areas with a differentiated resilience capacity in the Brazilian Amazon. Some climate data were used in this study, such as: annual rainfall, total rainfall during the less rainy trimester, total rainfall below 100 and 60 mm, minimum air temperature and vapour pressure deficit. We used biophysical data (NDVI, GPP, FPAR and LAI) to assess the temporal response of vegetation in order to express the effects of seasonal conditions and variations in weather and climate conditions. The biophysical data were obtained from the MODIS satellite, and the altitude data was provided by TOPODATA. The data integration was performed based in the correlation analysis for detecting redundancies between variables. Since the original data were highly correlated, we used the Principal Component Analysis (PCA) to identify which variables should be incorporated in the assessments of areas with ecological resilience. The year of 2005 was used due to the strong El Niño as well as the high deforestation records of the year 2004. The year of 2013 was our reference as average climate conditions. The first component to generate the maps was able to clarify 40.5% (2005) and 41.7% (2013). We have considered climate typology and resilience in the Brazilian Amazon as reference in the evaluation of these ecological thresholds by integrating the variables in ArcGIS.We were able to identify 8 zones with ecological features of transitional, which indicates the distinctions in their climate resilience. Analysing the years 2005 and 2013, it is clear that different climate typologies were rebuilt after the 2005 severe drought. The positive values in 2013 indicate that same classes have been recovered in eight years showing zones with differentiated resilience capabilities. These differentiated resilience capabilities may be associated to the effect of anthropogenic land-use change, but overall to natural ecological resilience of the Native Forest. The results indicate that the 17.2% increase in areas with high rainfall in the far west Amazon, in 8 years, indicate the great capacity of recovery of this native forests (with ecological resilience in the range of 0.7 to 0.8). The proposed methodology evidence that the response of biophysical variables from satellite information combined with typological climate conditions allow us to differentiate the diversity in resilience ecological capacity of the Amazon.

Potential of tropical rainforest microrefugia to sustain tropical biodiversity in Northeast Brazil

V. Montade (1) ; MP. Ledru (2) ; L. Bremond (3) ; C. Favier (4) ; CF. Verola (5) ; IR. Da Costa (5) ; IJS. Diogo (6) ; J. Burte (7) ; FH. Magalhães E Silva (8) ; ESPR. Martins (9)

(1) Ecole Pratique des Hautes Etudes, UMR 5554 ISEM, Montpellier, France; (2) Institut de Recherche pour le Développement, UMR 226 ISEM, Montpellier, France; (3) Ecole Pratique des Hautes Etudes, Umr 5545 isem, Montpellier, France; (4) Centre National de la Recherche Scientifique, Umr 5545 isem, Montpellier, France; (5) Universidade Federal do Ceará, Fortaleza, Brazil; (6) Universidade Estadual de Campinas, Campinas, Brazil; (7) Centre de Coopération Internationale en Recherche

Agronomique pour le Développement, Tunis, Tunisia; (8) Universidade do Estado da Bahia, Senhor do Bonfim, Brazil; (9) Fundação Cearense de Meteorologia e Recursos Hídricos, Fortaleza, Brazil

Although the Northeast Brazil is mainly characterized by a semi-arid climate that corresponds to the driest area of Brazil, a sub-humid climate persists in small mountainous areas close to the coast. Such very local climatic conditions enable the development of a highly diversified Neotropical rainforest that represents rainforest microrefugia surrounded by a xeric shrubland and thorn forest. Because these microrefugia are characterized by small areas with specific vegetation and microclimatic conditions, their potentials to sustain tropical biodiversity are generally underestimated within the future scenarios of climate change. In order to characterize the different communities and distributions of these rainforests we analyzed the present-day pollen rain in soil samples along an altitudinal gradient for several microrefugia from Northeast Brazil. We identified several ecological successions characterized by significant changes in rainforest assemblages whose distribution depends on water availability linked to several factors (e.g. elevation, slope, distance from the coast). To test their potential to sustain future tropical biodiversity we compared our calibration of pollen rain with fossil pollen data in one of these microrefugia. Despite the high sensitivity of rainforest to climatic variability evidenced by our study, the rainforest persisted and responded to past climate changes by recruiting key species among its highly diverse stock. Our results suggest that the high plant diversity of the microrefugium could play an important role in allowing the development of specific assemblages in response to different climatic conditions. Consequently, we demonstrate that identification and conservation of such microhabitats in the context of future climate change represent a crucial interest in policing the tropical biodiversity.

Congo Basin forests under pressure: the role of increasing population and strong international palm oil demand

A. Mosnier, (1) ; J. Pirker (1) ; G. Bocqueho, (1) ; R. Mant (2) ; B. Bodin, (2) ; D. Bokelo, (3) ; A. Makoudjou, (3) ; R. Ndinga, (3) ; P. Tonga, (3) ; P. Havlik (1) ; M. Obersteiner (1)

(1) IIASA, Ecosystems services and management, Laxenburg, Austria; (2) UNEP-WCMC, Cambridge, United Kingdom; (3) COMIFAC, Yaounde, Cameroon

The Congo Basin forest is the second largest rainforest area after the Amazon forest but contrary to the latter, it has been relatively preserved up to now. However, pressure on the Congo Basin forests is increasing with high population growth, large economic development needs and new opportunities from global markets, increasing the chances of future emissions from deforestation. Understanding the main drivers of deforestation and their evolution in the next decades can support the development of policies compatible with development objectives and the REDD+ initiative, which many countries of the region have joined. On the one hand, the majority of the population continues to depend on subsistence agriculture and informal natural resources exploitation for their livelihoods and the viability of such practices in the context of higher population density is questioned. On the other hand, large-scale forest and agricultural concessions driven by foreign investments and supported by the States are also flourishing in the region to take opportunity of growing international demand. Global palm oil production has more than doubled over the last decade and ambitious palm oil production targets are now included in the development strategy of the Congo basin countries.

We use the land use economic model CongoBIOM to explore projections of future land use in the Congo Basin, including the role of shifting agriculture and plantation expansion. CongoBIOM is adapted from GLOBIOM which represents land-based activities and land use changes at a 50x50km resolution level. It includes domestic and international demand for crops, livestock products and wood products. In the Congo Basin, the model represents deforestation from forest conversion to both subsistence and intensive agriculture and also from intensive fuel wood harvests. Forest degradation is caused by logging activities. We have built a global oil palm suitability map to improve the model representation of future oil palm expansion. Results are presented for the whole Congo Basin and in more details for three countries -Cameroon, the Republic of Congo and the Democratic Republic of Congo- to illustrate the variety of challenges the region will face to protect its forests and ensure economic development. We compute emissions from future land use change and test their sensitivity to several model parameters including future population and economic growth, and land carbon content from different sources (IPCC, FAO-FRA, NASA and WHRC).

From our results, deforestation over the next decades increases strongly in the Congo Basin: the average annual deforested area is 60% higher over 2010-2020 and 123% higher over 2020-2030 compared to the historical rate 2000-2010. The region doubles its palm oil production over 2000-2030 and also more than double exports but a high share of the total production is used to satisfy rapidly increasing domestic needs. More generally, we observe that future agricultural expansion in the Congo Basin is mainly driven by internal demand. The Democratic Republic of Congo and Cameroon will experience the highest pressures from the agricultural sector while in the Republic of Congo pressures on the forests will mainly come from timber exploitation. Since uncertainties in the carbon content of the forest land are quite important in the region, they lead to significant variations of emissions from deforestation in our computation. The Congo Basin countries represent an important challenge for the REDD+ framework as i) historical deforestation rate is not very informative to set-up Congo Basin countries' reference levels for future emissions from deforestation and ii) REDD+ policies will need to reach scattered and remote subsistence farmers to allow them satisfying their needs without destroying the forest.

P-2215-08

Estimating and Forecasting Carbon Stocks in Indian Tropical Forests using the LiDAR Technology

F. Munoz (1) ; M. Réjou-Méchain (1) ; N. Ayyappan (1) ; C. Véga, (1) ; J. Morel, (1) ; P. Grard (1)

(1) French Institute of Pondicherry, Pondicherry, India

Tropical forests play a major role in the cycle of terrestrial carbon, being at the same time both sinks and sources of atmospheric CO2. It is estimated that around 40% of forest carbon is contained in the above-ground biomass of trees, the stock of which, at the global scale, varies mainly through reforestation and deforestation. Monitoring the stocks of forest biomass is therefore a major issue for the reduction of uncertainties associated with the overall assessment of carbon. International political institutions are therefore increasingly demanding for an effective decrease in the uncertainties associated with the estimation of these stocks. The conferences of the United Nations on climate changes, the next one of which will be held in Paris in 2015 (COP21), have as a main objective to reduce greenhouse gas emissions in order to limit global warming. Each country is invited, on a voluntary basis, to quantify the stocks and flows of forest carbons in their territory. In south and south-east Asia, huge progress has been made in this area in the past decade, with good level research and technical competencies. However, the quality of works remains variable, and the efforts are made at the national scale with very little exchanges of knowledge and know-how between institutions of different countries. This isolation considerably limits the emergence of international standards in the monitoring of stocks of forest carbon. Developing new methods for monitoring forest carbon, widening ongoing works and stimulating exchanges of knowledge and know-how with regard to the monitoring of forest carbon stocks in south Asia, are some of the main objectives of the French Institute of Pondicherry (FIP) in South India. The emergence of methodologies that capitalize on the products of remote sensing is a major advance in the mapping of forest biomass at a large spatial scale. The mapping of forest carbon via remote sensing tools is therefore rightly foreseen as a cornerstone of the MRV systems (Measuring, Reporting and Verification) that are promoted by the UN-REDD (United Nations Collaborative Programme on Reducing of Emissions from Deforestation and Forest Degradation in Developing Countries) programme. Yet, the quality of products generated by remote sensing tools depends to a very great extent on the quality of field and remote sensing data that are used. This explains in part the strong inconsistencies that exist between the different forest carbon maps published recently at the world or pantropical scale. For example, in south and south-east Asia, these

inconsistencies are sometimes of the same order of magnitude as the values indicated in the maps. During the past few years, the FIP has invested a great deal in the processing of remote sensing data, and in particular of the data generated by the very promising LiDAR technology (airborne or terrestrial laser). These new technologies allow unprecedented measures of forest structures with a centimetre-level resolution through entire landscapes. Furthermore, the FIP has monitored forest dynamics in permanent forest plots at Uppangala, in the Western Ghats biodiversity hotspot, for more than 20 years. Coupling detailed information on forest dynamics with airbone and terrestrial LiDAR data opens promising perspectives to understand and forecast with high precision the ability of tropical forests to stock carbon.

P-2215-09

GHG emissions and mitigation – a model approach for the Brazilian Amazon

J. Ometto (1) ; AP. Aguiar, (1) ; LA. Martinelli, (2) ; M. Bustamante (3) ; T. Assis, (1) ; ED. Nora, (1) ; FS. Pacheco, (1)
(1) National Institute for Space Research (INPE), Earth system science centre, Sao Jose dos Campos, Brazil; (2) University of Sao Paulo, Center for nuclear energy in agriculture, Piracicaba, Brazil; (3) Universidade de Brasília, Departamento de ecologia, Brasilia, Brazil

According to the recent scientific literature on the field, about 70% of the terrestrial sink of CO2 derived from anthropogenic activities resides in tropical forests. Of the tropical belt, the South America Amazon encompasses the largest continuous broadleaf forest in the globe. Estimates accounts more than 50% of the tropical carbon sink to these forests. Tropical deforestation accounts from about 1/10th to 1/5th of the global anthropogenic emissions of carbon and carbon equivalent green house gases. Big uncertainties associated to these estimates rely on the quantification of above and bellow ground living biomass in tropical forests and its spatial distribution. Adding up to the uncertainly on carbon emission estimates, the deforestation is not a linear process, but a patchy activity in the landscape, characterized by dynamic processes in both spatial and temporal dimension. Thereby, studies on carbon sources, sinks and stocks are urgent observational needs for both remote and ground observation in the tropics.

This paper will present recent studies coupling observation, remote and modeling approaches to better estimate green house gases emissions from tropical deforestation, with special focus on the Amazon forest. The result present outcomes of the INPE-EM model, developed at the National Institute for Space Research, in Brazil. This is a spatially explicit modeling framework that incorporates the deforestation dynamics, the biophysical and socioeconomic heterogeneity of the region. As well, we will explore mitigation of greenhouse gases emissions within a sustainable development framework, in special associated to nutrient use and emissions of nitrous oxide.

Contribution of the analysis of diurnal cycles for understanding the mean seasonal cycle of rainforest photosynthetic activity in Central Africa

N. Philippon (1) ; B. De Lapparent (1) ; V. Gond (2) ; S. Bigot (3) ; T. Brou, (4) ; P. Camberlin, (1) ; G. Cornu, (2) ; V. Dubreuil, (5) ; N. Martiny, (1) ; B. Morel, (6) ; V. Moron (7) ; G. Sèze, (8)
(1) Centre de Recherche de Climatologie, Biogéosciences UMR6282 CNRS / UB, Dijon, France; (2) CIRAD, ES, Montpellier, France; (3) Laboratoire d'étude des Transferts en Hydrologie et Environnement (LTHE), Université Grenoble Alpes, Grenoble, France; (4) UMR 228 ESPACE-DEV (IRD, UM2, UAG, UR), Saint Denis, France; (5) LETG-Rennes-COSTEL, UMR 6554 CNRS / Université de Rennes 2, Rennes, France; (6) LE2P, EA 4079, Université de La Réunion, Saint Denis, France; (7) Aix-Marseille Université, CEREGE UM 34 CNRS, France, Geography, Aix-en-Provence, France; (8) LMD, UMR8539 CNRS / Université Paris 6, Paris, France

Global carbon, water and energy cycles are substantially driven by vegetation phenology. In particular tropical rainforests have been shown to be a key component of the climate system as they act as major water vapor sources and carbon dioxide sink. For these reasons their evolution in response to both human pressure and climate change is critical. As compared to the Amazonian and Asian rainforests, the rainforest of Central Africa experiences slower deforestation rates, so that its main threat for the next decades might come from climate change. So far, the response and sensitivity of the Central Africa rainforest to the mean seasonal evolution and inter-annual variability of climate has attracted little interest. Indeed, most of the studies focus on its Amazonian counterpart and suggest that solar irradiation is the main driver of the annual and inter-annual variations of rainforest photosynthetic activity, and the Central Africa climate itself is not well documented.

As a first step towards a better understanding of the Central Africa rainforest sensitivity to present-day climate variability and response to climate change, this study performs for a target region located between 0-5°N/12-19°E (thus documenting forest areas from 5 countries) and using space borne observations, a detailed analysis of the rainforest photosynthetic activity mean seasonal cycle comparing it with those of climate variables considered as potential drivers, i.e. rainfall, cloudiness and solar irradiation.

Several key points emerge from our study. First, the seasonal cycles of photosynthetic activity (EVI MODIS) and rainfall over our target region are both bimodal. However, the highest peak of EVI (March-May) coincides with the driest of the two rainy seasons while the lowest peak of EVI (September-October) coincides with the wettest of the two rainy seasons. Second, the two rainy seasons are not associated with two distinct lows in total solar irradiation and two distinct peaks in total cloudiness: the first rainy season (March-May) which is less rainy as compared to the second one (September-October), is also less cloudy and receives more total solar irradiation. This might explain the higher EVI values recorded. Third, the high total cloudiness recorded throughout the seasonal cycle actually hides marked seasonal variations in the frequency of the 5 main types of clouds analyzed. These cloud types have specific diurnal cycles which control those of solar irradiation (thus the daily light and energy available for photosynthesis), but also influence the remote sensed photosynthetic activity data (or index).

Our results clearly show that (1) nor the two dry seasons, nor the two rainy seasons do compare in terms of mean rainfall, cloudiness, solar irradiation and temperature, and (2) water and light availability have a respective weight in the Central Africa rainforest photosynthetic activity which evolves throughout the seasonal cycle. They also suggest that any evolution, due to climate change, of the complex diurnal cycles of rainfall, nebulosity and solar irradiation which characterize the equatorial climate regimes might perturb the rainforest phenology and enhance these ecosystems vulnerability.

P-2215-11

Bhabar Terai Forest Cover Reduction Causes Climate Change in the North Bank of the Brahmaputra Valley increased Severity in Flood

BP. Saikia (1)
(1) Gauhati University, Centre for animal ecology and wildlife biology, department of zoology, Guwahati, India

During the last few decades floods in the Brahmaputra basin had been extremely of large magnitude and high frequency and there were heavy floods in Assam almost every alternate year. The fragile hills of the Himalayan Mountain range are prone to major landslides that are getting aggravated due to wide ranging deforestation, mining in the catchment, rampant construction of embankments and roads and cutting in the Brahmaputra basin.

We have examined the decadal change in the forest cover of the Brahmaputra basin from 1970-80's to 2010 and compared with the increase in the level of flood severity, frequency and increasing level of the rising temperatures from the existing data sources and field survey on the North Bank of the river Brahmaputra.

During the period of the study this has been found that the decreasing forest cover has major role in the rising temperature and flood. On the entire North Bank of the

River Brahmaputra on the foothills of Himalaya there have specialized zone of Bhabar Terai forest. This has been seen that where these Bhabar-Terai zone has been removed from the foothill the severity of the flooding has been increased with the decadal rise of temperature in such areas. The rate of rainfall has been found increasing in the last four decades but the number of the rainy days has been decreasing.

After the 1950 earthquake and following flood in the year 1954 the entire basin of the Brahmaputra river changed forever. With the many fold increase of human population in the Brahmaputra valley the conversion of the forest land into agricultural lands started in a faster rate and continued till the 1996 Supreme Court ban on the timber logging and any such activity. Along with this forest destruction the flood occurrence in the Brahmaputra basin has been observed from the year '54, '62, '66, '72, '74, '77, '78, ' 84, '86, '87, '88, '89, '90, '91,'92, '93, '94, '95, '96, '97, '98, '99, '2000, 2011, 2012 and 2013 and is still continuing. It has been revealed from the present study that the magnitude increased with time and frequency of flood increased which direct positive correlation with the decadal rise in temperature and negative correlation with the decadal forest cover change in the North Bank of the river Brahmaputra in Assam specially the Bhabar and Terai forest which acts as the cushion for the speeding rainwater on the foothills zone of the Himalaya in the basin. It has been evident from the present study that forest cover in the foothills zone are very much necessary for resisting the impact of climate change such as increasing temperature, rainfall and flood. Hence, the forest cover has been necessarily found related with the severity of flood thus helps in curbing climate change impact.

P-2215-12

An Impact of Climate on Tree Species Diversity in Tropical Reserve Forest using Geospatial Domain

T. Vandana (1) ; K. Amit (1)
(1) Haryana Institute of Public Administration, Remote sensing, Gurgaon, India

Forest is a tool mentioned for ecological balance and environmental set up. It performs social, ecological and economical functions to the living organisms such as it preserves the natural resources for the sustainable use, lesser soil erosin, preserves the animal habitat etc. Forest degradation in the tropics is of significant concern because of the substantial losses of biomass and habitat fragmentation. Geographic Information System (GIS) has been proven in many studies and experiences to aid in the decision-making process based on Multi-Criteria techniques. The advancement in remote sensing coupled to Geographic information system expedites the adverse changes in forest vegetation and the assessment of impact of various factors such as climatic change or human activities on forests.This study aims to evaluate an assessment of tree species diversity of the Sariska Tiger Reserve using GIS and Multi criteria techniques. Vegetation indices among other methods have been reliable in monitoring vegetation change. One of the most widely used indices for vegetation monitoring is the Normalized Difference Vegetation Index because vegetation differential absorbs visible incident solar radiant and reflected much of the infrared. Data on vegetation biophysical characteristics can be derived from visible and NIR and mid-infrared portions of the electromagnetic spectrum. Four forest types, namely Anogeissus pendula, Boswellia serrata, mixed Anogeissus butea and mixed Acacia zizyphus are mainly dominant in the forest cover of Alwar district. Satellite data of LISS III (2012) give precise information of vegetation through reflectance value.

Forest carbon conservation and management: integration with sustainable forest management for multiple resource values and ecosystem services

JL. Peyron (1) ; A. Sample (2)
(1) ECOFOR, PARIS, France; (2) Pinchot Institute for conservation, Washington, United States of America

Forest carbon management is an important consideration in temperate forests as well as tropical forests. It is estimated that US forests absorb up to 15 percent of total US carbon emissions, or more than 200 Tg yr -1. Recent research suggests that this net carbon sink is declining, and that US forests could become a net carbon source within the next few decades unless decisive action is taken in the near term to alter this trajectory. Annual per capita carbon emissions in the US are triple those of France, and more than eight times those of Brazil or Indonesia, so many in the US forestry community consider it a moral responsibility to avoid this possible future. This paper will summarize ongoing research to determine whether carbon management is compatible with forest resource sustainability (continued production for a variety of goods and services), and whether forest carbon management enhances or detracts from other ecosystem services such as water and biodiversity. Examples are drawn from private forest lands managed primarily for timber and other economic values, and from public forest lands in which management for specific forest uses, values, and services are mandated by law or policy.

Understanding and directing small-scale private forest owner behaviour towards climate change adaptation

U. Pröbstl-Haider (1) ; R. Jandl (2) ; H. Formayer, (1) ; M. Suda, (3) ; W. Haider (4) ; N. Mostegl (1)
(1) University of Natural Resources and Life Sciences Vienna, Vienna, Austria; (2) Forest Research Center , Bfw, Vienne, Austria; (3) Technical University of Munich, Munich, Germany; (4) Simon Fraser University, Burnaby, Canada

Climate change will affect many productive forests across Austria, which may lead to significant economic loss, but also depicts various opportunities for future management. While the Federal Forest Service already takes climate change into account, little is known about adaptation of small-scale private forest owners, who manage 56% of Austria's forests. Consequently, this project will investigate human dimensions of climate change and small-scale forest owners' adaptation strategies. The main focus lies on their climate change perception, ways to influence their implementation of adaptation methods, the rising of their awareness of possible risks of inactivity, and the enhancement of their transition to resilient forests. The key challenge is to "re-interest" this group in their property and to increase the awareness of their required contribution. For this purpose, the project develops innovative concepts for attracting as many forest owners

as possible to implement adaptive measures. The core of the study builds a questionnaire combined with a discrete choice experiment, which aims at acquiring a thorough understanding of the salient factors influencing decision-making processes. This innovative methodologically approach initially combines forest growth modeling and visualization of potential effects within a stated preference method.

O-2216-02

How forests can support adaptation of landscapes systems to mitigate climate change? A landscape approach to sustainable forest management

S. Luque (1)
(1) IRSTEA - National Research Institute of Science and Technology for Environment and Agriculture, Mountain ecosystems, Grenoble, France

The world's forests are in a state of flux due to land-use and climate change, deforestation, afforestation, wildfires, insects and pathogen outbreaks. In the face of both anthropogenic and natural forces there is an increasing need to assess the value of our forests. The incorporation of the ecosystem service (ES) concept into the framework of forest management stems from a need to create a more holistic perception of forests, recognizing not only their economic value, but also their cultural and ecological values including their regulation capability. Thus, requirements of an optimized forest production and an environmental quality improvement represent a true challenge for the years to come. A fast reorganization of the system is needed in order to find the right balance between management within a forest ecosystem services approach at different scales. In particular, we need to consider a valorisation of wood resources and production, thorough knowledge of their vulnerability within an intensification management scenario.

As climate changes, societal demands for goods and services from forests are also changing. The recent decision of European government leaders to increase the share of renewable energy in Europe to 20% by 2020 is expected to result in a much greater demand for forest biomass for bio-energy generation. This higher demand will intensify the competition for resources between forest industry, the energy sector, and nature conservation/other protective functions and services (including biodiversity, protection from natural hazards, landscape aesthetics, recreation and tourism and climate regulation). A comprehensive and integrative approach from the plot level to the landscape level is needed through collaborative tools. Such tools also should inform on what level of spatial scale adaptation measures can be effective: can they just do it by managing the land within their jurisdiction, or are they dependent on changes at broader scales and do they need to collaborate with other land managers around? Scenario analysis and planning options for the future will be also presented based on specific case studies as exemplars. The work opens questions regarding the needs for a comprehensive adaptive forest management under changing environmental conditions to improve forest management in a wide range of territories.

The challenge that lays ahead demands gaining awareness of the increasing pressures on forests and forest resources and concern about the continuous changes in climate conditions that will increase forest degradation for what a holistic approach towards integrative solutions is needed.

O-2216-03

The loop effect: quantifying the mitigation potential of the forest sector when adaptation strategies are also taken into account. A case study for France

A. Barkaoui (1) ; JD. Bontemps (2) ; S. Caurla (1) ; P. Delacote (3) ; L. Antonello (4) ; P. Mérian (5)
(1) INRA, Laboratoire d'economie forestière, Nancy, France; (2) AgroParisTech, Lerfob, Nancy, France; (3) INRA, Economics, Nancy, France; (4) AgroParisTech, Laboratoire d'economie forestière, Nancy, France; (5) National Institute of Geographic and Forestry Information, Nancy, France

Objectives: (1) quantify the contribution of the French forest-wood product chain in terms of sequestration and substitution of carbon when we account for forest response to climate change and consequent forest managers adaptations; (2) assess the effects of the incertitude of current climate scenarios on the above carbon balance; (3) assess the potential consequences of an early introduction of adaptation measures.

Methodology: We use a spatially-explicit bio-economic Model of the French Forest Sector (FFSM++) that is able to consider and integrate: (a) effects of climate change over forest dynamic; (b) forest investment decisions (among groups of species) according to expected profitability (conditionally to cc); (c) market effects in terms of supply, consumption and trade of wood products depending on the stock of forest resources. Having both forest dynamic and forest products included, we can evaluate the carbon balance considering the following elements: (a) carbon sequestered in live and death biomass in the forest; (b) carbon sequestered in wood products; (c) carbon substituted when wood is used in place of fossil fuels; (d) carbon released by forest operations.

Results: When we run the model for the next century using IPCC A1B scenarios the average sequestration rate is 43.88 Mt CO2 eq. y-1 while the net energy substitution emissions is 13.59 Mt CO2 y-1. Together they form 16% of the French 2010 emissions (361 Mt CO2). The sequestered carbon is highly due to an increasing forest stock, that however tends to peak in about 100 years. In A2 and B1 scenarios the forest balance decreases by 0.51% and 1.20% respectively. Testing 12 different climatic models for the A1B scenario we obtain a coefficient of variation of 2.47% for the overall carbon balance. Allowing forest managers to have a perfect foresight on future climate favour broadleaved species but has a limited effect on the carbon balance.

P-2216-01

Community based Climate Change Adaptation: a Case of Community forestry programme in Nepal

NK. Bk (1)
(1) Kathmandu University, Department of Development Studies, Kathmandu, Bagmati , Nepal

Community forestry programme is a major community based climate change adaptation (BCCA) and potential mitigation strategy; recognized by climate change policy and National Adaptation Programme of Action (NAPA) of Nepal. In these regards, some community forestry user groups (CFUGs), in the support of donor organizations , are implementing practices of community based adaption plan, establishing fund as well as creating institutions to benefit from REDD (reducing emissions from deforestation and forest degradation) mechanism. However, there are very little evidences about the strength and limitations of such practices and its impacts on wider socio-economic development of vulnerable community.

Based on the paper presenter's 10 years long experience in the issues and the study of six community forest user groups, three from each of DFID/UK and CARE supported groups, the finding shows that the programme is suitable mechanism for planned, decentralized, cost effective, linked and inclusive adaptation strategies. The programme is initiated and groups are formed to address the issues of natural hazards and mal-adaptation practices the local people followed previously in responses to local changes. The groups adopt bottom up planning process to identify vulnerability and prepare adaption plan, collaborative effort to establish matching fund to implement prioritized activities and coordinating mechanism to integrate these activities into wider development programme. These practices increased the livelihoods security of marginal groups through increasing human and food security and forest product availability, building social capitals, use of indigenous knowledge and providing alternative livelihoods to the landless poor members, and deriving benefits from development service providers.

While community forestry policies and practices of Nepal seem climate change friendly exclusions persists and people who are member of the groups have opportunity

to get benefit from the adaptation fund while there are some households/communities are excluded from the groups. Also, limitation on extraction of forest products is in some instances undermining the livelihoods strategies of the forest dependant people limiting their adaptation capacity. There are also issues of resource access with members in particular can be constrained by poorly aligned jurisdiction.

The finding shows that the programme promotes entry points for pro-poor mitigation strategies. The growing stock of forest particularly in hills increased and the community forestry user groups have established resource distribution system based on wealth ranking of the groups, the mitigation strategies specifically the REDD mechanism may benefit to the poor category of the users. However, we find that the executive committees of CFUGs are politicized and the political ideology affects resource distribution. Also, there are high value forest trees, the illegal sale of which offers considerable financial intensives. So, particularly in the Terai, the conservation and management of forest may be competing with very high opportunity costs. Also, there are significant issues of land tenure conflicts between people and Government, VDCs (Village Development Committee), and communities, the result of which does not favor the protection, management and conservation of forest.

The findings suggest that CBCCA approach needs to integrate in rural development policies at landscape level. As the groups are growing as a local adaption funding institutions, the role of CFUGs should be linked with sources of credit and low-interest loans. To increase the community forest for mitigation, climate change sensitive forest management guidelines needs to developed and linked with national forestry activities. In addition, there is value in exploring PES (Payment for environmental services) and carbon markets more broadly than strictly REDD mechanism; Community forestry stakeholders should undertake experiential marketing of forest carbon in a volunteer market.

P-2216-02

Disentangling the climate change contributions of CO2 emissions from global forest bioenergy

F. Cherubini (1)
(1) Norwegian University of Science and Technology (NTNU), Trondheim, Norway

Many future energy and emission scenarios envisage an increase of bioenergy production in the global primary energy mix [1]. Bioenergy is the most important renewable energy option in studies designed to align with future RCP projections, reaching approximately 250 EJ/yr in RCP2.6, 145 EJ/yr in RCP4.5 and 180 EJ/yr in RCP8.5 by the end of the 21st century. However, many questions enveloping the direct carbon cycle and climate response to bioenergy systems remain open and partially unexplored. While the climate change effects of the different greenhouse gases (GHGs) are usually aggregated into common units (e.g., radiative forcing, CO2-equivalents, or °C), for example using emission metrics like the well-known global warming potential (GWP) or Global Temperature change Potential (GTP) [2], emission metrics for CO2 from forest bioenergy are not implemented in global emission scenarios. Bioenergy systems are largely assessed under the default climate neutrality assumption and the time lag between CO2 emissions from biomass combustion and CO2 uptake by vegetation is usually ignored, with integrated assessment models and policy directives mainly focused on the quantification and mitigation of the risks associated with deforestation and land use changes. Whereas recent studies show that the temperature change of CO2 emissions from re-growing biomass is characterized by an initial warming followed by a smaller long term cooling [3], an analysis that disentangles the role of CO2 emissions from bioenergy with a global coverage and within the policy relevant framework linking temperature peak and emissions is still missing [4]. Here, the characteristics of the climate system response to CO2 emissions from forest bioenergy is investigated within the 2 °C target and global spatially explicit maps of emission metrics for the climate impact characterization of CO2 emissions from forest bioenergy are produced. These metrics can be used to unravel the contributions to climate change of CO2 emissions from forest bioenergy, as here exemplified by assessing these emissions under the RCP8.5 scenario. The metrics are correlated with the site-specific turnover times and local climate variables and the characterized results are sensitive to the specific metrics used that inform about different dimensions of the climate system response to forest bioenergy. The temperature peak from bioenergy CO2 emissions is proportional to the maximum rate at which emissions occur and is nearly insensitive to the amount of cumulative emissions. While the transient climate response to cumulative emissions (TCRE) of CO2 from fossil fuels is approximately constant, the TCRE to bioenergy emissions depends on time, biomass turnover times, and emission scenarios. The linearity between temperature peak and bioenergy CO2 emission rates thus resembles the response to short-lived climate forcers. As for the latter, the timing of CO2 emissions from bioenergy matters. Under the international agreement to limit global warming to 2 °C by 2100, early emissions from bioenergy have smaller contributions on the targeted temperature than emissions postponed later into the future. The application of these metrics to CO2 emissions from forest bioenergy in the RCP8.5 scenario shows that emissions in 2015 cause a warming effect that is about 45% (expected range: 38-60%) of the gross emission flows when GWPs are used. On the other hand, the result in 2100 is a net climate cooling if GTPs are applied. A temperature peak about 35% (12-46%) less than that caused by an equal amount of emissions from fossil fuels is found. Without coupling the analysis with global climate models, CO2 emissions from forest bioenergy can thus be assessed under different climate change indicators and across various spatial and temporal scales using the global maps presented in this study.

P-2216-03

A bioeconomic modelling of logged tropical forests to simulate low-carbon strategies for Central African concessions

F. Claeys (1) ; P. Delacote (2) ; S. Gourlet-Fleury (1) ; A. Karsenty (1) ; F. Mortier (1)
(1) Centre for International Cooperation in Agricultural Research for Development (CIRAD), Tropical Forest Goods and Ecosystem Services (BSEF), Montpellier, France; (2) French National Institute of Agricultural Research (INRA), Laboratory of forest economics (lef), Nancy, France

Among the contributions expected from forest sectors in policies of climate mitigation, one consists in increasing forest carbon stocks by changing management practices. This activity, generally referred to as Improved Forest Management (IFM), is of major importance in the Congo Basin forests, where 20 millions of hectares are now managed for timber production. The carbon benefit generated by IFM activities is often obtained by a reduction of harvesting pressures on forest resources. In the case of Extension of Rotation Age/Cutting Cycle (ERA) projects, the reduction of emissions comes from the increase of Minimum Cutting Diameters (MCD) and/or the extension of Felling Cycle Duration (FCD). However, such activities have negative consequences for the profitability of timber companies. Climate instruments such as the mechanism of Reducing emissions from deforestation and forest degradation and the role of conservation, sustainable management of forests and enhancement of forest carbon stocks in developing countries (REDD+) promote a compensatory approach to cover these income losses by the valuation of avoided carbon emissions.

To determine the feasibility of such a carbon-based compensation, it is necessary to predict over the long term both the dynamics of forest carbon and the time schedule of timber incomes. The two are closely interrelated. Selective logging can alter the structure, the floristic composition, and thus, the carbon stocks of tropical forests. Modelling these forest-logging relationships is challenging. Selective logging implies to deploy a species level representation of timber harvesting but the high diversity of tropical forests, in pair with the scarcity of data, hinders the correct fitting of species-specific models.

We developed a bioeconomic approach coupling a mixture of inhomogeneous matrix models for forest dynamics and an object-oriented model for forest logging companies' operations. For forest dynamics, our methodology addresses the challenge of taking into account the high species richness by simultaneously clustering tree species into groups according to vital rate information and selecting group-specific explicative environmental variables. For the logging operations, the object-oriented approach allows us to precisely describe harvest choices under technical and economic constraints, in a highly configurable manner. In the case of a Central African forest concession managed by a typical sawnwood export-oriented company, we predicted the carbon stock evolution for a wide range of ERA scenarios and for a time scale of 100 years. For several categories of carbon credit, we calculated break-even prices that would enable carbon revenues to compensate logger's loss of timber incomes.

Our simulations are based on data from the M'Baïki site, in the Central African Republic (CAR), which has been monitored for 30 years through a collaborative partnership with various French and CAR institutional and research organizations. Economic data are taken from several forest concessionaires in Central Africa. We predicted that without any logging, carbon stock would increase naturally. When logging was simulated, the carbon stock decreased during the first felling cycle and although carbon recovery could be boosted by logging, this decrease was too sharp to catch up with unlogged levels. To ensure low break-even prices of carbon credits, ERA activities had to involve both FCD and MCD. In this case, we found a little dependence of the private discount rate and the alternative MCD and FCD, but a strong dependence of the way how carbon credits are accounted. Thus, from the perspective of the forest concessionaire, depending of the chosen type of credits, carbon revenues could compensate timber revenues for a large number of ERA projects.

We focused on IFM projects, but our approach remains appropriate for other strategies of forest sustainability improvement such as Reduced Impact Logging techniques or post-logging silvicultural systems. In the current context of REDD+ deployment, our work is a first step to bring some preliminary answers to the question of carbon-based compensation opportunities for industrial forest concessions in Central Africa, on the basis of an accurate modelling of tropical forestry.

P-2216-04

Dynamics of vegetation in Managed forest: the case of Missirah Forest in Senegal

LC. Faye (1) ; S. Bienvenu (2) ; K. Boateng (3)

(1) Kwame Nkrumah University of Science and Technology, Department of civil ingeneering, KUmasi, Ghana; (2) Institut des Sciences de l'Environnement, Faculty of science and technologyd, Dakar, Senegal; (3) Kwame Nkrumah University of Science and Technology, Natural resources, Kumasi, Ghana

In the global climate change discussion, forest management has become a major concern because of the significant role of forest in climate change as both pool and source of carbon dioxide. Climate change discussion points out the important role of forest sector in climate change mitigation leading to mechanisms like Clean Development Mechanism (CDM) and Reducing Emissions from Deforestation and Forest Degradation (REDD). The concept of REDD launched in the 11th Conference of the Parties in 2005 became later REDD+ integrating sustainable forest management, forest conservation, and carbon sink enhancement. In Africa, there are only few operational REED+ programs but, the idea behind the concept is not new in African forest sector. There have been many attempts to tackle the issue of deforestation in Africa and in these attempts; agriculture, urban growth and wood extraction were identified as the main drivers. In Senegal the driving factors of deforestation derived from the literature are mostly the same. Nevertheless some factors are more specific to some areas. In the southern part of Senegal namely in Tambacounda and Kolda which are the main charcoal supply areas of the country, deforestation is correlated to wood extraction mainly charcoal production. Charcoal production contributes for more than 30% in deforestation in Senegal. To curb deforestation due to charcoal production, some forests were specifically managed for charcoal production under management plans where rules are set to make the production sustainable. Past studies related to forest management in Senegal focused mainly on the decentralization of forest management process, the effect of the institutional pluralism on the decentralization and the management of forest resources, the function of the forest management plan in the new Senegalese Forest code, the evolution of forest management in Senegal, and the effects of charcoal production on woodland regeneration. However there is a lack of relevant information on the dynamic of vegetation in managed forest comparing vegetation state baseline to the situation after a full rotation period. This information are relevant in the light of the willingness to expand the process in a large number of forests. Therefore this study aims at assessing the dynamic of vegetation in Missirah Forest. Specifically it consists of characterizing vegetation type state in 2013, determining their dynamic through the mapping of the land cover land use types from1990 to 2014, and determining vegetation dynamics in terms of floristic composition and dendrometric parameters between 2002 and 2013

Missirah Forest is one the first 3 managed forests for charcoal production in 2004. A mapping of the land use-land cover types was combined with a tree inventory to characterize the current status of the vegetation in 2013 and its dynamics between 2002 and 2013 using 94 circular plots in table lands and 57circular plots in gallery forest. The mapping of the LULC identifies 6 vegetation types namely tree savannah, shrub savannah, degraded shrub savannah, gallery forest, farmland, and settlement areas. It reveals a decrease of area covered by vegetation at the expense of cropland and the appearance of a new vegetation type resulting from the degradation of the other vegetation type. The result of the tree inventory reveals that the vegetation types and the farmland shelter a total of 54 species belonging to 18 families and 42 genera. Inventory data were analyzed according to land use land cover types. Mean diameter at breast height (dbh), tree density, stem density, mean Lorel height and mean basal area in the different land-use land cover were greater in gallery forest. These dendrometric parameters were also found to be significantly different among vegetation types ($p<0.05$) in 2013. The analysis of variance(ANOVA) conducted on the negative binomial model shows that between 2002 and 2013 from a vegetation type to another the difference in terms of diversity is highly significant ($p<0.05$) while from a year to another it is not significant ($p>0.05$). The K-mean method applied to the IVI of species identifies three classes defining species with increased, decreased, and relative stability IVI. Dendrometric parameters show greater values in 2002 except for stem density in tree savannah. Significant difference was observed for tree density, basal area, and mean Lorey height between 2002 and 2013.

P-2216-05

Population growth and deforestation in the Lake Albert region (Uganda) at the start of oil production

V. Golaz (1) ; C. Médard (2) ; F. Kisekka-Ntale (3)

(1) INED, Paris, France; (2) IRD, Paris, France; (3) DRASPAC, Kampala, Uganda

In the early colonial days, a deep political and demographic crisis hit the eastern shores of Lake Albert, Uganda (Doyle). Large areas were then set aside as forest and game reserves. Later on migratory policies and practices shifted and the area became a land frontier. Migrant settlement was encouraged by government from the 1950s onwards. New settlements were promoted by the Ugandan State in response to international refugee crises, as well as national demand for land. Land patronage led to repeated encroachments on protected areas and severe deforestation. Since the 1990s, both the institutional role of central government, acting through a variety of bodies (the administration, the army, the forestry and wildlife services, etc.), and political patronage have consolidated Museveni's regime in somewhat contradictory ways. These contradictions shape access to land and natural resources locally at the start of a new oil frontier. Through a detailed mapping of population densities and growth and an analysis of qualitative interviews conducted in 2012-2014 in a collaborative research framework (M-PRAM, CPAS - IRD, Makerere University), we highlight increased vulnerability and inequalities as well as potential conflicts. Although climate variability is a factor of change locally, the short term issue shaping resource depletion is governance.

P-2216-06

Community Based Forest Management for Future Climate Change Mitigation and Adaptation – Evidences from Northwestern Mountain Region of Pakistan

K. Iqbal (1)
(1) University of Agriculture, Faisalabad, Faisalabad, Pakistan

Mountain regions are highly vulnerable to global climate change and people living in these areas are first to be affected because their livelihoods are dependent on natural resources (land, pastures, water and forests). Natural forests are a vital component of the daily lives of the mountain communities and it is well documented that degradation in forest resources has adverse effects on the livelihoods of these communities. Forest protection through sustainable forest management strategies is considered as an alternate strategy to mitigate the negative consequences of climate change but the governments of developing countries face many challenges regarding forest management due to poor top-down governance and corruption. Participatory forest management has emerged as an effective strategy for sustainable forest governance. In this perspective this paper reports the findings of an ongoing research projects regarding community based forest management and its link with climate change in northwestern Khyber Pakhtunkhwa (KP) province of Pakistan. KP province is less developed as compared to other provinces of the country, and its mountain areas are among the least developed regions. This area is regarded as highly vulnerable to climate change impacts. Farming, one of the major livelihood activity and is a main source of food for the local dwellers, is dependent on the climatic and weather conditions. Similarly, forest resources are also important for household income and meeting the needs for fuel for cooking.

In response to very high deforestation in the mountainous regions of KP, the government initiated the process of community based forest management in the province with the objective to reduce forest depletion with the help of community participation.

This paper attempts to analyze the impact of community forest management on climate change mitigation efforts as well as on the livelihoods of local communities. The paper also attempts to answer the question that how the efforts of the state and communities regarding climate change mitigation are augmented (or otherwise) with the change of system. More specifically, the paper addresses the following questions:

1. What are the patterns of climate change in the study area?
2. What is the impact of participatory forest management on livelihoods of local communities?
3. How local livelihoods and farming practices changing with time and what are the coping strategies of farmers in the event of climate extremes?
4. What are the perceptions of local people regarding sustainable forest management and climate change mitigation in the context of participatory forest management?
5. What is the link of participatory forest management with future climate change mitigation and adaptation?

Key-informant interviews and focus group discussion was used to collect information from farmers of selected villages. Life histories of some respondents were also recorded find-out how changes in forest management paradigm are linked with livelihoods and farming practices and climate change.

Linking adaptation and mitigation in carbon sequestration projects: evidence from Belize

R. Kongsager (1) ; E. Corbera (2)
(1) UNEP DTU Partnership, Copenhagen, Denmark; (2) Universitat Autònoma de Barcelona, Barcelona, Spain

We develop a multi-dimensional framework to explore the extent to which carbon forestry initiatives integrate adaptation concerns, and use three Belizean projects as case material. We demonstrate that the rhetoric of linking mitigation and adaptation is not easy to hold, because the mandate of forest carbon markets does not incorporate adaptation concerns. Projects' contribution to adaptation relate to unintended forestry and biodiversity aspects while, critically, their mitigation potential is debatable and their livelihood outcomes are limited in scope and relevance. We conclude that integration of adaptation and mitigation in Belize's carbon offset projects remains a laudable but elusive goal.

P-2216-08

Climatic impacts on managed forests: predicting the future from the past

S. Martel (1) ; D. Picart (1) ; C. Moisy (1) ; S. Lafont (1) ; D. Loustau (1) ; A. Bosc (1) ; O. Picard (2) ; V. Badeau (3) ; N. Bréda (3) ; J. Boiffin (3)
(1) INRA, Ispa, Villenave d'Ornon, France; (2) CNPF, Idf, Paris, France; (3) INRA, Eef ecologie et ecophysiologie forestières, Champenoux, France

Forests are one of the most vulnerable ecosystem under the coming climate change and a growing concern arise about their capacity to maintain ecosystem services such as production of timber, fiber and energy, climate and hydrological regulations, or soil and biodiversity protection. Climate effects are significant not only at a short time scale, but also on the temporal horizon of a forest life cycle, e.g. through continuous shifts in atmospheric CO2 concentration, air temperature and precipitation regimes induced by the enhanced greenhouse effect. This will affect not only the functioning of forests in situ but also the range and geographical distribution of forest tree species and therefore the spatial distribution of ecosystem services and production across countries and continents.

The long term sustainable management of European forests must account for these dynamic changes and the interactions between climate and forests. Observations of forest functioning growth and distribution for the last decades provide a rich information about forest response to climatic shifts and extreme events and the way management interplays with these impacts.

We present in this communication how two modeling approaches for predicting the future of managed forest at country scale might optimize past observations to strengthen their likelihood and reduce uncertainty of their projections. In situ observation networks such as flux tower networks (FLUXNET, ICOS), ICP forest network and National Forest Inventories are the main data sources used.

The climate niche modeling predicts the potential distribution of forest species in the geographic domain using past observations of climate and water balance and presence/absence of tree species. Results show an expected poleward shift of forest biomes or species due to global warming and water balance changes that may reach several 10s to 100s of km during the 21st century. Similarly, a process based model can be calibrated and evaluated using past observations to predict forest functioning as forced by climate scenarios. The energy balance and the carbon and water cycles in the soil-plant-atmosphere system are modeled at an hourly scale and integrated over an annual basis. As one of the main disturbance in the temperate forests, management is integrated through practices such as ploughing, thinning or clearcutting.

Long time series of flux measurements in monospecific forest stands are used to calibrate the model while adjusting parameters. In a second step, models have been run in various ecological conditions and we have compared the outputs to long time series of observed data from forest inventories or monitoring networks to model predictions. Last, we use climate projections derived from RCP scenarios until 2100 at 8x8 km grid to force the models.

This work is conducted across the French metropolitan area for 3 of the main European forest species: Maritime Pine, common Beech and Douglas-fir. Our results provide an evaluation of the ecosystem services (carbon sequestration, wood supply, water regulation) taking into account climate change. Based on these results we will

discuss about the way to manage/optimize these French forests in the future. To enhance cooperation between researchers and stakeholders, a panel of managers and decision makers has been involved to implement various forest management scenarios in the model.

P-2216-09

Managing of risks in Agriculture: Benefits of Conservation of forest resources in Anambra State, Nigeria

O. Ogbonna (1)
(1) University of Nigeria, Agricultural Extension, Nsukka, Enugu State, Nigeria, Federal Republic of

Forest management offers a promising alternative to depletion of forest resources. Continuous degradation of the forest reserve base has major effects on other segments of the economy. This includes reduction of forest cover leading to erosion and soil degradation. This study assessed the roles of farmers in conservation of forest resources; benefits of conservation of forest resources in the area and reasons for loss of forest resources in the area. Multi-stage sampling procedure was used to select 120 respondents for the study. Data were analysed with the use of descriptive statistics. Results show that reasons for loss of forest resources in the area included: excessive farming (M=2.8) and rapid urbanisation (M=2.0). Roles of farmers in conserving forest resources were: avoidance of illegal hunting and poaching (M=3.0), practicing continuous forestation (M=3.2) and prevention of bush burning in forest areas (M=3.3). Benefits of Conservation of forest resources in the area included: protection of forest cover (M=2.3), prevention of climate change (M=2.4) and retaining economic benefits from the forest (2.5). Hence it was recommended that there should proper planning for farming and urbanisation for conservation of forest resources in the area.

P-2216-10

Multiple trade-offs in forest management facing climate change

JL. Peyron (1)
(1) ECOFOR, PARIS, France

Forests are able to mitigate climate change through carbon sequestration, storage, and substitution. But these different options are generally conflicting. How should they be combined? This question is a first major challenge for forest management and policy. In parallel, forests are impacted by climate change through trends (beneficial or detrimental) and extreme events. They may adapt and deserve to be adapted to these gradual or brutal phenomena. Integration of trends and extreme events is a second major challenge for forestry. Adaptation and mitigation have to be distinguished because they are very different responses to climate change. In the same time, they are interrelated since mitigation supports carbon regulation as an ecosystem service influenced by forest adaptation. Synergies and trade-offs between forest adaptation and mitigation are a third challenge. Finally, climate change issues are only a part of sustainable forest management and trade-offs also exist between climate change measures and sustainability at large. This presentation will comment these four issues from models running at national and stand levels.

At national scale, the carbon balance of French forests will be projected over the 21st century according to scenarios combining various harvest options with different climate change intensities. At stand level, a micro economic model will combine trends and extreme events, mitigation options and climate change impacts in order to find the best rotation age. The results of these models at two different scales will then be discusses in the frame of sustainable forest management.

P-2216-11

National Strategy for Adaption to Climate Change in Hemiboreal Estonia: Forestry

H. Tullus (1) ; M. Suškevi□s (2) ; A. Tullus (3) ; R. Lutter (1)
(1) Estonian University of Life Sciences, Institute of forestry and rural engineering, Tartu, Estonia; (2) Estonian University of Life Sciences, Institute of agricultural and environmental sciences, Tartu, Estonia; (3) University of Tartu , Institute of ecology and earth sciences, Tartu, Estonia

Climate change can considerably affect ecosystems and different bioeconomy-sectors. In addition to climate change mitigation it is important to know relevant adaptation options. Many EU states already have national adaptation strategies and action plans. Estonia will have a comprehensive national adaptation strategy and action plan in 2016.

The special project for adaptation policies in Estonia is created in 2015: „Climate change adaptation strategy and measures for thematic fields of natural environment and bioeconomy: BioClim." (http://pk.emu.ee/en/structure/landscapemanagement/projects/bioclim/project/).

There is a chapter about forestry in the National Strategy Plan for Adaptation to Climate Change in Estonia. Also in the Estonian Forestry Development Plan until 2020 the climate change impacts and mitigation is concerned (http://www.envir.ee/sites/default/ files/elfinder/article_files/mak2020vastuvoetud.pdf).

Basic studies about climate change impact on functioning of forest ecosystems are conducted in Estonia in the Free Air Humidity Manipulation Experiment (FAHM, https://sisu.ut.ee/fahm1/main). FAHM experimental facility was created in collaboration with researchers of plant ecophysiology, applied ecology and forestry from University of Tartu and Estonian University of Life Sciences. FAHM is a unique open-air experiment where acclimation and functioning of trees and forest stands under elevated atmospheric humidity conditions is studied. Results of FAHM and their theoretical interpretation is a basis for prognosis of climate change impact on Estonian forest ecosystems and life activities of trees.

Climate change will likely cause significant long-term changes in the entire Estonian forest sector. The main impacts of climate change for hemiboreal forests and forest management in Estonia are:

- The proportions of tree species and balance between coniferous and deciduous forests will change.
- Forest industry must consider with changes in local wood assortment.
- The quality of timber may reduce.
- Extreme weather events may cause considerable and unavoidable damage.
- The risk of wind damages will increase.
- The reduced period of frozen ground makes timber harvesting more difficult.
- Increasing precipitation means more investment into forest roads and ditches.
- One of the most important possible hazards associated with climate change concerns forest pests and diseases, especially outbreaks of invasive diseases and mass production of insect pests.

Novel adaptation methods must be elaborated in forest plant production, tree selection and breeding, tending of forests, forest protection, felling systems and forest pathology.

P-2216-12

Potential Risk of Wildfire under Climate Change in Croatia

M. Vucetic (1)
(1) METEOROLOGICAL AND HYDROLOGICAL SERVICE, AGROMETEOROLOGICAL DEPARTMENT, ZGREB, Croatia

The weather conditions such as a long-lasting dry spell and insolation duration, high air temperature and strong wind essentially increase the potential risk for starting and spreading of wildfires. All these relevant factors are observed on the Croatian Adriatic coast and islands and lead to the conclusion that the Adriatic area is prone to wildfires during summer season. The main goal is to research the regional impact of climate change on the potential greater risk of wildfires in Croatia from May to

September. Monthly and seasonal severity rating (MSR and SSR) are used as indices for the potential risk assessment of forest fires which are one of the products of the Canadian Forest Fire Weather Index System. According to the map presentation of mean long-term seasonal severity ratings for the standard climatic period 1961-1990, the most endangered area is the mid-Adriatic coast with the adjacent islands. Using the secular weather series of Crikvenica and Hvar in the period (1901-2014), which represent the northern and middle Croatian coast and islands respectively, the secular variations of MSR has been estimated. In order to establish the eventual increase in potential wildfire risk on the Croatian mountainous hinterland and lowlands the secular data of Gospic, Zagreb-Gric and Osijek has also been used for the MSR assessment. A significant monthly increase (significant level is 0.05) in the MSR was observed for Crikvenica for all months of the period considered and for Hvar in June and July. This increase is particularly important for June, as it indicates the possibility of the earlier onset of the forest fire season on the Adriatic area. The analysis also showed spreading of high potential risk of wildfire from the mid-Adriatic to the northern, especially in July and August in the last 114 years. However, positive trend of potential risk of wildfire noticed in the eastern part of Croatia in the last 64 years. Tendency of increase the potential risk of wildfires in Croatia is in accordance with the projections of climate change. Thus, forest fire regime in our country fits well into the larger picture of increasing areas of high threat of wildfires in the Mediterranean and Eastern Europe in the summer months in future.

2217 - Global scenarios of land-use change and land-based mitigation, and their importance in the climate system

Land Use, Land Use Change and Forestry (LULUCF) contributed 24% of total greenhouse gas emissions and 11% of CO2 emissions in the 2000-2009 period (IPCC, 2014). Land-based mitigation strategies are essential to achieve the 2oC target, with most current scenario projections invoking substantial negative emissions from afforestation and from bioenergy with carbon capture and storage (BECCS), in addition to Reduced Emissions from Deforestation and Degradation (REDD+) and improved agricultural management. Reporting and accounting of some LULUCF activity is already embedded in international climate policy. Negotiations leading up to adoption of new international policies at the Paris 2015 Climate Summit include further LULUCF activities, particularly REDD+. This reliance on land-based mitigation options necessitates that LULUCF policy is in-line with the latest evidence across the natural, economic and social sciences, and that scientific research reflects policy needs. This presentation will review the importance of LULUCF mitigation options in current and planned policy, indicating mismatches with scientific knowledge, often due to different considerations of spatial and temporal scales. We will also explore time lags between the emerging scientific insights, policy targets and commitments and changes in activity leading to desired changes in physical and ecological systems.

For example, scientific research has long emphasised the importance of REDD+ as a low cost, multiple-benefit near-term mitigation option, although international policy is only just catching up. New analyses of the biophysical climate impacts of land use change from both observations and Earth System Modelling (ESM) further confirm the importance of tropical forests as providing a cooling effect through changes in the surface energy budget and in evapotranspiration rates. The biophysical climate effects of afforestation in temperate and boreal areas can however either amplify the biogeochemical cooling effects (e.g through enhanced evapotranspiration in summer) or dampen them (e.g. through reduced surface albedo in winter). At the global scale, net biophysical effects are small and biogeochemical effects of land sources and sinks of CO2 dominate the climate impacts of LULUCF. The regional nature of the effects and the still large uncertainty in the science imply that the evidence base is not yet sufficient to implicate changes in international mitigation policy, particularly related to afforestation/reforestation activities, although effects are likely be important to consider in regional or national adaptation policy. Biophysical effects should be considered in the current development of land-based mitigation scenarios and modelling capability for the next generation of integrated climate-nature-society-policy projections so the implications can be assessed.

Bioenergy has been one sector where controversies in scientific understanding, socio-economic modelling and policy implementation have been particularly apparent and there is a need for the stronger use of evidence and more joined up approach. Recent studies suggest that in the longer term bioenergy may provide larger offsetting potential than afforestation where contribution is small once forests reach maturity. However, to fully reach the potential it will be important to ensure technological improvements, assessment of full life-cycle costs, and the implementation of sustainability criteria. Given the potential lags in the scientific, technological and uptake steps, more resources needs to be put in place now or soon if BECCS is to be expected to contribute significantly to global mitigation by 2050.

'Land-Use and Climate, IDentification of robust impacts' (LUCID): What have we learned from this project (2008-2013)? Suggestions / attempts to move forward

N. De Noblet-Ducoudré (1) ; A. Pitman (2) ; V. Brovking (3)

(1) Laboratoire des Sciences du Climat et de l'environnement, CEA-CNRS-UVSQ, Gif-sur-Yvette cédex, France; (2) ARC Centre of Excellence for Climate System Science, The university of new south wales, Sydney, Australia; (3) Max Planck Institute for Meteorology, Hamburg, Germany

The objectives of the LUCID international project are to qualify and quantify robust biogeophysical and biogeochemical impacts of land-use induced land-cover changes on climate (LULCC), from pre-industrial times to nowadays, and from today till the end of the 21st century. By 'robust' we mean that is above the noise generated by model variability and consistent across multiple climate models.

Two steps were undertaken for the 1st phase: one focused on historical climate (from ~1870 till years 2000), and another looking into the future (outlook and papers may be found on our web site: http://www.lucidproject.org.au/index.html).

Seven modelling groups contributed to the historical part. They all conducted two series of two experiments using

observed interannually and seasonally varying SST and sea ice extent for both present-day and pre-industrial conditions, forced with two sets of land cover distributions reflecting the state of the canopy respectively in ~1870, and ~1992.

We have demonstrated that climate change in large regions of the northern hemisphere may be as much influenced by LULCC than by changes in global quantities (CO2, SSTs, ...), with either amplifying or dampening effects. Moreover extremes (e.g. temperature) simulated in climate models are quite sensitive to LULCC (Pitman et al. 2012). Detection/attribution of local to regional changes in climate/meteorology may therefore be strongly biased if one does not account for changes in local to regional land-uses. Similarly we emphasized that downscaling of global climate simulations must include land-cover (and/or land-use) changes.

We have also shown that the response of individual models to deforestation varies not only in magnitude but also in sign from one model to another for some variables such as latent heat flux. This diversity could certainly be better constrained by a proper evaluation of our land-surface models (or DGVMs) in both an off-line and on-line mode. There is a need to properly evaluate the sensitivity of our LSMs (and then our coupled LSM-GCMs) to land cover changes and to land uses using a wide range of observations as for example was done in Boisier et al. (2013 and 2014).

During the LUCID exercise, we have discovered that going from a set of crops and pasture maps to land-cover maps was not only a difficult task as it involves choices, but was also a mean to increase the dispersion between the models' results. There is therefore a need to harmonize the procedure to go from those maps to land-cover. This is highly important for the biogeophysical effect on climate, and is crucial for the carbon cycle. Moreover, as DGVMs become more complex and start to include better representation of crop function and management, we'll soon be facing the need to better interact upstream IAMs who provide climate modelers with such maps.

The LUCID community also contributed to the fifth Coupled Model Intercomparison Project (CMIP5) and analyzed scenarios of future climate change. Six CMIP5 modeling groups performed additional LUCID-CMIP5 simulations without anthropogenic land-use changes from 2006 to 2100. Those analyses revealed that the effects of land-use changes on mean annual temperature in RCP8.5 and 2.6 scenarios are significant for regions with land-use changes exceeding 10%. Changes in land-surface albedo, available energy, and latent heat fluxes are small but significant for most ESMs in regions affected by land-use change (Brovkin et al., 2013). These climatic effects are relatively small, as land-use changes in the RCP2.6 and RCP8.5 scenarios are small in magnitude and mainly limited to tropical and subtropical regions. Crops tend to warm climate in most areas and models. A causal link between LULCC forcing and the climate impact is found in some models where the presence of pastures tends to induce a local biogeophysical cooling which offsets a biogeochemical warming. Conversion to pastures thus may have a climate change mitigation potential but more detailed and idealized experiments are required.

Shared Socio-economic Pathways – a framework for assessing potential land use futures –

A. Popp (1) ; K. Calvin (2) ; P. Havlik (3) ; F. Shinichiro (4) ; E. Stehfest (5)

(1) Potsdam Institute for Climate Impact Research, Potsdam, Germany; (2) JGCRI, Joint Global Change Research Institute , College Park, United States of America; (3) IIASA, Laxenburg, Austria; (4) National Institute for Environmental Studies, Tsukuba, Japan; (5) PBL Netherlands Environmental Assessment Agency, The Hague, Netherlands

Today, land-use and land-use change are responsible for approximately a quarter of global greenhouse gas emissions, largely from tropical deforestation, methane emissions from livestock and rice cultivation, and nitrous oxide emissions from livestock and fertilized soils. But, the land system is also seen to contribute much to climate change mitigation in the future by providing biomass for bioenergy, improved agricultural management and conserving or even enhancing carbon stocks of ecosystems. The degree of both, future emissions but also mitigation potential of the land depend strongly on uncertain trends in population growth, dietary changes, trade, possible demand for non-food products such as bioenergy, future developments in agricultural yields and relevant policies. Over time, these uncertainties may result in very different land-use patterns and associated emissions.

Scenario analysis has been established as a tool to explore and evaluate such extensive uncertainties associated with possible future developments. Recently, new scenarios have been developed that are organized around two important dimensions: The five radiative forcing levels consist of four representative concentration pathways (RCPs) which determines the amount of climate change. The possible future socio-economic conditions that could correspond to individual forcing levels are then described in the shared socio-economic pathways (SSPs). The SSPs provide 5 different stories of future socio-economic development, including possible trends in agriculture and land use. Future emissions and carbon stock dynamics in the land system are a function of complex interaction between all kinds of socio-economic factors, including population dynamics, economic development, technological change, trade, cultural and institutional changes and interaction with other sectors such as bioenergy demand for energy supply and transport. In each of the SSPs, climate policies can be introduced to reduce emissions or to enhance carbon uptake to reach radiative forcing level targets consistent with the RCP scenarios.

In this presentation, we will first present relevant aspects of the SSP framework for the land system. Then, based on a study that applied the scenario matrix approach combining climate forcing and socioeconomic dimensions for so-called integrated assessment models (IAMs) with dedicated land use modules, we will focus on possible future pathways for these drivers and their consequences on the land system, associated emissions and mitigation potential.

Risk-aversion Behavior in Smallholder Farmers and Climate Change. Evidence from Empirical Work in Zambia

A. De Pinto (1) ; V. Smith, (2) ; R. Robertson, (1) ; A. Haruna, (1)

(1) International Food Policy Research Institute, Washington, DC, United States of America; (2) Montana State University, Economics, Bozeman, United States of America

When the economic effects of climate change are considered, decision-making under uncertainty and risk are arguably at the forefront of the problems that need to be analyzed. The consensus is that, in the developing world, smallholder farmers are among the most vulnerable to the effects of climate change and, especially, to the adverse consequences that derive from more volatile and extreme weather events with which climate change is associated. Further, there is overwhelming empirical evidence that risk considerations affect farmers' land allocation and other input usage decisions as well as their technology adoption choices. However, apart from the body of research on index insurance, an extensive review of the empirical literature that deals with climate change reveals that uncertainty and the role of risk-aversion are notably not taken into account in models that estimate the impacts of climate change on agricultural production, market prices and food security for the poor. In particular, those models do not consider the effects of climate change related increases in yield and price volatility on farm household choices with respect to production strategies that provide adaptation or mitigation services. In fact, farmers and farm households respond to changes in the riskiness of their decision making environments as well as to changes in expected average yields, crop prices and input prices. How they respond depends on many factors, but attitudes to risk are widely viewed as important in many contexts, not least when exogenous shocks such as climate change alter the fundamental nature of the production environment in which farmers operate. We therefore explore the role of risk in the farm household's production decisions by using a widely available household survey of farmers in Zambia to build a theoretically based empirical model of land-use choices. The model accounts for attitudes to risk in analyzing the effects of climate change on farm-level land allocation to crop production. The empirical specification

is based on a relatively simple discrete-choice model (nested logit) augmented by risk variables consistent with a mean-variance utility function. After the system is shocked with changes in temperatures, precipitation, and distribution of crop yields consistent with regional effects of climate change, the household decisions and the resulting production trends are aggregated and evaluated at the country level. Shifts in the geographical pattern of crop production appear evident using this analysis with crops like millet and cassava largely replacing maize production. More importantly, results indicate that in the case of Zambia the aggregate effects of risk-mitigating decisions exacerbate trends driven by the biophysical changes caused by climate change. These decisions represent a form of adaptation of small households to the changing climate. The effects of this form of adaptation, developed in the constraints of smallholder production, appear to be detrimental for the total output from the agricultural sector with important implications for market prices and food security for both the rural and urban poor. Three important conclusions follow from our analysis. First, risk matters; its effects on farmers' production decisions should not be ignored and should be accounted for in empirical models of the impacts of climate change. Second, concentrating on farm-level responses to climate change is not sufficient. It is essential to develop methods of aggregating individual responses to climate-change-related shifts in risk so that they can be reflected in models of regional and national crop and livestock markets. This is required to better understand the implications of climate change for ecosystem services and food and income security. Third, our results suggest that not accounting for farmers' risk attitudes can lead to significant mistakes in policy planning. It is also the case that a more accurate estimate of the effects of climate change on farmers' land-use and production decisions will enable policy makers to more accurately assess the benefits and costs of a wide range of policies intended to mitigate climate change's adverse effects.

O-2217-02

Quantifying the impact of LULCC on biogeochemical cycles into the future under alternative mitigation and policy scenarios. What are the carbon and water costs of different mitigation options?

M. Groenendijk (1) ; P. Anthoni (2) ; A. Arneth (2) ; A. Bondeau (3) ; P. Ciais (4) ; JC. Doelman (5) ; P. Friedlingstein (1) ; F. Humpenoeder (6) ; A. Krause (2) ; W. Li (4) ; C. Müller (6) ; N. De Noblet-Ducoudré (4) ; A. Popp (6) ; TAM. Pugh (2) ; S. Sitch, (1) ; E. Stehfest (5) ; D. Van Vuuren (5) ; C. Yue (4)

(1) University of Exeter, Exeter, United Kingdom; (2) KIT, Atmospheric environmental research, Garmisch-Partenkirchen, Germany; (3) Institut Méditerranéen de Biodiversité et d'Ecologie Marine et Continentale, Aix-en-Provence, France; (4) Laboratoire des Sciences du Climat et de l'Environnement, Gif-sur-Yvette, France; (5) PBL Netherlands Environmental Assessment Agency, Bilthoven, Netherlands; (6) Potsdam Institute for Climate Impact Research, Potsdam, Germany

Future impacts of land-use and land-cover changes (LULCC) on the biochemical cycles and biophysics are highly uncertain. Firstly, there are large uncertainties in possible future scenarios due to socio-economic parameters (e.g., food demand, trade liberalisation, technological development). Secondly, there are uncertainties in how cropland, pasture and natural vegetation respond to changes in climate. With a model comparison we address both these uncertainties. Three different future scenarios are run with the Integrated Assessment Models (IAMs) IMAGE and MAgPIE. The socio-economic setting in all scenarios is based on the Shared Socioeconomic Pathways 2 (SSP2), and all scenarios include climate change impacts for RCP2.6, which have direct effects on crop yields and terrestrial carbon stocks, and indirect effects on land-use dynamics. A bio-energy with carbon capture and storage scenario (BECCS) and an afforestation and avoidance of deforestation scenario (AD+AFF) are compared to a reference scenario with no land-based mitigation (REF). The land use changes from these 6 IAM scenarios are subsequently used to run the 4 Dynamic Global Vegetation Models (DGVMs) JULES, LPJ-GUESS, LPJml and ORCHIDEE. This comparison will show the impact of different future mitigation scenarios on the carbon and water balance, the development of natural vegetation and crop yields over the 21st century.

O-2217-03

Understanding the role of land management for carbon and climate mitigation under RCP 4.5 and RCP 8.5 using the Community Earth System Model

P. Lawrence (1) ; B. O'neill (2)

(1) National Center for Atmospheric Research, Climate and Global Dynamics Division, Boulder, United States of America; (2) National Center for Atmospheric Research (NCAR), Boulder, CO, United States of America

As part of the Coupled Model Intercomparison Project phase 5 (CMIP5), land cover change and wood harvest were prescribed as major climate forcings for historical and future Representative Concentration Pathway (RCP) projections. Lawrence et al. (2012) described how land cover change was prescribed in all of these simulations and how the climate system and carbon cycle responded to the land cover change in concert to other transient forcing in the Community Earth System Model (CESM). The attribution of carbon cycle and climate changes directly due to land cover change however, were not possible due to the design of the CMIP5 experiments. Through a series of new CESM simulations we have attributed the land cover change impacts for the historical time series as well as RCP 4.5 and RCP 8.5 with and without land cover change. These simulations show that the direct land cover change fluxes to the atmosphere found in the CMIP5 simulations did not account for the lost uptake of carbon that would have been possible in the absence of land cover change and wood harvest. Once these losses are taken into account, the historical losses of terrestrial carbon increased from 61.2 PgC to 129.6 PgC, the RCP 4.5 uptake of 62.8 PgC changed to a loss of 5.8 PgC, and the RCP 8.5 loss of 49.0 PgC increased to 168.8 PgC. In order to assess the potential of land management to mitigate carbon and climate consequences we are currently simulating RCP 4.5 and RCP 8.5 with large scale global afforestation scenarios compared to maximum biofuel production through increased crop lands. In this talk we present the differences in all of these experiments for both ecosystem carbon and climate. To conclude this presentation we will provide details on the proposed land use simulations for CMIP6, currently being designed in the Land Use Model Intercomparison Project (LUMIP).

Zero-Tillage lessens soil CO2 emissions the most under arid and sandy soil conditions: results from a meta-analysis

K. Abdalla (1) ; V. Chaplot (2) ; P. Chivenge (1)

(1) University of KwaZulu-Natal, Centre for Water Resources Research, School of Agricultural, Earth & Environmental Sciences, Pietermaritzburg, KwaZulu-Natal province, South Africa; (2) Institute of Research for Development (IRD), Laboratory of oceanography and climate (locean), pierre and marie curie university, Paris, France

The management of agroecosystems plays a crucial role in the global C cycle with soil tillage leading to known organic carbon redistributions within soils and changes in soil CO2 emissions. Yet discrepancies exist on the impact of tillage on soil CO2 emissions and on the main soil and environment controls. A meta-analysis was conducted using 46 peered reviewed publications totaling 174 observations comparing CO2 emissions from tilled (T) and no-tilled (NT) soils with the objective to quantify tillage impact on CO2 emissions and to assess the main controls. On average, T soils emitted 21% more CO2 than NT soils, which corresponded to a significant difference at $P<0.05$. The difference increased to 29% in sandy soils from arid climates with low soil organic carbon content (SOCC<1%), but tillage had no impact on CO2 fluxes in clayey soils of high SOCc (>3%). Finally, nitrogen fertilization and crop residue management had little effect on the CO2 responses of soils to tillage. These results on the role of soil and environmental conditions on soil CO2 emissions response to tillage are expected to increase our understanding of carbon outputs from terrestrial ecosystems as well as to set up effective mitigation measures of climate change

mitigation.

P-2217-02

Potential impacts of forestation on the future climate change in Southern Africa

A. Babatunde (1) ; M. Naik (1)
(1) Univesrity of Cape Town, Environmental And Geographical Science, Cape Town, Western , South Africa

Many studies have projected the future climate change over Southern Africa, but without including the influence of on-going forestation activities in the region. The present study investigates how the forestation activities may alter the projected climate change. For the study, two regional climate models (RegCM4 and WRF) were applied to simulate the present-day (1970-2005) climate, and the future (2030-2065; IPCC RCP 4.5) climate, with and without forestation. The simulations account for the potential impacts of natural bush encroachment and the commercial forestation over the eastern part of South Africa. The results agree with previous studies in that the elevated greenhouse emissions would induce warming over Southern Africa in the future, but the results further indicate that forestation would enhance the warming over the forested area and induces cooling elsewhere. The additional warming over the forested area is due to the albedo-effect of the forestation, while the cooling is due to the dynamic feedback of the local warming over the forested area. For similar reasons, the forestation would induce both wet and dry conditions over the sub-continent in future. As a result of its combined influences on rainfall and temperature, the forestation would enhance drought frequency over some areas, but reduces it over other areas in Southern Africa. This study suggests that using forestation to mitigate the impacts of global warming may produce unintended climate impacts over some areas in Southern Africa. Hence, the biophysical effects of forestation in Southern Africa should be weighed against the biogeochemical benefits.

P-2217-03

Low-Density Development and the Increasing Greenhouse Emissions in Malaysian Special Economic Zones

A. Barau (1)
(1) Universiti Teknologi Malaysia, Urban and Regional Planning, Johor Bahru, Johor, Malaysia

Low-density development is one of the major problems associated with rapid urbanization in the global south. Special economic zones (SEZs) constitute new layers of capital driven urbanization and industrialization in many Asian emerging economies. In many Asian countries, SEZs cause rapid fragmentation of landscapes within and around urban areas. This paper focuses on Iskandar Malaysia, one of the most successful emerging SEZs in Southeast Asia. This economic region has attracted more than US$25 billion so far from the expected US$100 billion investments in housing, education, tourism and infrastructure to be realized by 2025. Recent studies have projected that by 2025, if the business as usual model continues, the region's greenhouse emissions and energy consumption will increase more than 70% and 80% respectively. The paper aims to link and discuss how fragmentation of agricultural landscapes, mangroves, coastal vegetation and other green areas give rise to increasing emissions through new urban development projects. The current study relied heavily on fieldwork, landscape metrics for calculation of landscape change using GIS and FRAGSTATS. The study findings used established examples within the region and beyond, to estimate increases in emissions and carbon storage capacities from fragmented agricultural landscapes, mangroves, new low-density development activities, and expanded roads. The findings clearly showed that landscape change is one of the principal source of carbon emissions that climate scientist underestimate in the Asian emerging economies. The study highlights the critical threats of low-density development in increasing carbon emission.

P-2217-04

Understanding complex networks, trade-offs and synergies within the science-policy domain for land-based climate mitigation

R. Berman (1) ; MD. Rounsevell (2)
(1) University of Edinburgh, School of Geosciences, Edinburgh, United Kingdom; (2) University of Edinburgh, School of geographical sciences, Edinburgh, United Kingdom

The agriculture, forestry and other land use sector (AFOLU) is a major contributor to greenhouse gas (GHG) emissions. Mitigation within this sector, as well as the interplay between mitigation and adaptation, are crucial therefore in efforts to address climate change. The highly complex institutional structures of global climate policy and the 'wickedness' of the climate change problem lead to trade-offs and synergies, or overlaps and gaps, across land-based mitigation and adaptation policy. Hence there is a need to investigate and examine the mechanisms surrounding the policy environment. Many scientific studies on mitigation and adaptation claim important policy implications from their findings. Whilst a time-lag between the scientific understanding on both direct and indirect trade-offs and synergies within climate adaptation and (land-based) mitigation and policy may be expected, other gaps within the policy arena are likely to exist.

We map these complex policy and scientific arenas through a content analysis of the global scientific knowledge of climate change (from peer-reviewed literature) and of global policy approaches (using International Environmental Agreements). Overlaps and synergies between relevant topics and sectors that exist across different policy and science themes are identified and analysed through a network analysis approach. This approach enables not only the identification of key topics within the scientific and policy documents, but also the degree of overlap between these topics.

This presentation summarises the findings of a series of research questions which have sought to unpack the complex networks between science and policy, but also within global climate policy itself. These include:

- What are the key trade-offs and synergies within global land-based climate policy?
- How has the science-policy relationship changed historically?
- Is there a current mis-match between the global scientific understanding of land-based mitigation and adaptation and global climate policy?

By mapping the current policy network, we show that opportunities for policies to have triple-wins, supporting adaptation, mitigation and sector specific development. Furthermore, we identify gaps within the political environment to which future policy decisions should seek to contribute in order to deliver resource-efficient, land-based mitigation. Comparing the political network to the mapped network of current scientific understanding, we identify key trade-offs that policy needs to account for, and explore how this has varied over time.

P-2217-05

Land Use Change as Barrier and Enabler for Integrated Climate Change Responses

I. Brown (1) ; D. Feliciano (2)
(1) James Hutton Institute, Aberdeen, United Kingdom; (2) Institute of Biological and Environmental Sciences, School of Biological Sciences, Aberdeen, United Kingdom

Land has a finite supply but is subject to an increasing range and intensity of demands that usually involve complex interactions between climate and socioeconomic factors. We have used detailed land use survey data and interviews to investigate these interactions in Scotland (UK) and how they may shape future landscapes using scenario analysis that combines these data with global drivers. The analysis shows the importance of considering 'path dependency' in the evaluation of both adaptation and mitigation land use options. It also highlights that current separation of adaptation and mitigation strategies can result in them 'competing' for the same area of land.

Biophysical factors that influence land supply, including climate and soils, have been analysed using land capability/suitability concepts to investigate the changing options

available for land managers. Socioeconomic factors have been summarised in terms of the 5 Ps (Policy, Preferences, Prices, Power, Path Dependence) to provide a framework for understanding their relative influence. These influences vary between different localities and regions, and particularly between lowland and upland landscapes. High quality land in the lowlands is currently prioritised for food production and much of the land in the uplands has very limited options therefore is effectively prioritised for nature conservation, tourism and recreation. This leaves an area of land that is currently of intermediate quality ('the Squeezed Middle') which has many competing and increasing demands: food, energy, water, afforestation, flood protection, infrastructure etc.; in particular, this land together with the uplands is identified as crucial for meeting climate mitigation targets for GHG emissions reduction.

However, the changing climate further complicates issues because it is affecting land quality (ie. supply) concurrent with changes in demand due to drivers such as globalisation and new technology. The relative influence of top-down and bottom-up factors are therefore changing temporally and geographically, and are particularly exemplified by reactive adaptation responses to recent anomalous or extreme weather. Scenario analysis shows how these factors may play out in the future and how policy could have a more positive influence by encouraging integrated and planned adaptation in coordination with mitigation objectives.

We find that local preferences and the role of path dependence are currently having a high influence on land use decisions. Although land use options are being modified as climate change modifies land capability, the preferences of land managers are to extend options with which they are already familiar. This is usually due to aversion to the risks involved with uptake of new options and concerns over loss of policy support (particularly from the subsidies of the EU Common Agricultural Policy). As a consequence, adaptation measures tend to be mainly reactive and mitigation measures are extensions of those already in use.

In more marginal locations, the role of subsidy support is crucial in influencing land use choices, and this has resulted in new woodland tending to be marginalised to the poorest quality land despite its potential advantages in delivering both adaptation and mitigation benefits. On both high quality and marginal land, the role of policy in counteracting negative influences could be considerably enhanced through stronger spatial targetting of measures based upon local characteristics.

It is particularly salient to note that most land managers acknowledge that seasonal weather, which influences their planning and activities, is changing (regardless of attribution to anthropogenic cllimate change) and they recognise this as a key challenge that they need to better understand and manage. However, path dependence is often entrenched because to fully adapt to change requires negotation and coordination with other land users over a larger area. Currently, policy is mainly developed sectorally and implemented through individual measures that discourages this coordination.

P-2217-06

Global assessment of the biophysical climate impacts of deforestation

A. Cescatti (1) ; R. Alkama (1)
(1) Institute for Environment and Sustainability, Climate Risk Management, Ispra, Italy

Deforestation impacts climate in two major ways: affecting the atmospheric CO2 concentration and modulating the land-atmosphere fluxes of energy and water vapor. Given the important role of forests in the global carbon cycle, climate treaties account for land-based mitigation options like afforestation, reforestation and avoided deforestation or forest degradation. On the contrary, predicted climate impacts of biophysical processes, such as the exchange of energy and water vapor, are still uncertain in sign and magnitude, and therefore have not been considered in climate negotiations to date. Direct observations of the biophysical climate effects of forest losses and gains are therefore required to constrain model predictions, reduce the uncertainty of model ensembles, and provide robust recommendations to climate policy.

In this work we report an observation-driven global analysis of the biophysical impacts of forest losses and gains on the local climate, based on a combination of Earth observations of forest cover, surface radiometric temperatures and in-situ air temperatures. Our results document that deforestation causes local changes in air temperature that varies in sign and magnitude according to the climate zone. In addition, forest losses affect the local climate also by altering the diurnal and annual temperature variation at all latitudes. These experimental evidences provide a global and robust quantification of the local climate sensitivities to deforestation and a novel assessment of the mitigation potentials of forests on the diurnal and seasonal temperature variations. Overall, the observation-driven, global quantification of the biophysical signal of deforestation provided in this study may support the inclusion of land biophysics in climate negotiations and the definition of novel protocols for the measurement, reporting, and verification of these relevant effects.

P-2217-07

Quantifying the relative importance of land cover change from climate and land-use in the representative concentration pathways

T. Davies-Barnard (1) ; P. Valdes (2) ; A. Wiltshire (3) ; C. Jones (3) ; J. Singarayer (4)
(1) University of Exeter, Exeter, United Kingdom; (2) University of Bristol, Bristol, United Kingdom; (3) Met Office Hadley Centre, Exeter, United Kingdom; (4) University of Reading, Reading, United Kingdom

Climate change is projected to cause substantial alterations in vegetation distribution, but these have been given little attention in comparison to land-use in the Representative Concentration Pathway (RCP) scenarios. Here we assess the climate-induced land cover changes (CILCC) in the RCPs, and compare them to land-use land cover change (LULCC). To do this, we use an ensemble of simulations with and without LULCC in earth system model HadGEM2-ES for RCP2.6, RCP4.5 and RCP8.5. We find that climate change causes an expansion poleward of vegetation that affects more land area than LULCC in all of the RCPs considered here. The terrestrial carbon changes from CILCC are also larger than for LULCC. When considering only forest, the LULCC is larger, but the CILCC is highly variable with the overall radiative forcing of the scenario. The CILCC forest increase compensates 90% of the global anthropogenic deforestation by 2100 in RCP8.5, but just 3% in RCP2.6. Overall, bigger land cover changes tend to originate from LULCC in the shorter term or lower radiative forcing scenarios, and from CILCC in the longer term and higher radiative forcing scenarios. The extent to which CILCC could compensate for LULCC raises difficult questions regarding global forest and biodiversity offsetting, especially at different timescales. This research shows the importance of considering the relative size of CILCC to LULCC, especially with regard to the ecological effects of the different RCPs.

P-2217-08

Uncertainties of future land use change and the potentials of land-based mitigation - an analysis with the SSP scenarios and the IMAGE 3.0 integrated assessment modelling framework

JC. Doelman (1) ; E. Stehfest (2) ; D. Van Vuuren (3)
(1) PBL Netherlands Environmental Assessment Agency, Climate, Air and Energy, Bilthoven, Netherlands; (2) PBL Netherlands Environmental Assessment Agency, The Hague, Netherlands; (3) PBL Netherlands Environment Agency, PBL, Climate, air pollution and energy, Bilthoven, Netherlands

Historically, the continuous increase in anthropogenic land use has been an important driver of CO2 emissions and biodiversity loss. The scale and dynamics of future land use change (LUC) are very uncertain. The recently proposed concept of Shared Socio-economic Pathways (SSPs) allows us to systematically analyze some of the uncertainties. Integrated assessment models, like IMAGE, can explore the linkages within these scenarios between socio-economic drivers, technology projections, developments in the energy system, policy assumptions

and implications for future land-use. It can also look at future land use projections which are dynamically coupled to changes in the global climate and carbon cycle. This provides the possibility to determine the potential of land-based mitigation options, and directly assess the climate and carbon effects under different scenarios. In this contribution, we present a recent IMAGE analysis using the SSPs to explore the uncertainty in future land use in relation to mitigation action.

The analysis shows anthropogenic land use (crop and pasture land) could increase by 4 million km2 (SSP3, driven mostly by population growth and dietary changes), but also decrease by 7 million km2 (SSP1, as a result of yield improvements and intensification). Cumulative CO2 emissions from LUC by 2100 range from an increase of 280 Gt CO2 (SSP3) to a decrease of 70 Gt CO2 (SSP1), equivalent to an increase of 36 ppmv and a decrease of 9 ppmv CO2 in the atmosphere respectively.

Land-based mitigation measures are an important component of ambitious climate mitigation scenarios. The implementation of options such as bio-energy, reforestation, REDD, agricultural intensification or dietary change have large potentials. However, the net impact depends highly on the context of implementation. Socio-economic trends and non-land climate mitigation substantially affect the land-based mitigation potential, which is typically very location-dependent. The SSP analyses shows the potential of a range of mitigation options. An example is the implementation of REDD in an SSP1 scenario with ambitious climate mitigation, where areas with large carbon stocks are protected. This results in additional intensification of agricultural land due to limited land availability, and a shift of agricultural expansion to areas with lower carbon stocks. Due to this measure, carbon emissions are reduced by 87 Gt CO2, equivalent to 11 ppmv CO2 in the atmosphere.

Next to biogeochemical climate effects, biophysical climate effects of LUC have a substantial impact. Regionally, the net temperature effect of changes in the land energy balance due to differences in albedo or evapotranspiration can be in the same order of magnitude as projected global warming. The location of change is very important, as deforestation in the tropics can lead to a surface warming of 0.5-1 degrees compared to a surface cooling in the highest latitudes of 3-4 degrees (Davin & Noblet-Ducoudré, 2010). As part of the LUC4C FP7 project, the biophysical effects of the SSP land use projections will be studied in collaboration with earth system models.

P-2217-09

Genetic diversity of perennial grass species in response to temperature during germination

AJ. Escobar Gutiérrez (1) ; LQ. Ahmed (1) ; JL. Durand (2)
(1) INRA, Lusignan, France; (2) INRA, Environnement et Agronomie, Lusignan, France

Grasslands cover more that 40% of earth's surface and at least 30% of the 160 Mha Agricultural Surface Area of Europe. They are among the largest ecosystems on earth and one of the major sources of forage. Further, in the context of climate change, grasslands are considered, similar to forest, as an important sink for atmospheric CO2. The agricultural use-value of grasslands depends on their floristic composition and the structure of their canopy. These two intertwined features directly determine the quality and the quantity of the biomass harvested by grazing or mowing. Perennial ryegrass (Lolium perenne L), tall fescue (Festuca arundinacea Schreb) and coksfoot (Dactylis glomerata L.) are the major perennial grass species in temperate and Mediterranean regions. However, during the lifespan of grassland, both floristic and genetic compositions as well as canopy structure evolve under the influences of environmental factors and the competitive interplay between individual. Floristic and genetic composition evolves because of individuals' mortality and recruitment of new species and genotypes from the soil seed-bank or natural sowing. Temperature is one of the major factors controlling plant development rates (i.e. plant phenology, organogenesis and expansive growth). It is important in controlling seed germination. Indeed, higher plant species, as well as populations, varieties and cultivars within species, respond differently to temperature during the critical period of germination and seedling establishment in the field. Literature is vast on this subject that is always a topical issue. In the context of global change, breeding grasses adapted to new ranges of temperature could be necessary. Knowing the variability of responses to temperature by different accession of germplasm is an unavoidable first step towards such breading. Thus, the objective of the work presented here was to analyse the genetic variability of L. perenne, F. arundinacea and D. glomerata in response to temperature during germination.

Eight populations of L. perenne L., nine populations of F. arundinacea and six populations of D. glomerata were evaluated. Four replicates of one-hundred seeds per population were tested for germination in the dark under eight single temperature regimes between 5 and 40°C with 5 °C. Maximum germination (%), apparent initial time of germination and germination rates were estimated.

The novelty of this work comes from the wide range of temperatures evaluated (5 to 40°C). Striking results show that no germination at all was observed at 40°C for any of the 23 populations under study. However, it was observed that, within each species, the response of populations to temperature shows high variability and statistically significant differences ($P<0.05$). Optimal temperature for germination ranged from less than 10°C to 26°C. Further, it was observed a differential sensitivity to our extreme treatments (5 and 35°C).

Overall, these results demonstrate that genetic variability does exist within the three studied grass species for response to temperature during germination. This should prompt i) physiologist to extend to other processes the analyses of response to temperature, and ii) plant breeders to collect and analyse populations of grasses from sites with extreme environmental conditions. We suggest that seed germination of populations from septentrional and cold sites is enhanced by high temperatures and limited by colder temperatures and vice versa for warm-adapted populations from the South. The variability discovered in this study should serve breeders to create grass varieties for the future.

P-2217-10

Land Degradation and Resource Based Economy – A Case Study in Indian Sunderbans

T. Ghosh (1) ; S. Saha (1)
(1) Jadavpur University, School of Oceanographic Studies, Kolkata, India

The Indian part of Sunderbans is highly vulnerable due to climate change impacts like sea level rise, erosion, salinization of soil and water, cyclones, etc. This study is an attempt to identify the drivers impacting the traditional resource based economy and consequent adaptation. Kultali (21051/N, 88030/E to 21056/N, 88034/E), an administrative area (Block) in the district of South 24 Parganas' within Indian Sunderbans on the Bay of Bengal is a very backward area in terms of poverty ratio and vulnerability index (Human Development Report, Govt. of India, 2009). The villages namely Bhubaneswari, Maipit, Binodpur, Baikunthapur, Kishorimohanpur and Bhubaneswari Char under the Kultali Block are under study, situated between the confluence of River Matla and River Thakuran. This area is highly vulnerable due to their close proximity to Bay of Bengal, frequent cyclones, coastal flooding and subsequent land inundation every year. The inhabitants solely depend on the traditional primary activities depending on natural resources to make their sustenance. In agriculture, mono-cropping is the only way of livelihood for the population, with high level of exposure to climate change and natural hazards. Inland fishing is another practice on subsistence basis, while the more vulnerable section depends on offshore fishing. Increasing salinization in river water and soil resulted from sea level rise and frequent inundation, negatively affects the fertility of soil, yield of crops and fish catch, which in turn affect the local economy. The situation has become worsen after cyclone 'Aila' on 25th may 2009, when extreme level of inundation left behind saline water stagnation for a considerable time causing deposition of salt layer on the productive topsoil, leaving the land unproductive for longer time. Consequently, change in land-use pattern as well as change in occupational structure has observed. Minimal effort to switch over to salt tolerant variety of paddy and other variants of vegetables and fruits traditionally grown are found insufficient. Hence, the workforce in the community finds agriculture as a 'loss business' and lacking any other alternate skill they intend to migrate as a

non-skilled daily labourers. Feasible adaptation measures may be recommended with further to revive this resource dependent subsistence economy.

P-2217-11

Spatial and temporal variabilities of land uses as affected by global change: a focus on Mediterranean agriculture

C. Giupponi (1) ; V. Mojtahed (1)
(1) Ca' Foscari University of Venice, Venice Centre for Climate Studies, Venezia, Italy

At the global level, climate and socio-economic changes determine the patterns of the allocation and trade of resources in all markets. Top-Down computable general equilibrium (CGE) models, using only economics factors of production (capital and labour mostly) and ignoring natural resources constraints, look at the effects of global trends and generate trajectories of socio-economic indicators, such as prices of commodities in the global markets, volumes of trades, gross products per country and sectors. Those models are commonly used to analyse the evolution of global economies, under the pressure of climate change drivers, but their approach impose substantial simplifications in terms of spatial aggregation and limited consideration of temporal variabilities.

When considering adaptation of social and ecological systems to climate change, their inherent complexity and non-linearity and spatial and temporal variabilities put the usefulness of consolidated CGE approaches under question. As a consequence, other methodological approaches are explored, and in particular more and more scholars adopt a Bottom-Up approach, which utilises agent-based models (ABM). ABM's embrace a much finer spatio-temporal detail, in particular, with the ambition to analyse the behavioural diversity of agents, as a consequence of their diverse interactions with the surrounding environment and their bounded perceptions of the changing world.

This work explores the potential for integration of the two approaches, with ABM models being used to simulate land use change dynamics, with consideration of spatial (i.e. territorial) and temporal (i.e. climatic extremes and economic shocks) variabilities, driven by CGE models providing the macro-economic trends under the effects of global change scenarios.

We focus on how global change may affect land-use allocation at the regional level, under the influence of limited natural resources, land and water in particular. We specifically explore how constrains and competition for natural resources may induce non-linearities and discontinuities in agro-ecosystems behaviour.

With the purpose to develop an approach that could be implemented worldwide as a means for zooming down from the global to the regional scale, an ABM prototype was developed and run with readily available global databases in three [VM1] test areas around the Mediterranean Basin, in agricultural regions of Morocco, Italy and Spain[VM2] . Starting with extremely simplified and averaged settings; we sequentially introduce the available information about spatial and temporal variability and simulate the dynamics of water and land-use allocations and their consequences on economic performances. The coherency of the outcomes of ABM simulations with the macro trends provided by the CGE model is discussed in view of possible further developments in terms of improved integrated multi-scale simulation of global change scenarios and economic development.

P-2217-12

Low Emission Development Strategies in Agriculture. An Agriculture, Forestry and Other Land Uses (AFOLU) Perspective

A. Haruna, (1) ; A. De Pinto (1) ; G. Hyman (2) ; J. Tapasco (2) ; M. Li (3) ; HY. Kwon (1)
(1) International Food Policy Research Institute, Washington, DC, United States of America; (2) International Center for Tropical Agriculture, Cali, Colombia; (3) International Food Policy Research Institute, EPT, Washington, DC, United States of America

Resource use in many developing countries, from crop production to deforestation, is responsible for the bulk of greenhouse gasses (GHG) emissions. We also know that there are instances in which the agricultural and forestry sectors can provide low-cost climate change mitigation opportunities. From a technical point of view, reducing expected increases in GHG emissions in agriculture requires the adoption of transformative approaches in the use of resources. A growing body of literature analyzes the effects of alternative agricultural practices; the livestock sector has also been the target of research on mitigation opportunities and the mitigation potential of forests, soil and other biomass, has been amply analyzed as well. However, from a policy-making perspective, the design of low emission development strategies is an example of multi-objective decision making in which policies target the reduction of GHG emissions while other goals such as increasing agricultural productivity and food security or attaining objectives such as export goals or economic growth, are preserved. Furthermore, it is important to consider that all countries are part of a global economic system and it is critical that policies are devised with full recognition of the role of the international economic environment which can significantly affect the long-term viability and the budgetary implications of mitigation policies. The challenge at hand is therefore to reconcile the limited spatial resolution of macro-level economic models that operate at a subnational or national level with models that function at a higher spatial resolution, which allow to properly account for changes in carbon stocks and GHG emissions. To our knowledge there are only a few examples of analyses with similar objectives: Golub et al (2013) examined the impact on food consumption and income of implementing mitigation policies at national and regional levels. Schneider et al (2008) estimated mitigation potentials of U.S. agriculture with regionally disaggregated data and changes in welfare within the agricultural sector. Rutten et al. (2014) evaluated the effects of select climate change and economic growth scenarios on Vietnam's economy. Havlik et al. (2014) estimated the effects of transitioning to more efficient livestock production system on GHG mitigation and the economy. In this work we demonstrate that different models, all widely accessible to the public, can be brought together to help policymakers in their evaluation of trade-offs, opportunities, and repercussions of alternative mitigation policies in the agricultural sector. While the focus of this work is on Colombia, the analytical framework can be applied to any country interested in exploring country-wide effects and economic viability of climate change mitigation policies in agriculture. The approach is based on the use of public and widely accessible data and we believe that the flexibility and transparency of the approach proposed in this study can increase decision-makers' trust in the results. It appears clear from our analysis that policy-makers need substantial support in their decision-making process as the range of options they face can be very diverse and the effects of their decisions have important, and sometimes unexpected, repercussions. The effects of the policies we simulated cover the entire spectrum of potential outcomes. We find win-win policies (reducing land allocated to pasture increase revenues and carbon stock and reduces GHG emissions), policies with tradeoffs (limiting deforestation in the Amazon and a moderate increase in oil palm area increases carbon stock, decreases emissions, but reduces revenues) and policies that seem to generate clearly inferior results (substantial increasing the area allocate to oil palm cultivation reduces carbon stock, increases emissions and reduces revenues). Given the complexity of low emissions development strategies, modeling approaches, frameworks, and tools should be adaptable, open, and transparent. Modeling frameworks should be adaptable so that policy makers can explore the consequences of using different data sets and incorporate new information as it becomes available. Modeling frameworks and tools should be open to the inclusion of input from different models and transparent so that the robustness of the results can be assessed. We believe that the modeling framework proposed in this work fits these characteristics. Stakeholders, from government agencies, to producer and consumers' organizations to farmers, will benefit from policies devised with the support of solid evidence and the effects of which can be investigated and evaluated by all the parties affected.

Implications of bioenergy production under various future land system pathways

F. Humpenoeder (1) ; A. Popp (1) ; J. Dietrich (1) ; B.

Bodirsky (1) ; A. Biewald (1) ; U. Kreidenweiß (1) ; H. Lotze-Campen (1) ; C. Müller (1) ; S. Rolinski (1) ; M. Stevanovic (1) ; I. Weindl (1) ; D. Klein (1)
(1) Potsdam Institute for Climate Impact Research, Potsdam, Germany

Bioenergy use in the energy sector, particularly in combination with carbon capture and storage (BECCS), plays a key role for reaching ambitious climate targets. But the large-scale production of bioenergy, which potentially requires considerable amounts of fertile land and water (Bonsch et al., 2014, GCB Bioenergy), can have side effects on land-use dynamics, land-related GHG emissions and food prices. For instance, CO2 emissions from deforestation associated with bioenergy production could lower the mitigation effect of bioenergy use in the energy sector (Popp et al., 2012, Ecol Econ). However, avoiding land use change and associated CO2 emissions due to bioenergy production could result in higher prices for food (Popp et al., 2011, Environ Res Lett) and also bioenergy (Klein et al., 2014, Environ Res Lett). There is a huge body of literature on bioenergy potentials and trade-offs with climate protection, sustainability and food security goals (Creutzig et al., 2014, GCB Bioenergy). However, most of these publications focus on single aspects, while a comprehensive and consistent analysis taking into account various uncertainties of future land system pathways, such as future food demand, development of agricultural yields, and availability of land for agricultural expansion, is still missing.

In this study, we analyze the implications of bioenergy production under various future land system pathways with the global spatially explicit land-use optimization model MAgPIE. Our general scenario setup is based on SSP2 (O'Neill et al., 2015, Glob Environ Chang) and includes global bioenergy demand (2nd generation) that increases linearly to 300 EJ by 2100. We assess the global medium to long-term implications of bioenergy production in terms of land-use dynamics, associated GHG emissions, and bioenergy and food prices. How these environmental and socio-economic indicators evolve under bioenergy production throughout the 21st century depends on key characteristics of the future land system. We test the sensitivity of these indicators to the following land system parameters that directly or indirectly affect bioenergy production: future bioenergy yields (irrigation, feedstock availability), pricing of land-related GHG emissions, forest protection, trade liberalization, future food demand, and productivity increases in the agricultural sector. Finally, we identify trade-offs and synergies related to bioenergy production along the analyzed future land system pathways.

Our results show, for instance, that GHG emission pricing strongly reduces deforestation related to bioenergy production. Consistently, CO2 emissions from land-use change are lower under GHG emission pricing. However, bioenergy as well as food prices considerably increase with GHG emission pricing due to competition for land. Thus, there is a trade-off between land-based mitigation via bioenergy and food security: low CO2 emissions from land-use change coincide with high food prices, while high CO2 emissions from land-use change coincide with low food prices.

P-2217-14

Disturbance climate in Eastern of Democratic Republic of the Congo

M. Kasangala Junior (1) ; MN. Mugeruza (2)
(1) National Institute of Agronomic Studies and Climate Research, Geography, Uvira, South-Kivu Province, Democratic Republic of the Congo; (2) Higher Technical Institute of Development, Geography, Uvira, Democratic Republic of the Congo

In DR Congo , in South - Kivu province , specifically in the territory of Uvira, Fizi, Mwenga and Shabunda , the influx of Rwandan and Burundian refugees in 1992 and 1994. And the population displacement caused by war 1996 and 1998 were at the base of the massive felling of trees in the forests therein and practice of bushfire. These trees were felled every day to serve as firewood, construction and service to millions of people and bushfire to easily obtain cultivable extended to capture wild animals and pastoral aims. Naturally, this region comprises 5 ecological zones which are the coastal plain, the tray means, the highlands and woodland. The region also has two climatic seasons including the rainy season which extends from September to June and the dry season which lasts 2 months, all the months of July and August of each year. The environment in this part has been degraded due to massive deforestation and practice bushfire. These two negative factors were the basis for the deterioration of the climate in this part of country. These massive cuts uncontrolled wood and unquantified and bushfire caused few years later in 2006 and 2007 climate change ever experienced in the region. This climate change has led to a disruption of the agricultural calendar and a sharp increase in heat. Crop period would normally start with the beginning of the rainy season in September was postponed in December or January. The rain was almost rare throughout the region during this period, and once she fell here and there on bare soil where water carried everything in their path. The flow of many rivers has decreased significantly ways and most of the rivers had dried completely. A kind of temporary drought is established. It was suffocating for lack of water everywhere. Meteorological services of the country gave each time the alert climate of the region where the temperature still ranged between 30 and 35 ° signal Many people have fallen ill and many children died of this climate change. Many wild and domestic animals perished. The plant diseases have been developed, particularly called cassava mosaic disease appeared. This disease has made cassava much less productive while cassava is the staple food most consumed in the middle. The plants were dried by lack of water. Famine is installed around the region. Communities of people, groups of people moved themselves further into the forest in search of more productive and reassuring for survival places. Alarm calls initiated by local leaders , civil society and development organizations on the climatic disturbance in that region has allowed political authorities - administrative and non - governmental organizations of development to get involved to stop all this ecological and climatic catastrophe.

To this effect, the following measures were taken:

- Formal prohibition massive cutting wood
- Priority Reforestation of denuded areas
- Cutting wood on authorization by the competent authorities
- Prohibition of bushfire
- Education and community awareness about the dangers of mass slaughter of trees and the practice of bush fire and their impact on climate change.

Seven years later, despite the efforts, the situation has not yet returned to normal.

P-2217-15

Addressing climate change mitigation and adaptation together: A global assessment of agriculture and forestry projects

R. Kongsager (1) ; B. Locatelli (2) ; F. Chazarin (2)
(1) UNEP DTU Partnership, Copenhagen, Denmark; (2) Center for International Forestry Research (CIFOR), Lima, Peru

Adaptation and mitigation share the ultimate purpose of reducing climate change impacts. However, they tend to be considered separately in projects and policies because of their different objectives and scales. Agriculture and forestry are related to both adaptation and mitigation: they contribute to greenhouse gas emissions and removals, are vulnerable to climate variations, and form part of adaptive strategies for rural livelihoods. We assessed whether climate change projects in forestry and agriculture integrated adaptation and mitigation, by analyzing 201 projects from adaptation funds (e.g., UNFCCC Adaptation Fund), adaptation plans (e.g., National Adaptation Programmes of Action), mitigation instruments (e.g., Clean Development Mechanism), and project standards (e.g., Climate Community & Biodiversity (CCB)). We analyzed whether projects established for one goal contributed explicitly to the other (i.e., whether mitigation projects contributed to adaptation and vice versa). We also examined whether their activities or expected outcomes allowed for potential contributions to the two goals. Despite the separation between the two goals in international and national institutions, 37% of the project documents explicitly mentioned a contribution to the other

objective, although only half of those substantiated it. In addition, most adaptation (90%) and all mitigation projects could potentially contribute at least partially to the other goal. Some adaptation project developers were interested in mitigation for the prospect of carbon funding, whereas mitigation project developers integrated adaptation to achieve greater long-term sustainability or to attain CCB certification. International and national institutions can provide incentives for projects to harness synergies and avoid trade-offs between adaptation and mitigation.

Legacy effects of repeated land-use changes in the LPJ-GUESS dynamic vegetation model

A. Krause (1) ; A. Arneth (2) ; A. Bayer, (3) ; M. Lindeskog, (4) ; TAM. Pugh (3)

(1) KIT, Imk-ifu, Garmisch-Partenkirchen, Germany; (2) KIT, Atmospheric Environmental Research, Garmisch-Partenkirchen, Germany; (3) Karlsruhe Institute of Technology, Imk-ifu, Garmisch-Partenkirchen, Germany; (4) Lund University, Lund, Sweden

This contribution is aimed at the session «Global scenarios of land-use change and land-based mitigation, and their importance in the climate system"- conveners Arneth/ Stehfest/Popp.

Natural terrestrial ecosystems store large amounts of carbon in living biomass and soils. During the last centuries, wood harvest and deforestation of primary forests for pastures and croplands greatly altered carbon, water and nutrient cycles and thereby also affected secondary vegetation dynamics after the cessation of agriculture. Historically most terrestrial biosphere models have only accounted for net changes in land-use aggregated at coarse scales of 0.5° or more. However, the extent to which finer-scale details of land-use change dynamics, particularly the detailed land-use history of a site, influence ecosystem and carbon dynamics is not well understood. In this study we investigate the legacy effects of repeated land cover transitions between natural vegetation, pastures, croplands and managed forests over different time intervals in the LPJ-GUESS dynamic vegetation model. We identify the extent to which land-use transitions are reversible, and quantify lags in system response, finding that these results are strongly dependent on the land-use history. Implications for regional and global scale estimates of land-use change emissions and the feasibility of reforestation projects to sequester carbon are discussed.

P-2217-17

A Cascade Modeling Approach to the Assessment of Climate Induced Land Use Change

A. Lungarska (1) ; PA. Jayet, (1)

(1) INRA, Economie Publique, Thiverval-Grignon, France

Land use and land use change are inherently related to climate change (Pielke, 2005). Furthermore, they are interconnected as each one is influencing the other. In this study we assess the effects of climate change on human activities, namely agriculture and forestry, and the resulting land use change for France. Our modeling approach combines sector-specific mathematical programming models and statistical tools in a multistage algorithm. As a first step, the effects of climate on agriculture and forestry are captured through a generic crop model (STICS, Brisson et al., 2009) and a statistical model of tree growth and mortality. The results obtained are then used in the second modeling stage. They are exploited as parameters in economic models for the two sectors: the agricultural supply-side model AROPAj (Galko & Jayet, 2011) and the partial equilibrium model of French forestry, FFSM++ (Caurla et al., 2013). These two models allow us to evaluate the potential gains for their corresponding sectors. The final, third, step of our modeling approach consists in an econometric (statistical) land use model where agricultural and forestry rents are approximated by the results from the sector-specific models. Thus, we can estimate land use shares of five major categories: (i) agriculture, (ii) forestry, (iii) urban, (iv) pastures, and (v) other; at the scale of a homogeneous grid with resolution of 8 km x 8 km covering metropolitan France for the period 2000 - 2100. The major advantage of our modeling approach is that it accounts for variation in biological productivity due to climate change and at the same time it can test different socioeconomic scenarios such as new price vectors, management practices and public policies.

Geoinformation-based morphometric flood risk and vulnerability analysis of Kubwa settlement, Abuja

MI. Mahmoud (1) ; C. Christopher (2) ; M. Thiel, (2) ; D. Alfred (3) ; SA. Halilu (4)

(1) Kwame Nkrumah University of Science and Technology, (KNUST), Civil engeneeirng department- grp climate change and land use, Kumasi, Ghana; (2) Institute of Geography and Geology, Remote sensing, Wurzburg, Germany; (3) College of Engineering, Geometrics Engineering Department, Kwame nkrumah university of science and technology, Kumasi, Ghana; (4) National Space Research and development Agency (NASRDA),, Strategic space applications, Abuja, Nigeria, Federal Republic of

Natural landscapes have profoundly been changed due to human activities. In particular, land use and land management change affect the hydrology that determines flood hazard. In this research, the use of historical remote sensing dataset is used to assess the vulnerability of people and places to potential risk associated to settlements especially from flooding events linked to lowland and floodplains. The motivation for this work is that global trends of disaster occurrences are on the increase in urban cities and peri- urban settlement. Hence there is urgent need to assess the vulnerability of places and people to natural hazards such as flood risk especially in developing countries to improve disaster risk reduction (DRR) programmes in urban areas. In here a geoinformation-based approach is adopted to initially map land cover change of Abuja and environ and to understand settlement morphology, and identify settlement such as Kubwa vulnerable to flooding event. Landsat (TM, ETM+ and OLI) image series from 1986, 2001 and 2014 were used to generate retrospective and contemporary landscape maps using support vector machines (SVM). To unlock changes in plan implementation, result of the remote sensing-based land use maps was compared to the original land use map. It was apparent that residential areas have increased remarkably by more than 50%. To determine built area encroachment into the flood zone and floodplains, identify and classify the area into the different levels of vulnerability, a floodplain morphometric information extraction from public domain satellite-based DEMs geohazard modeling such as flood susceptibility due to landscape as well as climate extreme events. Finally, the assessment revealed that the central part of Kubwa, is largely a lowland which is observed to be densely populated and, is most affected by flood incidences due to soil sealing resulting to poor infiltration. Other characteristics include settlement encroachment into the flood zone and floodplains, clogging of the drains and lack of land use planning. The outlook of this study therefore recommends the need for geospatial land use planning, improved drainage infrastructure in delineated high risk zones, enforcement of standards and codes, community education/ participation, among others.

P-2217-19

Urban Land Use Change Effects on Coastal Forest Ecosystem: A Case of Dar es Salaam, Tanzania

A. Masanja (1)
(1) Institute for Environment and Development Studies, Environment, Dar es Salaam, Tanzania, United Republic of

This study assessed the impacts of coastal urban land use changes and climate change on coastal forests. The study analyzed the impacts of climate change on coastal livelihoods and their implication on coastal forest degradation; the impacts of coastal urban and peri-urban expansion on coastal forest ecosystems; examined existing strategies in addressing coastal forest degradation; and developed strategies for integrated coastal urban and peri-urban land use plans in support of climate change adaptation and coastal forest conservation.

The study applied the Geographical Information System (GIS) to map the changes of land use in Peri Urban Areas of Dar es Salaam, a participatory rural appraisal using questionnaires and key interviews was applied to assess the impacts of land use changes on coastal forest ecosystem surrounding communities particularly impacts on coastal livelihoods.

The study found that change in land cover from vegetation to residential buildings and paved land surfaces due to urban land use alters completely the functional properties of land including its ecosystem services that exists before changing the land use. In addition to the impacts of land use change due to urban development, the growing urban population is directly linked to the surrounding as well as distant forest ecosystem services. The shift in livelihoods of communities from coastal to forest based activities due to impact of climate change on coastal environmental services exacerbates stress on coastal forests. Continued pressure of urban and peri-urban growth and livelihood activities on coastal forests contributes to coastal deforestation and forest degradation.

This study concludes that land use changes in settlements that surround ecosystems have caused changes in ecosystem services. However, change in land uses is highly caused by population growth because when one more person enters a new area, creates demand of an area for shelter and an area for performing activities for livelihood. This agrees with the human ecology theory of succession and invasion. When there is population influx in areas surrounding an ecosystem, such an ecosystem is subject to high pressure of degradation. Therefore, unguided land use development has adverse effects to the ecosystem services. Dar es Salaam watershed ecosystems which were once a home for millions of various biodiversity species have been affected by land use/cover changes in surrounding urban and peri urban areas. The study recommended for an integrated ecosystem approach to mitigate the impacts of land use change on forest ecosystem.

P-2217-20

Significant Contribution of Oil and Gas Industries in Temperature increasing in Northern Coast of the Persian Gulf

H. Moradi (1) ; AA. Malekizadeh (2)
(1) Isfahan University of Technology, Department of Natural Resources, Isfahan, Islamic Republic of Iran; (2) Isfahan University of Technology, Department of natural resources, Isfahan, Islamic Republic of Iran

Pars Special Economic Energy Zone (PSEEZ) was established in 1998 for the utilization of South Pars oil and gas resources. The gas resources of PSEEZ is about 9% of all gas reservoirs explored in the world. Since 2002, the operation at the PSEEZ is active. It is planned that the PSEEZ will have about 28 phases of refineries and petrochemical plants. Before coming oil and gas activities to the region, there was a unique landscape as mangrove forests, muddy coasts, wetlands, rangelands, farm lands, etc. Although all the phases are not operating but the landscape totally has been changed. Usually, the industrial activities causes an increasing in the local temperature directly (e.g. stacks and flares) or indirectly (landuse/cover changes). In this paper, we studied the landuse/cover changes as well as the changed in local temperature from 1998 to 2013. To do this, we used the Landsat5 ™ and Landsat8 (OLI) satellite images between May 1998 (Before construction started) and May 2013 (after 10 years operation). We made the temperature maps from Infrared thermal bands (i.e. TM 6 and OLI 10). Our results showed that a 100% increase in industrial zones and flares areas, a decrease of 34.11ha in mangroves cover (mostly in Basatin Bay), and a decrease of 12864 ha in natural rangelands (mostly in mountain-side looking to industrial zones) are the major changes. However, the wastewater releases from Phases 9 and 10 could be a reason to destroy the mangroves. Marine watercourses in our study area have been decreased by 1761.7 ha where 1509 ha has been changed to bare lands and 119 ha to industrial zones. This decrease is because of filling the shallow waters and drying the Mohr River. Moreover, the wet lands have changed from 6683 ha in 1998 to 418 ha in 2013. Comparing the landuse/cover changes with the temperature map revealed a positive correlation. The results showed that the mean temperature increase by 2.86 C from May 1998 to May 2013. The findings showed that temperature ranges are different in two dates where in 1998 is between 24C-55C and for 2013 is between 25C-61C. Moreover, in 1998, temperature class 26C had covered the most area of the studied area by 34224 ha where this has decreased to 24416 ha in 2013. In 1998, in overall, only 7400 ha had the temperature lower than 26C but in 2013 only 5 ha. In 1998, the area of the temperature class 37-44C was 58366 ha which is decreased to 18852 ha in 2013. The area of temperature class of 45C-49C I this time period did not changed and was about 60000ha. Therefore, the major changes in area of temperature class happened in 50C-55C which increased from 10569ha in 1998 to 56760 ha in 2013. In 1998, the latest temperature which is observed in the study area is 55C with 25 ha but in 2013 we observed a new class of temperature 55C-61C with 3824 ha. If we have a closer look at the landuse/cover changes map and temperature map, we could found that changing the shallow waters to bare and industrial lands caused an increase of about 17C in the filled areas. Moreover, making dry the wet lands for industrial lands has been caused an increase of about 5C to 6C where this increase because of the Mohr River is about 14C. Our results revealed that although the industrial development and its activities has a direct impacts on local temperature but the landuse/cover changes coming by the development has also a major impacts.

P-2217-21

Agriculture and livestock under the effects of climate change

M. Nofuentes Ramos (1) ; L. Cañas Ramírez (1) ; JA. Morgui (1) ; E. Vazquez, (1) ; A. ÀGueda, (1) ; P. Occhipinti, (1) ; C. Grossi, (1) ; R. Curcoll (1) ; O. Batet, (1) ; S. Borràs, (1) ; X. Rodó (1)
(1) Institut Català de Ciències del Clima, Barcelona, Spain

Current practices in agriculture and livestock are closely linked with climate change. Surplus nitrogen use agriculture and intensive livestock production represent a major contribution to the increasing concentrations of various greenhouse gases (GHGs). Moreover, climate change affects crops and farms around the world, due to increased temperatures, weather extremes and incidence of floods and droughts.

Agriculture represents one of the main emitters of nitrous oxide (N2O), methane (CH4) and ammonia (NH3). Farming in the EU now accounts for 7% of global emissions of GHGs. Since the second half of the twentieth century the increased use of nitrogen fertilizers resulted in losses of nitrogen into the water and into the atmosphere. Intensive livestock production contributed to the emissions of methane (CH4).

Rising temperatures, reduction of water resources in many areas, changes in the frequency and distribution of rainfall, droughts and floods, etc., directly affect agriculture. Every one of these changes can lower the agricultural production in certain areas as much as traditional crops are abandoned and lost for future climate adaptation. Increases in temperature will help pests and diseases to proliferate in crops with a consequent reduction in both the quantity and quality of agricultural production.

Furthermore, livestock production is directly affected by climate change too. Under high temperatures herds suffer more illnesses and stress as a consequence of a decrease in grazing and grazing time as less rainfall will disrupt the seasonal availability of pastures. Disturbances over crop forage will reduce the herd livestock production while increasing production costs.

We open the debate on livestock production and their effects on ecosystem metabolism (missions of GHGs) by

discussing the production capacity of traditional practices of livestock management in different protected areas in Spain, where adaptation of the vegetation to both managed grazing (forest burning, intensive pastures, seasonal migration) and severe climate has shaped the landscape. As an applied use of GHGs monitoring from the ClimaDat Project, we will debate the variability in mitigation of greenhouse gases emissions by different options of land use management.

New global land use under climate change and freshwater restrictions

A. Pastor (1) ; A. Palazzo (2) ; F. Ludwig (1) ; P. Havlik (2) ; P. Kabat (2)

(1) Wageningen University, Wageningen, Netherlands; (2) IIASA, Laxenburg, Austria

Allocation of agriculture commodities and water resources is subject to changes due to climate change, population increase and changes in dietary patterns. This study focused on including global water availability including environmental flow requirements with water withdrawal from irrigation at a monthly time-step in the GLOBIOM model. This model allows re-adjustment of land-use allocation, crop management, consumption and international trade. The GLOBIOM model induces an endogenous change in water price depending on water supply and demand. In this study, the focus was on how the inclusion of water resources affects land-use and, in particular, how global change will influence repartition of irrigated and rainfed lands at global scale. We used the climate change scenario including a radiative forcing of 2.6 W/m2 (RCP8.5), and the environmental flow method based on monthly flow allocation (the Variable Monthly Flow method) with high and low restrictions. Irrigation withdrawals were adjusted to a monthly time-step to account for biophysical water limitations at finer time resolution. Our results show that irrigated land might decrease up to 40% on average depending on the choice of EFR restrictions. Several areas were identified as future hot-spots of water stress such as the Mediterranean and Middle-East regions and parts of South-East Asia where theWater Stress Indicator (WSI) ranges from 0.4 to 1 by 2050. Other countries were identified to be in safe position in terms of water stress such as North-European countries. Some countries such as India expect a significant increase in water demand which might be compensated by an increase in water supply with climate change scenario. Re-allocation of rainfed and irrigated land might be useful information for land-use planners and water managers at an international level to decide on appropriate legislations on climate change mitigation/adaptation when exposure and sensitivity to climate change is high and/or on adaptation measures to face increasing water demand. For example, some countries are likely to adopt measures to increase their water use efficiencies (irrigation system, soil and water conservation practices) to face water shortages, while others might consider improving their trade policy to avoid food shortage.

P-2217-23

Metrics for the net climate effect of land use change in support of land based mitigation and adaptation policies

L. Perugini (1) ; A. Arneth (2) ; A. Cescatti (3) ; N. De Noblet-Ducoudré (4) ; G. Grassi (5) ; J. House (6) ; B. Quesada (2) ; E. Robertson (7) ; M. Santini (1) ; A. Wiltshire (7)

(1) Euro-Mediterranean Center on Climate Change, Division on Climate Change Impacts on Agriculture, Forests and Ecosystem Services (IAFES), Viterbo, Italy; (2) KIT, Atmospheric Environmental Research, Garmisch-Partenkirchen, Germany; (3) Institute for Environment and Sustainability, Climate Risk Management, Ispra, Italy; (4) Laboratoire des Sciences du Climat et de l'environnement, CEA-CNRS-UVSQ, Gif-sur-Yvette cédex, France; (5) European Commission, Joint Research Centre, Forest resources and climate unit, Ispra, Italy; (6) University of Bristol, School of geographical sciences, Bristol, United Kingdom; (7) Met Office Hadley Centre, Exeter, United Kingdom

Land Use and Land Cover Changes (LULCC) have a recognized effect on climate, both in terms of changes in the carbon cycle due to changes in vegetation and soil carbon (biogeochemical effects) and through variations of the surface energy budget mediated by albedo, evapotranspiration, roughness etc. (biophysical effects). While the increase of greenhouse gas (GHG) concentration in the atmosphere affects the climate in the long term and at global scale, biophysical effects result in short term changes in seasonal and/or annual surface temperatures with a prevalent local to regional effect. In addition, the climate signal of biogeochemical processes are independent to geographical location of the LULCC, whereas biophysical effects vary greatly in sign and magnitude depending on the latitude and ecosystems where they occur. For example, observations and model results suggest that deforestation has a predominantly warming effect in the tropics due to reduced evapotranspiration, exacerbating GHG effects, and a cooling effect in the boreal regions in the winter due to increased albedo, running counter to GHG effects, with some warming effects due to reduced evapotranspiration in the boreal summer.

The international policy process within the United Nation Framework Convention on Climate Change (UNFCCC) focuses entirely on GHG and their global effects. At the local level a combination of the global biogeochemical and local biophysical effects following LULCC are important for local climate, ecosystems, their biodiversity and the water cycle. Policies at the local to regional level that aim to address both mitigation and adaptation objectives will thus be less effective if they ignore the synergies and tradeoffs between biogeochemical and biophysical effects.

The paper presents a tool of practical use in support of assessment of mitigation/adaptation land policies, allowing a straightforward comparison of the estimated climate impacts of different LULCC transitions. Through a meta-analysis of the existing scientific literature, we quantified how the LULCC-climate change interplay affects regional vs. global scale, and biophysical vs. biogeochemical ecosystem-atmosphere exchange, providing a simple climate metric that summarize the changes in temperature and precipitation following LULCC. Compared to alternative approaches proposed so far, our strategy was to focus on the regional climate signals rather than on global average effects, considering that ecosystems and communities are affected and have to adapt to local climates.

P-2217-24

Land use response to the climate change in the Great Hungarian Plain?

Z. Pinke (1)

(1) Szent István University, Environmental Protection and Landscape Ecology, Gödöllő, Hungary

This poster presents the concept of interactions between environmental conditions and the productivity as well as the extension of Hungarian arable lands.

Firstly, a descriptive analysis demonstrates the synchronity of the tide of arable lands and climate change. Hungary lies on the border of hot and warm summer subtypes of the humid continental zone. Its plains were transformed into homogeneous grain-producing regions during the 19th century modernization that linked to river regulations. As I see the humidity of the late and post-Little Ice Age (between the mid1870s and the mid1940s) was an important factor in process of this landscape transformation. On the one hand, the late 19th century Hungary replied to the increasing flood-hazard with the intensification of river regulation. On the other hand, the relative precipitation surplus of the humid cycle palpably reduced the drought-proneness of the Great Hungarian Plain (GHP), thus providing a low risk opportunity to convert wetlands into tillages in tens of thousands of square kilometres. The extension of arable lands reached their saturation level between 1913 and the mid1940s, while the beginning of their decrease overlapped precisely with the end of the humid climatic cycle. This decline has been going on in Hungary since the late 1940s. As a part of this process severe droughts and excess surface water inundations have led to the rapid abandonment of croplands in huge areas (e.g. 1952, 1963, 1999, 2010).

Secondly, the paper presents the results of statistical examinations of seven crops - barley, corn, oats, potato, rye, sunflower, and wheat - losses due to droughts and excess surface water events at a national and a county scale between 1921 and 2010. The relationship between

the Pálfai Drought Index (PaDI), extension of inundated areas and annual crop yields was examined by ANOVA, the differences between crop yields in counties by t-test at a 5% significance level. It is an important methodological aspect that the annual yields of periods with approximately the same technological standards should be compared. Years with extreme yield fluctuations in wartime events (1944–45), technological transition (e.g. 1959–1975), transformation of property and economic structure (1990–1994) were eliminated. Thus, besides 30 years long meteorological periods (1921–1950, 1951–1980, 1981–2010), four homogenized technological periods were created (1921–1938, 1946–1958, 1976–1989, 1991–2010).

The closest relationship appeared between crop yield losses and values of the drought index in periods with high PaDI standard deviation. Deviations within 30-years long periods indicate a long-term trend towards an increasing frequency of extreme droughts since the late 1980s. The last technological period (1991–2010) when the standard deviation of drought indices is the highest in the examined 90 years, the yield losses of five out of seven crops indicate a significant and close relation to PaDI values. These results indicate a major transformation in the meteorological conditions of cropland farming. Over the last one and a half decades extreme droughts and inundations have alternated rapidly. Corn deserves a special attention for several reasons. Besides wheat, it is corn that has the most extensive harvest area in Hungary. In the past decade it covered some 26–28% of Hungarian croplands. Since growing season of corn (June–August) is highly exposed to drought, the fluctuation of corn yields showed a close linear relation to drought indices in three out four technological periods and in the three 30-year long periods (e.g. between 1981 and 2010 R^2=0.78; y = −0,4657x + 8,3674; 30 couples).

The most conspicuous phenomenon is that more extremes happened in the last two decades than in the former seven decades. The impact of the climatic variability on the crop yields has been more and more apparent in the regression coefficients. It is partly for this reason that the average yields of the most drought-prone counties that lies in the GHP and covered the majority of former floodplains fall below the national average. Such a high level of exposure to drought fundamentally queries the economic rationale of cropland farming, led to the abandonment of vast areas of cropland and justifies the objective of the European Water Framework Directive that is the water retention in the former floodplains of the Great Hungarian Plain.

Carbon emission from land-use change is substantially enhanced by agricultural management

TAM. Pugh (1) ; A. Arneth (1) ; S. Olin, (2) ; A. Ahlström, (2) ; A. Arvanitis, (1) ; A. Bayer, (1) ; GK. Klein (3) ; M. Lindeskog, (2) ; G. Schurgers, (4)

(1) Karlsruhe Institute of Technology, IMK-IFU, Garmisch-Partenkirchen, Germany; (2) Lund University, Lund, Sweden; (3) PBL Netherlands Environmental Assessment Agency, Bilthoven, Netherlands; (4) University of Copenhagen, Department of geosciences and natural resource management, Copenhagen, Denmark

It is over three decades since a large terrestrial carbon sink was first reported. The magnitude of the net sink is relatively well known, and its importance for dampening atmospheric CO2 accumulation, and hence climate change, widely recognised. But the contributions of underlying processes are not well defined, particularly the role of emissions from land-use change (ELUC) versus the biospheric carbon uptake (SL). In the absence of appropriate global-scale observations, process-based terrestrial biosphere models can facilitate understanding of present-day carbon cycling, whilst also underpinning climate projections in Earth System Models (ESMs). Yet representations of many fundamental processes in these models are neglected or immature, especially regarding land management. Here we quantify the effect of representing agricultural land management in a Dynamic Global Vegetation Model. Accounting for harvest, grazing and tillage resulted in cumulative ELUC since 1850 ca. 70% larger than in simulations ignoring these processes. The vast majority of ESMs in the recent IPCC Fifth Assessment Report omit these processes, suggesting an overestimation in their terrestrial carbon sink, or an underestimation of SL, of up to 1.0 Pg C a−1. Management processes influencing crop productivity per se are important for food supply, but had little influence on ELUC.

P-2217-26

Avoided Economic impacts of climate change on agriculture: integrating a Land Surface Model (CLM) with an Economic Model (iPETS)

X. Ren (1) ; M. Weitzel (2) ; B. O'neill (3) ; P. Meiyappan, (4) ; S. Levis, (2) ; E. Balistreri, (5) ; M. Dalton (6)

(1) National Center for Atmospheric Research, Boulder, CO, France; (2) National Center for Atmospheric Research, Boulder, CO, United States of America; (3) National Center for Atmospheric Research (NCAR), Boulder, CO, United States of America; (4) University of Illinois, Champaign, United States of America; (5) School of Mines, Golden, United States of America; (6) NOAA, Seattle, United States of America

Agricultural systems not only provide food but also are an important part of the economy for many countries. Crop yields are highly dependent on the level and variation of temperature, precipitation, CO2 concentration and extreme events, including heat waves, droughts, and storms, and are therefore vulnerable to the effects of climate change. We will assess the impacts of climate change under two different climate projections (RCP8.5 and RCP4.5) and two different socioeconomic pathways (SSP3 and SSP5) in order to quantify the reduction in impacts on agricultural systems as climate change is reduced, and the dependence of this reduction on the socioeconomic development pathway that is assumed.

Previous studies have investigated climate effects on crop yield as well as implications for agricultural markets, prices, land use, and food security. Regarding the climate effect on yield, studies tend to take two different approaches: process-based crop models (e.g., Yao et al., 2007; Moriondo et al. 2011) or statistical relationships between climate variables and yields (e.g., Lobell et al, 2011; Schlenker and Lobell, 2010). Both approaches show that climate change can have positive or negative impacts on different crop types at different locations and over time. Studies that go beyond impacts on crop yields to investigate effects on agricultural markets (e.g., Nelson et al., 2011) also show that there can be agricultural winners and losers, especially over the next few decades, while over time if the degree of climate change worsens then impacts turn more uniformly negative. Recently, the Agricultural Model Intercomparison and Improvement Project (AgMIP) published a set of studies (Agricultural Economics, vol. 45(1)) examining the effect of climate change relative to a no-climate-impact baseline. Fewer studies have evaluated the benefits of mitigation on agricultural system, i.e., avoided impacts.

In this study, the integrated Population-Economy-Technology-Science (iPETS) model, a global integrated assessment model for projecting future energy use, land use, and emissions, will be used in conjunction with the Community Earth System Model (CESM), and particularly with the Community Land Model (CLM), to evaluate the consequences of reducing climate change from RCP8.5 to RCP4.5. The analysis will be global, with results in iPETS produced at the level of nine world regions, and will span the period 2005–2100. We will employ climate impacts on crop yield calculated with CLM, driven by CESM simulations of these two RCPs from the CMIP5 database. These yield effects will be applied within the iPETS model, imposed on baseline (no climate) scenarios for SSP3 and SSP5. These baseline scenarios will be produced in iPETS by tuning to existing IAM simulations for these scenarios. CLM-based estimates of arable land and yield effects on productivity will be aggregated from the grid cell level to the level of the aggregate economic regions in iPETS, and applied to the respective parameters in the model. By comparing the outcomes from two alternative scenarios, we are able to evaluate the avoided impacts of climate change due to climate effects on agricultural systems. We will measure impacts in terms of yield, food prices, consumption, and GDP.

P-2217-27

Land-use/cover changes in the Uttarakhand Himalaya: assessment and mapping

VP. Sati (1)
(1) Mizoram University, Aizawl, Geography and Resource Management, Aizawl, Mizoram, India

Land is a dynamic and complex combination of factors – geology, topography, hydrology, soils, microclimate and communities of plants and animals. Land-use stands for the pattern of man's activity on a piece of land for economic functions and land cover changes denote to the type of feature, changes on the earth's surface. This paper aims to assess the land-use/cover changes in the Uttarakhand Himalaya. It also examines the factors affecting land-use/cover changes. Both qualitative and quantitative approaches were used for conducting this study. Data were obtained from the primary and secondary sources. A case study of 12 villages (Khanda Gad sub-watershed) was carried out and a household level survey was conducted on land-use/cover changes. Secondary data were gathered from the government records i.e. State Economic and Statistical Directorate, Dehradun. Land-use data from 1980 to 2009 were gathered and land cover changes were assessed through using various statistical methods and mapping. Participatory research appraisal was used to elaborate data through rapid field visit of the region. Farmers, extension workers and officials of various departments related to agriculture, horticulture and forest were interviewed to know the present trend of land-use/cover change. Five categories of land-use such as forestland, uncultivable land comprises; area under non-agriculture and waste land, other uncultivable land comprises; cultivable waste, pasture, and land under nurseries, orchards, trees and bushes; fallow land and net area sown were separately discussed. This study shows that forest covers 61% area followed by sown area (13%). Out of the total area sown, fertile patches of tarai (the plain area comprises Udham Singh Nagar) and Doon valley (comprises by plain area of Dehradun and Pauri districts) occupy above 70% area sown while, the other part of the state, which is known as the mainland of Uttarakhand (comprises 92.6% geographical area) has very less sown area. Other uncultivable land covers 16%, uncultivable land is 8% and fallow land is 2%. Temperate forests – pine, oak and coniferous – constitute forest land-use. In the mainland, the cultivable land is generally found in the valley regions and in the mid-altitudes and it is characterised by the narrow patches of terraced fields. Cultivation of subsistence cereal crops dominates the cropping pattern. Area under cash crops – fruits and vegetable is quite less. The land under cultivable waste, pasture, nurseries, orchards, trees and bushes is also found in the mid-altitudes and the highlands. Land cover changes were assessed. About 1.83% forest land was increased during 1980-2009. In Dehradun District, 10.6% forestland was increased. Meanwhile, area sown was almost stable in the mainland whereas in Dehradun district, about 6.06% area sown was decreased. In a nutshell, changes in all categories of land were noticed from 3.9% in other uncultivable land to 0.9% in area sown. Climate change impact on forest and cropping pattern was noticed. Within forest land-use, area under pine forest was observed increased upto 10% and oak forest cover decreased subsequently. This was occurred mainly due to warming of valleys and mid-altitudes. Similarly, cropping pattern has largely been changed from cultivation of subsistence cereal crops to cultivation of paddy, wheat and cash crops, as the case study shows. The major driving forces of land-use/cover changes were illustrated. State's conservation measures (Forest Act of 1982), People's participation (establishment of 'Van Panchayat) and Chipko movement were observed as the driving forces of increase in forestland. Change in food habits was other driving force that transformed cropping pattern. Even, high population growth rate (about 2%) was registered in the whole Uttarakhand Himalaya, area sown was stabilized. High intensity and frequency in weather induced natural hazards such as cloudburst triggered debris-flow; flashflood, landslide and mass-movement have also changed land-use/cover changes.

P-2217-28

Impacts of changes in land surface processes on the West African Monsoon variability : Results from the LUCID inter-comparison project

S. Sy (1) ; B. Sultan (2) ; N. De Noblet-Ducoudré (3) ; AT. Gaye (4) ; N. Ousmane (5) ; M. Wade, (6) ; F. Yohann (7)
(1) LPAOSF/LOCEAN, Dakar, Senegal; (2) IRD, LOCEAN, Paris, France; (3) Laboratoire des Sciences du Climat et de l'environnement, CEA-CNRS-UVSQ, Gif-sur-Yvette cédex, France; (4) University Cheikh Anta Diop Dakar, Laboratory of atmospheric and ocean physics, Dakar, Senegal; (5) ANACIM, Dakar, Senegal; (6) Univ. Cheikh Anta Diop, Lpaosf, Dakar, Senegal; (7) KINOME, Paris, Paris, France

West Africa has been highlighted as a hot spot of land surface-atmosphere interactions. The effect of changes in land surface processes on West African Monsoon (WAM) variability have been found very improtant. In this study, we analyze the outputs of the project Land-Use and Climate, Identification of Robust Impacts (LUCID) over West Africa. LUCID uses seven land-atmosphere models with common experimental configurations to explain the strong and constant impact of the land-use and land cover change (LULCC) between the preindustrial period and present day. Focusing our analysis on Sahel and Guinea zone where the changes in the extent covered of crops and pastures between 1870 and 1992 exceeds 5%. These studies have analyzed the performances of the individual GCMs/LSMs model involved in LUCID to simulate the WAM interannual variability. The results showed that the magnitude of these variability varies significantly from model to model resulting two major 'features' varying from one model to another : the land-cover distribution and the simulated sensitivity to LULCC. Changes in land surface properties in each individual model depend on how these represent and respond to a land-cover perturbation have been shown, as well as their simulated impacts on fluxes, rainfall and surface temperature. Finally, the climatic impacts of LULCC to those resulting from the changes in sea surface temperatures, sea ice extent, and increased greenhouse gases on WAM were evaluated. We found that for a number of variables (available energy, temperature, available water etc..), the amplitude of the impact of LULCC is similar to the impact of increased greenhouse gases and warmer oceans, but with opposite sign.

P-2217-29

Land Use Change, Desertification and Development Nexus in the Thar Desert Region of Rajasthan, India

N. Varghese (1)
(1) Indira Gandhi National Open University, School of Extension and Development Studies, Delhi, India

Desertification is the persistent degradation of dryland ecosystems due to human activities and variations in climate. Currently, 41 percent of the landmass worldwide is prone to desertification and around two billion people are affected by desertification and degradation of land. The major deserts in the world, particularly in China, Mongolia, Africa and India are expanding at an alarming rate. The expansion of deserts implies lesser availability of land for agriculture and allied activities which provide food and livelihood security to millions of people across the world. The chief drivers of desertification include deforestation, over grazing, over cultivation, logging, pressure of population, industrialization and poor land use practices.

Planning Commission of India has identified 15 resource development regions in the country, also known as the Agro Climatic Zones. Among the various regions, the Western Dry Region covers nine districts of the state of Rajasthan. The huge portion of Rajasthan is desiccated and houses the biggest Indian desert- the Thar Desert. The population in this region has been increasing at a rate faster than national average. This has led to increased pressure on land for food security of the increasing population and fodder security for the livestock. Due to less rainfall, people in this region practice a mixed farming system and livestock forms an integral part of their livelihoods. Some of the districts of this region are also characterised by a livestock density that is even higher than population density. The composition of livestock has also seen a change over the years in this region with the cattle and buffalo population being replaced by small ruminants. This is mainly because of low fodder requirement of the latter as compared to the former. Another important feature of this region which is also important as one of the drivers of desertification is the source of irrigation. In most of the districts of this region

more than 80 percent of the irrigation and in some districts even upto 100 percent of the irrigation is done by wells and tube wells. This has important implication from the view point of desertification and sustainable agricultural practices considering the already low levels of ground water in the desert regions. The forest cover in these nine districts is showing a declining trend owing to the land being diverted to cultivation. Besides forests, the area under other land uses is also being diverted to cultivation. This can have serious implications on sustainability of the livelihoods and extent of poverty of the people in these districts. This in turn has implications on the health and other human development indicators. In this paper, the author has used Markov Chain analysis to see the direction of change in the land use pattern in the districts covered under the Western Dry Region. It was observed that among the various land use patterns, there was a high probability of the land under forest being diverted to cultivation. This could have serious implications in terms of desertification as all the nine districts covered under the Western Dry Region of Rajasthan are already very low in terms of forest area. The author has also examined the linkages between various human development indicators of these districts in light of the changing land use pattern in the districts. For this purpose, using various development and desertification indicators, respective indices were worked out for the nine districts. The districts were then ranked on the basis of both the indices and it was observed that there was a negative correlation between development and desertification. The districts which were relatively better off in terms of development indicators were incidentally the districts having worst desertification indicators. A negative correlation was observed between development and desertification. This leads to a very important question that is development being done at a cost? In light of the various findings of this study the author has also suggested policy prescriptions for arresting desertification in the Thar Desert Region of Rajasthan.

P-2217-30

The Morphology of Urban Risk to Flooding In Metro-Manila, Philippines: Patterns of Exposure and Vulnerability Based on Informality and Land Use/ Cover Change

MCT. Vicente (1) ; GT. Narisma (2) ; FP. Siringan (3) ; MAY. Loyzaga, (4) ; CFP. Del (1) ; PG. Sanchez (1) ; E. Gozo (2) ; JEG. Perez (3) ; RS. Dayawon (1)

(1) Manila Observatory, Geomatics for environment and development program, Quezon City, MM, Philippines; (2) Manila Observatory, Regional climate systems program, Quezon City, MM, Philippines; (3) University of the Philippines Marine Science Institute, Quezon City, MM, Philippines; (4) Manila Observatory, Quezon City, MM, Philippines

The Project, "International Research Initiative on Adaptation to Climate Change-Coastal Cities at Risk (IRIACC-CCAR): Building Adaptive Capacity for Managing Climate Change in Coastal Megacities" is on-going from 2011-2016. Canada's International Development Research Centre (IDRC) manages IRIACC-CCAR in collaboration with three main research granting bodies, known as the Tri-Council: The Social Sciences and Humanities Research Council (SSHRC), the Natural Sciences and Engineering Research Council of Canada (NSERC) and the Canadian Institutes of Health Research (CIHR). Under this transdisciplinary IRIACC-CCAR Project, Metro-Manila is a study site, along with Bangkok, Lagos and Vancouver. A component of this research for Metro-Manila, undertaken by the Manila Observatory with local partners and described below, is the study on the morphology of urban risk to flooding, which applies multi-temporal and multi-resolution remote sensing and geographic information systems (RS-GIS).

The specific objectives of this study are to: (1) Generate historical and updated locations of urban poor settlements, (2) Identify the spatial and temporal characteristics of the said settlements in relation to other land use/ cover and infrastructure, the former especially considering residential areas, commercial and industrial sites as well as vegetation, (3) Describe the patterns of urbanization and physical development, such as by the emergence, growth, spread and even the disappearance of the said human settlements, (4) Study the factors contributing to flood risk, which then need to be addressed.

Part I of the research gives the context of informality and vulnerability to flooding in terms of general land use/ cover change from 1972-2009 (LANDSATs courtesy of NASA). Part II involves change detection of informal settlements, that is, in 1997 and 2000 (SPOT courtesy of NAMRIA) as well as 2010 (ALOS AVNIR and PRISM courtesy of JAXA). Part III then concerns overlaying thematic layers of flood risk, where Risk ≈ f(Hazard, Exposure and Vulnerability) (UNDP 2004 and UNDRO 1979). In terms of hazard, this flood risk is especially attributed to low elevation coastal zones or LECZs, which are continuous areas along shores that are equal to or «less than 10 meters above sea level» (masl) and, as such, are prone to inundation (McGranahan, G., Balk, D. and Anderson, B. April 2007). Moreover and as a reflection of poor drainage, river choke points were also observed and validated (Siringan, F. and Perez, J.E., on-going research).

Resulting maps show an overall increasing trend in expansion or growth and distribution or spread of the informal settlements. These are found in marginal, hazard-prone and compromising locations, such as coasts, riverbanks and landfills but near advantageous sites, like major roads as well as industries and commerce. Also, the 1997 and 2000 clustering of informal settlements around socioeconomic attractors seem to give way to more movements towards the fringes of the metropolis in 2010. Dense and overcrowded formal and informal communities ("mixed" settlements), showing comparatively less signs of structural degradation, initially emerged and then declined. This appears closely associated with income and land tenure, which need to be studied more deeply. Very high resolution (VHR) satellite imageries are then necessary in order to monitor informal housing and livelihood, given their dispersion as small and large agglomerations as well as relatively small and degraded structures or spatial units. Besides poor drainage, factors contributing to flooding are: Haphazard urban expansion, densification, industrialization and commercialization and decline in vegetation. The study of broad and detailed land use/ cover across time may also benefit from hyperspectral satellite imageries. Salient patterns of exposure and vulnerability to flooding then form evidence-based decision-support towards better planning for preparedness and resilience, as by co-beneficial climate change adaptation as well as risk reduction and management (CCA-DRRM).

P-2217-31

The Changes of Crop Distribution and its Water Balance Effects in the West Liaohe River basin, China

Y. Yang (1) ; L. Yang (1)

(1) Institute of Geographic Sciences and Natural Resources Research, CAS, Beijing, China

As one of the origins of dry farming in North China, West Liaohe River Basin is located in the districts with high production of maize, which is the main producing area in China and the important commodity grain base. As a sensitive area of global change, West Liaohe River basin is located in the eastern agriculture and animal husbandry edge of the western of Northeast Plain, which showed an obvious warming trend and frequent drought in the recent years. Due to the increase of population, water resources development and utilization activities is increased, and the land desertification, vegetation degradation problems are becoming serious by the interaction of human activity and climate change. This study taking the West Liaohe River basin as a case study area, analyzing of the crops distribution changes and spatial agglomeration situation in 2000, 2005 and 2010, using remote sensing tools and GIS technology. On this base, using the water balance model, quantitatively calculate the different periods of the water balance of the different crop types based on GIS technology and mathematical statistics in the West Liaohe River basin, And then systematically evaluated the water balance effects of crop distribution variations from 2000 to 2010, and scenario simulated the water balance effects of crop layout changes in different climate conditions, by establishing the water balance response statistics model. The study indicates that, (1) Water resources pressure substantially reduced from 2000 to 2005, by 26.71hundred million m3. And increased slowly from 2005 to 2010, by 5.50 hundred million m3. (2) The actual irrigation increase 14.31 hundred million m3, accounting for 26.81% of available water in the West Liaohe River basin from 2000 to 2005, influenced by the main crops area increased substantially. And water resources pressure continue to rise, the actual irrigation increase 0.88 hundred million m3 in the West Liaohe River basin from

2005 to 2010, influenced by the main crops area increased slowly. (3) The pressure of water resources was enhanced significantly in the West Liaohe River basin under different climatic conditions (normal year and dry year), the actual water demand for irrigation were respectively 12.94 hundred million m3 and 16.43 hundred million m3, there was serious contradiction between the water resources supply and demand. (4) Adjusting crop planting structure, developing water-saving agriculture and improving the utilization efficiency of water resources would become the main route of agricultural sustainable development in the West Liaohe River basin.

2218 - Land-based mitigation: agriculture, forests, bioenergy

Emission and mitigation hotspots in the land use sector across the tropics

M. Herold (1) ; M. Rufino (2) ; RR. Roman Cuesta (1) ; L. Verchot (2) ; V. De Sy (3) ; S. Carter (1) ; A. Valerio (1) ; C. Martius (2)
(1) Wageningen University, Wageningen, Netherlands; (2) Center for International Forestry Research (CIFOR), Bogor, Indonesia; (3) Wageningen University, Centre for Geo-Information, Wageningen, Netherlands

Deforestation is the largest net source of GHG emissions in the tropics, and mitigation initiatives such as REDD+ should consider agriculture as it is a key driver of deforestation. Climate-smart agriculture (CSA), so far an agriculture technologies focused exercise, can potentially reduce deforestation as the underlying assumption is that higher yields take pressure off forests. However, this cannot be taken for granted and deserves a closer look from science, policy and investment perspectives. If implemented in the right way, CSA has the potential for win-win outcomes as CSA aims to achieve both mitigation and adaptation goals. This also fits the recent focus in climate debates on agriculture as a driver of deforestation and ecosystem degradation, and can become an integral part of the solution to saving the world's forests.

In this session, we present new scientific findings on how agriculture and REDD+ are linked, how these are addressed in country strategies, and how an integrated perspective can exploit synergies and address conflicts. New data showing where and by how much agriculture is driving deforestation, and the potential emissions reductions from reducing this driver will be discussed. We present a new tropical analysis on the contribution to GHG emissions from the AFOLU sector that offers a spatially explicit view of where the AFOLU hotspots of emissions are located and what is the relative contribution of forests vs non-forests we also analyze the potential to achieve mitigation through CSA. Presentations will be short to allow for a moderated discussion. The presentation and related discussions aim to stimulate an interactive debate around the possible linkages between REDD+ and CSA - both in policy and practice. The results can feed into ongoing discussions and ideas of a broader "land use agreement" incorporating both REDD+ and agriculture that is still high on the UNFCCC agenda. With the new data and results generated by several research partners, we are able to underpin the discussions with better understanding and bring critical issues to the forefront, such as: where and how can land-based mitigation through CSA be successful in reducing GHG emissions?

Developing a sustainable charcoal sector in Africa

H. Neufeldt (1) ; P. Dobie (1) ; M. Iiyama, (1) ; K. Sander, (2)
(1) ICRAF, Nairobi, Kenya; (2) World Bank, Washington DC, United States of America

Charcoal is a vital source of energy for millions of people around the globe and one of the most commercialized resources in sub-Saharan Africa, yet policies to effectively govern the sector are lacking in many countries. Authorities in countries around the world tend to view charcoal production and use as an environmental and health problem. However, if managed properly charcoal provides a low-cost and locally available energy source that has the potential to become sustainable and contribute significantly to poverty alleviation.

This paper discusses the main obstacles to a sustainable charcoal value chain in sub-Saharan Africa and identifies key areas where interventions are required to improve sustainability while ensuring charcoal continues to provide livelihood benefits. It provides evidence of how a sustainable, transparent and properly regulated and governed charcoal sector could be part of the solution to energy access and economic challenges faced by many developing countries.

The paper summarises the most up-to-date literature on the issue at this time. Although the focus is on sub-Saharan Africa, some of the recommendations may be equally applicable to other charcoal-dependent developing countries.

Key recommendations

- Improve sustainability in the charcoal sector, and reduce associated degradation, through exploring community-based forest management options, growing trees outside forests, strengthening tenure and property rights, and implementing guidelines on sustainable harvesting and production.
- Improve governance across the charcoal value chain to create a regulated, transparent and coordinated sector which formally contributes to national economies.
- Invest in capacity development in improved kiln technologies, co-management of public or protected forests, agroforestry, woodlots, small-scale plantations, and financial management and reporting to improve sustainability and governance of the sector.
- Increase participation by disempowered stakeholders in the charcoal sector to encourage greater uptake of more efficient technologies and more sustainable management practices.

Transform the negative image of charcoal, allow sub-national governments to earn charcoal revenues and tap into internationally recognized mechanisms to create incentives for investment in a sustainable charcoal sector.

ORACLE: Opportunities and Risks of Agro-systems & forests in response to CLimate, socio-economic and policy changEs in France

N. De Noblet-Ducoudré (1) ; I. Garcia De Cortazar-Atauri (2) ; JD. Bontemps (3) ; JC. Calvet (4) ; D. Carrer (5) ; J. Caubel (1) ; P. Delacote (6) ; PA. Jayet, (7) ; N. Laanaia (1) ; L. Antonello (8) ; D. Loustau (9) ; A. Lungarska (7) ; S. Wieruszeski (1)
(1) Laboratoire des Sciences du Climat et de l'environnement, CEA-CNRS-UVSQ, Gif-sur-Yvette cédex, France; (2) INRA, Agroclim, Avignon, France; (3) AgroParisTech, Lerfob, Nancy, France; (4) Meteo-France, CNRM, Toulouse, France; (5) Meteo France, CNRM-GAME, Toulouse, France; (6) INRA, Economics, Nancy, France; (7) INRA, Economie publique, Thiverval-Grignon, France; (8) AgroParisTech, Laboratoire d'economie forestière, Nancy, France; (9) INRA, ISPA, Villenave d'Ornon, France

Our rapidly changing climate significantly affects production of agricultural and forestry products throughout the world, with potential impacts on land-use practices and land-cover choices. In parallel, socio-economic decisions and environmental policies are evolving as agriculture and forestry are called to play a major role in the cost-effective climate mitigation portfolio. The Common Agricultural Policy for example is moving towards "de-coupling" and "greener" schemes, with increased concern for the environment. There is also growing pressure on scarce resources and increasing competition over soils for the production of food, feed, wood, energy and a broad range

of environmental services.

To provide insights on a) the potential risks and opportunities for agriculture and forestry, and b) possible future patterns of land use, the scientific challenge is to account simultaneously for i) climate change and its expected effects on productivity and more generally on the functioning of agro-ecosystems, and ii) the evolution of the socio-economic and policy environment.

Yet the Intergovernmental Panel on Climate Change reports have reviewed model projections of climate change impacts over Europe but most of those projections did not adequately account for climatic variability (in climate projections and impacts). The potential for risks or benefits have therefore not yet been systematically explored, thus reducing our level of confidence in those projections. It is then imperative to increase our understanding of the range of plausible impacts of climate change on agro-ecosystems and forests to better work on adaptation strategies for these sectors. This can only be done using a combination of a) diverse modelling approaches and observations, b) reliable quantification of uncertainty, and c) syntheses of published results.

The ORACLE project (https://oracle.lsce.ipsl.fr/) tried to systematically explore the potential implications of various scenarios of climate change and changes in socio-economic and policy environment for land-use in France, taking explicitly into account the link between uncertainty on climatic drivers and ecosystem responses on the one hand, and adaptation decisions on the other hand. ORACLE brings together climatologists, agronomists, economists, hydrologists and statisticians with a common goal: better inform the relationships between climate constraints and land uses. We focus on French major anthropogenic ecosystems (crops, pasture and managed forests). We have tried to make the best use of the most recent findings of various projects and available databases, the most relevant literature, and the most up-to-date models of vegetation and economics. Our time scale of interest spans the very recent past (last 30 years), and the future regional climate projections for the 21th century with various horizons of interests (2050 and 2100).

Evaluation of potential risks or opportunities for cropland have been examined via a suite of indicators that are either computed directly from meteorological variables, or from generic biosphere models. Climatic indicators provide information on climate only, but with a selection of those that are relevant for a specific managed system (Graux et al. in prep.). Eco-climatic & Biotechnic indicators are directly computed from meteorological variables but designed to be ecosystem-specific (Caubel et al. in press). Other Eco-climatic & Biotechnic indicators are derived from simulations using generic vegetation models, with a prior definition and calibration of the indicators. The areas where a specific crop type is either at risk or potentially cultivable based on an analysis of the combined changes in all indicators.

Assessing low emissions development pathways for the agricultural and land use sector

U. Kleinwechter (1) ; P. Havlik (1) ; N. Forsell, (1) ; M. Gusti, (1) ; YW. Zhang, (1) ; O. Fricko, (1) ; K. Riahi (1) ; M. Obersteiner (1)

(1) IIASA, Laxenburg, Austria

With a contribution of almost one quarter to total anthropogenic greenhouse gas (GHG) emissions and associated abatement potential, its role as a source of biomass for bioenergy production, and potential for sequestration from afforestation, the agricultural, forestry, and land use sector (AFOLU) has to be an integral part of any global low emissions development strategy for climate change mitigation. Studies have sought to identify the required contribution of the sector to long-term climate stabilization and have evaluated its technical and economical mitigation potential. Detailed yet comprehensive analyses of the low emissions agricultural development pathways that form part and result from climate change mitigation strategies are scant. It is not yet well understood where to set priorities for mitigation efforts, both geographically and sectorally. It is further not clear which role specific technologies aimed at reducing GHG emissions in agricultural production processes will have to play.

Applying the IIASA integrated assessment modelling framework with the Global Biosphere Management Model (GLOBIOM) used for the AFOLU sector we create mitigation scenarios to reduce emissions to levels consistent with attaining a 2-degree climate target. The analysis is carried out for three Shared Socio-economic Development Pathways (SSP) up to the year 2050. A basic set of model simulations is carried out with the existing set of agricultural technologies to create standard mitigation cases for each SSP. An extended set of simulations implements additional assumptions on add-on technologies for mitigation in agricultural production processes.

The extent of agricultural mitigation to limit emissions to levels consistent with a two degree target is 2.1 GtCO2eq/yr, 2.9 GtCO2eq/yr and 3.7 GtCO2eq/yr under SSP1, SSP2, and SSP3, respectively. Abatement of emissions from land use change (LUC) consistently accounts for around 80% of the total. Mitigation potentials of CH 4 and N2O from agricultural production are around 11% to 14% and 7%, respectively.

An assessment of priorities for AFOLU mitigation highlights the fundamental role that developing and emerging economies will have to play. Mitigation efforts should be prioritized to regions with the highest economic abatement potentials at emissions price levels consistent with the two degree target, namely Brazil and the rest of South America, the Congo Basin and Western Africa, Southern Africa, and China. Within those regions and depending on regional emissions patterns and the resulting abatement potentials, either a focus on the reduction of LUC CO2 or on emissions from agricultural production should be prioritized. In the regions with large areas of humid tropical forests mitigation efforts should focus on the reduction of deforestation, hence mitigation of land use change emissions. These include the Congo Basin and Southern Africa, where almost the entire abatement potential relates to LUC. In China, mitigation efforts are required in agricultural production. The reduction of CH4 from enteric fermentation accounts for about 50% of total abatement and CH4 and N2O from crop production, including rice, and manure management contribute another 25%. Brazil and Western Africa have also abatement potential from the reduction of LUC CO2. In both regions, however, the reduction of CH4 from enteric fermentation constitutes an important part of the mitigation portfolio.

Mitigation technologies are found to have an important role to play in particular in regions that should prioritize abatement of agricultural emissions. While mitigation technologies can increase overall global AFOLU abatement only marginally, they can have significant impacts on emissions from crop and livestock production. In China, add-on technologies potentially contribute 4% additional abatement in crop production and 23% in livestock production. In Brazil, mitigation of GHG from livestock production could be raised by up to 34%. Finally, in spite of the currently high importance of land use change and associated emissions, future trends suggest that more priority should be given to mitigation of agricultural emissions and the use of add-on mitigation technologies when moving into the second half of the century.

Land-based mitigation: a social-ecological positive feedback loop? Some insights from the Global Land Project

S. Boillat (1) ; KH. Erb (2) ; O. Mertz (3) ; F. Scarpa (1) ; P. Verburg (4)

(1) Instituto Nacional de Pesquisas Espaciais, Centro de Ciência do Sistema Terrestre, São José dos Campos, SP, Brazil; (2) University of Klagenfurt, Institute for social ecology, Vienna, Austria; (3) University of Copenhagen, Department of geography and geology, Oster, Denmark; (4) VU University, Institute of environmental studies, Amsterdam, Netherlands

Feeding a growing human population, while at the same time mitigating climate change, is a major challenge of this century. The competing demand for land for providing, among others, food, fiber, energy, ecosystem services and carbon sinks and stocks, makes land-based mitigation a particularly tough task (Smith et al. 2013). Sparing land leads to an important trade-off

between the need to perform agricultural intensification, which increases emissions, and at the same time reduce emissions through the reduction of deforestation and land cover change. While the share of total anthropogenic emissions from land use, land use change and forestry (including deforestation) has been diminishing, emissions from agriculture have continued to grow steadily (Tubiello et al. 2015). Furthermore, new research has found that land management impact on surface temperature are substantial and have been overlooked up to now, stressing the need to integrate land management to improve assessment of human impacts on the climate (Luyssaert et al. 2014). This contribution has the objective to give some insights into possible synergies, trade-offs and feedback loops related to land-based mitigation measures. It builds on different research achievements of the Global Land Project, part of the Future Earth program, which hosts the largest community of active researchers and practitioners in land system science. Insights from two GLP endorsed projects related to REDD+, REDD-PAC in Brazil and the Congo Basin and I-REDD+ in Southeast Asia allow to identify methodological challenges in implementing land-based mitigation measures and assessing their impacts on biodiversity, food security and forest carbon stocks. These challenges include 1) the definition of reference emission levels in highly dynamic land use and management change contexts, 2) the estimation and integration of carbon stocks and sinks in degraded forests, abandoned lands and mosaic landscapes, 3) the need for broader and more complex criteria for forest definition, 4) matching spatially explicit data to assess possible synergies and trade-offs between desired functions of land, like for example carbon sequestration and biodiversity conservation, and 5) the assessment of just benefit distribution and risk of elite capture of incentives related to land-based mitigation. On the base of these challenges, we discuss the potential of new concepts for analyzing and measuring land-use intensity to assess the possible impacts and feedback loops related to land-based mitigation measures.

Agroecological practices adopted by Malagasy farmers to reduce farms carbon footprint in the Central (Itasy) and East Coast (Analanjirofo) of Madagascar

N. Rakotovao (1) ; J. Razakaratrimo (1) ; TM. Razafimbelo (2) ; S. Rakotosamimanana (3) ; M. Jahiel (4) ; A. Albrecht (5) ; S. Deffontaines (3)

(1) University of Antananarivo, Laboratoire des Radiolsotopes, Antananarivo, Madagascar; (2) University of Antananarivo, Laboratoire des Radiolsotopes, Antananarivo, Madagascar; (3) Agrisud International, Antananarivo, Madagascar; (4) Centre Technique Horticole de Tamatave, Tamatave, Madagascar; (5) Institut de Recherche pour le Développement, Umr eco&sols, Montpellier, France

For decades, Malagasy farmers have to deal with the low performance of the agricultural system and cope with the threat of food insecurity. This low productivity is caused by various factors including lack of means of production and degradation of natural resources such as loss of soil fertility. In addition, the effects of climate variability constrained farmers to shift constantly cropping calendars. Therefore, agroecology was proposed to farmers on one hand to cope with food insecurity by increasing agricultural production and diversifying crops in order to get more sources of incomes and on another hand to restore the production environment such as watersheds, soil and water availability and to contribute to climate change adaptation. First, this work aimed to estimate the carbon footprint of farms in two regions located in the Central and the East Coast of Madagascar. Secondly, the contribution and influence of the agroecological practices adopted by farmers to carbon footprintsat farm scale was assessed. The annual flux of the three main greenhouse gases encountered in the agricultural sector including the carbon dioxide (CO2), the methane (CH4) and the nitrous oxide (N2O) expressed in CO2 equivalent is considered as the carbon footprint of each farm. Twenty smallholder farms selected from farm typologies per region were studied: twelve for the Central Highlands and eight at the East Coast. Farms located in the central region were characterized by intensification of annual cropping systems using agroecological practices such as intensified rice system which alternates flooding and drying of rice fields, composting organic residues and planting fruit trees in association with annual cropping systems. Agricultural activities of farms located in the East Coast were based on clove plantation associated with annual crops either in simple specie agroforestry or mixed tree species agroforestry and the traditional twice-a-year rice cropping system. Farm resource flow maps were developed in order to represent all of the structures and characteristics of each farm. GHG-source and -sink compartments' inventory was carried out and emission factors adapted to each zone were selected form the literature. A local/specific farm carbon footprint calculator was developed.The results showed that farm carbon footprint average amounted to 3.04 Mg CO2eq ha-1y-1and 7.69 Mg CO2eqha-1y-1 in the central and in the east coast respectively. Farms in the East Coast showed high carbon footprint because of the traditional twice-a-year rice cropping. In the Central Highlands, the intensified rice cropping system reduced the farm carbon footprint by reducing methane emission, composting organic residues reduces also farm carbon footprint up to 30% by improving carbon storage in soils. In the East Coast, agroforestry allowed a farm carbon footprint reduction between 15 to 51% due to carbon storage in woody biomass. These results showed another aspect of the beneficial impacts of agroecological practices when adopted by smallholder farmers in Madagascar, at farm scale, to climate change mitigation.

The contribution of agroforestry systems to climate change mitigation – Assessment of C storage in soils in a Mediterranean context

C. Chenu (1) ; R. Cardinael (2) ; T. Chevallier (3) ; A. Germon (3) ; C. Jourdan (4) ; C. Dupraz (5) ; B. Barthes (3) ; M. Bernoux (3)

(1) Agroparistech, Umr ecosys, Grignon, France; (2) IRD and AgroParisTech, Umr eco&sols, Montpellier, France; (3) Institut de Recherche pour le Développement, Umr eco&sols, Montpellier, France; (4) CIRAD, Umr eco&sols, Montpellier, France; (5) INRA, Umr system, Montpellier, France

Agroforestry is a land use type where crops and trees are grown together in the same place and at the same time. Agroforestry systems have the advantage of providing multiple products (e.g. wood, fruits) or services (e.g. biodiversity enhancement, erosion control) whilst maintaining agricultural production. If they are known to store carbon into the biomass of the trees, they could also increase soil organic carbon (SOC) stocks. However their impact has rarely been studied under temperate or Mediterranean conditions and has mostly concerned superficial soil layers. Our objectives were (i) to quantify and spatialize SOC stocks in an agroforestry system and in an adjacent agricultural plot, (ii) to assess what SOC fractions are responsible for possible additional carbon storage, and (iii) to quantify all organic inputs entering the soil. The trial was established in 1995 in southern France. Hybrid walnut trees are intercropped with durum wheat. SOC stocks were measured on 200 soil cores down to 2 m soil depth, and particle-size fractionation was performed on 64 soil samples. Carbon stocks of trees and of the herbaceous vegetation in the tree rows were also quantified. A trench was dug to 4 m soil depth to quantify tree fine root distribution and biomass. Minirhizotrons were installed at different depths to study tree fine root turnover. Annual additional SOC storage rates were estimated at 259 ± 59 kg C ha-1 yr-1 (0-30 cm) and at 350 ± 88 kg C ha-1 yr-1 (0-100 cm). Additional storage was mainly due to particulate organic matter fractions (> 50 µm) and 10 to 15% was associated to clay particles. When the aboveground biomass of the trees was taken into account, total organic carbon storage rate reached 1.11 ± 0.16 Mg C ha-1 yr-1. High tree root densities were observed at depth, but root turnover decreased with depth. Agroforestry systems provide higher amounts of carbon at depth than other agricultural practices, such as no-till farming, and could therefore provide a more stable C storage in the long-term.

This study was funded by ADEME within the Agripsol project as part of the Reacctif program.

P-2218-02

The contribution of agroforestry systems for climate change mitigation - A systematic analysis

D. Feliciano (1) ; D. Nayak, (1) ; P. Smith (2) ; E. Wollenberg, (3) ; H. Neufeldt (4) ; J. Hillier, (1)

(1) Institute of Biological and Environmental Sciences, School of Biological Sciences, Aberdeen, United Kingdom; (2) University of Aberdeen, Institute of Biological & Environmental Sciences, Aberdeen, United Kingdom; (3) Gund Institute for Ecological Economics, School of environment and natural resources, Vermont, United States of America; (4) ICRAF, Nairobi, Kenya

Climate change mitigation and food security are two of the main challenges of human society. Agroforestry systems, defined as the presence of trees on external and internal boundaries, cropland, homestead plots or on any other available niche of farmland, can provide both climate change mitigation and food. There are several types of agroforestry systems with different rates of above ground and soil carbon (C) sequestration. The amount of carbon sequestered will depend on the type of system, climate and region. We undertook a meta-analysis that included data collection from several studies on carbon sequestration for different agroforestry systems, climates and regions in the world. The objective was to provide information on more types of agroforestry systems than those considered by the IPCC. The results from the meta-analysis show that greater carbon sequestration occurs when the land use change is from cropland to a woodlot system in the case of above ground carbon sequestration, and from fallow to a woodlot system in the case of soil carbon sequestration. Results also show that tropical climates are the most favourable for above ground carbon sequestration in agroforestry systems. Time since the change in land use is another variable to take into account, as soil carbon sequestration is generally negative up until 5 years after the transition to an agroforestry system. Our analysis provides a wider range of options that can inform practitioners in case they also need to base their choice of agroforestry system in relation to the carbon sequestration benefits. Carbon stocks before land use change, the variance and the soil sampling design were the main gaps in the literature reviewed. These gaps should be addressed in future studies if the implementation of agroforestry systems is considered as having an important role for C sequestration.

P-2218-03

Development of a global level decision support tool to reduce agricultural emissions

D. Feliciano (1) ; D. Nayak, (1) ; S. Vetter, (1) ; J. Hillier, (1)

(1) Institute of Biological and Environmental Sciences, School of Biological Sciences, Aberdeen, United Kingdom

The tool described is an Excel-based tool which brings together several empirical models to estimate greenhouse gas emissions (GHG) in rice, cropland and livestock systems, and to provide information about the most effective mitigation options. Greenhouse gas emissions are estimated in terms of total GHG emitted in kg of carbon dioxide equivalent per hectare (kg CO2eq ha-1) and in terms of GHG intensity, i.e., kg of carbon dioxide equivalent per unit of product (kg CO2eq kg-1). This tool allows for management-relevant GHG assessments to be made with relatively little effort. Management practices are chosen by the user and mitigation options are estimated and ranked according to its mitigation potential. The aim of the tool is to accommodate a range of users from an introductory to advanced level, depending on objectives and issues like time, existing knowledge, or data available. This paper describes the methods used to develop a tool to enable policy makers to explore the most appropriate GHG mitigation options available for any region worldwide. Since the target users are policy-makers and policy advisers, this tool was built to be user-friendly, and not time consuming. Apart from these characteristics, the tool differs from other tools available because it provides information about mitigation options according to a variable baseline management and it does not ask for detailed management practices (low input data required).

P-2218-04

Limiting factors on low uptake of Clean Development Mechanism based projects in Africa: Lost opportunities during first commitment period of Kyoto Protocol

L. Mahamane (1)

(1) African Forest Forum (AFF), Nairobi, Kenya

Africa countries like other developing countries in the rest of the world signed and ratified the Kyoto Protocol in order to benefit from the clean development mechanism (CDM) funds aimed at mitigating greenhouse gas emission from land used based activities. A study was conducted in 10 African countries aimed at identifying the main limiting factors on low uptake of CDM forest based projects in Africa. The study was a desk review and focused group discussions during training workshops on rapid forest carbon stock appraisal (RaCSA) for academia, research, staff from relevant government ministries, extension services and civil society organisations. The data collected was analyzed using qualitative research approaches where key themes and frames were generated. Quantitative data was analyzed using appropriate statistical procedures. It was evident from the UNFCCC database, since 2004 to 2014, only 2 % of all registered CDM projects were from Africa as compared to 84 % from Asia and Pacific Ocean, 13 % from Latin America and Carribean and 1 % from Economies in Transition. Of the 2 % from Africa, a very negligible percentage was from biomass as compared to hydro, wind and other GHG gases. This demonstrated very limited number of CDM projects that could have significantly wide scale on investment, improved economy and mitigation of GHG emissions from land based sector.

The major identified limiting factors on low uptake of CDM forest based and other related projects were: complicated processes on developing CDM projects especially on how to initiate project idea note (PIN) and develop project design document (PDD). This was compounded with inadequate capacity from Africa especially on the methodology resulting to heavy transactional costs of hiring international experts to support local communities and African governments to develop and implement CDM projects. The stringent rules on implementation of Kyoto Protocol on afforestation and reforestation programmes also played a significant role. For instance, CDM reforestation activities as per the Kyoto Protocol was to take place if there has been no forest since 31st Dec. 1989 or afforestation activities if there has been no forest for atleast 50 years. These periods specified, most of the African areas were forested. Also a number of African countries have not agreed on clear definition of forest to enable investors participate on forestry based CDM project. The other limiting factor is political instability and war among African states that continuously scared investors. This hindered formulation of forest based policies that will capitalize on emerging payment of ecosystem services. These factors among others constitute lost opportunities during the first commitment period of Kyoto protocol for African countries. Enhanced capacity among forestry stakeholders, formulation of favourable policies and continuous update of Kyoto Protocol to suit emerging circumstances in the African continent will be critical on accelerating the validation, registration and implementation of forest based CDM project in Africa.

Rennes, France; (9) INRA, Umr pegase, Rennes, France; (10) INRA, Umr sas, Rennes, France; (11) INRA, UR SOLS 0272, Orléans, France; (12) INRA, Urep, Clermont-Ferrand, France; (13) Supagro, Umr system, Montpellier, France; (14) Scotland rural college, Economics, Edimburg, United Kingdom; (15) INRA, Umr fare, Reims, France; (16) INRA, Depe, Paris, France

In Europe, agriculture is responsible for 10.2% of greenhouse gas (GHG) emissions, with concomitant opportunities for mitigation. This sector can contribute to abatement objectives via three levers: a reduction in N2O, CH4 and CO2 emissions, additional carbon storage in soil, and biomass and energy production (substitution effect). The objective of this study was to assess technical measures to reduce GHG emissions at the farm level in a European context without reducing production outputs. France was chosen as a case study with a typical intensive and diversified agriculture.

Ten measures, split into 26 sub-measures, were selected from an initial list of 100 "candidate" measures. The selection process was based on five criteria: the expected effect on production, the GHG abatement potential, the current availability of the technology required to implement the measure and of validated scientific knowledge establishing its efficacy, the applicability of the measure, including its social acceptability, and the potential synergies or antagonisms with other agri-environmental objectives, including adaptation to climate change.

The ten selected measures were linked to 1) nitrogen management in the field (better adjust fertiliser application rates, introduce more legumes in arable crop rotations and temporary grasslands), 2) management practices which increase carbon storage in soils and biomass (reduced tillage, cover crops and grass buffer strips, agroforestry and hedges, grassland management), 3) livestock diets (unsaturated fats or additive in ruminant diets, better adjust the amount of proteins), and 4) energy production and consumption on farms (methanisation and flares, energy savings). Their abatement potential and cost were accurately calculated and compared, using a marginal abatement cost curve approach (Moran et al., 2011).

Results showed that the overall abatement potential can be broken down into three groups. One third of the cumulated abatement potential corresponds to sub-measures with a negative technical cost. These sub-measures are based on an improved efficiency of inputs like N fertilizers, animal feed and energy, thus reducing GHG emissions and costs, with no negative effect on production (win-win measures). Moreover, these sub-measures have a positive expected effect on water and air quality and no antagonism exists with the objective of adaptation to climate change.

The second group corresponds to sub-measures with a moderate cost (<€25 per metric ton of CO2e avoided). These sub-measures require specific investments (e.g. methanisation) or modifying the cropping system slightly more (reduced tillage, legumes, agroforestry). However, these additional costs or lower incomes are partially compensated for by a reduction in other costs (fuels) or additional marketable products (biogas, electricity, wood).

The third group corresponds to sub-measures with a high cost (>€25 per metric ton of CO2e avoided). These sub-measures require investment with no direct financial return (flares), the purchase of specific inputs (nitrification inhibitors, unsaturated fats or additives incorporated into the diet of ruminants), dedicated labour time (cover crops, hedges) or involve greater production losses (grass buffer strips reducing the cultivated surface area for example).

When calculated under current national inventory rules, the overall annual abatement of all these measures represents 10% of annual emissions from agriculture. This percentage is higher when calculations are based on higher tier approaches.

It is concluded that cost-effective technical levers exist for agriculture to support greenhouse gas mitigation without hampering production and adaptation goals.

Land Use Emissions Abatement and Consequences for Food Prices

M. Stevanovic (1) ; A. Popp (1) ; B. Bodirsky (1) ; F. Humpenoeder (1) ; M. Bonsch (1) ; I. Weindl (1) ; J. Dietrich (1) ; S. Rolinski (1) ; A. Biewald (1) ; X. Wang, (1) ; C. Müller (1)

(1) Potsdam Institute for Climate Impact Research, Potsdam, Germany

Considerable emission cuts of greenhouse gases (GHG) are required in order to prevent further warming of the planet and to reduce the risk of severe impacts attributed to climate change (Meinshausen et al., 2009, Nature 458: 1158-1162). The agricultural, forestry and other land use sector (AFOLU) is one of the central players in such mitigation efforts as it itself contributes with 20-25% to overall GHG emissions, but also allows for negative emissions by removing GHGs, mainly carbon-dioxide (CO_2), from the atmosphere (IPCC AR5, 2014). To this end, climate mitigation policies need to take AFOLU options into account, but science needs to understand and highlight possible trade-offs and socio-economic impacts of AFOLU-based climate mitigation. For instance, large scale land use change can have adverse impacts on various ecosystem services, such as conservation of biodiversity, water retention, food provision etc. Similarly, a direct pricing of GHG emission could affect commodity prices from the agricultural sector through increased cost of agricultural production and further compromise food security. Using an agro-economic, spatially explicit model (MAgPIE; Lotze-Campen et al., 2008, Agric. Econ. 39: 325-338; Popp et al., 2014 Nat. Clim. Change 4: 1095-1098) that estimates cost-optimal land use patterns of global agricultural production, we show that mitigation measure both at the supply or demand side of the AFOLU sector can strongly reduce major GHG emissions in form of carbon-dioxide from land use change, and nitrous-oxide (N_2O) and methane (CH_4) stemming from agricultural production activities. However, supply side emission reduction measures, such as avoided deforestation and less polluting agricultural management and practice incentivized by a GHG emission tax, lead to strong increases of food prices (~250% of price index under a reference scenario, BAU, at the end of the century), which are mostly driven by the pricing of CH_4 emissions stemming from the livestock production sector. On the contrary, measure that target demand side management, including better food waste management and a "demitarian" diet with halved livestock calorie demand in daily food intake compared to present day livestock product consumption in developed countries, allow for additional potential for carbon uptake on abandoned agricultural land and even decreases the prices throughout the 21st century. However, in order to further eliminate residual emissions, especially the cumbersome CH_4 gas, a synergy of the two emission reduction strategies is required. This combined strategy curbs the non-CO_2 emissions further, cutting down N_2O and CH_4 to 50% and 40% respectively, relative to BAU. A stringent abatement of CH_4 emissions (by 60%) through combination of the demand and supply side policies demonstrates generally lower food prices over the century than is the case with only supply side mitigation policy. In conclusion, our study demonstrates the considerable potential of food demand management in reducing GHG emissions from the AFOLU sector without jeopardizing food security and beneficial to the environment.

P-2218-07

Terrestrial carbon sinks: the critical role in deep greenhouse gas reduction scenarios and ecological limits to large scale carbon dioxide removal

MS. Torn (1) ; L. Smith (2) ; D. Sanchez, (3) ; JH. Williams, (4) ; A. Jones, (1)

(1) Lawrence Berkeley National Laboratory, Earth Sciences Division, Berkeley, CA, United States of America; (2) University of California Berkeley, Energy and Resources Group, Berkeley, CA, United States of America; (3) UC Berkeley, Energy and resources group, Berkeley, United States of America; (4) Energy and Environmental Economics (E3), San Francisco, United States of America

Pathways to achieving deep greenhouse (GHG) reductions (such as 80% reductions by 2050) have implications for carbon cycle science. This talk will highlight the critical role that terrestrial carbon sinks and mitigation of non-energy GHGs have in reading deep decarbonization goals.

In addition, many climate change mitigation scenarios include terrestrial atmospheric carbon dioxide removal (BCDR) or carbon neutral bioenergy production through bioenergy with carbon capture and storage (BECS) or afforestation/reforestation. Very high sequestration potentials for these strategies have been reported, and

we evaluate the potential ecological limits (e.g., land and resource requirements) to implementation at the 1 Pg C y−1 scale relevant to climate change mitigation for U.S. and global scenarios. We estimate that removing 1 Pg C y−1 via tropical afforestation would require at least 7×106 ha y−1 of land, 0.09 Tg y−1 of nitrogen, and 0.2 Tg y−1 of phosphorous, and would increase evapotranspiration from those lands by almost 50%. Because of improved carbon capture technologies, we are updating (and reducing) our previous estimates for switchgrass BECS (previous estimate was 2×108 ha land and 20 Tg y−1 of nitrogen (20 % of global fertilizer nitrogen production)). Miscanthus could meet the same biomass production with much lower N demand. Moreover, transitioning the U.S land currently under corn- ethanol production to no-till perennial grasses for bioenergy would meet U.S. needs and have additional environmental benefits (such as improved wildlife habitat and soil restoration). Therefore, there are important ecological limits to BCDR and carbon-neutral bioenergy production as well as significant potential benefits depending on implementation.

P-2218-08

An assessment of Brazilian biofuels expansion from a climate-resilient pathways framework

W. Wills (1) ; M. Obermaier (2) ; C. King, (3) ; A. Xavier (3) ; B. Scanlon (4) ; M. Moreira (5)

(1) Universidade Federal do Rio de Janeiro (UFRJ), Instituto alberto luiz coimbra de pós-graduação e pesquisa de engenharia (coppe), Rio de Janeiro, RJ, Brazil; (2) Universidade Federal do Rio de Janeiro (UFRJ), Instituto Alberto Luiz Coimbra de Pós-Graduação e Pesquisa de Engenharia (COPPE), Rio de Janeiro - RJ, Brazil; (3) University of Texas - Austin, Energy institute, Austin, United States of America; (4) University of Texas - Austin, Bureau of economic geology, Austin, United States of America; (5) Agroicone, São Paulo, Brazil

Climate change's impact on society, health, and nature is a global challenge with local effects and needs for response. One of the upmost concerns about climate change is the possibility that its impacts can offset any gains we have accomplished thus far in terms of human and sustainable development, particularly in less developed regions (World Bank, 2010). A highly promising means to achieve desirable future states is the development of climate resilient pathways (CRPs) (Denton et al., 2014) which are "… development trajectories that combine adaptation and mitigation to realize the goal of sustainable development" with the explicit target to simultaneously seek to maximize synergies and minimize trade-offs among those three pillars.

Biofuel development certainly entails a combination of climate mitigation and sustainable development needs, but also adaptation in agriculture and water resources. Originally seen as a solution for climate change mitigation, energy independence, and rural development (Sachs, 2005; Hazell and Pachauri, 2006), recent research has linked biofuels production to biodiversity loss, depletion of water resources, food insecurity, and, contrary to earlier studies, increases in GHGs emissions due to indirect deforestation and nitrogen fertilizer application (Fargione et al., 2008; Gibbs et al., 2008). In this context, Brazil, one of the world's largest biofuel producers, is largely considered a success story given low per ha GHG emissions, availability of land for energy crops, low induced deforestation and social inclusion targets for family farmers (Goldemberg et al., 2008; Nassar et al., 2010; Schaffel et al., 2012).

However, sustainable production of Brazilian biofuels is now put to a test as both national and international demand for domestically produced biofuels is rising, including export of sustainably produced biofuels, thus driving biofuels production into new lands and microclimates. Furthermore, climate change is now predicted to affect agricultural productivity and water resources availability in Brazil, potentially increasing conflicts between different land uses, including those of food versus fuel (Lapola et al., 2010; Assad et al., 2010; La Rovere et al., 2011).

Understanding the interrelationships between different land uses, water demand and supply, and energy production is thus imperative in order to identify potential medium to long-term consequences of current biofuel policies, the potential options to mitigate these impacts, and to take advantage of potential opportunities for sustainable development and adaptation in agriculture, including export of sustainably produced biofuels.

In this context, assessing Brazilian biofuels under a under a CRP framework may thus provide important policy contributions for planning of climate change and development. Considerable efforts have been made in order to identify and analyse key challenges for sustainable production of biofuels in Brazil. However, existing studies (e.g., Goldemberg et al., 2008; Fargione et al., 2008; Lapola et al., 2010; La Rovere et al., 2011) have focused on isolated impacts of biofuel production or case studies, rather than providing integrated assessments of policy-relevant (including climate policy) energy, land use, and water issues. In this context, our presentation aims to inform policymakers and stakeholders on potential biofuels expansion scenarios in Brazil under climate change until 2030 in order to enable sound policymaking that mitigates adverse impacts on land use, water resources, and food security, while simultaneously promoting sustainable production of biofuels. We do so through a multi-institutional modelling effort (carried out by three research centers from Brazil and US) that integrates basin-scale water resources impact assessment, land-use change analysis, and energy-economy-wide modelling of socioeconomic and GHG impacts due to biofuels use. Our presentation will focus on explaining our methodological framework for CRP assessment and present first results obtained in the areas of water resources and land use management.

P-2218-09

Planetary limits to Bio-Energy Carbon Capture and Storage (BECCS) negative emissions

A. Wiltshire (1) ; T. Davies-Barnard (2) ; C. Jones (1) ; J. Lowe (3)

(1) Met Office Hadley Centre, Exeter, United Kingdom; (2) University of Exeter, Exeter, United Kingdom; (3) Met Office, Lead scientist of avoid, Exeter, United Kingdom

Most but not all IPCC WG3 emission scenarios stabilising climate at low levels, such as the 2 degree C climate target require large scale deployment of Bio-Energy Carbon Capture and Storage (BECCS). BECCS allows for negative emissions, which is the artificial removal of carbon dioxide from the atmosphere (CDR). BECCS can therefore offset anthropogenic emissions, and even lead to overall net negative emissions. In this study we consider three alternative scenarios of BECCS deployment ranging from the conversion of existing agricultural areas, moderate levels of land conversion and an extreme level of tropical land conversion to maximise yields. These scenarios are used in combination with simulations from the HadGEM2-ES earth system model to consider the implications of climate change on yield and the emissions associated with deforestation, as well as the biophysical effect on climate associated with the land-use change. These are combined to assess the net climate effects of large-scale BECCS deployment. Overall, in our assessment we find the contribution of BECCS is unlikely to exceed cooling of 0.7 deg C by 2100. The median estimate of total negative emissions in the IPCC WG3 database compatible with the 2C target is 166 GtC. The highest estimates presented here is 130GtC.

P-2218-10

Assessment of options for land use in a post-2020 world

P. Wylie (1) ; J. Funk, (2) ; J. Brana-Varela, (3)

(1) IUCN - International Union For Conservation of Nature, Global Forest & Climate Change Programme, Washington, DC, United States of America; (2) UCS - Union of Concerned Scientists, Washington, DC, United States of America; (3) WWF US - World Wildlife Fund for Nature, Forest and climate program, Washington, DC, United States of America

Agriculture, forestry and other land use (AFOLU) account for nearly 25% of global GHG emissions while also absorbing a significant amount of emissions according to IPCC AR5. In this light, IUCN and a group of leading organizations focused on UNFCCC negotiations have been reaching out to Parties to discuss the role of the forest and land sectors in the new climate agreement.

Expert workshops over the last 18 months in Bonn and Lima, as well as an expert panel at the Global Landscapes Forum, advanced discussions and identified solutions for this important issue. All of those events included the REDD+, LULUCF, and agriculture negotiators, in order to ensure the discussions covered the full scope of land-use issues. These discussions highlighted risks to the integrity of a new climate regime if the role of the land sector is not adequately or appropriately reflected in the Paris agreement.

Taking stock of recent publications on the subject and the current status of land use, land-use change and forestry (LULUCF), REDD+, degradation and land-related CDM discussions in the UNFCCC, the relative strengths and weaknesses of options for how the land sector might be addressed in a post-2020 ADP agreement, will be highlighted. This set of options will have been discussed at a targeted workshop the month before amongst ADP lead negotiators.

Based on recent research, key questions that to be addressed will focus on:

- What specific attributes are needed in a framework to promote ambitious emission reductions from the land sector?
- Based on summaries of the INDC submissions to date and beyond, what are Parties to the UNFCCC already preparing domestically to recognize the importance of the land use into their post-2020 contributions?

Beyond global agreement in Paris at COP21, what can the international scientific community and both international & domestic organizations do to support permanence in any future gains on the emission gap via ambitious action within the land sector?

2219 - Politics and numbers: Political and technical challenges in reducing emissions from forests with REDD+

ORAL PRESENTATIONS

K-2219-01

The REDD+ policy arena and the politics of numbers and information sharing

M. Brockhaus (1) ; A. Angelsen (2) ; GM. Di (3)
(1) CIFOR, Bogor, Indonesia; (2) Norwegian University of Life Sciences, School of economics and business, As, Norway; (3) University of Leeds, Leeds, United Kingdom

Forests are an integral part of the international climate mitigation agenda. Transformational change beyond the forestry sector is required to realize the mitigation potential from avoided deforestation and forest degradation (REDD+). In the envisioned REDD+ architecture, payments will be made for carbon and non-carbon results, which need to be measured, reported and verified (MRV). Highly technical information needs to be translated into financial action. Information and information sharing are key features in REDD+ far beyond the MRV of carbon and co-benefits. In addition, dense webs of political actors and economic interests come to the forefront as countries become «ready for REDD+».

Evidence-based policy design and formulation aims at devising policies based on rigorous and objective information (Petrosino et al. 2001). While a factual basis is crucial, decision making is inherently a political process, and the outcome of procedural and technical policy solutions are affected by power relation in the relevant policy arena. Multiple actors, both governmental and non-governmental, with their multiple interests, bargain and negotiate to formulate public policies, often in network structures formed around their interests. Such a process may not produce optimal outcomes (Peskett and Brockhaus 2009, Moog et al 2012 conference paper, Brockhaus and Angelsen 2012). National REDD+ policy processes should be understood as negotiated political processes, with politics and political economy aspects being critical for the outcomes. Effective, efficient and equitable (3E) outcomes are then constrained or enabled by the political conditions which are contextual to the specific country and REDD+ policy domain. To understand the constraints and opportunities in policy processes, design and implementation, we have to recognize the political nature on these processes.

This paper deals with a particular aspect of the politics of numbers in REDD+, namely how information, measures and numbers are produced and used to support specific views on what REDD+ should look like. In particular, we investigate: (1) what are existing procedures for information sharing, (2) who holds information and has to be consulted in REDD+ policy design and implementation, and (3) which institutional and actor-related factors enable or hamper evidence-driven definition, measurement and reporting as well as diffusion of numbers and information across the REDD+ policy arena.

We draw on the "4I" framework developed in Brockhaus and Angelsen (2012), and investigate how institutional stickiness, as well as actors' ideas and interests interact with the fourth I in the REDD+ arena, information, and how this affects the potential for transformational change required to realise REDD+ outcomes. We present results from a global comparative research project (GCS) undertaken by the Center for International Forestry Research (CIFOR) since 2009 in 14 countries in Africa (Burkina Faso, Cameroon, DRC, Ethiopia, Mozambique, and Tanzania), Latin America (Brazil, Bolivia, and Peru), and Asia-Pacific (Indonesia, Nepal, Laos, Papua New Guinea, and Vietnam). The comparative analysis is based among other elements on country-level analyses of the drivers of deforestation, and the institutional and political economy context in which REDD+ policies are being designed, a media based discourse analysis, a policy network analysis, and a content analysis of REDD+ policy documents. All these elements were designed for comparative analysis through the development of extensive guidelines (for an overview on methods and specific guidelines see Brockhaus and Di Gregorio 2012; Brockhaus et al 2012; Di Gregorio et al 2012).

Our findings indicate that despite the increasing levels of investments in countries' MRV systems, as well as analysis, knowledge and early lessons from ongoing REDD+ policy processes, there is still limited understanding and in consequence, limited action for curtailing the impact of politics on numbers and information on effectiveness, efficiency and equity of a REDD+ mechanism, and what factors would enable effective information sharing. In addition, our evidence indicates limited political will and interest in "getting the numbers right", and that data insecurity and lack of clarity may serve then as a justification for inaction.

K-2219-02

Politics of numbers in REDD+: the case of reference levels

A. Angelsen (1) ; M. Brockhaus (2) ; HA. Teklay (1)
(1) Norwegian University of Life Sciences, School of economics and business, As, Norway; (2) CIFOR, Bogor, Indonesia

Designing and implementing REDD+ assumes quantification of past and current carbon emissions, constructing a counterfactual future scenario for emissions (i.e. the reference level - RL), as well as indicators for (change in) non-carbon benefits. Most REDD+ countries are characterized by a poor data foundation for undertaking such quantifications, resulting in high uncertainties. In addition, choices have to be made related to what exactly should be measured (including the definition of what constitute a "forest"), the approach to measuring the selected variables (e.g. scope, quality standards), and how the data should be independently verified.

This lack and uncertainty of relevant data creates a fertile ground for "gaming", defined as the manipulation of data for own benefits. "Gaming" does not imply fabricating data (although that might happen too), but rather processes where the unavoidable choices in data generation are heavily influenced by self-interests. Different stakeholders

have different interests in what to be measured, the magnitude of the selected variables, and how the variables should be measured and verified. The most obvious example is how to set the RL in a result-based system: a high RL will give higher estimated emissions reductions and thereby higher payments to those assigned the rights to sell emission reductions. Even without payments, the RL provides a benchmark for measuring the performance of projects and policies, with the credibility and reputation of NGOs, donors and governments being at stake. More generally, what is being measured shapes the political agenda and how different interests are being balanced in the political process. What is being counted counts.

We hypothesize that the degree and nature of gaming with numbers depends on both the underlying uncertainty, the extent and quality of the existing data base, the stakes at play, the informal constraints set by the political environment (e.g. transparent and critical debates), and the formal process for generation and verification of data. We use the RLs in REDD+ as our empirical case, and review RL proposals submitted to UNFCCC by key REDD+ countries. While UNFCCC provides general guidelines for setting RLs, scope for systematic biases of RL exist in the definition of forest, reference period for historical deforestation, adjustments for national circumstances, activities included, pools included, and the emission factors applied.

K-2219-03

Operational approaches for mapping tropical forest biomass and degradation patterns using optical and radar satellite data

N. Barbier (1) ; P. Couteron (1) ; F. Von Poncet (2) ; M. Schlund (2) ; C. Mathian (3)

(1) IRD-UMR AMAP, Montpellier, France; (2) Airbus Defence and Space, Immenstaad, Germany; (3) Airbus Defence and Space, Toulouse, France

Tropical forest mapping is a basic need for a wide range of users, from fields as diverse as forestry, mining and conservation or for gaining carbon credits under practices related to the Reduced Emissions from Deforestation and forest Degradation (REDD+) framework. Technical difficulties to validate cost-effective procedures to monitor forest structure from space are a hindrance to the increase in number and impacts of REDD+ projects, especially those that aim tackling forest degradation (i.e. REDD's second D). Even punctual logging operations (e.g. selective logging) can lead to a persistent decline in forest goods and thus be a precursor to forest degradation. For projects quantifying and mapping dense tropical forest structure and dynamics at region to country level is a challenging, yet pressing need, notably but not exclusively for assessing carbon stocks and fluxes. The 'Forest' project, funded by EIT - Climate KIC (UE) aims at providing state-of-the-art mapping products for stakeholders requiring a reliable monitoring of tropical forest structure and derived variables. It is built on Airbus satellite fleet bearing optical and radar sensors. It refers to ground and airborne LiDAR data from Central Africa and South America as to calibrate signal inversion under high standards of quality control. The present contribution gathers the results of sensitivity studies carried out by the project team, using very high resolution optical data, as well as synthetic aperture radar data. We present the potential of these two complementary sources of data for assessing critical forest parameters such as above ground biomass density, canopy height and degradation levels.

Despite their broad availability, medium to high resolution optical imagery (e.g. Modis, Landsat 8 or Spot 5) exhibit important limitations when it comes to quantify forest structure variation in high biomass density environments. In contrast to the deforestation phenomena, signals over tropical forests are known to saturate early after canopy closure, bluring the measurement of degradation or biomass. Moreover, instrumental noise (BRDF, atmospheric pollution) is often higher than signal. It is therefore necessary to turn to other spaceborne biophysical observables to monitor forest parameters. In the optical domain, Fourier texture features obtained from very high spatial resolution (e.g. Pléiades) optical data provide non-saturating proxies for stand parameters, including above-ground biomass, within the highest standards of precision (RMSE < 15%) and accuracy achieved to date from remotely sensed data. The influence of acquisition geometry (sun-view angles), that usually hamper regional or multi-temporal studies combining multiple acquisitions can be handled as to avoid biases. These results, and the increasing availability of large swath VHR sensors (Spot 6-7), open the way to applications requiring operational large scale forest structure and degradation monitoring and mapping, except in very cloudy contexts.

Weather-independent TerraSAR-X / TanDEM-X radar satellite data offer an interesting alternative for degradation monitoring, especially when observation frequency is critical. Amplitude change detection of radar time series can indeed be used to automatically detect small scale selective logging or other disturbances. Interferometric SAR features (coherence and INSAR height) derived from TanDEM-X mission data have proved to be correlated to forest structure parameters, enabling consistent estimates of forest height and biomass for large areas at high resolution. In regions where accurate external terrain models are available, e.g. from airborne lidar LiDAR campaigns, the approach using INSAR heights can achieve high accuracies in tree height (LE90 of 7.5m) and biomass (RMSE below 10%) estimation.

Both SPOT6/7 and TanDEM-X data allow producing accurate LULUCF maps compliant with the six land categories mandatory for GHG Reporting as specified by IPCC guidelines. Thanks to information on forest structure, further stratification of the forest area into a range of forest types, including intact and degraded forests, can be achieved. These classes will represent the state of forests as a result of forest disturbance history and can be used to measure the performance and effectiveness of a wide array of mitigation actions as part of MRV schemes.

O-2219-01

Are REDD+ subnational initiatives protecting and improving the wellbeing of local stakeholders?

W. Sunderlin (1) ; SC. De (2)

(1) Center for International Forestry Research, Forest and Livelihoods, Bogor, Indonesia; (2) CIFOR, Forests and livelihoods, Bogor, Indonesia

REDD+ aims to restrict forest-based greenhouse gas emissions and increase removals. In REDD+ subnational initiatives, this is to be achieved in part by restricting forest access and conversion (negative incentive) and by protecting and improving the wellbeing of local stakeholders (positive incentive). One of the main means to achieve the latter is to produce a reward stream large enough to compensate the opportunity cost of forgone forest conversion, and to deliver it to stakeholders on condition that they successfully protect and enhance local forests (performance-based mechanism). Success in protecting and improving wellbeing is not a foregone conclusion, among other reasons because the most forest-dependent households are those most vulnerable to restrictions on access and conversion, because it has been challenging to produce the large and reliable stream of funding initially envisioned for REDD+, because (for lack of a strong performance-based mechanism) subnational initiatives have been placing strong reliance on non-conditional incentives, because organizations establishing REDD+ on the ground have found it difficult to create an appropriate tenure foundation that reinforces or stimulates forest stewardship while providing effective rights of exclusion to protect forests against outside claims, and because of the technical challenge of establishing effective MRV systems.

This presentation examines the performance of REDD+ in protecting and improving the wellbeing of local stakeholders on the basis of evidence in six countries, encompassing 22 subnational initiatives, 150 villages, and 4,200 households. Half the villages and households are inside and half are outside REDD+ initiatives, enabling robust comparison. Socioeconomic household data were collected at two points in time (2010-2011 and then 2013-2014) enabling longitudinal comparison of the effects of various kinds of interventions. The household data are both objective (e.g. income, assets) and subjective (respondent perception of the causes of wellbeing change over time). Data were collected on the full range of REDD+ interventions, including restrictions on forest access and conversion, forest enhancement, tenure clarification, environmental education, conditional and non-conditional livelihood incentives, and others.

Among the findings are that REDD+ negative incentives have a noticeable effect on forest-dependent households. This is because of high average dependence on agriculture and on clearing forests through shifting cultivation to maintain soil fertility and create new farmlands. Given the high dependence on agriculture, the perceived reasons for improved and worsening wellbeing relate strongly to the covariate fortunes and misfortunes of weather (sufficiency of rain, drought, etc.) and crop and livestock abundance and survival. REDD+ (with considerable variation among initiatives) does have a measurable effect on wellbeing – both negative and positive – but perhaps less than one might have anticipated given that REDD+ has been underway for seven years.

Indeed, REDD+ has had many challenges getting off the ground, and has a long way to go before realizing its objectives. Among the chief obstacles are political and economic interests (at all scales of governance) tied to the conversion of forests to non-forest uses, the difficulties in producing a sufficiently large and stable stream of rewards, and considerable difficulties in establishing an appropriate tenure foundation.

O-2219-02

Calibrating carbon cycle models to determine tropical ecosystem biomass stocks: A Tier 3 certification approach

F. Maignan (1) ; B. Poulter (2) ; N. Najdovski (2) ; P. Ciais (1) ; N. Barbier (3) ; J. Chave (4) ; S. Luyssaert (1) ; F. Von Poncet (5)

(1) Laboratoire des Sciences du Climat et de l'Environnment, Gif sur Yvette, France; (2) Montana State University, Ecosystem dynamics lab, Bozeman, United States of America; (3) IRD-UMR AMAP, Montpellier, France; (4) CNRS, Laboratoire evolution et diversité biologique (edb), umr 5174, Toulouse, France; (5) Airbus Defence and Space, Geo-intelligence, 88090 Friedrichshafen, Germany

According to the latest IPCC report land use and land-use change contributes to 9-11% of total anthropogenic greenhouse gas emissions each year and thus changes in land management could provide short-term solution to mitigating climate change.

Initiatives to protect and enhance carbon stored in forests are meant to be enhanced through the implementation of the Reducing Emissions from Deforestation and Forest Degradation (REDD+) mechanism and countries are supposed to take an active role in its implementation. REDD+ requires biomass to be accurately measured, reported and monitored so that carbon can be protected and efforts are remunerated through a result-based principle.

One key challenge is related to how to measure biomass with sufficient accuracy for reporting and in a cost-effective manner related to the pricing of carbon. Taking these constraints into consideration, REDD+ reporting of biomass has been categorized into:

- high uncertainty estimates, i.e. Tier 1 using global biomass density estimates,
- to moderate uncertainty, i.e. Tier 2 using country-level biomass densities,
- and to low uncertainty, i.e. Tier 3, using carbon cycle models calibrated with forest inventory data.

Here we discuss a pathway for estimating Tier 3 carbon stocks in tropical regions using a carbon cycle model, ORCHIDEE, that is calibrated with forest inventory data and constrained by remote sensing data, to estimate project-level carbon stocks and fluxes in above- and belowground biomass pools. ORCHIDEE is in a class of ecosystem models known as Dynamic Global Vegetation Models, and simulates the establishment, growth, and mortality of trees using principles from eco-physiology.

Using tropical forest inventory data, the ORCHIDEE model is calibrated to reproduce growth rates of over and understory trees, and mortality, resulting in estimates of carbon and their change over time in biomass and in soil carbon pools. For project-level implementation, forest canopy height measured from either airborne LIDAR or space-based RADAR is assimilated to ORCHIDEE to extract corresponding carbon values.

Consequently, gridded maps of aboveground biomass, belowground biomass, soil carbon, leaf area index, net primary production, and net ecosystem exchange, at the corresponding spatial resolution, or mapping unit, to that of the canopy information, can be provided for REDD+ programs fulfilling the Tier 3 criteria. We demonstrate this processing chain for sites in French Guiana, Gabon and Cameroon.

O-2219-03

Expert perceptions on cost of increasing biospheric carbon in landscapes in Finland, Indonesia, Peru and Tanzania

M. Larjavaara (1) ; M. Kanninen, (2)

(1) University of Helsinki, VITRI, Helsinki, Finland; (2) University of Helsinki VITRI, Helsinki, Finland

Good understanding of global variation in prices of adding biospheric carbon to landscapes could lead to a better allocation of scarce funding. Unfortunately, comparisons have been complicated by variability in ways to quantify cost and carbon benefits and how complications such as unsecure land tenure have been taken into account. Our objective was to quantify expert perceptions on cost of increasing biospheric carbon in Finland, Indonesia, Peru and Tanzania by conducting face-to-face interviews. For this purpose we developed a simple carbon bookkeeping tool with a spreadsheet and a more user friendly versions. We applied this future scenario carbon calculator, "CarboScen", in 64 interviews on 8 landscapes in 4 countries. The experts represented governments, NGOs, private sector and research and had their focus in national, subnational or local level. Prior to the interviews we parameterized CarboScen with best available local data on carbon densities and global understanding on speed of carbon density changes after a transition in land use. Instead of the normal, cost per sequestered unit of carbon, we asked the experts to imagine a payment of 1 USD and 10 USD paid annual for every extra ton of carbon stored in the landscape relative to a reference, business-as-usual, scenario. We then asked what kind of land use changes these payments could cause by showing carbon implications of numerous land use changes suggested by the interviewee with CarboScen. According to the perceptions of the experts of land use, marginal costs of adding carbon increased rapidly as the tenfold hypothetical payment of 10 USD lead to only a two or three fold additional carbon store relative to a 1 USD payment. The perceptions on the quantity of carbon added with a given payment were roughly proportional to carbon density of the landscape. Therefore adding carbon to the extremely carbon dense landscapes dominated by tropical peatlands in Indonesia was approximately ten times more efficient than in landscapes in Finland and Peru and the difference to landscapes Tanzania was even greater. Based on the reasoning of the interviewees, these large differences in cost of increasing carbon were caused mainly by differences in technically maximal mitigation potential, income from alternative land-uses and the understanding of the assumed "good governance and efficient distribution of the funding". It is likely that these perceptions reflect actual differences in cost of increasing carbon, and therefore should be taken into account when designing global climate change mitigation strategies.

O-2219-04

Pathways for sustainable REDD+ policies in Brazil

A. Soterroni (1) ; FM. Ramos (1) ; A. Mosnier, (2) ; AXY. Carvalho (3) ; RCM. Souza (1) ; M. Buurman (4) ; G. Câmara, (1) ; PR. Andrade (1) ; J. Pirker (5) ; R. Mant (6) ; V. Kapos (6) ; M. Obersteiner (5)

(1) National Institute for Space Research (INPE), Sao Jose dos Campos, Brazil; (2) International Institute of Applied Systems Analysis (IIASA), Ecosystems Services and Management, Laxenburg, Austria; (3) Institute for Applied Economic Research (IPEA), Brasilia, Brazil; (4) Institute for Geoinformatics at the University of Münster (IFGI), Münster, Germany; (5) International Institute of Applied Systems Analysis (IIASA), Laxenbourg, Austria; (6) United Nations Environment Programme (UNEP), World Conservation Monitoring Centre (WCMC), Cambridge, United Kingdom

Brazil's forests constitute 13% of the global forest area and almost 30% of the tropical forest area. They account for

a significant proportion of global terrestrial biodiversity and store about 20% of global above ground forest carbon. At the same time, Brazil's has a vigorous and dynamic agribusiness, being the world's largest producer and exporter of coffee, sugar, and orange juice, and is highly ranked in the production and export of soybean, corn, ethanol, pork, beef, and poultry chicken. Reconciling these two realities presents a major challenge to scientists and policy makers that will require up-to-date and accurate land cover/land use data and modeling tools. Within this context, the REDD-PAC project aims at providing a global forum for sharing and improving global data on forests and deforestation drivers and developing best practices for national REDD+ and land-use planning (see http://www.redd-pac.org). One of the main outcomes of the REDD-PAC project is the development of the GLOBIOM-Brazil model, a partial equilibrium, spatially explicit global land-use model for Brazil's agricultural, forestry and bioenergy sectors, over a 0.5 by 0.5 degrees spatial grid, adapted from IIASA's GLOBIOM. Among other refinements, validated with 2010 IBGE agriculture census data and PRODES/INPE deforestation data, the model includes a detailed and up-to-date representation of Brazil's land cover/land use data together with the main regulations of Brazil's new Forest Code (FC).

Here we present GLOBIOM-Brazil simulation results in the assessment of the economic and environmental impacts, over the period of 2020-2050, of FC's key new policies, namely, the restoration obligation (RO) of illegally deforested areas, the small farms amnesty (SFA) and the environment debt offset mechanism based on the CRA, a tradable legal title of forest surpluses. When compared to the non-additional policies scenario (NAPS), the FC has an overall positive impact on land cover changes and corresponding carbon emissions, with an increase of Brazil's forested area. This is accomplished without much impact in food production, which continues to grow during the coming decades, but, mostly, by conversion of abandoned land and low productivity pastures, mainly in the Amazon. We also observe that the RO policy is effective only to the extent that the ban on illegal deforestation is fully enforced, in order to avoid the trading between pristine and restored forests. As expected, both the SFA and the CRA mechanism have deleterious environmental impact, since they sensibly reduce the total forest deficit area to be restored by landowners. On the other hand, our simulations indicate that the CRA mechanism is effective in protecting areas of pristine forests, still rich in biodiversity, in regions subject to high economic and demographic pressure, such as the Atlantic Forest and the deforestation arch in the Legal Amazon.

Addressing uncertainty upstream and downstream of emissions reductions accounting from deforestation and forest degradation: examples from Panama and Zambia

J. Pelletier (1) ; S. Goetz (1) ; N. Laporte, (2) ; C. Potvin, (3) ; J. Busch (4)
(1) Woods Hole Research Center, Falmouth, United States of America; (2) NASA SERVIR project, Falmouth, Ma, United States of America; (3) McGill University, Biology, Montréal , Canada; (4) Center for Global Development, Washington, DC, United States of America

Uncertainty in emissions and emission changes estimates constitutes an unresolved issue for a future international climate agreement. Uncertainty can be addressed 'upstream' through improvements in the technologies or techniques used to measure, report, and verify (MRV) emission reductions, or 'downstream' through the application of discount factors to more uncertain reductions. Uncertainties is an important consideration in the REDD+ context since 1) the land-use/cover change and forestry (LULUCF) sector is identified as the sector where uncertainties are the largest, 2) many developing countries still lack capabilities for estimating stocks and flows from forests, 3) the financial mechanism planned for compensating developing countries in their successful efforts to slow, halt or revert forest cover change could include the use of offsets. The integration of REDD+ in the climate regime is providing a new impetus to deal with uncertainty as the offsetting of more certain emissions from fossil fuel with uncertain ER (Emission Reductions) from REDD+ remains an open question with possibly large consequences.

In the context of Reducing Emissions from Deforestation and forest Degradation (REDD+), we provide a diagnosis of the main sources of error to greenhouse gas estimation from land-cover change and overall error using Monte Carlo analysis, using data from Panama, in Central America, and from Zambia, in Southern Africa. For Zambia, we estimate the overall error in emissions from land-cover change and partition the different sources of error starting from national forest inventories. For Panama, we look at the effects of forest monitoring improvements on reductions in uncertainty. We also test five downstream proposals for discounting uncertainty of the potential credits received for reducing emissions. We compare the potential compensation received for these emission reductions to the cost of alternative upstream investments in forest monitoring capabilities.

We show that upstream improvements can noticeably reduce the overall uncertainty in emission reductions. Furthermore, the costs of upstream investments in improved forest monitoring are relatively low compared to the potential benefits from carbon payments; they would allow Panama to receive higher financial compensation from more certain emission reductions. When uncertainty is discounted downstream, we find that the degree of conservativeness applied downstream has a major influence on both overall creditable emission reductions and on incentives for upstream forest monitoring improvements. Of the five downstream approaches that we analyze, only the Conservativeness Approach and the Risk Charge Approach provided consistent financial incentives to reduce uncertainty upstream. We provide policy relevant inputs for those countries to reduce uncertainty in estimates, taking into account natural variability and measurement errors. More generally, we provide recommendations on approaches to be use to address uncertainty upstream and downstream of accounting, especially relevant if REDD+ emission reductions are to be traded for emission reductions from other sectors.

O-2219-06

Addressing emissions from agriculture and agriculture-driven deforestation: opportunities for land-sparing and climate-smart agriculture

S. Carter (1) ; M. Herold (1) ; M. Rufino (2) ; K. Neumann, (1) ; L. Kooistra (1) ; L. Verchot (3)
(1) Wageningen University, Wageningen, Netherlands; (2) CIFOR / CCAFS, Nairobi, Kenya; (3) CIFOR, Bogor, Indonesia

Deforestation and forest degradation are major contributors of global greenhouse gas (GHG) emissions, accounting for a large proportion of many developing countries' GHG emission budgets (Baumert et al., 2005). According to Hosonuma et al (2012), in 13 countries agricultural expansion is responsible for 100% of deforestation. In this study we consider both emissions from agriculture-driven deforestation, and emissions from existing agricultural land to assess the mitigation potential of the agriculture sector. The inclusion of emissions from agriculture-driven deforestation aligns with recent interest in including agriculture in REDD+ strategies, which aim to directly address the driver of deforestation.

Emissions from agriculture are available at the national level however despite recent efforts to map and quantify land use and land cover change (ESA, 2013; FAO & JRC, 2012; FAO, 2014; Hansen et al., 2013), we consider that these are not suitable to determine agriculture-driven deforestation. This is because deforestation in this case has a focus on land-use changes (from forest to agriculture), so deforestation data based on a forest land-use definition is required. Gross change data are required since, in the cases of China, India and Vietnam for example, large-scale afforestation projects will mean that gains to forest area will underestimate deforestation (FAO 2010). Differences in data coverage, spatial resolution of datasets and in particular definitions of agriculture and forests make comparisons and integration difficult. A new approach combining available datasets of deforestation will be presented which estimates that agriculture-driven deforestation results in 4.3 GtCO2e y-1 from loss of above and below-ground biomass. We use empirical data on forest loss and use data on deforestation drivers to convert this to area of agriculture-driven deforestation.

Using our data on emissions from both agriculture and agriculture-driven deforestation, we consider at the national level the mitigation potential. We demonstrate the use of a systematic framework, which considers sequentially (1) the level and main source of emissions, (2) mitigation potential, (3) enabling environment and (4) risks. The level and source of emissions (1) considers the main source of emissions from either agriculture or agriculture-driven deforestation. Mitigation potential (2) assesses the potential for using climate-smart interventions in the agriculture sector or land-sparing options to address agriculture-driven deforestation. Land-sparing options are supply side interventions which reduce the need for the expansion of agriculture land. The enabling environment (3) is assessed by considering the governance, or engagement in REDD+ which can support the implementation of interventions. Risk (4) assessments identify the potential vulnerability of communities to changes to the agricultural system, and we use food insecurity as an indicator. Findings estimate the mitigation potential of existing agricultural land can be up to 1 GtCO2e y-1. Land-sparing interventions which close the yield-gap, or rehabilitate degraded land offer opportunities to mitigate up to 1.3 GtCO2e y-1 in the tropics where there is potential to close the yield gap or utilize available land and there is a good enabling environment. We highlight countries which are likely to require increased support to implement mitigation initiatives and where safeguarding is required to avoid risks to livelihoods.

This research supports discussions on REDD+ which acknowledge the inherent link between REDD+ and agriculture due to competition for land. We draw on recent debates on land-sparing, and discuss supporting policies which will be required to ensure that negative feedbacks are not realized. Although there is a need to look beyond the interventions covered in this study, we find a large potential for mitigation from these options. This study gives a comprehensive overview of national emissions and mitigation priorities within the forest and agriculture sectors, which can guide decision making and investments at the international level.

The Warsaw Framework for REDD+: Implications for national implementation

C. Voigt (1) ; F. Ferreira (2)

(1) University of Oslo, Public and International Law, Oslo, Norway; (2) Ministério das Relações Exteriores, Divisão de Clima, Ozônio e Segurança Química, Brasília, DF, Brazil

The adoption of the Warsaw Framework for REDD+ (WFR) [1] in 2013 has to a large extent concluded negotiations on REDD+ under the UNFCCC. Together with previous decisions, the WFR sets the requirements for developing countries to access results-based finance for mitigation actions in the forest sector, while attributing to the Green Climate Fund a «key role» among the entities channeling results-based finance to REDD+.

This article describes the WFR and indicates some of its implications for the implementation of REDD+ in developing countries. Rather than a commentary of each decision, it outlines the WFR from the perspective of measuring, reporting and verification (MRV) processes for REDD+ actions and access to results-based payments. The WFR has further centralized these processes. Such centralization has implications for the implementation of REDD+, in particular for those actors who favored a decentralized and/or subnational approach.

Centralization in this context means a concentration of procedures under the accountability of a national authority – one of the main innovations generated by the WFR. By linking the REDD+ MRV process to national reporting obligations under the UNFCCC and related procedures, it is the national government (i.e. the UNFCCC Party) that ultimately assumes accountability for REDD+ results to the international community.

Furthermore, by creating a national entity or national focal point, the WFR attributes to developing countries the prerogative to determine who is authorized to obtain and receive results-based payments on their behalf. The centralization under the WFR, therefore, goes considerably beyond the national, "border-to-border" approach to implementation and MRV of REDD+ activities. Centralization may, in fact, lead to increased accountability as it implies that there is a responsible national entity and that implementation and results of REDD+ activities will be/should be aligned with other obligations under the UNFCCC, such as national communications and inventories. This, in turn, requires increasing the level of inter-agency coordination and collaboration among the multiple stakeholders involved with implementing REDD+ activities.

Such an approach also increases transparency and coordination of actions and support through the use of an info hub and the application of the same guidelines and methodologies for all activities seeking results-based finance for REDD+ activities.

The objective of this paper is to stress that the UNFCCC has adopted a centralized approach at the national level. This may require adjusting national strategies and the relationship among actors at the national level in order to obtain results-based finance. This message, we believe, has not yet reached many stakeholders implementing REDD+, resulting in several initiatives currently being labeled as REDD+ which may not be in accordance with the multilaterally agreed rules.

The oral presentation will be structured in the following way:

1. Brief introduction to the WFR

2. Results-based finance for REDD+ activities and the requirements to obtain such

3. The MRV process

4. The roles of the National Entity/National Focal Point and the Green Climate Fund in accessing results based payments

5. The importance of the WFR for national implementation: identification of (actual/potential) effects and implications

[1] The WFR consists of decisions 9-15/CP.19.

Framework for Assessing Proximate Drivers, Agents, and Underlying Causes of Deforestation and Forest Degradation in REDD-plus Demonstration Sites in the Philippines

L. Bugayong (1) ; P. Dolom, (1) ; HL. Capinpin, (1) ; J. Nicmic, (1) ; A. Carandang, (1)

(1) Forestry Development Center, College of Forestry and Natural Resources, UPLB, Los Banos, Laguna, Philippines

International negotiations on REDD+ under the UNFCCC led to the COP-19 agreement to encourage countries to take action to reduce the drivers of deforestation and forest degradation. In order to define specific strategies for REDD+ and related measures, an analysis of drivers of deforestation and forest degradation is required for the DENR-GIZ project National REDD+ System Philippines. The study used the ASEAN Regional Knowledge Network's Decision Support Tool for identifying drivers of deforestation and forest degradation in two REDD+ demonstration sites in Eastern Samar and Davao Oriental, Philippines. An analysis of the forest cover change between 2003 and 2010 using available maps and official statistics was made. Carbon stock change analysis was done to determine the carbon stocks and emissions of identified land uses. The agents, proximate drivers and underlying causes of deforestation and forest degradation were identified through key informant interviews and focus group discussions. A participatory discussion and identification of priority proximate drivers through stakeholder-identified criteria resulted in a relative ranking of the drivers that need to be addressed by the project. Results of the field data gathered were subjected to further analysis to come up with opportunity costs of converting natural forest to other land uses. The results of this study will serve as inputs in the planning of strategies to address the drivers of deforestation and forest degradation in the REDD-plus demonstration sites.

An Algorithm to Harmonize Different Sources of Land Use Information: Building a New Land Use Map for Brazil

AXY. Carvalho (1) ; G. Câmara, (2) ; M. Buurman (3) ; FM. Ramos (2) ; A. Soterroni (2) ; RCM. Souza (2)
(1) Institute for Applied Economic Research (IPEA), Brasilia, Brazil; (2) National Institute for Space Research (INPE), Sao Jose dos Campos, Brazil; (3) Institute for Geoinformatics at the University of Münster (IFGI), Münster, Germany

The last decades have witnessed an increasing use of land use models for several purposes, including policy evaluation and land use prediction. In general, these models try to capture the dynamics of different land cover and use classes, on a geographic grid, over sequential periods. Having a good input base map, with well estimated starting areas for the considered land use and cover classes, is important for the models to properly represent future shifts in land use dynamics. On the other hand, building a good land use input map involves combining information from different sources. In many situations, it is necessary to combine data from satellite images and data from property surveys. This is the case when one builds land use models for Brazil: in general, it is necessary to take into account information collected by the Institute of Geography and Statistics (IBGE), and combine this data to satellite images for land use, and to vector maps for protected areas.

Combining information from different sources may not be straightforward, because of inconsistencies caused by measurement errors, remote sensing image precision, and discrepancies for when information was collected, for example. In this paper, we present an innovative methodology, named Minimum Distance Allocation Method (MDAM), to help build a consistent map, based on the combination of different sources of data. The proposed algorithm is based on a minimization problem, according to which property survey data can be allocated to overlapping or surrounding model geographic units. Optimization restrictions are specified so as to avoid assigning crop, pasture or planted forest area to a model geographic unit located completely inside a preserved park, for example. Based on the proposed methodology, we constructed a new base map for Brazil, to be an input into the GLOBIOM land use model. In the end, we obtained estimates for number of animals (bovines), pasture area, planted forest area, area and production for different crops, per simulation unit. Although the exercise was performed to prepare inputs for GLOBIOM, the reader will find the MDAM general enough, so that it can be employed to prepare consistent input base maps for any land use model.

P-2219-03

Land use changes and emissions from deforestation in Guatemala: advances and challenges to prepare this Central American country for REDD+

E. Castellanos (1) ; D. Fernandez (1) ; G. Fuentes, (1)
(1) Universidad del Valle de Guatemala, Centro de Estudios Ambientales y de Biodiversidad, Guatemala, Guatemala

In spite of the fact that Guatemala is consistently listed as one of the most vulnerable countries to climate change, adaptation needs and gaps have not been the focus of governmental and non-governmental organizations dealing with climate change issues. Rather, most of the work on climate change for the last 15 years has focused on capitalizing on the potential for income from international sources derived from carbon-offset projects, first as part of the Clean Develop Mechanism CDM and more recently as part of avoided deforestation initiatives.

Our research group has accompanied this process for the last 15 years and this paper will present the most important advances in terms of producing the hard data needed to show recent deforestation and reforestation trends in the country, as well as advances in defining the governance system required to implement the National Strategy Against Deforestation which is the basis for REDD+ initiatives in the country.

We first discuss forest cover change information for Guatemala, where we observe a steady drop in the net deforestation rate from a high value of 1.7% measured for the period 1991-2001, to 1.3% for 2001-2006, to 1.0% for 2006-2010. This drop is not a result of a drop in the gross amount of cleared forest. Rather, it is a result of an increase in the forest regenerated, which includes new plantations and forest regenerating after disturbances such as fires and as secondary growth in abandoned agricultural fields. This is in part the result of a successful incentive program by the central government both for large and small holders (PINFOR and PINPEP), which provides monetary incentives for people and communities who plant new forests or preserve existing forest cover. Ironically, these programs have not been able to generate a single carbon credit because of problems demonstrating additionality.

In terms of the governance needed to reduce deforestation and to generate marketable carbon credits, this paper describes various significant advances in recent years. A climate change law was passed in 2013, which mandates the implementation of a series of policies to reduce and compensate emissions from sectors such as energy, industry and transportation. It includes some provisions to create a national registry for carbon-offset projects, which could set the basis for the development of an internal carbon trading system.

Beyond these national initiatives, many sectors within the country, including several government offices, are very actively pursuing the development and implementation of REDD+ initiatives to attract international investments. We will describe some of the governing issues under discussion, particularly the intergovernmental coordination needed to implement a proper Monitoring, Reporting and Verification (MRV) system and the discussions around the fair distribution of potential income from avoided deforestation projects in protected areas between the communities implementing the activities to reduce deforestation and the central government who is the legal owner of the land and therefore of the carbon credits to be generated. This of course has been a difficult issue to negotiate, which has resulted in tension between the communities and the central government.

Many of these issues and challenges are typical of situations encountered in developing countries around the world that have been pursuing the elusive goal of bringing in enough funding to reduce or stop their deforestation problems. Unfortunately, even after many years of work, international markets for carbon credits appear to be unreachable to communities in need of funds to improve their adapting capacites. National carbon markets may prove to be a more feasible solution.

P-2219-04

Agriculture-charcoal interactions as determinants of deforestation rates and forest degradation: Implications for REDD+ design in Zambia

A. Cattaneo (1) ; J. Pycroft (2) ; M. Kokwe, (3) ; A. Arslan (4) ; L. Lipper, (4)

(1) Food and Agriculture Organization of the United Nations (FAO), Agricultural Development Economics Division, Rome, Italy; (2) European Commission (IPTS, EU JRC), Seville, Spain; (3) Food and Agriculture Organization of the United Nations (FAO), Zambia represenation, Lusaka, Zambia; (4) FAO of the UN, Agricultural Development Economics Division, Rome, Italy

This paper simulates the relative contribution to deforestation and forest degradation of the two largest proximate drivers of deforestation in Zambia, which are charcoal production and agriculture, under different scenarios over the period 2015-2022. Different options to reduce land use change are examined using a computable general equilibrium model capturing Zambia's different agroecological zones (AEZs). The model assumes that forests used for unsustainable charcoal production are degraded, or can also be in part converted to land for agriculture use. However, land can also be deforested directly for agricultural use without going through charcoal production.

Results highlight how the interplay between charcoal and agriculture is important in determining deforestation rates and forest degradation in Zambia. For example, measures addressing exclusively charcoal drivers, such as decreasing its demand through improved stove

efficiency or improving sustainability of production reduce forest degradation, but are ineffective in reducing deforestation rates because land is cleared anyways due to demand for agricultural land. Conversely, measures addressing agricultural drivers, such as better reducing fertilizer subsidies in a targeted manner, or reducing land degradation through increased adoption of SLM measures, manage to considerably reduce deforestation rates, but have little impact on forest degradation.

Table 1. Predicted cumulative impact on forests in Zambia under different scenarios for the period 2015–2022: area deforested directly for agriculture, attributable to charcoal, and forest degaradation (million hectares).

	Deforestation directly for Agriculture	Deforestation through Charcoal	Forest Degradation	Total: deforestation + degradation
Business-as-usual	1.03	1.37	2.06	4.46
Stove efficiency (+30%)	1.44	0.97	1.46	3.87
Charcoal sustainability	1.69	0.71	1.06	3.46
Reducing fertilizer subsidies	0.65	1.38	2.06	4.08
Reducing land degradation	0.69	1.37	2.06	4.11
Potential REDD+ package	0.68	0.71	1.06	2.45

Simulations indicate that with a potential REDD+ package proposing a reduction of fertilizer subsidies in agroecological zones (AEZs) I and IIa, reducing land degradation through sustainable land management practices, combined with making charcoal production more sustainable and improving stove efficiency, approximately 1 million hectares of deforestation could be avoided in the period 2015–2022, and forest degradation reduced in an area of 1.06 million hectares.

We also report on welfare effects on small and large farm rural households in different Agro-ecological zones. The Business-as-usual scenario, as assumed in our simulations, is one where incomes grow over a period of 8 years by 120% to 150% among rural households. In AEZs I, IIa1, IIb, and III these gains are reduced only marginally (–1%to –4%) by the implementation of the REDD+ package envisaged in these simulations. Conversely, both small and large farm households in AEZ IIa2 are considerably negatively affected by the REDD+ package (–15% relative to BAU). These results would indicate that financial resources available under REDD+ may need to be allocated asymmetrically so that households in AEZ IIa2 are provided with appropriate incentives for losses incurred due to constraints associated with a REDD+ package. This would be particularly important because of the 990,000 hectares of reduction in deforestation, 400,000 are in AEZ IIa2.

P-2219-05

Drivers of deforestation in REDD+ countries: Results from a pan-tropical remote sensing analysis

V. De Sy (1) ; M. Herold (1) ; F. Achard (2) ; R. Beuchle, (2) ; S. Besnard, (1) ; J. Clevers, (1) ; E. Lindquist, (3) ; L. Verchot (4) ; A. Wijaya, (4)

(1) Wageningen University, Wageningen, Netherlands; (2) Joint Research Centre (JRC), Institute for environment and sustainability (ies) forest resources, ISPRA , Italy; (3) Food and Agriculture Organisation of the United Nations, Rome, Italy; (4) CIFOR, Bogor, Indonesia

Within the United Nations Framework Convention on Climate Change (UNFCCC), negotiations are ongoing to build a framework for reducing emissions from deforestation and forest degradation, and to enhance forest carbon stocks in (sub)tropical non-annex I countries (REDD+). The UNFCCC considers addressing the drivers of deforestation and degradation crucial for the development and implementation of national REDD+ strategies and action plans, and encourages REDD+ countries to identify drivers and activities causing forest carbon emissions. Monitoring and tracking human activities that result in forest carbon change (e.g. deforestation by agricultural expansion, mining etc.) is crucial. Earth Observation data can be used to derive information on follow-up land use which generates understanding about proximate causes and drivers of deforestation. This research assesses and quantifies deforestation drivers in South America, Africa and Southeast Asia in a systematic manner, building on the 2010 global Remote Sensing Survey of the FAO Forest Resource Assessment. Deforestation drivers are assessed by visual interpretation of forest change patches depicted from satellite imagery to derive follow-up land use of deforestation from 1990 to 2005. This allows to quantify the proportion of deforestation drivers which are then used to assess forest carbon emissions per driver. The focus for this conference will be on presenting the spatial distribution, trends and trajectories of regionally specific drivers of deforestation and associated carbon emissions.

P-2219-06

The action of indigenous peoples of the Amazon and the political economy of environmental change

D. Delgado Pugley (1)

(1) Université Catholique de Louvain, Etudes du développement, Louvain, Belgium

This communication aims to analyse the attempts to reform land and resources management policies that emanate from the global climate regime and concern the Upper Amazon region. It examines some of the coalitions, alliances, and negotiation strategies that have accompanied and shaped the process of climate change politics from the preparation of COP 15 in Copenhagen (2009) to the preparation of COP 21 in Paris (2015). Using a form of multi-sited ethnography, it compares and contrasts the involvement in REDD+ (reducing emissions from deforestation and forest degradation in developing countries) negotiations of two transnational movements: the indigenous peoples movement, and the forest conservation coalitions. How do indigenous peoples of the Amazon region have occupied the political space created by climate change negotiations? Have they succeeded in gainning recognition and better access to resources and services within national boundaries? Do states, environmental organizations and indigenous peoples have found ways to avoid deforestation?

By following key mobilization processes of indigenous peoples during the period studied (2010–2014) in Peru, Colombia and Bolivia this paper aims to show the impact that indigenous peoples already have as political actors in the conservation of Amazonia. This comunications aims to contribute to the understanding of the role of indigenous social movements in normative global orders by focusing on the way this political realm transforms the relationship between the «human» and «the environment» engaging non state actors on this task.

P-2219-07

Do REDD+ social safeguards reach the 'right' people?

J. Jones (1) ; B. Ramamonjisoa (2) ; N. Hockley, (1) ; A. Rasoamanana (2) ; R. Mandimbiniaina (2) ; S. Rakotonarivo (1) ; M. Poudyal, (1)

(1) Bangor University, School of environment, natural resources and geography, Bangor, United Kingdom; (2) University of Antananarivo, Ecole supérieure des sciences agronomie, Antananarivo, Madagascar

There is extensive debate about the potential impact of the climate mechanism REDD+ on the livelihoods and welfare of forest-dwelling people. To provide carbon credits, a forest carbon scheme must slow the rate of emissions. If this is achieved by slowing the expansion of agricultural land there is clearly a local cost. Madagascar has attracted significant investment in REDD+ and has a number of pilot projects with World Bank support. We focus on one such REDD+ pilot – the Ankeniheny Zahamena Corridor (CAZ). Some 2500 households around the corridor have been identified under World Bank safeguards as containing 'project affected people (PAPs)' and are receiving individual income generation projects as compensation. There has been controversy as to how such people are identified. We carried out intensive field work in one administrative unit, mapping the location of each household and selected

a random sample stratified by location for detailed household interviews about livelihoods, food security, and assets. We compared the characteristics of households identified as eligible for compensation with those not identified as eligible. We found that people living closest to the forest, with livelihoods most dependent on the forest, were less likely to be identified as PAPs while those living closest to the village centre and with powerful social positions were more likely. We interpret this as evidence of elite capture of the benefits being distributed. Given the extremely poor information available on local populations (even the location of quite significant villages is not available from maps), and the unwillingness of people's whose livelihood depends on illegal agricultural expansion to self-identify, it is unsurprising that the official process faced challenges. We question whether the approach of identifying and compensating particular households is practical in such settings and discuss what this means for ensuring that REDD+ can be implemented without harming local people's livelihood.

P-2219-08

Forest Degradation, Regeneration, and Farmers' Income: Evidence from Smallholders' Decisions in Vietnam

M. Li (1) ; A. De Pinto (1) ; TS. Thomas (2)
(1) International Food Policy Research Institute, Washington, DC, United States of America; (2) International Food Policy Research Institute, Washington, United States of America

The interactions between agricultural production, forest conservation, and economic development are complex. Higher agricultural output prices and technologies that increase yield are expected to increase farmers' income and stimulate forest clearing, while higher agricultural input prices have mixed effects. On the one hand, an increase in the opportunity costs of labor makes agriculture less profitable and can reduce pressures on forests. On the other hand, raising costs associated fertilizer price may induce shift to extensive production systems that use more land and less fertilizer. This study presents new evidence about these relationships by focusing on forest degradation, regeneration, and farmers' income in Vietnam.

Vietnam has recently experienced forest transitions from net deforestation to net reforestation as many European countries and the United States underwent in the past. From 2000 to 2010, approximately 1.6 million hectares of timber forests were restored in the country. Reforestation, however, coincided with a net reduction of rich and medium timber forests, the area of which declined by 0.16 million hectares and 0.27 million hectares, respectively. In the meantime, the area of agricultural land increased by almost 2 million hectares, due largely to the expansion of permanent crops. Thus, understanding how agricultural sector affects forest resources and how these changes in turn affect rural economy have important implications for policy making.

The purpose of this study is to empirically examine the impacts of agriculture production on forest degradation and regeneration in Vietnam in the 2000-2010 decade. We compile highly detailed forest data for two years 2000 and 2010, which are derived from fine-scale vector data of land use developed by the International Center for Research in Agroforestry (ICRAF). The forest data are merged with ~40,000 household-level observations in ~ 3,000 communes from the 2008 Vietnam Household Living Standards Survey, which provides extensive information about farmers' income and expenditure. Using the data set, we address three questions: (1) How did agricultural output prices, input prices, and off-farm wage affect forest degradation and regeneration? (2) How did these changes subsequently influence farmers' income? (3) How did these influences vary with intensive agricultural production regions and frontier agricultural production regions?

Our study makes two contributions to the literature. First, the coexistence of forest degradation and regeneration in Vietnam provides an opportunity to study the influence of small farmers' decisions on forest resources at the micro level. The detailed forest data allow identifying changes in forest species, which helps to distinguish forest degradation from restoration. This is particularly important because to assess the impact of forest resource change on climate change, it is necessary to understand how forest carbon density changes. An oversight of the spatial pattern of forest species may cause misleading estimates.

Second, this study provides empirical evidence of the interactions between agricultural production, forest conservation, and economic development. Land use change is arguably the most pervasive socioeconomic forces affecting economic and environmental systems. These forces drive a large portion of global economic and environmental problems. Solving these problems requires a renewed focus on these interactions.

Under-estimation of forest biomass loss with REDD+ standard reporting method

S. Mermoz (1) ; A. Bouvet (1) ; T. Le Toan (1)
(1) CESBIO (Centre d'Etudes Spatiales sur la BIOsphère), Toulouse, France

Tropical deforestation is estimated to total approximately 13 million hectares per year in the period 2000-2010. Tropical deforestation, resulting from different causes, is thought to be a major contributor to GHG emissions, leading to emissions of CO2 and, if the biomass is burnt during the clearing process, additional non CO2 gases. Emissions from tropical deforestation, forest and peat degradation are currently estimated to be 15% of the world's anthropogenic GHG emissions, mainly through CO2 emissions (in the range of 8-20%). In response to the evidence by the scientists of the value of protecting forests in tackling climate change, policymakers have developed a family of policies, collectively known as Reducing Emissions from Deforestation and Degradation (REDD+) to provide a financial incentive to governments, agribusinesses and communities to maintain rather than reduce forest cover. A key question for REDD+ measurement reporting and verification (MRV), is how much aboveground biomass (AGB) or carbon has been released. The standard method for REDD+ MRV consists in using earth observation optical data to assess change in forest cover, together with a priori knowledge of values of forest carbon per unit area. The shortcoming of the method is the lack of reliable distributed forest carbon density (biomass). In addition, current MRV results using optical remote sensing are dependent on the retained UNFCCC forest definitions, which are characterized by threshold values of tree crown cover, tree height, and minimum area. Synthetic Aperture Radar (SAR) data are sensitive to forest AGB; thus an adequate SAR system, with long wavelength, could provide mapping of AGB and its change over time to be used for estimating carbon emissions. The available long wavelength SARs are 25 centimetres wavelength (L-band). Whereas AGB of dense tropical forest cannot be retrieved from L-band SAR data, biomass mapping of low AGB forests using spaceborne ALOS-PALSAR data has been object to several studies. Recently, mapping of savanna forest AGB has been achieved at 100 m resolution over Sub-Saharan Africa [1]. In this paper, the focus is on the assessment of African tropical AGB over the so-called 'non forest' class, which is not taken into account into REDD+ processes. To do so, the AGB map from [1] has been improved and AGB from this map has been assessed in various countries over areas from the Landsat tree cover benchmark map [2] that are not considered as forests. The AGB map from [1] at 100 m resolution results from an inverse model based on the empirical regression derived from insitu data and 2007 ALOS PALSAR data. A collection of AGB estimates over 81 plots (mean plot size is 0.98 hectare) from 7 African countries was used in this study to improve the AGB map. The mean AGB is computed over tree crown cover values lower than 30%, the most widely used threshold. The results show that biomass loss estimation is clearly under-estimated when using standard methods such as changes in forest cover using spaceborne optical data. For example, the biomass stocks of non forest class in Zambia, a UN-REDD partner country, is 1,509Mt in this study and represent 31% of total biomass stock in Zambia (4,914 Mt), where fires make a significant contribution to greenhouse gas emissions in miombo woodlands that cover almost half of the country. The biomass stocks of non forest class in Zimbabwe, another UN-REDD partner country, is 1,078Mt in this study and represent almost the total biomass stock in the entire Zimbabwe (1,086 Mt). Such a high AGB value associated to the non forest class leads to a significant underestimation of the carbon emissions associated to deforestation and degradation of savanna woodland. Within higher latitudes, mean AGB in non forest class was found to be logically lower but far from negligible. Therefore, SAR data could support REDD+

MRV, especially with the launch of BIOMASS satellite in 2020.

Large scale agrofuels projects in the Tana River Delta, Kenya: an assessment of their purported climate benefits and their impact on ecosystem service delivery for the local population

L. Mukhwana (1) ; O. Hamerlynck, (2) ; Q. Luke, (3) ; S. Duvail (4) ; D. Nyingi (5)

(1) International Development Reseach Centre, Nairobi, Kenya; (2) Kenya Wetlands Biodiversity Research Team, Nairobi, Kenya; (3) National Museums of Kenya, Kenya Wetlands Biodiversity Research Group, Nairobi, Kenya; (4) IRD, UMR 208 «Patrimoines Locaux», Nairobi, Kenya; (5) National Museums of Kenya, Nairobi, Kenya

Over the past decade, the Tana River Delta in Kenya has attracted a lot of interest from foreign investors aiming to start large-scale development projects for agro-fuel production. Most of these projects have failed either to commence or to thrive but others are continuously coming up. From 2010, Bedford Biofuels a Canadian company acquired 160 000 ha of Land on the terraces surrounding the delta with the plan to convert it to a vast Jatropha curcas plantation. The rationale behind the investment was that the delta lands are unproductive and could be used to produce cheap and climate-friendly agro-fuels.In order to check this assumption a survey was conducted in May 2012 on the project area, assessing its woody vegetation and standing carbon stocks in order to compare their potential for REDD+ schemes with the proposed direct land use change by conversion to agro-fuel farms. This carbon stock assessment, combined with a wider analysis of the ecosystem services provided by the delta terraces, have shown that there are more opportunities for the local communities in their current use of the Tana Delta land than in the option of the conversion to a vast Jatropha field. In this presentation we put emphasis on the risk of developing large scale agro-fuels projects without properly taking into account the various values of the ecosystem to the local users and without considering the existing customary land tenure rights.Resilience to climate change is more likely to improve when land rights are secured for traditional semi-nomadic livestock keeping and participatory land use planning with all use planning with all users.

The development of FOREST: a Fully Optimised and Reliable EmissionS Tool

A. Nouillas (1) ; N. Barbier (2) ; A. Barker (3) ; P. Bicheron (1) ; AC. Capel (4) ; N. Chenet (4) ; M. Deheza (5) ; C. Mathian (6) ; F. Maignan (7) ; N. Najdovski (8) ; J. Nightingale (3) ; N. Origo (3) ; F. Von Poncet (9) ; B. Poulter (8) ; M. Rageade (4) ; M. Schlund (9)

(1) Airbus Defence and Space, Toulouse, France; (2) IRD-UMR AMAP, Montpellier, France; (3) National Physics Lab, Earth observations, Teddington, United Kingdom; (4) ONF International, Climate department, Paris, France; (5) CDC Climat Research, Paris, France; (6) Airbus Defense and Space, Toulouse, France; (7) Laboratoire des Sciences du Climat et de l'Environnment, Gif sur Yvette, France; (8) Montana State University, Ecosystem dynamics lab, Bozeman, United States of America; (9) Airbus Defence and Space, Geo-information services, Friedrichshafen, Germany

The objective of this poster is to present the different scientific components of the FOREST (Fully Optimised and Reliable EmissionS Tool) project that gathers since 2014 the expertise of seven European institutions working together thanks to funding provided by the project funded by the EIT- Climate KIC.

The FOREST project aims to positively respond to the growing demand of forest carbon stakeholders for trusted, fully integrated and cost effective Measuring Reporting Verification (MRV) service components, enabling forest carbon projects and initiatives to achieve carbon goals, i.e. emission reduction and/or stock enhancement. It brings essential building blocks for such services including the observations from space, the local in-situ ground measurements to calibrate these observations, the forest maps and the theoretical model needed to estimate and manage the carbon sequestrated in forested areas. By providing cost effective capacities driven by market and end users, the project will improve the process of MRV for forest carbon at project/national scale.

Remote sensing by satellite is a practical way to get large geographical and ideally global information about forests, especially in remote regions that are difficult to access. Satellite imagery, optical and radar, is used to basically determine land cover/use and land cover/use changes and to map forests. It provides essential information that is used:

- to establish historical forest maps
- to feed carbon model
- to design / optimize sampling scheme
- to understand drivers of deforestation & degradation
- to measure performance of projects and effectiveness of public policies

Although pre-operational solutions exist, some issues such as the lack of standardization, the overall cost (transaction and implementation) or the overall achievable quality & reliability can hamper the development of the forest projects and undermine market attractiveness. There is considerable room for improving existing methods and to design innovative solutions, for developing solutions that bring effective value to money, for tackling pending issues that are key priorities in the international negotiations such as degradation monitoring.

The FOREST partners are currently working on developing 'forest mapping' and 'carbon modelling' services relying on:

- Provision and processing of Earth Observation (EO) data (optical and radar) for deriving primary products required in the assessment of forest cover and change,
- Determining canopy texture features at local and regional scales based on these EO data for a better characterization of forest structure
- Developing the ORCHIDEE carbon flux model which is already recognized by the scientific community towards its operational implementation in national and regional REDD+ MRV systems.
- Quality Assurance, calibration and validation strategies for each step supported by existing ground based in situ measurements or products accuracy assessment already established through robust metrological practices will allow to provide an uncertainty for the overall services.

In order to assess the market size for this technology and to evaluate the potential savings for project developers a market analysis will be performed.

The poster will present the technical approach of this project as well as the different outcomes that can be achieved through this interdisciplinary collaboration.

P-2219-12

Conservativeness and technical corrections foster broad participation and advanced reporting standards for REDD+

D. Plugge (1) ; T. Baldauf (2) ; M. Köhl (1)

(1) Institute for World Forestry, University of Hamburg, Hamburg, Germany; (2) Institute for World Forestry, Johann heinrich von thünen institut, Hamburg, Germany

The proposed presentation deals with one of the main issues for scientists and policy makers regarding the combat against global climate change in the realm of tropical forests: the realization of a credible mechanism to reduce emissions from deforestation and forest degradation (REDD+).

One of the major topics within building the framework for REDD+ are uncertainties associated to estimating reduced emissions via a measurement, reporting and verification (MRV) system. IPCC requires applying the principle of conservativeness to address these uncertainties (IPCC 2006) by constructing a reliability interval around a carbon stock estimate and utilize the lower bound of the interval for reporting. This, however, can have severe consequences to countries that are willing to participate in the REDD+. Despite successfully reducing emissions, some countries may have little to no chance of achieving benefits from REDD+ due to high uncertainties and the application of the principle of conservativeness (Köhl et al. 2009, Plugge and Köhl 2012, Plugge et al. 2013). In consequence, this would preclude many countries from participating in REDD+. Broad participation is, however, one important prerequisite to make the mechanism a success, e.g. to reduce undesired displacement of emissions (leakage) as explicitly mentioned in the safeguards (UNFCCC 2011) or to achieve the overall 2°C goal. Consequently, to be able to participate in REDD+, countries need to implement higher MRV and reporting systems standards (Tier 2 or Tier 3). At the moment most countries are not in a situation to meet these high standards due to (among others) capacity or costs constraints.

In this study we identify a way of how to overcome the consequences that uncertainties and the principle of conservativeness may have with regard to the participation of countries in the mechanism. To lower the entry threshold for countries interested in REDD+, recent discussions (Grassi et al. 2013) involve the option of temporarily reducing the strictness of reporting and applying a discount for uncertainties. The study analyzes the effectiveness of this proposal for two accounting periods. Our results confirm that by lowering the entry threshold participation is fostered and benefits from reducing emissions are achieved by the countries. However, at the same time our results show that countries would make a profit by maintaining low reporting standards with associated high uncertainty. Nevertheless, continuously advancing in the MRV and reporting standards is a prerequisite for participation in REDD+. To overcome this discrepancy we propose to allow for adopting technical corrections implemented in the Kyoto Protocol also for REDD+ reporting. Technical corrections are used for a backward recalculation of reported values when the MRV and reporting standards have been improved towards higher standards. We show that by including technical corrections countries profit more than by maintaining low standards. Therefore, the combination of conservativeness and technical corrections represents a coherent solution to promote reliable and advanced reporting, foster broad participation, and achieve benefits from REDD+.

Land-use change, mainly the conversion of tropical forests to agricultural land, is a massive source of carbon emissions and contributes substantially to global warming [1]. The future development of forest area is uncertain, but deforestation is projected to persist as a significant emission source in the absence of new forest conservation policies, especially under increasing demand for agricultural commodities. Despite the general scientific agreement on environmental benefits of forest conservation, and although the United Nations Framework Convention on Climate Change (UNFCCC) has affirmed the potential role of forests in stabilizing the global climate, no global action has yet emerged to conserve natural forests. One key issue for the implementation of REDD (Reduced Emissions from Deforestation and Degradation) is how to address leakage of emissions [2]. Without full participation of all countries in a forest conservation scheme, emission reductions in one location could result in increased emissions elsewhere, as agricultural expansion, the main driver for deforestation, could just be displaced rather than avoided (international leakage). However, carbon leakage is not only relevant in the context of regionalized forest protection efforts. Another risk associated with a global REDD scheme that so far has not been quantified in the literature is the shift of land-use pressures to non-forest ecosystems (non-forest leakage), simply because they are the only remaining resource for agricultural expansion. Such ecosystems may also be rich in carbon. First, areas under natural vegetation other than forests, such as shrublands and savannas, can also store considerable amounts of aboveground carbon. Second, carbon-rich soils also play a major part in the terrestrial carbon balance and have to be taken into consideration. For this reason, carbon stocks decline strongly after land is converted from grasslands and pastures to cropland. Finally, agricultural activity can reduce carbon sequestration by preventing regrowth of natural vegetation on abandoned agricultural land.

In this study, we estimate land-use and associated carbon stock dynamics for different global terrestrial carbon policies at global and regional scale using the land-use optimization model MAgPIE (Model of Agricultural Production and its Impacts on the Environment) [3, 4]. We show that a global forest policy could reduce carbon emissions by 77 Gt CO2, but would still allow for decreases in carbon stocks of non-forest land by 96 Gt CO2 until 2100 due to non-forest leakage effects. Furthermore, abandonment of agricultural land and associated carbon uptake through vegetation regrowth is hindered. Effective mitigation measures thus require financing structures and conservation investments that cover the full range of carbon-rich ecosystems. However, our analysis indicates that greater agricultural productivity increases would be needed to compensate for such restrictions on agricultural expansion.

Ensuring community benefits; case study of REDD+ in Ghana

AR. Saeed (1)
(1) University of Reading, Geography and Environmental Science, Reading, United Kingdom

In the last decade, United Nations negotiations have been on going on using forests to mitigate climate change via the mechanism known as Reduced Emissions from Deforestation and Forest Degradation plus the added value of conservation, enhancement of forest carbon stocks and sustainable forest management (REDD+). With support from organisations like the World Bank and the collaborative efforts of UNDP, UNEP and FAO, forest countries across the globe have started to get REDD+ ready. Getting REDD+ ready includes running pilot projects and implementing other readiness initiatives to feed into the systems and strategies countries are laying out for REDD+ and to reform already existing climate and forest governance institutions. The purpose of this research is to understand how local communities harness such new carbon economy opportunities (or not). The study is a multi-sited case study approach in Ghana employing systematic literature review, semi-structured interviews, actor mapping, focus groups and document analysis as the main methods of identifying what can be learnt at the international level from the local level implementation of such carbon mechanisms.

P-2219-15

Future scenarios for the north of Amapá State considering REDD+ as a conservation tool

E. Sotta (1) ; V. Guadalupe (2) ; LJGD. Aguiar (3) ; VF. Santos (4) ; L. Martorano, (5)
(1) Empresa Brasileira de Pesquisa Agropequaria – EMBRAPA, Embrapa Amapá, Macapá, Brazil; (2) Ativos Socioambiental, Brasilia, Brazil; (3) Universidade Federal de Pelotas, Meteorologia, Pelotas, Brazil; (4) Instituto de Pesquisas Científicas e Tecnológicas do Estado do Amapá – IEPA, Lab. de sensoriamento remoto e análises espaciais aplicado a ecossistemas. aquáticos – lasa, Macapá, Brazil; (5) Embrapa, Agrometeorologia, Belém, Brazil

The ecosystem services provided by forests are important for ecosystem maintenance, and support, protect or affect the activities and human well-being. Much of the forests in the north region of Eastern Amazon are under some type of protection, being one of the most pristine areas of the Amazon. In Amapá these forests may be threatened by being in an area of the border with French Guiana, where the current political development of the State is being targeted, resulting in actions that modify the current scenario and pressure on natural resources in the region.

This study assessed how the provision and maintenance of ecosystem services such as carbon stocks can contribute to local and regional sustainable development. This study allowed creating development scenarios for the northern region of Amapa to 2030. These results contribute to the discussion of a policy to subsidize programs aiming at reduction of emissions from deforestation and degradation (REDD) and payment for ecosystem services (PES) implementation, by defining priority areas in the border region between Amapa and French Guiana.

This study was conducted in the northern region of the State of Amapa across the municipalities of Calçoene and Oiapoque. This area lays within the Guyana Shield, which is characterized by a low population density, difficult access to remote forest areas and for being a geological and biological unit where high levels of endemism and biodiversity exists.

The opportunity cost of avoiding forest conversion was generated using information of the net present value (NPV) of four land use activities (forest, cattle ranching, and gold mining) and the average carbon stock values of these land use categories. This latter data was associated with a land transition matrix, processed using the REDD Abacus SP software. The output was the differences derived from the returns of the forest and those land uses that will replace it, with differences in carbon stocks of the emissions avoided by not converting the forest to other uses. Three opportunity cost scenarios were modelled to which a sensitivity analysis was done and, based on these results, scenarios were simulated.

The cumulative reduction of forest cover in 2030 was higher in the pessimistic scenario compared to the other two simulated scenarios. In the optimistic scenario, we observed a clear effect in reducing deforestation by implementing a program of PES-REDD+, which resulted in a level of deforestation close to the historical projection.

The opportunity cost of avoiding the conversion of land use at the current per ton of carbon price (R$ 14.6/tCO2e = $ 7.5/tCO2e) varied between R$ 3.00/tCO2e and R$ 2410.00/tCO2e, corresponding to a potential annual reduction of emissions between 0.14 and 0.02 tCO2e per hectare. The largest potential abatement of emissions derived from avoiding forest conversion to cattle ranching activities (0.14 tCO2e.ha-1.year-1) at a cost of R$ 3.00/tCO2e. Included variations in profitability (NPV) of land uses associated with the three scenarios of deforestation, livestock continue to be the most attractive activity for the implementation of a REDD + project.

In modeling the opportunity cost in terms of the three scenarios of deforestation, we found that the pastures activities remained as the most attractive activity for developing REDD+ projects, with an average cost of R $ 4.93 ± 2.73/tCO2e for the three scenarios, at the current average price per ton of carbon. This shows the potential of establishing a program of payment for environmental services with small cattle ranching producers who practice a low-productivity activity.

The balance between the implementation of conservation policies and economic development will give the state alternatives for successfully implement REDD+ mechanism. However, this success will depend on strengthening of institutional capacities and land regularization measures, which will provide the necessary information to the construction of the policies and the REDD+ strategy of the state. This study gives various elements to support the construction of such a policy, especially for the construction of its baseline.

2220 - Landscape level adaptation and mitigation: integrating science, policy and practice

This abstract is a submission to parallel session N° 2220 of theme 21: Landscape & ecosystems adaptation, with the title «Landscape level adaptation and mitigation: integrating science, policy and practice»

The IPPC Climate Change 2014 Synthesis Report states it is very likely that surface temperature and sea levels will continue to rise and that extreme weather events become more frequent and severe. The interaction of climate change with other drivers of global change amplifies existing risks to social-ecological systems, and creates new ones. Adaptation to climate change should therefore

be acknowledged as a long-term driver of economic, social, political and cultural transformations.

Ecosystem services are often valued for their immediate material or cultural benefits to human well-being, although in the medium- to long-term ecosystem services that sustain such benefits (referred to as regulating and supporting services in the Millennium Ecosystem Assessment terminology) must be considered. In the context of climate change and its expected dramatic and likely abrupt impacts on ecosystems and on societies, an additional role for ecosystems towards human well-being has been considered, and referred to as Ecosystem-based Adaptation. Going one step further, a broader framework can be proposed for the identification, understanding and management of so-called adaptation services. Adaptation services are defined as the benefits people derive from the capacity of ecosystems to moderate and adapt to the effects of climate change.

Adaptation services differ from ecosystem services by formally recognising the intrinsic ability of ecosystems to provide valuable services for societal adaptation by (i) buffering risks, (ii) providing options and (ii) transforming. In contrast to ecosystem-based adaptation, which has been addressed under decision-making status quo, for adaptation services to emerge and inform effective adaptation, new decision contexts that incorporate the integrated transformation of values, rules and knowledge are required. In particular, new transdisciplinary knowledge will be required to drive such social changes, and to achieve consensus on decisions and actions.

As a first step, the uptake of the concept of adaptation services by scientists, managers and policy makers requires proof of the concept and identification of key underpinning mechanisms so as to move beyond a conceptual definition and iconic story lines, and to develop innovative management solutions. In this presentation we will demonstrate such a proof of concept by means of a common methodological framework applied to ecosystems from a range of latitudes and with key roles in ecosystem-based adaptation to climate change.

This framework facilitates implementation of an adaptation services approach and enables synthesis across case studies. In particular, using such a comparative approach we propose hypotheses on functional mechanisms underpinning adaptation services required to support transition and transformation of socio-ecological systems, such as the role of keystone species and keystone functional groups or the role of different types of response diversity. Landscape connectivity already does, and is expected to play a key role for transition and/or transformation of fragmented systems.

We then identify initial principles for the management of adaptation services that range from the management of pre-existing adaptation services that will support autonomous adaptation, to planned adaptation by steering new adaptation services, and to the restoration of adaptation services in degraded ecosystems. Lastly we discuss alternative adaptation pathways that could meet multiple objectives of nature conservation and human well-being.

Ecosystem services in forest conservation for climate change mitigation: a cross-site analysis of REDD+ projects

J. Förster (1) ; R. Seppelt, (2) ; T. Vaclavik (2)
(1) Helmholtz Centre for Environmental Research - UFZ, Dept. computational landscape ecology / dept. environmental policy, Leipzig, Germany; (2) Helmholtz Centre for Environmental Research - UFZ, Computational landscape ecology, Leipzig, Germany

This presentation is part of parallel session 2220 «Landscape & ecosystems adaptation» with the title «Landscape level adaptation and mitigation: integrating science, policy and practice».

The presentation provides insights into the role of ecosystem services in projects for reducing emissions from deforestation and forest degradation (REDD+). The role of ecosystem services in the design of 39 REDD+ projects was analysed in a cross-site comparison, revealing opportunities and trade-offs in delivering climate change mitigation, adaptation and sustainable development at the landscape level.

REDD+ has become a well-established building block of climate change policies under the UNFCCC. Policies require REDD+ projects to comply with safeguards for maintaining and enhancing forest ecosystem services. This cross-site analysis of REDD+ projects indicates, that the majority of REDD+ projects do address multiple ecosystem services relevant to climate change mitigation, adaptation and sustainable development, with benefits to local communities. However, the analysis also reveals challenges when it comes to the effectiveness of REDD+ projects in mitigating carbon emissions and at the same time providing benefits to local communities.

The findings of this analysis inform on 1) how REDD+ projects comply with safeguards defined in UNFCCC policies, and 2) how REDD+ projects contribute to mitigation and adaptation at a landscape level.

K-2220-03

REDD+ delivery models at landscape level: the crucial role of private sector, for session «N˚ 2220 -¬□ Landscape & ecosystems adaptation» with the title «Landscape level adaptation and mitigation: integrating science, policy and practice»

I. Nhantumbo, (1)
(1) International Institute for Environment and Development, Natural resources group, Edinburgh, United Kingdom

Addressing REDD+ requires interventions at scale to address the drivers of deforestation and forest degradation within large landscapes where competing users and land uses provide an opportunity and a challenge in reducing emissions. IIED has been conducting research to understand the role and risks of private sector in REDD+ as well as the institutional and policy frameworks that govern their involvement in implementation of REDD+ - particular focus was on carbon rights and benefit hsaring. A database of 115 REDD+ initiatives in Africa, Asia and Latin America was constructed. Case studies from DRC, Mozambique and Tanzania provided for detailed analysis of the legislations and institutional arrangement in place at national and local level. This presentation will share some of the key findings related to issues of carbon rights and benefit sharing as clarity on this is core to REDD+ delivery models that are inclusive, equitable and sustainable. In addition, IIED is conducting research and testing REDD+ at the Beira Landscape Corridor in Mozambique including three provinces (Manica, Sofala and Zambezia) in which four models were identified to address key drivers in agriculture, biomass energy, timber and non-timber harvesting practices. The role of private sector in implementing sustainable land use changes to reduce emissions is important. However, it has been equally acknowledged that public finance for REDD+ can only do so much. Private capital is needed to provide the impetus for large scale and sustainable investment required for meaningful and measurable emissions reduction. There are questions however: what is the formulae for this private capital and who are the winners and loosers? Is the model economically viable as well as socialy and environmentally sound? Are the local small scale enterprises requiring the capital to invest in sustainable land uses likely to be a conduit for generating profits for financiers alone or they stand to gain as well? What safeguards need to be in place to secure win-win solutions?

O-2220-01

The role of ecosystems in Disaster Risk reduction

J. Kloos (1) ; J. Frélichová (2) ; S. Van Der Meulen (3) ; F. Renaud (4) ; E. Lorencová (2) ; Z. Sebesvari (1)
(1) United Nations University, Institute for environment and human security unu-ehs, Bonn, Germany; (2) Czechglobe, Department of human dimensions of global change, Brno, Czech Republic; (3) Deltares, Utrecht, Netherlands; (4) United Nations University, Institute for environment and human security (unu-ehs), Bonn, Germany

Ecosystems have the capacity to play an important role in disaster risk reduction (DRR) as well as in climate change

adaptation (CCA). In the context of DRR, ecosystems contribute to hazard mitigation as well as to the reduction of the so called "underlying risk" as outlined in the Hyogo Framework of Action (HFA, 2005). Although engineered structures are still preferred and promoted by planning authorities dealing with disaster risk reduction in many cases, there is an increasing number of applications of ecosystem based solutions in disaster risk reduction worldwide. Similarly ecosystem based adaptation (EbA) measures in CCA are gaining recognition. Examples of such measures are wave dampening by willow or mangrove forests, functional green infrastructure in urban areas or sustainable land management in drylands. The ESP working group on Ecosystem Services and Disaster Risk reduction aims to integrate the concept of ecosystem services into DRR and CCA and provides a platform for research investigating the potential of ecosystem-based approaches for Disaster Risk Reduction (DRR). After discussing relevant concepts and identifying potential synergies, this presentation will showcase a number of applications in a range of contexts based on the existing research activities within the working group. For some selected cases, the role of ecosystem services and how they contribute to reducing risks and vulnerabilities and/or contribute to climate change adaptation will be presented. The presentation will also highlight linkages to other ESP working groups that provide solutions for disaster risk reduction from specific ecosystems perspective, such as for fresh water and marine environments.

O-2220-02

A Community Forestry-landscape based approach to climate change adaptation

R. Pairojmahakij (1) ; R. Triraganon, (1) ; D. Gritten, (1) ; B. Poudyal, (2)
(1) RECOFTC, Bangkok, Thailand; (2) RECOFTC, Kathmandu, Nepal

International debate on the role of forests in climate change has thus far mainly focused on their potential to mitigate Greenhouse Gas emissions (GHGs), particularly through the REDD+ mechanism. However, the role of forests in contributing to climate change adaptation has been gaining recognition. In addition to the efficiencies in linking adaptation and mitigation funding and project activities, a key rationale for focusing on forest landscapes for adaptation is the reliance of approximately 450 million people on forests in the Asia Pacific region alone. The contributions of forests to the livelihoods of these local communities is significantly higher than previously thought and thus a major contributor to their adaptive capacity. Conversely, local communities may prove to be critical in on the ground implementation of activities to support ecosystem resilience. Community forestry (CF) in this context is of particular importance as a modality for providing multiple benefits to local communities, and the various assets required for adaptive capacity in a context of climate change. The focus of this research article is to present a CF based climate change adaptation framework, which is grounded in 10 case studies in Cambodia, Indonesia, Nepal, Thailand, and Vietnam, and the recent piloting of this framework in the Terai of Nepal.

Ecosystem services as determinants of social-ecological system transformations: Dojran Lake, Macedonia

L. Ilieva (1) ; C. Giupponi (2) ; D. Bojovic, (1)
(1) Ca' Foscari University of Venice / Euro-Mediterranean Centre on Climate Change, Venice, Italy; (2) Ca' Foscari University of Venice, Venice Centre for Climate Studies, Venice, Italy

Global environmental change often triggers abrupt and irreversible ecosystem shifts resulting in transformations of social-ecological systems. The capacity to adapt to such variable and uncertain conditions is a unique learning opportunity to better understand factors underpinning system's resilience to shocks. This study examines a social-ecological system through the lens of ecosystem services and their role as determinants of a transformation. The project Integrated Water Resource Management (IWRM) at Dojran lake in Macedonia applied the ecosystem services framework to examine the impacts of sudden natural disasters affecting Dojran Lake in Macedonia. Once a significant site in the Balkan peninsula, known for its water health benefits, fisheries, and abundant hydrological resources for agriculture and surrounding settlements, the lake has experienced two extreme shocks resulting in flood (1955 – 1956) and drought (1989). The shocks were detrimental for the small, mesotrophic -eutrophic lake of 42.5 km2 and with the maximum depth of 10 m. The research is focused on the latter, anthropologically driven, event, which lead to a 60 cm drop in water level of the lake, a recession of lake's margins up to 100 m from the main settlement, the disappearance of much of the western littoral zone, and significant biodiversity loss. All these resulted in long-term impacts on the social-ecological system and overall economic downturn associated with collapse of the local fisheries industry and decreased tourism.

In the attempt to better understand how did the abrupt transformation affect ecosystem services and human wellbeing, we collected and analysed information through the following activities:

1. identification of main stakeholders at Dojran lake and analysis of their relevant role in the process of transformation;
2. analysis of social, ecological, and economic factors defining the current state of the system;
3. identification and prioritization of ecosystem services and their current conditions;
4. exploration of the stakeholders' visions about desired future social-ecological pathways and consultation of the development strategies of the local government.

The collected information contributed to the development of a holistic picture of the actors and components necessary to understand the resilience of the system, emphasizing the dynamic character of the internal transformation processes.

The research was further guided by the principal question of how the listed information can provide insights for the management and conservation of the altered social-ecological system. Results show that the state of ecosystem services provision has dramatically decreased; nevertheless they continue to be determinant for local communities' wellbeing and an indicator for their adaptive capacity. We identified recreational services, fisheries and agricultural production as the key ecosystem services. Their intensified exploitation, however, is guided by past livelihood patterns, which can hardly be supported by the current state of the ecosystem and which can be exposed to further risks in the perspective of climatic changes. Although the visions about the prospects of development in the area were rather heterogeneous, there is a common shared awareness of the need to preserve and valorise key ecosystem services.

The analysis of past sudden social-ecological transitions through an ecosystem services approach provides a comprehensive framework for the research of adaptive and coping capacities inherent in the system and the identification of its main vulnerabilities. These results represent a step forward towards identifying enabling factors to incorporate ecosystem services in the development process of the area, while strengthening the capacities for adaptive management of social and ecological systems in view of possible future shocks.

Impacts of land cover changes on ecosystem service delivery using remote sensing, GIS and social innovation tools at Duiwenhoks catchment

M. Tshindane (1)
(1) South African National Biodiversity Institute, Climate Change Adaptation Division, Western Cape, South Africa

Historic spatial land cover databases consisting of maps and land use patterns are important tools for monitoring impacts of land cover change. Such a database was constructed for Duiwenhoks catchment in the Western

Cape, South Africa from 1940 to 2010 in order to assess land cover dynamics at a long scale (70 years). This, coupled with attribute climatic data and streamflow dynamics will be useful in modelling future hydrologic patterns, ecosystem services sustenance and resilience to natural and anthropogenic impacts such as floods and increased vegetation clearing for agricultural purposes respectively in the 21st half century (2050) using ACRU. To achieve this, black and white Aerial Photographs (AP's) were used to build the land cover maps roughly in a decadal series (1940, 1950, 1960, 1970, 1990 and 2010) with the exception of 1980 due to bad raw datasets which was technically deemed impractical to be used for this study. Research tools for the project were advanced software in GIS (ArcGIS 10.1) and Remote Sensing (ERDAS Intergraph 2014 and ENVI 4.4) to perform desktop applications like geo-referencing, image cropping, mosaicking, projection and post classification. The project used remote sensing tools for textural analysis, Principal Component Analysis (PCA), supervised and unsupervised classification to build the spatial land cover maps. An error matrix using 80 sampling points per land cover class and ground truthing was used to quantify the degree of correctness resulting in a 60% overall classification and 58% Kappa index. Furthermore, interviews with the farmers, long-standing residents, private land owners, and the Duiwenhoks Water User Association and conservation planners were used to assess trends and the effectiveness of environmental policy and ecosystem based adaptation mechanisms that are rolled out by different organisations in the study area. Findings of the study show a loss of natural vegetation from the 1940's especially in riparian zones of the middle catchment. An observed increase in dam construction also indicate the increase in demand for irrigation water for both crops and livestock production. With good national and international policies in place to promote environmental sustainability in South African Water Catchment Management Areas, there is great potential for rehabilitation and conservation of ecosystems and the physical environment. However, the limitation of application of policy at a local fine scale level is one of the reasons which appear to lead to failure of preventing unsustainable land cover change such as in riparian zones. Firstly, catchments differ in their heterogeneous statuses signalling a need to structure locally developed environmental adaptation tools. Other studies indicate that the hierarchical list of planning documents and environmental issues become diluted in terms of their relevance to local development due to a weak alignment of policies and legislation (Sitas et al. 2013). The on-going gabion construction project (Duiwenhoks Goukou Wetland Rehabilitation project) is one of the success adaptation mechanisms being rolled out in the Duiwenhoks catchment because prior to its conclusion, several of the objectives like maintaining streamflow and halting river bank erosion appear to have been achieved. Additional to the gabion construction adaptation response, the alien vegetation clearing exercise has also proved to be yielding substantial results in the middle catchment. However, at the upper catchment below the Langeberg Mountains, the alien clearing programme should have immediately followed up the clearing exercise by planting endemic plants that will protect the soil from further erosion due to its looseness and exposure to runoff. Therefore, alien clearing should take note of the seasons in which to act on because performing the exercise in mid-winter makes the exposed soil erosion debris which waits to be washed into the main river and other feeding streams.

Traditional plant-phenological observations at the Hungarian Meteorological Service

E. Vincze (1)
(1) Hungarian Meteorological Service, Budapest, Hungary

The relationship of the vegetation and climate is obvious from the first observations of the nature. Climate change has a strong impact on the flora of each country, which can be followed by the study of phenology. The task of plant-phenology is to observe and analyse the periodically recurring biological processes such as budburst, flowering, fruit ripening, and leaf fall. This is the scientific discipline, which is able to link vegetation dynamics with climate variables.

Phenological observations in Hungary started in 1871. The observation system of the Hungarian Meteorological Service (OMSZ) collapsed and revived time by time, until it was closed because of financial problems in 2000. Due to the reorganization of the institute, unfortunately, a part of the datasets were destroyed. Between 2009 and 2014 within the framework of a scientific research fund we had an opportunity – beside the main tasks of the project – to study the archive records.

In the last two years we collected detailed statistics about the digitalized and the only-paper datasets and tried to methodize the whole available digitalized and paper-based database. The paper will present the archive phenological data collection of the Hungarian Meteorological Service between 1871 and 2000.

P-2220-04

Economic Contribution of Communal Land Restoration to Rural Livelihood; a Case Study in Ethiopia

YT. Weldesemaet (1)
(1) Watersheds Organisational and Livelihood Affairs Support, Research and Development, Addis Ababa, Ethiopia

Restoration of natural capital in areas with conservation interest has significant potential in the conservation of biodiversity and thereby increasing the economics of the area. Despite such qualitative assertions, quantitative accounting of restoration areas is hardly ever assessed in Ethiopia. Therefore, this study attempted to quantify the economic net benefits of the restoration of degraded community conservation area by comparing the cost of restoration inputs; with the income generated from the restoration outputs. The restored conservation area cost and benefit are projected temporally to 2025 the time when the restoration outputs yield maximum and spatially to the large-scale communal land holdings in the study region. The study findings indicated that not all economically valued restoration outputs contribute to conservation area community incomes. The present net benefit from the study area generated an income of USD 158, which is almost half the national per capita income during the study. After the restoration outputs yielded maximum, net benefit expected from this study area increased incomes of beneficiaries six times more. Whereas restoring all the communal land in the study area would increase incomes to USD 4,526, which is way over what the government aims to achieve with its acclaimed 2025 Growth and Transformation Plan. However, to realize this it will require thorough research for the development of markets for different bio-geographic zones and evolving appropriate working plan prescriptions. Moreover, the possibilities of linking these services to international protocols in conservation of natural resources, global warming, and world trade have to be explored.

2222 - Semi-Arid Regions Adaptation

ORAL PRESENTATIONS

O-2222-01

Adaptation Research in Semi Arid Regions of South Asia

S. Gajjar (1)
(1) Indian Institute for Human Settlements, Environment and Climate, Bangalore, India

Faced with high climate variability and a multitude of development challenges, people in the semi-arid regions of Africa and Asia are particularly vulnerable to climate-related risks. Interventions to date have focused mainly on short-term solutions, leaving large gaps in our understanding of which responses will enable widespread, effective and sustained adaptation over longer time horizons.

The Adaptation at Scale in Semi-Arid Regions (ASSAR) project aims to fill the above knowledge gap. Central to the ASSAR project is a focus on multi-stakeholder processes, which help in identifying key adaptation and development-related vulnerabilities, and determining responses that can yield tangible and lasting benefits to society.

Key insights are emerging from South Asia's multi-institutional team's research and interaction with a range of stakeholders. Over the past year, policy makers, senior government officials, community members, academics as well as practitioners were engaged through a variety of formats including key informant interviews, participatory workshops and research validation events.

Initial research findings suggest that the welfare cost of climate change impacts in India varies across geographies and sectors. Given the high prevalence of natural resource based livelihoods, high incidence of poverty and inherent socio-economic inequalities, a significant section of the population is ill-equipped to adapt to current and projected climate variability. While households dependent on agriculture are directly affected, those living in urban areas are also affected by declining agricultural productivity. At the same time, rapid and largely unplanned urbanization manifests in an intense competition for resources and land. Quality of life for marginalized groups in urban areas is characterized by lack of access to social capital, poor quality of jobs and exclusion from public services. This begs the question whether migration for livelihood diversification or improved well-being actually translates into a reduction in vulnerability, or simply into a differently characterized vulnerability.

Practitioners working with urban dwellers and rural households over decades carry unique tacit knowledge of local barriers to effective adaptation, mal-adaptive practices and the unintended outcomes of current institutional, policy and governance structures. As part of ASSAR, climate scientists aim to generate climate messages with the intention to test whether improved climate information heightens adaptive capacity, for those whose lives and livelihoods are directly exposed to climate-related risk. Social scientists are poised to study local governance structures that control the sharing of common resources such as water and forests, as well as patterns of migration across a rural to urban continuum. Research across different domains is driven by the need to produce knowledge which is useful to vulnerable people living in semi-arid regions, either directly or through policy influence.

Using a collaborative research approach, while drawing upon the experiences of practitioners, ASSAR aims to inform climate change adaptation policy and practice in ways that strengthen livelihoods and sustain the well-being of the most vulnerable. Conducting and aligning such research is a complex task, requiring at all levels, leaders who can converse in several disciplinary discourses, becoming conduits of scientific and practical knowledge across different communities. At the same time, the project generates valuable lessons for future research initiatives aspiring to contribute to climate change adaptation.

Famine, climate, agriculture and desertification in Northeastern Brazil : from historical reconstruction to future adaptation

MP. Ledru (1) ; F. Soares De Araújo (2) ; LR. Zanette (2) ; L. Bremond (3) ; C. Favier (4)
(1) Institut de Recherche pour le Développement, UMR 226 ISEM, Montpellier, France; (2) Universidade Federal do Ceará, Departamento de biologia, Fortaleza, Brazil; (3) Ecole Pratique des Hautes Etudes, Umr isem, Montpellier, France; (4) Centre National de la Recherche Scientifique, Umr isem, Montpellier, France

The previsions say that the semiarid regions in the world are between the most impacted by the global climate change. In Northeastern Brazil, among the environmental (lost of biodiversity, extreme droughts), social (migrations, diseases exposition) and economics (reduction on income generation, in employment rates, and in the Gross Domestic Product) of global warming, it is affirmed strong pressures specially over the environment, the agriculture and livestock because of the increase of the rain irregularity and increase of evaporation. During the last century Northeastern Brazil and more particularly the state of Ceara, was submitted to successive catastrophic droughts that enhanced severe famine and massive migrations towards the big urban centers in southeastern Brazil. Land use in this semi arid area has increased the size of degraded areas and the intensity of degradation and desertification. Overgrazing by livestock is the main origin for the degradation process. However, with the climate warming and the drastic decrease of livestock production, farmers were forced to revert to more primitive forms of subsistence farming with a land rotation system (nomadic farming) that relies on fire for vegetation clearing during the dry season. With the increase in human population density and the partitioning of the large landlord farms, the interval between each land use cycle has been decreasing.

The IPCC 2014 report shows that increase in temperature change in seasonality and decrease in precipitation will strongly affect this region although a large uncertainty due to the scarcity of environmental datas that prevents a good precision in most of the reconstruction models.

The multidisciplinary project developped at the UFC in the frame of a cooperation with IRD aimed to reconstruct the climate and landscape changes during the 20th century. The project is multidisciplinary and is using an historical reconstruction of land use based on microfossil data, the current state of vegetation cover and the genetic diversity of key indicator species.

Modern landscapes are described in different types of degradated areas, from well preserved to very degraded, through botanical surveys and remote sensing analyses. The evolution of the landscape during the last century is analysed on the base of paleo ecological methods adapted to shorter time scales. Short sediment cores were collected in selected dams within the different ecosystems and changes in landscape are reconstructed on the base of bio indicators and microcharcoal analyses. These changes are compared with observed climate datas. Climate and man influence and impact on the desertication processes are defined at fine scale and analysed separately. We aim to answer the following questions: (i) what is the history of land use and diversity loss in areas under a degradation/desertification process in the last century?(ii) What is the quality of the biodiversity in the surrounding area of the degraded areas ? iii) How the defined ecosystem services could be used for natural or induced restoration/recovery of the degraded areas?(iv) what will be the resilience of the remaining Caatinga areas for the next century ?

This project started in 2014 and is carried out by researchers at the Federal University of Ceará, Brazil – UFC and the Institute of Evolutionary Sciences of the Montpellier 2 University, France.

O-2222-03

Adaptive Capacity and Risk management: Evidence from household-level data from semi-arid tropical villages in India

A. Rahman (1) ; C. Singh (2) ; P. Mudliar (3)
(1) Indian Institute for Human Settlements, Bangalore, India; (2) Indian Institute of Human Settlements, Bangalore, India; (3) iihs, Bangalore, India

Objective
This paper attempts to provide evidence on how households respond to climatic variability and extreme events such as droughts/floods in the semi-arid regions villages of India. It looks at how vulnerabilities inherent in farming households and the risks faced by them, which shape and affect local adaptive capacity. Two key questions which this paper would be address are – the impact of climate change on food production and the extent of climate induced migration. The paper focusses on semi-arid regions since this region is highly vulnerable to several socio-economic risks apart from rainfall-related production risk.

Background
Semi-arid regions constitute almost 53 percent of India's land cover, where agriculture is the primary source of livelihood. In addition to being drought-prone and being vulnerable to rainfall-related production risks, semi-arid regions are characterized by higher levels of poverty, poorer asset ownership, higher indebtedness, smaller land holdings, and lower levels of land productivity. Poor performance of agriculture and lack of other livelihoods options further limit their capacities to anticipate and respond to climatic variability.

Data
Household level panel data for 17 villages in India has been collected by the International Crops Research Institute for Semi-Arid Tropics (ICRISAT) which is used for the analysis here. This is a unique dataset in the sense that it provides an opportunity to track the economic status of households over time along with the information whether they faced droughts/floods during the period and the response adopted by them.

Relevance of the Research
This research would enable a deeper understanding of the conditions under which household vulnerabilities in semi-arid regions are shaped. This has direct implications for their current and future ability to adapt to climate change. The uniqueness of the data helps us identify which households are vulnerable to climate change, measure the impact of climate change on household assets and production patterns, and measure adaptation responses to climate shocks. In a nutshell, this paper aims to answer questions related to vulnerability, impacts and adaptation within the context of climate change in semi-arid villages in India.

O-2222-04

Tropical warm semi-arid regions expanding over temperate latitudes in the projected next century

A. Rajaud (1) ; N. De Noblet-Ducoudré (2)
(1) Laboratoire des Sciences du Climat et de l'environnement, Gif-sur-Yvette cédex, France; (2) Laboratoire des Sciences du Climat et de l'environnement, CEA-CNRS-UVSQ, Gif-sur-Yvette cédex, France

Two billion people today live in so-called dry lands (Millenium Ecosystem Assessment, 2005), where extreme climatic conditions prevail, and natural resources are limited. The future of those drylands is therefore challenging for many human beings. Drylands are expected to expand under several scenarios of climatic change (e.g. Feng and Fu, Atmos. Chem. Phys, 2013). However, no study focuses specifically on the evolution of strictly climatically defined semi-arid zones. These represent the frontier areas where intermediate conditions might shift either towards fully arid (desert), or less water-limited (favorable to rainforests), climate.

Climatic transformations of today's and future warm semi-arid regions raise the following two issues: 1) will these regions expand and thus widen the area where specific water-limited development issues must be addressed? 2) How will climatic conditions evolve in today's semi-arid regions, and what does it imply for development programs?

To address these, we adopted a bioclimatological approach based on the Koppen climate classification (e.g. Rubel and Kottek, Meteorol. Z., 2010). Monthly surface air temperature and precipitation are combined to identify bioclimatic regions. Geographical migration of these regions can thus be followed over time. We focus on the warm semi-arid class, characterized by a mean annual temperature exceeding 18°C and water-limitation criteria calculated from the seasonal distribution of rainfall and temperature.

A multi-model ensemble of CMIP5 projections was selected to draw and analyze the evolution of current and future warm semi-arid regions according to 3 representative concentration pathways of increasing emissions (RCPs 2.6, 4.5 and 8.5). The Koppen climate classification was first applied to key-periods – beginning, middle and end of the 20th and 21st centuries – to localize past and future warm semi-arid regions. Then time-series for the classification were built using a 15-year running average climatology from 1901-1915 to 2086-2100, in order to characterize trends and variability in the evolution of those regions. Averages over a 15-year interval allow to buffer the large interannual variability.

According to the CRU datasets, global expansion of the warm semi-arid area has already started, following the global warming trend since the beginning of the 20th century (~+13%). Climate models are able to capture this trend albeit with a delayed increasing trend. This expansion will continue according to all projections, especially for the most severe scenarios, reaching ~19% and 51% respectively for RCP2.6 and RCP8.5 (multi-model mean). This will be most significant outside the actual tropical belt towards the North Pole. This poleward migration is of ~1°, 7° and 10° for respectively RCP2.6, 4.5, and 8.5.

Two processes mainly explain this expansion: warming and drying. Drying is mostly responsible for the conversion from equatorial, subhumid climates within the tropical belt. Beyond 30° of latitude, warming is directly responsible for the conversion of cold semi-arid towards warm semi-arid climates; particularly so in RCP8.5. A third category concerns the conversion of temperate climates to warm semi-arid, outside of the tropics. In this case, both warming and drying processes are at stake, as drying effects are amplified in warmer conditions.

Those various transitions may have drastic but also very distinct ecological and sociological impacts. We therefore stress that many of the warm semi-areas that will appear in the future may need to be dealt with differently than tropical semi-arid regions in the past.

O-2222-05

(Re)conceptualising maladaptation in policy and practice: towards an evaluative user-focused framework for semi-arid regions

E. Carabine (1) ; L. Jones, (1) ; L. Schipper (2)
(1) Overseas Development Institute, Climate and Environment Programme, London, United Kingdom; (2) Overseas Development Institute, Stockholm Environment Institute, Berkeley, United States of America

Maladaptation is a concept that has received notable policy attention in recent years, but has yet to be fully explored in both conceptual and practical terms. As a consequence it suffers from a lack of consensus around its definition and application in policy and programming. While there is general agreement that maladaptation involves action to adapt to change that increases vulnerabilities or reduces adaptive capacity, there is disagreement over what causes such action.

One of the reasons why maladaptation is such a powerful term is that it encourages practitioners and policy-makers to recognise that the decisions they take now to address climate change can backfire and inadvertently make people more vulnerable in the longer-term. However, a lack of consensus and clarity on how to characterise maladaptation currently prevents decision makers from

being able to apply the concept in practice.

In the context of semi-arid regions, the immediacy of many development challenges, the susceptibility of these areas to existing climate variability and the inherent non-linearity of these systems contribute to a higher risk of maladaptive outcomes arising from development or adaptation strategies.

We outline five areas of conceptual clarity needed in understanding and evaluating maladaptation in semi-arid regions and elsewhere.

First, deliberate non-action should, if contributing to increased climate risks and negative outcomes for people and communities, be considered as maladaptation. The semi-arid lands of East Africa, for example, have long been actively marginalised from the economy and politics. Over the past decades, a lack of development in these regions over long periods has contributed to high levels of vulnerability.

Second, a strategy that has not considered the impacts of climate change should constitute maladaptation. For example, many pastoralist communities have been encouraged to diversify livelihoods as a result of persistent drought. But moving away from semi-nomadic pastoralism can erode existing adaptive capacity, leading to greater vulnerability.

Third, a fundamental component of maladaptation is time. It is only with time that the success or failure of interventions will become evident. This trait is well illustrated in the context of groundwater abstraction for adaptation in semi-arid regions, which may be maladaptive in the longer term.

Fourth, semi-arid ecosystems, livelihoods and economies are not static. Moreover, under climate change, climate risks and vulnerabilities to particular climate variables are likely to shift. Semi-arid systems are characterised by non-linear and unpredictable dynamics in both their socio-economic and ecological components.

Fifth, distributional aspects of adaptation are important because climate change is likely to affect segments of the population differently, both in terms of direct impacts as well as influences on wider drivers of development, and the act of implementing (or choosing not to implement) an adaptation strategy can fail to uniformly reduce climate risks across all social groups. For example, strategies to enhance and diversify livelihoods for adaptation to climate change and variability can reinforce inequalities in terms of gender, or livelihood types.

Building on this reconceptualisation of maladaptation, we present the groundwork for a framework that can lend itself to qualitative and quantitative assessment of adaptation strategies, and clarify the differences between four distinct types of adaptation outcomes – ranging from optimal adaptation to maladaptation. Most importantly, we have used the framework to highlight a number of different 'symptoms' that can act as early warnings for maladaptive outcomes, hoping to guide policy makers in achieving early-diagnosis.

In doing so, our aim has been to make this onerous concept more tractable and applicable to planners and practitioners so as to diagnose strategies likely to lead to maladaptation. It is our hope that this work will stimulate debate and galvanise interest in advancing efforts to understand, and critically, to avoid maladaptation in semi-arid regions in the face of increasing climate risks in the coming decades.

Innovative strategies to adapt climate change impact on traditional rain fed agriculture in semi arid regions: A case of North Kordofan in Sudan

E. Abdelgalil (1)
(1) university of Gezira, water management and irrigation institute, Wad Medani, Sudan

The purpose of this paper is to develop agricultural and water management strategies to help poor traditional rain fed farmers to adapt climate change impact on agriculture in North Kordofan region in Sudan. Historic climate data from the study area were collected and analyzed using CROPWAT model version 8.0. Reference Evapotranspiration (ETo), effective rainfall and irrigation requirements to develop different sowing dates strategys were also measured using CROPWAT model. Field visits observations and discussion with farmers also helped the author in results justifications. The study found that early sowing dates is better than late sowing in traditional rain fed sector in North Kordofan. Early sowing date secured water for almost 70 days of the crop cycle. Also under early sowing dates, soil moisture can maintain the crop at a later stage of growth. The paper investigated that drought tolerant Sesame crop replaced the millet crop for climate adaptation purposes in North Kordofan. This research study is considered the first to develop agricultural and water management strategies to cope with climate change impact on traditional rain fed agriculture in North Kordofan, Sudan. The paper highlights innovations farmers are making to adjust to the changes they observe.

P-2222-02

Understanding agricultural vulnerability: An approach to identify and understand vulnerability of an agrarian based livelihood system in a watershed area

S. Divya (1) ; S. Badiger (2) ; J. Krishnaswamy (2)
(1) ATREE, Livelihoods, Bangalore,Karnataka, India; (2) Ashoka Trust for Research in Ecology and the Environment, Bangalore, India

Epistemological understanding of vulnerability and its assessment methods follow two main schools of thought: (1) the 'contextual vulnerability', where vulnerability (or inversely resilience) is seen as an inherent characteristic of the system (in our case a socio-ecological system), these confound the manner in which the system responds to external stressors; and (2) the 'outcome vulnerability', where the primary focus is on the impacts of a hazard (which is a process in itself driven by some other primary drivers). Indicator based vulnerability studies have gained increasing importance in the last decade, particularly within dominant framing of the climate change along with other structural variables. Within this methodology, indicators are used as proxies in order to quantify components contributing to vulnerability. This is done at either household or community level, or both essentially depending on its intent to identify points of interventions. The primary weakness of these methods lies in arriving at meaningful weights for the sub-components and the indicators. The assumption of direct causal linkages between indicators and vulnerability is another pertinent factor in these methodologies.

We discuss these weaknesses in the methods while applying the conventional indicator approach to an empirical case in semi-arid Karnataka. We compared the effectiveness and usability of indicators to study structural drivers of vulnerability. Household and community scale analysis was carried out in semi-arid region of Karnataka. The agrarian based livelihood in this area is primarily dependent on ground water resources. We used adapted versions of three indicator based vulnerability assessments; Livelihood Vulnerability Index (LVI), LVI IPCC and the Livelihood Effect Index (LEI). These methods highlighted the main variables driving vulnerability of farming communities in this region. Results indicated that financial sub-components were the largest contributor to both household and community level vulnerability. The LVI-IPCC method indicated that exposure to climatic events was greater than the adaptive capacity and this significantly contributed to vulnerability of the community. Results from the LEI, suggests that individual households in this area will be more affected by climate change than communities.

This study demonstrated the inability of indicator-based methodologies to represent intricate ground realities, which indexes tend to over simplify. Assumptions of linear two dimensional relationships can inaccurately attribute vulnerability to a particular causal factor. Moreover these methodologies largely ignore the requirement of minimum threshold capitals that determine the functioning state of a system.Based on the results and analysis of this study we suggest a framework for developing methodologies for vulnerability assessment suitable for a particular agro

climatic zone. In this framework vulnerability is treated as a dynamic concept moderated by socio economic, socio political processes and human-environment relationships. The framework incorporates the concept of minimum threshold in the capitals ,a concept widely used in "Law of Minimum", (Justus von Liebig, 1840), which propounds that there are capitals that govern the state of a system and growth is determined by the scarcest resource required by the system. We suggest that there are certain key parameters particular to a specific agro climatic zone that defines the vulnerability of the system. This framework is aimed at providing a pragmatic methodology for comparison of vulnerability across regions in similar agro climatic zones. The framework attempts to map the impacts of coping and adaptive strategies on components of a socio ecological system, through analysis of drivers and enablers of vulnerability within a particular spatial scale, having explicit links to other scales. This can contribute towards developing appropriate policy intervention strategies to facilitate adaptation processes for particular agro climatic zones.

P-2222-03

Studies of Long Term Changes in Climate and Environment in South-East Georgia – A Key for Sustainable Development

M. Elashvili (1) ; K. Kvilividze (2) ; L. Navrozashvili (2) ; L. Sukhishvili (2)
(1) Ilia State University, School of Natural Sciences and Engineering, Tbilisi, Georgia; (2) Ilia State University, Tbilisi, Georgia

Recognizing the fact that we are living in a constantly changing world became actual during the last decades, and promoted numerous studies related to environmental consequences of climate change and human impact. In this sense, study of past changes in environment and, its effect on human society coupled with better understanding of current state of the environment delivers key information to project future changes and their effect.

South-East Georgia represents natural polygon of long term changes in the environment to be caused by combination of natural and anthropogenic factors. In the convention adopted by UN in 1994 on 12th of September – A/AC.241/27, among the regions which are under the risk of desertification and draught Trans Caucasus is also mentioned. On the map developed in 1998 by natural resources and conservation service of US Department of Agriculture Iori upland is situated in the area of moderate, high and very high risk. The semi-arid Iori and Shiraqi highlands in South-East Georgia are characterized with annual precipitation <600mm and shows open steppic landscape today. However archaeological studies deliver evidences of well-developed bronze and early Iron Age settlements in the areas almost devoid of water resources today. Archaeo-Botanic studies also assume that the region was covered by forests instead of steppes.

The goal of current study is: to shed light on historic changes in the environment of the region, its natural and anthropogenic factors and consequently response of human society on these changes; to assess rate and scale of ongoing desertification process during the past decades; to project future possible changes in the environment and based on past experience elaborate adaptation and mitigation policy.

The proposed investigation is focused on identifying the source of modern changes to the environment in South-East Georgia and to discern the relationships of this environmental change to current and past actions of the human population. Long-term, sub-regional records of these changes will be constructed in terms of: 1) physical changes of vegetation; 2) changing patterns of land use/land cover, and settlement; and 3) changing aspects of land quality in relation to agriculture.

Climate change is a serious challenge to sustainable development. Historical study of desertification, as one of the main consequences of climate change coupled with anthropogenic stress, can provide valuable materials for understanding the mechanisms of climate change. Research and understanding of these mechanisms are very important in order to come up with the solutions for sustainable development; therefore the present research (project) will ultimately contribute to developing long term mitigation and resilient strategies and policies for sustainable development of the region.

P-2222-04

Water Crises in a Semi Arid District of Haryana: Trends, Concerns and Alternatives

R. Kumar (1) ; MK. Teotia (2)
(1) Centre for Research in Rural and Industrial Development, BRGF Project, Chandigarh, India; (2) Centre for Research in Rural and Industrial Development (CRRID), Urban Governance and Development Unit (UGDU), Chandigarh , India

Water problems in Asia today are severe—one out of five people (700 million) does not have access to safe drinking water. The stress on Asia's water resources is likely to intensify in future. According to the IPCC, by 2050, more than one billion people in Asia alone are projected to experience negative impacts on water resources as a result of climate change. In India the average per capita availability of water, estimated at 1,600 cubic meters per year, is expected to fall to around 1,000 cubic meters per year by 2050 based on current population projections. District Mahendergarh of North-western state of Haryana and selected for the study falls in semi-arid zone. Mahendergarh has serious water deficit due to absence of perennial rivers, deep water aquifers (about 40 meters in some blocks), scanty & irregular rainfall etc. The mean annual rainfall in Mahendergarh district is less than 300 mm which is also highly erratic. People receive water in much less quantity than their requirements. The agriculture, forestry and horticulture are affected badly due to unavailability of irrigation water which affects the availability of food grains, vegetables and fruits etc. The desertification is visible in the district. The poor water quality is another serious concern as ground water in many parts of the district is brackish. The paper, based on ongoing research by the authors, tries to explore trends, concerns and alternatives in water crises in District Mahendergarh, Haryana, India.

P-2222-05

Lake Chad : present situation and possible future water management

J. Lemoalle (1) ; M. Géraud (2)
(1) IRD, G-Eau, Montpellier Cx5, France; (2) Université Paris 1 – Panthéon Sorbonne, Paris, France, Prodig, Paris, France

Lake Chad lies in an endoreic basin located in the centre of Africa, on the southern margin of the Sahara in the semi-arid Sahel belt. The lake has varied at different time scales according to changes in the rainfall over its basin. In the recent past, after a rather wet period (1950-1970), the lake size has decreased sharply with the Sahel droughts (1970-1995) with occasional drying out of the northern basin of the lake, before a partial recovery (1995-2015).

Most of the pessimistic declarations in the media about the future of Lake Chad originate from the dry 1980 situation. The present state of the lake, since the beginning of the 2000s, has been that of a moderately low water level, with large marshes and abundant natural resources (fisheries, recession cultivation and cattle breeding) for an estimated population of 2 million people living on the lake and its shores (2013), and exporting food in the surrounding region. Endogenous innovations in family agriculture have been the key for the adaptation of the local people to the lake's variability.

The lake recession in the period 1970-1990, concomitant with droughts over the lake's basin, triggered the decision of the Heads of State of the riparian countries (Nigeria, Chad, Cameroon and Niger) to study the possibility to transfer water from the Congo basin to the Chad basin in order to increase the level in Lake Chad. The project presently supported by the Lake Chad Basin Commission (LCBC) aims at transferring about 6.2 billion cubic metres per year from the Ubangui River, a tributary of the Congo River with a cost estimated at 14.5 billion US dollars.

This transfer would avoid a drying out of the northern part of the lake (about 0.6 million inhabitants) in case of drought over its basin. But it would not allow for a mitigation of the drought impact over the whole Chari basin, the main tributary to the lake, presently home to 35 to 40 million people but foreseen to reach 80 million in 2040.

The question is whether the climatic change underway may increase or not the probability of a drought over

the Lake Chad basin. The recent IPCC- AR5 report has concluded that the rainfall trends should be moderate over the Chari basin, but with a great uncertainty and no clear indication on the direction of the change. In the short term and as a first step, the ongoing and projected LCBC basin wide programmes aiming at increasing agricultural water productivity and resilience to climate change may be usefully developed and increased.

P-2222-06

The role of cactus pear (Opuntia ficus-indica (L.) Mill.) in the conservation of water and soil in the Skhour Rhamna drylands (Province of Rhamna, Morocco)

M. Mejjati Alami (1) ; M. Chikhaoui (1) ; IS. Kanga (1)
(1) IAV Hassan II, Natural Resources and Environment, Rabat, Morocco

Seasonal and annual fluctuations in rainfall, and drought, are quite common phenomena in arid lands of Morocco. In addition to anthropogenic activities, these phenomena generate soil erosion, which in turn cause desertification.

The conservation of soil and water in these environments relies on adaptive measures, which are necessary to rehabilitate and prevent soil erosion. Therefore, the choice of drought resistant species and the ones having low demands on edaphic conditions is required. In this regard, cactus (Opuntia ficus-indica), can be one of the best choices.

This work was carried out in the rural town of Skhour-Rhamna, an arid area of the province of Rhamna in southern Morocco. We aim to evaluate the effect of planting cactus on the conservation of water and soil. Therefore, we set to study the effects of cactus plantations on the physicochemical properties of soil and vegetation. We used a comparative approach holding cactus plantation in plots with different ages and planting densities and a control plot without planting cactus. Two experimental plots were selected, one with plantation of 3 years of age having a density of 5000 plants / ha, and an older one (6 years) with a planting density of 6700 plants / ha.

We collected soil samples from each plot at different depths, which then were analyzed for organic matter and particle size determination. In parallel, we measured the infiltration rate. We also assessed the vegetation parameters such as the plant cover, the species diversity and abundance.

The results showed that planting cactus has a statistically significant effect on the organic matter content and the plant cover. Plots under cactus plantations showed the best water infiltration rates. So planting cactus in arid zones could conserve soil by reducing runoff and minimizing soil loss by erosion.

P-2222-07

Analysis of Rainfall Characteristics Relevant to Agricultural Planning in Narok County, Kenya

E. Mutuma (1) ; E. Micheli (2) ; S. Murimi (3) ; V. Land (2)
(1) Kenya Agricultural Research and Livestock Organization, soil and water management, NAIROBI, Kenya; (2) Szent Istvan University, Soil science and agricultural chemistry, Godollo, Hungary; (3) Kenyatta University, Geography, Nairobi, Kenya

Climatic factors play an important role in determining the production of food crops in the semi-arid regions of Africa. This is a region characterized by a low and highly variable distribution of rainfall spatially and over time, which constitutes a limiting potential for crop yields. Both short and long rainy periods experience dry spells that substantially influence agriculture. There are also spells where rainfall is excessive in these regions resulting in floods and excessive erosion. Understanding of the behaviour of the wet and dry spells could improve management of the agricultural activities by farmers. The objectives of this study were explore the characteristics of annual and seasonal rainfall and to simulate stochastically the dry and wet spells using Markov models. In-depth interviews were conducted with 120 small-scale farmers to establish what constitutes agriculturally relevant rainfall characteristics for small-scale farmers. Famers' perceptions reflected seasonality, distribution and intensity. Half of the respondents felt there had been a change in seasonality. Ninety percent of the farmers' claimed that the amount of rain throughout the first season had decreased with 98% of the respondents having the same sentiments for the second season. A significance test that there is no change in annual rainfall over time resulted in a t-value of 1.7033. The significance level of this t-test is 0.3044; hence there was no statistically significant change in annual rainfall within the study period. The number of days of rainfall shows a significant decrease within the study period for both long and short rain seasons. The risk of suffering losses when crops that are sensitive to dry spells of up to 10 days are planted in March 1st is therefore more than 75 percent. Long dry spells at sensitive times of plant development (germination, flowering, seeding) could spell disaster for farmers. The risk of dry spells after planting have increased over the decades making farming for small-scale agriculturalists even more risky. The findings of the study suggests the need for the development of a comprehensive agricultural and climate change and variability policy that takes into account the mounting risks associated with agricultural production among small holder farmers.

P-2222-08

The impact of Climate change to agricultural production of the coastal to reservoirs areas and creation of adaptation mechanisms

P. Normatov (1)
(1) Tajik National University, Meteorology and Climatology, Dushanbe, Tajikistan

The food products manufacture in Tajikistan already faces many serious difficulties caused mainly prompt growth of the population, mountain topography, limitation of farmlands accessible to grain crops and livestock because of abrupt inclinations both high eminences and improper microclimates. The average mean arable land on the person makes 0.14 ha/person who at comparison with global average 0.26 ha/person is low enough.

Researches of dynamics of change of climatic parameters in three agricultural areas adjoining to the Nurek reservoir in Tajikistan have shown that the mid-annual temperature for 20 years (1968-2000) has raised 1.0-1.5 oC that has led to decrease in relative humidity on 3-6 % and to increase potential evaporation on 10-26 % in annually. For example, in the Yavan valley of the Republic of Tajikistan recommended irrigation regimes are connected with the over-expenditure of water resources. Last specifications on irrigation modes to take the Yavan valley on mean annual value of humidity (0.35) to the category of droughty areas. But as show the obtained data, for last 20 years evaporation in a valley has decreased almost on 300 mm (17 %) and the amount of precipitation has risen on 70 mm (11 %). As a result, value of humidity has risen to 0.45. Hence present irrigating norms for cultivation of cotton in the Yavan valley -1100 m3/ha and 3000 m3/ha for a Lucerne are overestimated. Calculations show that unproductive losses of water only on two valleys make more than 60 Mln.m3.

In present paper results of researches on creation scientifically reasonable the scenario and recommendations for cultivation of crops with high value of efficiency and steady against climatic and stressful situations and also increase in efficiency of units of irrigation water and the irrigated lands are presented.

P-2222-09

Strategies of sustainability, green building and climate change in Brazil

J. Rezende (1)
(1) Universidade Federal do Rio Grande do Norte - UFRN, Industrial Engineering, Natal - RN, Brazil

The project Strategies of sustainability, green building and climate change in Brazil has the following general aim: diagnose and provide the development of sustainability strategies of coexistence with the climate change in Brazil.

In Brazil, the project Strategies of sustainability and climate change in South Africa and Brazil will be operationalized in

the state of Rio Grande do Norte, in the city of Caiçara do Rio do Vento (means Fisher of Wind's River). The city has a population of 3,400 inhabitants and is located in the northeastern semi-arid region. The region has an average annual rainfall of 520 mm.

Global warming has generated greater interaction of human beings difficulties with the land. The main difficulties are related to water supply, thermal discomfort and the difficulty of undertaking agricultural crops that provide subsistence activity to the population. Thus, sustainability strategies are needed to address global warming.

Was identified that the global warming can be handle with a strategy of sustainable construction. In this case, the sustainable construction is the starting point to create the individual's living condition in the environment that suffers with the warming. The habitat is the starting point for the individual to undertake adequate transformations and living with the weather phenomenon.

Were developed activities of sustainable construction with natives and students, trying to present and share some sustainable technologies and practices.

The application of sustainability strategies to a Sustainable Construction is characterized by the following pillars-fundamentals: 1 - Construction and sustainable energy; 2 - Waste management; 3 - Preservation of biodiversity and the ecosystem; 4 - water resources management; 5 - Education, involvement of child and youth in cultural, creativite, environmental, social, inclusive and participatory activities; 6 - Formulation and participation in public policies; 7 - Self / Empowerment / Entrepreneurship; 8 - Tourism; 9 - Agriculture; and 10 - Cultural and Historical rescue and cultural economy.

Intervention activities was also important to the culture and the development of the cultural economy (music, art, crafts, dance, festivities), also important to sustainability strategies developed in order to deal with climate warming.

The project Sustainability Strategies and Climate Change in Brazil, from the proposed methodology seeks to accomplish through action-research methodology to collect information and the creation of knowledge about sustainability strategies to deal with global warming. The project will provide the realization of sustainable buildings in the communities served, as well as the transfer of knowledge to local staff, as well as the construction of a collective knowledge of other sustainability strategies that can be developed for better association with global warming.

It stands out on the farm the adoption of a sustainable management model, a kind of sustainability philosophy was very important to rural properties. The management philosophy was based on an opening to absorb various learnings and openness to volunteering.

The importance of recycling PET bottle is the fact that the polyethylene terephthalate is a thermoplastic polymer that takes the environment about 400 years to degrade. Given the argument justifies the importance of the activity of researching the recycling and reuse of PET bottles. It's been developed strategies by the Brazilian university Universidade Federal do Rio Grande do Norte (UFRN) to share the findings between rural communities affected by climate warming. The social impacts of the project in the communities was documented in documents, photos and videos. The social impacts provide skills development focused on sustainability. The design of the house with PET was presented in some meetings in order to receive suggestions to improve the construction process proposed. Sustainable building experience in UFRN is also being developed.

The project presents waste management mechanisms to guide communities, municipalities, organisations and businesses regarding the type of sustainability management models to implement and explore innovative methods to improve the relationship with climate change.

P-2222-10

Are Smart Policies Really Smart? Analyzing the Implications of Smart Policies on Risk Management in India

C. Singh (1) ; P. Mudliar (1) ; A. Rahman (1)
(1) Indian Institute for Human Settlements, Bangalore, India

Since the new government's ascent into power in India, there has been much focus on creating 'smart' policies. Two such 'smart' discourses are smart cities in urban areas and climate smart agriculture (CSA) in rural areas, both of which focus on addressing development deficits and planning for climatic risks in India. This paper critically analyses these discourses to understand their implications on negotiating inherent socio-economic vulnerabilities and existing inequalities, and managing current and future climate risks.

Smart cities have been vigorously projected as the Prime Minister's pet project with $1.2 billion allocated for developing 100 smart cities in India. The idea of smart cities has been greeted in India with an equal measure of hype and skepticism. Although there is still no clear consensus on what a smart city means, it is generally agreed that 'smart' refers to using technology to solve urban problems. In a country that still lacks basic housing, water, and energy infrastructure, as well as access to health and education services, there is much debate about whether smart cities will be able to address these pressing issues. Moreover, apart from a draft concept note, India lacks a national policy on smart cities. The recent budget avoided the term 'smart city', allocating funds to the Delhi-Mumbai corridor and Gujarat International Finance Tec-City (GIFT), India's first smart city, instead. In the absence of a well-defined policy, there are concerns over how the $1.2 billion will be utilized for urban development and whether it will mainstream climate risk management. It is also unclear how cities in already stressed environments such as in semi-arid regions, will evolve to negotiate development and climate risk management goals.

In rural landscapes, agriculture is constrained by various non-climatic dynamics such as deteriorating soil fertility, depleting groundwater levels, market dynamics tied in with global price fluctuations, and migration towards urban centres. Increasing climatic variability and projected climate change, especially in resource-constrained areas such as semi-arid regions in India, are expected to interact with existing vulnerabilities, exacerbating them and potentially making agriculture an unsustainable livelihood. To address this growing concern, climate smart agriculture (CSA) has emerged as a way to mainstream a suite of mitigation and adaptation strategies that can help make agriculture and agricultural livelihoods more resilient to climatic changes. In 2011, the Government of India set up the National Institute for Climate Resilient Agriculture (NICRA) with a budgetary allocation of $64.81 million. With a core mandate of long-term strategic research on the impacts of projected climate change on Indian agriculture and demonstration of existing best practices to help farmers cope with current climate variability, NICRA is a crucial actor in India's CSA discourse.

In light of these developments, this paper traces the evolution of the smart policy discourse in India by examining the evolution of smart cities in urban areas and CSA in rural areas as well as the key actors and organizations shaping these discourses. By doing so we contribute to the larger smart city discourse that has begun to shun the term 'smart city' and questions whether it has become a term that has reached the end of its usefulness. We also argue that while CSA forefronts vulnerability to climate change, it potentially obscures larger development issues and inherent vulnerabilities. There is also the danger of old wine in a new bottle where existing agroecological techniques that have been practised by farmers traditionally, are being repackaged to make their livelihoods 'smart'. While the investment such a discursive shift attracts is useful, we argue that it is important to understand how such policy trajectories create winners and losers.

In conclusion, while the term smart invokes a variety of desirable visions of a utopia where technology is used to operate infrastructure achieving efficiency and sustainability, we argue that it is important to question whether 'smart' policies truly makes rural and urban living and livelihoods more resilient to current and future climatic risks.

P-2222-11

Investigating climate trends and impacts in semi-arid regions of Africa and South Asia: implications for climate change adaptation and development

M. Zaroug (1) ; J. Daron (2) ; A. Bazaz, (3)
(1) ACDI/ CSAG at University of Cape Town, Cape Town, South Africa; (2) UK Met Office, Exeter, United Kingdom; (3) (Indian Institute for Human Settlements), Bangalore, India

Semi-arid regions, such as the African Sahel, are typically located in the boundary between extremely dry (e.g. arid) and much wetter (e.g. humid subtropical) climate zones. The semi-arid regions of Africa and South Asia are subject to high year-to-year rainfall variability and people living in these regions are particularly exposed to the impacts of climate variability and climate change; the success of the seasonal rains can be critical to people's survival and their livelihoods. As the Earth warms, trends towards harsher or more productive climatic conditions will therefore have significant consequences for how people in semi-arid regions live with the environment and sustain their livelihoods.

The Adaptation at Scale in Semi-Arid Regions (ASSAR) project is one of four projects being funded through the Collaborative Adaptation Research Initiative in Africa and Asia (CARIAA). We will present the latest evidence and understanding of climate-related variability and trends, in the semi-arid regions of Africa and South Asia, gathered by scientists working in the Climate and Biophysical Impact (CBI) team of ASSAR. In general, the weight of evidence suggests that climate change is having largely adverse effects on natural systems supporting people's livelihoods in semi-arid regions of Africa and South Asia. Temperatures in these regions are rising at above global average rates and in some locations this is leading to measurable impacts on human and natural systems. However, significant year-to-year and longer-term variability in rainfall patterns means that any attribution of rainfall trends to global climate change is complicated. Also, future projections show large disagreements in the direction of rainfall changes and climate models are subject to large uncertainties that complicate any interpretation of climate messages. Ultimately the impacts of climate change on human and biophysical systems will manifest themselves through the combined effect of changes in temperature, rainfall, humidity and other climate-related variables. Moreover, it is only by understanding specific system sensitivities and adaptive capacities that useful information can be derived to support adaptation research and practice. Examples of how climate variability and change is impacting socio-ecological systems in semi-arid regions of Africa and south Asia will be provided.

The CBI team is made up of climate scientists, crop modellers, hydrologists, ecologists and social scientists. In the first year of the project the team developed a series of "Regional Climate Messages" documents that were produced for the four regions under investigation, namely Southern Africa, East Africa, West Africa and India. The documents provide information about historical and future climate aimed at informing policymakers, practitioners and researchers working in these regions - key results will be shared. In addition, the team is continuing to work alongside colleagues in the ASSAR project to provide tailored information that can directly feed into the adaptation-focused research. Ultimately the wider ASSAR project research aims to both generate transferable knowledge related to issues of adaptation across multiple scales of governance and to develop transformative scenarios that influence adaptation and development planning in the focus regions.

P-2222-12

Analysis of Desertification Process and Impact of Climate Change by using Satellite data in the Algerian Steppe

A. Zegrar (1)
(1) Centre of Spaces Techniques, Observing the earth, Arzew, , Algeria

The degradation of natural resources in arid and semi-arid areas was highlighted dramatically during this century due to population growth and transformation of land use systems. The Algerian steppe has undergone a regression over the past decade due to drought cycle, the extension of areas cultivated in marginal lands, population growth and overgrazing. These phenomena have led to different degradation processes, such as the destruction of vegetation, soil erosion, and deterioration of the physical environment. In this study, the work is mainly based on the criteria for classification and identification of physical parameters for spatial analysis and multi-sources to determine the vulnerability of major steppe formations and their impact on desertification. To do this, we used satellite images Alsat-1 (2009) (IRS 2009) and LANDSAT TM (2001). These cross-sectional data with exogenous information could reduce the impact of climate change in the semi arid ecological diversity of steppe formations. This longitudinal study based on the use of remote sensing data is to analyze the evolution of steppe ecosystems. The application, through specific processes, including the supervised classification was used to characterize the main steppe formations. An analysis of the vulnerability of plant communities was conducted to assign weights and identify areas most susceptible to desertification. Vegetation indices are used to characterize the forest and steppe formations to determine changes in land use.

This study will map the different components of the steppe, highlighting the magnitude of the degradation pathways, which affects the steppe environment, allowing an analysis of the process of desertification in the region.

P-2222-13

Crop supplemental irrigation experiences in Burkina Faso

B. Zongo (1) ; D. Abdoulaye, (2) ; B. Barbier (3) ; D. Thomas, (4)
(1) International Institute for Water and Environmental Engineering (2iE), Ouagadougou, Burkina Faso; (2) International Institute for Water and Environmental Engineering (2iE), Laboratoire d'hydraulogie et des ressources en eau, Ouagadougou, Burkina Faso; (3) CIRAD , Umr geau, Dakar , Senegal; (4) Univesrité de Liège, Department of rural economic and development, Gembloux, Belgium

This study assesses the impact of supplemental irrigation from small man-made basins on cereal production in climate variability and change context marked by dry spells in the Sahelian zone of Burkina Faso. After two years, the experiments showed that this innovation in family farms increases maize yield and allows growing a second crop with the surplus of water available in the basin. At the end of the 2012-2013 campaign, the average maize yield was estimated 2.5t/ha on experimental plots (EP) and 1.7t/ha on control plots (CP). The average yield of the 2013-2014 campaign was evaluated as 3.3T/ha and 0.9t/ha for EP and CP respectively. Increase in yield is 0.8t/ha for the 2012-2013 campaign and 2.4t/ha during 2013-2014. It appears as well as the yield obtained on EP in 2012-2013 and 2013-2014 for bridging cereal need of 2 and 6 additional persons respectively in agricultural households compared to the CP. The review of the Net present value, internal rate of return and the Net benefits increase ratio show that the profitability to practice supplemental irrigation depends on the types of basins.

2223 - Modeling Our Agricultural Future

ORAL PRESENTATIONS

K-2223-01

The Agricultural Model Intercomparison and Improvement Project: Transdisciplinary and Multi-scale Agricultural Projections of Climate Change Impacts

C. Rosenzweig (1)
(1) NASA Goddard Institute for Space Studies, New York, United States of America

The Agricultural Model Intercomparison and Improvement Project (AgMIP) is a major international effort linking the climate, crop, and economic modeling communities with cutting-edge information technology to produce improved crop and economic models and the next generation of climate impact projections for the agricultural sector.

Currently, AgMIP has over 700 participants from more than 45 countries contributing their expertise to over 30 projects and activities. The goals of AgMIP are to improve substantially the characterization of world food security due to climate change and to enhance adaptation capacity in both developing and developed countries.

Since 2010, AgMIP has engaged stakeholders and researchers to assess climate impacts on food security and plan for a more resilient future. AgMIP has built a cutting-edge assessment framework on both global and regional scales, which links climate, crops, livestock, and economics to help decision-makers better understand how climate change will reverberate through complex agricultural systems and markets.

AgMIP initiatives include regional integrated assessments, global economic assessments and global crop modeling activities, data and tools to facilitate multi-model and multi-discipline assessments, and cross-cutting themes to help interpret agricultural model results for decision-making. Results from these initiatives contributed to the Intergovernmental Panel on Climate Change Fifth Assessment Report, provide important context for national and regional stakeholders interpreting climate change risks, further state-of-the-art global food security assessments and agricultural models, and deliver key inputs, such as commodity prices, into regional integrated assessments.

AgMIP is now planning a coordinated global and regional assessment of future food securtiy under changing climate.

K-2223-02

Projecting grassland sensitivity to climate change from an ensemble of models

JF. Soussana (1) ; F. Ehrhardt (1) ; R. Conant (2) ; M. Harrison (3) ; M. Lieffering (4) ; G. Bellocchi (5) ; A. Moore (6) ; S. Rolinski (7) ; V. Snow (8) ; L. Wu (9) ; A. Ruane (10)

(1) Inra, Paris, France; (2) NREL, Colorado State University, , Fort Collins, CO, United States of America; (3) Tasmanian institute of Agriculture, Burnie, Australia; (4) AgResearch Grasslands, Palmerston North, New Zealand; (5) Inra, Grassland ecosystem research, Clermont-Ferrand, France; (6) CSIRO, Canberra, Australia; (7) Potsdam Institute for Climate Impact Research, Potsdam, Germany; (8) AgResearch, Christchurch, New Zealand; (9) Rothamsted Research, Rothamsted, United Kingdom; (10) NASA Goddard Institute for Space Studies, Climate Impacts Group, New York, NY, United States of America

The grassland biome covers about one-quarter of the earth's land area and contributes to the livelihoods of ca. 800 million people. Increased aridity and persistent droughts are projected in the twenty-first century for most of Africa, southern Europe and the Middle East, most of the Americas, Australia and South East Asia. A number of these regions have a large fraction of their land use covered by grasslands and rangelands. Grasslands are the ecosystems that respond most rapidly to precipitation variability. However, global projections of climate change impacts on grasslands are still lacking in the scientific literature. Within AgMIP, based on the C3MP protocol initially developed for crops, we have explored the sensitivity of temperate grasslands to climate change drivers with an ensemble of models. Site calibrated models are used to provide projections under probabilistic climate change scenarios, which are defined by a combination of air temperature, precipitation and atmospheric CO2 changes resulting in 99 runs for each model times site combination. This design provides a test of grassland production, GHG (N2O and CH4) emissions and soil carbon sensitivity to climate change drivers. This integrated approach has been tested for 12 grassland simulation models applied to 19 sites over three continents. We show here that a single polynomial emulator can be fitted with high significance to the results of all models and sites, when these are expressed as relative changes from the optimal combination of climate drivers. This polynomial emulator shows that elevated atmospheric CO2 expands the thermal and hydric range which allows for the development of temperate grasslands. Moreover, we calculate the climatic response surface of GHG emissions per unit grassland production and we show that this surface varies with elevated CO2. From these results we provide first estimates of the impacts of climate change on temperate grasslands based on a range of climate scenarios.

K-2223-03

Impacts and implications of global and regional climate change for agriculture

C. Müller (1) ; J. Elliott (2)

(1) Potsdam Institute for Climate Impact Research, Potsdam, Germany; (2) University of Chicago and Argonne National Laboratory Computation Institute, Chicago, United States of America

Agriculture faces severe challenges from increasing demand for agricultural food and non-food products, the need to decrease its environmental burden and to build resilience against climate change impacts. While impacts and adaptation measures need to be assessed and understood at local scales, much of their cross-interaction and societal implications can only be understood at regional to global scale analyses. The Agricultural Model Intercomparison and Improvement Project (AgMIP) and the Intersectoral Impact Model Intercomparison (ISI-MIP) have conducted comprehensive global-scale assessments of climate change impacts on agricultural productivity and related sectors (e.g. water, markets) that allows for understanding the scope of the climate challenge for agriculture and food security, including an assessment of associated uncertainties. Climate change under the RCP8.5 emission scenario has the potential to reduce global crop production of the 4 major crops by 24 to 43%, which may be amended by positive effects of carbon dioxide fertilization to losses of 8 to 24%. Climate-driven reductions in availability of irrigation water could lead to a loss of 20-60Mha of irrigated cropland. Associated adaptation responses in land-use patterns, trade and consumption are able to compensate for climate-driven impacts but lead to higher food prices (20% on average). Challenges that need to be addressed at the global scale are the increasing disparity between high- and low productivity countries, which often reflects the disparity in development. Also, increasing variability under climate change is a robust finding across the board of scenarios and will require adequate measures to avoid devastating effects, especially for the poor.

FACCE MACSUR: Modelling Agriculture with Climate Change for Food Security

M. Köchy (1) ; M. Banse (1) ; R. Tiffin (2) ; F. Ewert (3) ; N. Scollan (4) ; F. Brouwer (5) ; R. Rötter (6) ; A. Bannink (7) ; F. Sinabell (8)

(1) Thünen Institute, Market analysis, Braunschweig, Germany; (2) University of Reading, Centre for food security, school of agriculture, policy and development, Reading, United Kingdom; (3) University of Bonn, Institute of crop science and resource conservation, Bonn, Germany; (4) Aberystwyth University, Institute of biological, environmental and rural sciences, Aberystwyth, United Kingdom; (5) Wageningen UR, LEI, The Hague, Netherlands; (6) Luke, Natural Resources Institute Finland, Mikkeli, Finland; (7) Wageningen UR, Animal sciences group, Wageningen, Netherlands; (8) WIFO - Austrian Institute of Economic Research, Vienna, Austria

FACCE MACSUR (http://macsur.eu) is a network of currently 270 scientists from 18 European and associated countries for improving the European capacity of modelling the effects of climate change and socio-economic changes on agriculture. This concerns crop and grassland production, livestock production, farm management related to adaptation and mitigation measures, and development of price relations on national to global markets. The emphasis is on the linking of models and data across scientific disciplines. We will present an overview of achievements in the network. Collaborative efforts in the network include the advancement of modelling methodologies, agreement on common modelling scenarios for joint evaluation, comparison of model performance, development of new research projects, organization of training courses and workshops, and interactions with decision-makers, farmers, and other stakeholders. MACSUR collaborates internationally with AgMIP and MACSUR members are engaged in many other international projects and networks.

In the field of crop modelling, MACSUR has set-up and performed a comprehensive, unique model comparison study on simulating crop rotations using long term trial

data from various locations in Europe and looking at various output variables; also an inventory has been made on the available crop models and modelled cropping systems for Europe by the MACSUR CropM partners. MACSUR developed extensive databases on important ongoing and future modelling studies in Europe and it also embarked on developing a centralized system for data storage, distribution and visualization of model results. The knowledge hub systematically analysed scaling methods with focus of scaling up weather and soil information for regional and (supra-) national climate change (CC) impact assessments and related uncertainties for a range of crop models. A large ensemble of 26 crop models has been used for a systematic climate sensitivity analysis based on impact response surface. New CC scenario data was developed for selected locations and regional case studies in Europe and use was made of agroclimatic indicator approaches to indicate shifts in (multiple) risks to wheat production in the EU. Five PhD courses have been organized, dealing with various issues of generating data and applying modelling techniques for assessing CC impacts and adaptations to CC.

In the field of modelling of permanent grasslands, livestock and farms, the main focus across these diverse disciplines was to bring together specialists on a common subject. MACSUR established a performance comparison across several prominent models. Modelling of livestock productivity focused on the impacts of changing climatic conditions on dairy cow health, mortality and milk quantity and quality, and provided contributions to regional case study research. Datasets were identified relating to animal health and disease, and gaps in knowledge were explored at a broad level.

In socio-economic modelling, MACSUR focused on the soft-linking of crop production models to economic models at national and global levels and on comparisons of projections of crop price changes considering global trends in populations, politics, and climate.

Regional case studies constitute opportunities for linking models with less spatial heterogeneity and a longer tradition of model linkage across scientific disciplines. They also allow studying practical effects of the impacts of climate change and discussing them with stakeholders. Our case studies in Finland, Austria, and Italy suggest that a simple climate envelope approach (moving production zones of crops northward) neglects important interactions with soils (water holding capacity) and effects on landscape function/ecosystem services and rural livelihoods.

In the next two years, MACSUR will improve modelling the impacts of weather extremes and consider variations in farm management, cross- and multi-scale issues, uncertainty and error propagation. Exploration of techniques to improve the characterisation (e.g. quality) of feed sources in farm-scale models will also be addressed. Understanding the reasons for the difference between optimal and realised grassland and crop yields and finding solutions for linking these economic models at national to global scales remains a challenge for the next years. Furthermore, we will include more regional case studies and intensify our interactions with stakeholders.

Methods and Results
Given the incertitudes on the climate change impacts on C4 crops, projections of regional maize production remain speculative. Assessment of the impacts of atmospheric CO2 concentration ([CO2]) on crop yield and resources uses using mechanistic models becomes increasingly important. Free Air [CO2] Enrichment (FACE) studies offer data to test and improve model quality. The objective of this work by the AgMIP Maize group was (i) to test multiple maize models for [CO2] responses against data gathered from a FACE study under two water regimes carried out in Germany during 2007 and 2008, and (ii) to pave the way to potential model modifications so as to improve their simulations of crop responses to [CO2]. The Experiment combined two [CO2] levels with two watering regimes. Yield, leaf area, soil water content and [CO2] levels were recorded both years, 2008 only exhibiting significant water deficit. After a preliminary calibration based on non limiting water conditions and under ambient [CO2] treatments of both years, a blind simulation was undertaken for the other treatments: High [CO2] (550 ppm) 2007 and 2008, both watering regimes, and DRY AMBIENT 2007 and 2008. Secondly, with full growth and yield data along with soil moisture data of all treatments, improvements of simulation results were attempted. Changes made to the models have been documented and submitted for further analysis. The results revealed: minimal [CO2] impacts with low variations among « uncalibrated » models except for the dry season of 2008 where the observed drought impact was simulated by the majority of models; most models caught but underestimated the CO2 impact on crop water status, leaf area, grain number and yield; the CO2 effect on transpiration was generally properly simulated, transpiration per leaf area decreasing but green leaf area duration increasing at 550 ppm [CO2]. As more data from FACE experiments become available, it will be highly desirable to replicate this exercise in order to come up with more robust conclusions on these responses and to improve model response to CO2.

Bayesian Inference for the Ricardian Model

B. Abidoye (1)

(1) University of Pretoria, Centre for Environmental Economics and Policy in Africa (CEEPA). Agricultural Economics, Hatfield, Pretoria, France

The Ricardian model is one of the most widely used models to analyze the impact of climate change on agriculture. This paper seeks to empirically extend the

model by showing how one can explore the relationship between temperature, rainfall and land values/farm net revenue via non-parametric approach and characterizing model uncertainty on the impact of variables such as soil fertility measurement and water flow on net farm revenue. We use our derived methodology to investigate the impact of climate change on cropland in Africa using an 11-country survey of over 9000 farmers administered as part of a Global Environment Facility (GEF) project. We find that the relationship between rainfall and farm net revenue exhibits some nonlinearities in Africa but not that strong for temperature. Climate change scenarios from Atmospheric Oceanic General Circulation Models (AOGCMs) is also carried out.

Evaluating the impact of climate change on the agricultural sector is important to assess vulnerability of an economy to climate change and feeds into planning decisions. Current and future impacts on agriculture, magnitude of the impact and distribution of the impact are important questions that needs to be answered for effective planning and policy. Traditional models of crop agriculture such as crop-growth simulation models, agronomic economic models and integrated assessment models are based mainly on climate-crop physiology and development models' parameters that are generated from experimental research. They are typically calibrated into field situations using daily crop development responses to a combination of climate and weather variables and input factors such as soil, water and fertilizer. These models can handle some adaptation and crop management responses through variety selection, incorporating fertilizer use as an adaptation response or changing planting dates. While these adaptation measures can be interesting, they do not adequately capture farmer behavior in reality. We are more interested in models that incorporates farmer's responses to economic factors such as prices (substitution of inputs based on prices) and the ability of farmers to switch crops and plant multiple crops based on responses to climate.

The contribution of this paper is in presenting the Ricardian Model in a Bayesian framework, that relaxes the assumption of linear relationship between climate and agricultural performance through the use of semi-parametric approach and also characterizes model uncertainty in the choice of variables to be included in the model by integrating the variable selection process into the Ricardian model estimation that reflects the uncertainty surrounding the "correct" specification which becomes valuable for predicting the impact of climate change on agriculture. Specifically, we will describe a Bayesian posterior simulator that combines the literature on semi-parametric estimation, Bayesian variable selection and data augmentation. Our underlying mod- eling framework is the same as the Ricardian model. However, the Gibbs sampler algorithm builds upon the simulator in Koop and Poirier (2004) and incorporates the stochastic search variable selection (SSVS) method described in George and McCulloch (1993) to determine the posterior probability that climate and soil characteristics have an influence on agricultural productivity. As in Abidoye and Herriges (2013), we will argue that the model incorporating SSVS presents a form of Bayesian model averaging integrating competing models into a single structure that can be more valuable in predicting the impact of climate change under different climate scenarios. The model is applied using data from a survey of over 9000 farmers administered as part of a Global Environment Facility (GEF) project in 11 African countries in 2003.

P-2223-02

Exhibiting model elasticities to facilitate model intercomparison: an example with a simple land-use model

T. Brunelle (1)
(1) CIRED, Nogent-sur-Marne, France

In the coming decades, agriculture is projected to experience both demand and supply shocks originating from climate change, growing food needs or increasing demand for bioenergy. This specific context prompts a need for numerical assessments to anticipate the economic and environmental consequences of possible futures. Studies, however, disagree in the extent and direction of the impact of shocks on agriculture. If some progress has been made to reduce the overall variability across models (Nelson et al., 2014), the nature of some discrepancies remains unclear.

To get at the root of these discrepancies, this study applies a simple methodology to explicit the yield, area and demand responses to price. These parameters picture the core mechanisms of models and are critical in estimating the impact of shocks on agriculture (Hertel, 2009).

We present here the results of this methodology for the NLU model (Souty et al. 2012). NLU is a partial equilibrium that simulates changes in agricultural intensification at the global level under various assumptions regarding biomass demand. In this model, yield and area elasticities are not parametrized, but are derived from a cost minimization program taking into account spatial biophysical constraints. We focus here on the supply side as the demand for biomass products is exogenous in our model and thus inelastic to price.

First, changes in yields and areas are computed in response to a +1% p.y. exogenous price shock to 2050. To facilitate the comparison with available econometric estimates, we undertake a similar analysis in the past. Elasticities are then calculated according to a range of food prices relative to those of inputs (land and fertilizer). We show that these functions sum up the core model dynamics and can facilitate the model diagnostic. Finally, we show how our results can be used for the assessment of a biofuel promotion policy.

P-2223-03

Projected global crop yield variability under ENSO and the NAO

K. Childers (1) ; K. Frieler, (1)
(1) Potsdam Institute for Climate Impact Research, Potsdam, Germany

Future food supplies under a changing climate hinge on our ability to understand and adapt to changing precipitation and temperature patterns, which fuel global agriculture supplies. Projections suggest that potential yields of many crops will decrease as temperatures rise. Few studies, however, have addressed the predictability of the spatial and temporal variations over interannual to decadal timescales. In many regions the climate over such periods can be described in terms of large-scale climate indices such as the El Nino/Southern Oscillation (ENSO) and the North Atlantic Oscillation (NAO) index. These climate teleconnections result in semi-periodic global patterns of precipitation and temperature, which can alter growing season conditions over large geographical areas and have been shown to directly impact the regional and national yields of several crops. By analyzing the frequency and duration of such patterns in global climate model projections and the effects of each phase on potential agriculture yield, it may be possible to better project global yield variability. Here we present such an analysis of the global yield patterns of three major cereal crops (maize, rice and wheat) and soy on a 0.5 x 0.5 degree grid generated within ISI-MIP. Potential crop yields are simulated using climate projections for four RCPs from HadGEM2-ES. The combined crop model ensemble indicates regional yield averages differ from neutral years by up to 10% during opposing phases of ENSO and the NAO. Furthermore, average ENSO phase responses are not perfectly symmetric and are linked to yield decreases for some regions under both warm and cool phases. In general, the major cereal crops show the strongest ensemble response to ENSO, particularly in the northern U.S. and Europe. The effects of NAO phase are significant over a smaller geographical area than ENSO, but with similar or slightly higher magnitudes. The spatial patterns associated with each phase are further supported in many highly agriculturally productive regions by significant time series correlations between annual yield and NAO or ENSO indices. By linking agriculture yields to climate teleconnection indices we increase the predictability of decadal yields. In addition the association may be extended to impacts from other sectors, allowing for projections of exposure to coincident regional effects.

P-2223-04

Evaluation of Agro-Climatic Index in Korean Peninsular Using Multi-Model Ensemble Downscaled Climate Prediction of CMIP5

U. Chung (1) ; JP. Cho, (1) ; MC. Seo, (2) ; WS. Jung, (3)
(1) APEC Climate Center, Climate Change Research, Busan,

Republic of Korea; (2) National Institute of Crop Science, Crop production and physiology research division, Jeonju, Republic of Korea; (3) KonKuk University , Department of applied bioscience, life & environmental sciences, Seoul, Republic of Korea

The agro-climatic index is one of the ways to assess the climate resources of particular agricultural areas on the prospect of agricultural production; it can be a key indicator of agricultural productivity by providing the basic information required for the implementation of different and various farming techniques and practicalities to estimate the growth and yield of crops from the climate resources such as air temperature, solar radiation, and precipitation. However, the distribution of agricultural climate resources varies depending on the climate change, and the agro-climate index can always be changed because the index is not an absolute. Recently, many studies which are related the uncertainty of future climate change have been being actively conducted with multiple ensemble approach by developing and improving dynamic downscaling of climate information as well as statistical downscaling. RCP (representative concentration pathways) future scenarios of the Fifth Assessment Report of IPCC (intergovernmental panel on climate change) have been used in many recent studies. In this study, the agro-climatic index of Korean Peninsula, such as plant and crop period based on each base temperature, growing degree day, frost free day, and heating and cooling degree day were calculated for assessment of the indices' temporal and spatial variations and uncertainties of the indices on climate change; the downscaled historical climate (1976-2005) and RCP future climate sceneries of AR5 (2011-2040) were applied to the calculation of the index. Additionally in the study, the assessments of the agro-climatic index and multi-model ensemble were considered for the practicability of the agricultural digital climate map of RDA (rural development administration).

The result showed each average of six agro-climatic indices of nine individual global climate models, as well as multi-model ensembles agreed with agro-climatic indices which were calculated by the observed data. It was confirmed that multi-model ensembles, as well as each individual global climate model emulated well on past climate in the four major Rivers of South Korea (Han, Nakdong, Geum, and Yeoungsan and Seumjin). The six agro-climatic indices of the Korean Peninsula were estimated to increase in nine individual global climate models and multi-model ensembles in future climate scenarios. However, spatial downscaling still needs further improvement since the agro-climatic indices of some individual global climate models showed different variations with the observed indices at the change of spatial distribution of four Rivers. The differences and uncertainties of the agro-climatic indices have not been reduced on the unlimited coupling of multi-model ensembles. Further research is still required; however, the differences started to improve when combining of three or four individual global climate models in the study. The agro-climatic indices which were derived and evaluated in the study will be the baseline for the assessment of agro-climatic abnormal indices and agro-productivity indices of the next research work. For example, if we assume that the temperature of winter will decrease in some areas of Nakdong, Yeongsan and Seumjin Rivers since frost free day has been estimated to increase in those regions in future climate projections, the assessment of frost free day of the regions will be able to take advantage of the assessment of the increasing uncertainty of agro-productivity of the winter crop or agricultural cropping system (e.g., double cropping system) by analyzing agro-climatic abnormal index (e.g., frequency of frost).

P-2223-05

Coffea arabica yields decline in Tanzania due to climate change: global implications

A. Craparo (1) ; P. Van Asten (2) ; P. Läderach (3) ; L. Jassogne (2) ; S. Grab (1)

(1) University of Witwatersrand, Geography, Archaeology and Environmental Studies, Johannesburg, South Africa; (2) International Institute of Tropical Agriculture (IITA), Systems agronomy, Kampala, Uganda; (3) International Center for Tropical Agriculture (CIAT), Ciat - asia, Hanoi, Vietnam

Coffee is the world's most valuable tropical export crop. Recent studies predict severe climate change impacts on Coffea arabica (C. arabica) production. However, quantitative production figures are necessary to provide coffee stakeholders and policy makers with evidence to justify immediate action. Using data from the northern Tanzanian highlands, we demonstrate for the first time that increasing night time (Tmin) temperature is the most significant climatic variable responsible for diminishing C. arabica yields between 1961-2012. Projecting this forward, every 1°C rise in Tmin will result in annual yield losses of 137 ± 16.87 KgHa-1 (P= 1.80e-10). According to our ARIMA model, average coffee production will drop to 145 ± 41 KgHa-1 (P=8.45e-09) by 2060. Consequently, without adequate adaptation strategies and/or substantial external inputs, coffee production will be severely reduced in the Tanzanian highlands in the near future. Attention should also be drawn to the arabica growing regions of Brazil, Colombia, Costa Rica, Ethiopia and Kenya, as substantiated time series evidence shows these areas have followed strikingly similar minimum temperature trends. This is the first study on coffee, globally, providing essential time series evidence that climate change has already had a negative impact on C. arabica yields.

P-2223-06

Global crop yield response to extreme heat stress under multiple climate change futures

D. Deryng (1) ; D. Conway (2) ; N. Ramankutty (3) ; J. Price (1) ; R. Warren (4)

(1) University of East Anglia, School of Environmental Sciences, Norwich, United Kingdom; (2) Grantham Research Institute on Climate Change & the Environment,, London school of economics and political sciences, London, United Kingdom; (3) LIU Institute for Global Issues and Institute for Resources, Environment and Sustainability, University of british columbia, Vancouver, Canada; (4) Tyndall Centre, University of East Anglia, Advanced research fellow at the tyndall centre, Norwich, United Kingdom

Extreme heat stress during the crop reproductive period can be critical for crop productivity. Projected changes in the frequency and severity of extreme climatic events are expected to negatively impact crop yields and global food production. This study applies the global crop model PEGASUS to quantify, for the first time at the global scale, impacts of extreme heat stress on maize, spring wheat and soybean yields resulting from 72 climate change scenarios for the 21st century. Our results project maize to face progressively worse impacts under a range of RCPs but spring wheat and soybean to improve globally through to the 2080s due to CO2 fertilization effects, even though parts of the tropic and sub-tropic regions could face substantial yield declines. We find extreme heat stress at anthesis (HSA) by the 2080s (relative to the 1980s) under RCP 8.5, taking into account CO2 fertilization effects, could double global losses of maize yield (□Y = −12.8 ± 6.7% versus −7.0 ± 5.3% without HSA), reduce projected gains in spring wheat yield by half (□Y = 34.3 ± 13.5% versus 72.0 ± 10.9% without HSA) and in soybean yield by a quarter (□Y = 15.3 ± 26.5% versus 20.4 ± 22.1% without HSA). The range reflects uncertainty due to differences between climate model scenarios; soybean exhibits both positive and negative impacts, maize is generally negative and spring wheat generally positive. Furthermore, when assuming CO2 fertilization effects to be negligible, we observe drastic climate mitigation policy as in RCP 2.6 could avoid more than 80% of the global average yield losses otherwise expected by the 2080s under RCP 8.5. We show large disparities in climate impacts across regions and find extreme heat stress adversely affects major producing regions and lower income countries.

P-2223-07

Rising CO2 emissions benefit global crop water productivity

(5) Potsdam Institute for Climate Impact Research, Potsdam, Germany; (6) Karlsruhe Institute of Technology, IMK-IFU, Garmisch-Partenkirchen, Germany; (7) University of Natural Resources and Life Sciences,, Boku, Vienna, Austria; (8) University of Florida, Gainesville, United States of America; (9) Grantham Research Institute on Climate Change & the Environment,, London school of economics and political sciences, London, United Kingdom; (10) International Institute for Applied Systems Analysis (IIASA),, Ecosystems services and management program, Laxemburg, Austria; (11) Lund University, Lund, Sweden; (12) Swiss Federal Institute of Aquatic Science and Technology (EAWAG), Dübendorf, Switzerland; (13) NASA Goddard Institute for Space Studies, New York, United States of America

Climate change threatens global water and food security, especially in arid regions where water availability is already a critical limiting factor of agricultural productivity. Yet, increasing atmospheric carbon dioxide (CO_2) concentrations are expected to raise rates of crop photosynthesis whilst also increasing the ratio of crop yield to water use, or crop water productivity (CWP). The potentially large positive effects of rising CO_2 on CWP will have major implications for increasing crop yields and reducing pressure on freshwater resources. However, to date there has been no systematic evaluation of global crop model simulation of CWP response to CO_2 and climate change, and estimates of carbon fertilisation effects on crops based on observations continue to be controversial.

Our study addresses these gaps; by providing the first comprehensive global scale assessment of the combined effects of climate change and CO_2 on global CWP using a large multi-model ensemble (originating from the Agricultural Modelling Intercomparison and Improvement Project (AgMIP), and by directly comparing model results with observations. Our modelling results suggest combined effects of climate change and CO_2 are substantial, leading to increase in CWP by up to 13-27% globally (ensemble median, with a range of different crop types) by the 2080s relative to the 1980s. The range increases to 17-35% in water scarce arid regions. This suggests significant alleviation of negative effects of climate change on crop yield and pressure on water use in these regions. Yet, the spread of CWP results doubles when considering climate and CO_2 effects, reflecting uncertainty in modelling methodology and assumptions about CO_2 response, which are large due to the lack of experimental observations globally. We show the spatial distribution in the impacts on four major crops critical for global food security: maize, wheat, rice and soybean. Our results indicate CO_2 fertilisation effects play a key role in future agricultural production and water management and emphasise the importance of extending experimental observation, especially in arid and semi-arid regions.

Our study addresses global scale modelling of an important dimension of agricultural production that is intimately connected with water resources. The effects of CO_2 are shown to be large, key uncertainties are highlighted and needs for modelling and empirical research identified. These results demonstrate the need to diagnose further reasons for differences between crop model simulations of CWP and promote wider incorporation of CO_2 effects in global food and water resource assessments.

P-2223-08

Options for a sustainable food future and agricultural sector greenhouse gases mitigation

P. Dumas (1) ; T. Searchinger (2) ; S. Manceron (3) ; C. Le Mouël (4)

(1) CIRAD, Cired, Paris, France; (2) WRI, Washington, DC, United States of America; (3) INRA, Depe, Paris, France; (4) INRA, Smart, Rennes, France

By 2050, the agricultural sector should produce food to feed an increased and wealthier population, while reducing environmental impacts. In particular, conversion of natural ecosystems and greenhouse gas emissions are serious potential impacts of agricultural production.

To take up this challenge, many options exist for the agricultural sector. Some are on the supply side, such as increasing the efficiency of livestock production, increasing the efficiency in crop production inputs, or a sustainable increase of aquaculture. Others are on the demand side, such as changes in diets, reduction of losses and wastes or, more controversially, reduction in population increase. The overall consequences of those options on land-use and greenhouse gas emissions, especially when taken together, are not easy to assess in a transparent and consistent way.

To tackle this challenge, a simple balance model with detailed biophysical modules is developped to assess the consequences in term of greeenhouse gases emissions reductions of various options for the agricultural sector, under the constraint of feeding the world.

The reference year balances are based on FAOSTAT food commodity balances. Demand is set exogenously based on population and diets, trade is based on import dependence and export market shares, and loss coefficients are used. Transformation through livestock sectors and oil crops crushing allows to determine production, and, with exogenously set yields, land-use. In the reference case, yields and demands evolutions are based on FAO projections. Detailed modules of livestock, aquaculture, land-use change emissions, nitrogen cycle and rice methane emissions allow to determine transformation and emission coefficients, as well as the consequences of diverse options. The model integrates those informations at the global scale on several regions, allowing to assess in a transparent way the consequences of the options used together.

The methodology and the model results will be presented for change in livestock efficiency, rice methane emissions mitigation options, changes in diets and increases in nitrogen use efficiency.

P-2223-09

Detecting the early stage of Phaeosphaeria leaf spot infestations in maize hybrid lines under different climate change scenarios using in situ hyperspectral data

A. Elhadi (1) ; H. Deng (2) ; J. Odini (3) ; E. Abdel-Rahman (3) ; O. Mutanga (3)

(1) University of The Witwatersrand, Johannesburg, School of Geography, Archaeology and Environmental Studies, Johannesburg, South Africa; (2) Intuit Mountain View, Data mining, CA, United States of America; (3) University of KwaZulu-Natal, School of agriculture, earth and environmental sciences, Pietermaritzburg, South Africa

Phaeosphaeria leaf spot (PLS) is considered as one of the major diseases that threat the stability of maize production in tropical and subtropical African regions. PLS is a foliar disease in maize caused by the ascomycete fungus Phaeospharia maydis (Henn.), and has spread widely in areas of high rainfall and moderate temperatures. PLS can result in a considerable reduction in photosynthetic leaf area as the spots coalesce , cause premature leaf drying thus reduce plant cycle and sharp decrease in grain size and weight and result in early plant death. The objective of the present study was to investigate the use of hyperspectral data in detecting the early stage of PLS in tropical maize. Maize ground-based hyperspectral data were collected at the field level from healthy and early stage of PLS over two years (2013 and 2014) using a handheld Spectroradiometer. Leave samples for full biochemical analysis ware collected form the healthy leaves and early stage of PLS to test the impact of PLS on the maize plant properties. An integration of a new developed guided regularized random forest (GRRF) and traditional random forest (RF) was used for feature selection and classification respectively. The 2013 dataset was used to train the model, while the 2014 dataset was used as independent test dataset.

Results show that there were statistically significant different in biochemical between the healthy leaves and early stage of PLS within certain biochemical variables such as nitrogen, phosphorus, calcium and magnesium. The new developed GRRF was able to reduce the high dimensionality of hyperspectral data by selecting key wavelengths with less autocorrelation. These wavelengths are allocated at 420 nm, 795 nm, 779, 1543 nm, 1747, nm and 1010 nm. Using these variable ($n = 6$), random forest classifier was able to discriminate between the healthy maize and early stage of PLS with and overall accuracy of 88% and kappa value of 0.75. This study demonstrates the potential of hyperspectral data in detecting the early stage of PLS in tropical maize. The study offers insight to the potential of large-scale mapping and monitoring of the

early stage of PLS in tropical maize using space borne and/or airborne hyperspectral data.

P-2223-10

Optimal groundwater extraction for irrigated agriculture in the littoral North of Senegal under climate uncertainty, implications on irrigation water availability

A. Faye (1) ; M. Siwa (2)
(1) Senegalese Institute of Agricultural Research (ISRA), Bureau d'analyses macro-économiques, Dakar, Senegal; (2) International Food Policy Research Institute (IFPRI), Environment and production technology division, Washington, DC, United States of America

Recent studies on climate change in West Africa showed climate vulnerability of the agricultural sector in Senegal with future increase of temperatures and variable rainfall patterns (McSweeney et al., 2010; Jalloh et al, 2013). Climate perturbations will probably have an impact on Senegalese agricultural production and farmers' livelihood.

To date, climate related research has mostly focused on rainfed crops specifically cereals and legumes in Senegal (Jalloh et al., 2013; Sène et al., 2006). Irrigated agriculture particularly horticultural crops mostly grown in the littoral north called Niayes, where at least 40% of Senegalese horticultural products are produced, have attracted less attention in terms of climate change or variability studies. In the Niayes, research have been focusing on how climate affects the aquifer recharge and they generally point out the negative effect of climate on aquifer recharge and depth (Aguiar, 2010; DaSylva, 2005, 2009; etc.).

Farmers grow irrigated crops during the dry season from October to June and use exclusively groundwater resource for irrigation needs. Groundwater is also used by other actors like industries, the Senegalese water company, municipalities, and rural populations. As research has shown, climate variability combined with anthropic action may threaten water availability for irrigation and other uses.

In this paper, we evaluate the optimal patterns of groundwater extraction for irrigation under climate uncertainty, and the potential gains from improved groundwater management. We establish a baseline for economic efficiency in resource management, by solving an optimization problem which captures the social planner's decision-making problem under uncertainty and limited foresight. We construct a stochastic dynamic programming model of resource management to maximize the sum of current benefits together with the net present value of future benefits from groundwater extraction for irrigation - which also takes into account groundwater extraction for other usages and the stochastic levels of rainfall that affect aquifer recharge. Results from this forward-looking optimization problem are compared to the myopic optimization behavior that farmers might typically display, under different climate states (normal, wet and dry), in order to assess the gains from improved resource management.

We use an agricultural production model that is calibrated to data from this part of Senegal, using the Positive Mathematical Programming approach of Howitt (1995), and taking into account the costs of water extraction. We use the outputs of the agricultural production model to estimate the demand for water within the agricultural sector, and characterize the climate conditions with data on precipitation from the National agency of meteorology. Last but not least, the data on hydrological aspects are drawn from the literature (Gaye, 1990; Faye, 1995; El Faid, 1999; Tine, 2004; DGPRE, 2005, 2009) and the direction of management and planning of water resources (DGPRE) of Senegal.

Our results illustrate the value of improved groundwater management in the horticultural sector of Niayes, and suggest the importance of including resource management in the plans for adaptation of agriculture to climate change for this region of Senegal.

Climate change impacts on Apple trees phenology in northeastern parts of Iran

Y. Hojjatollah (1) ; C. Ahn (2) ; S. Maryam (3)
(1) University Of Isfahan, Climatology, Isfahan,Isfahan, Islamic Republic of Iran; (2) Apec climate center, Pusan, Republic of Korea; (3) Farzanegan Amin high school, Isfahan, Islamic Republic of Iran

Apple is one of the most important agricultural products of Iran. Global warming can effects on many sectors especially agricultural products and food security. One direct consequence of a warmer climate is the earlier onset of Bud break and flowering stages of deciduous trees such as apple in spring and earlier ripening in the end of growing season. The main objective of the present work is to assess the climate change impacts on Apple trees phenology, especially beginning of flowering in spring and ripening time of apple in the end of growing season. These two phonological stages are very important because of the sensibility of Apple orchards to early spring and late autumn frost risk. To do this we used historical data of available meteorological stations as well as CCSM4 outputs for the daily maximum and minimum for the upcoming 3 decades (2006-2039).The phonological data was collected from the Golmakan agrometeorological station during 1999-2006. On the base of UTAH model and using the phonological and historic climatic data we estimated the phonological phases of apple during next 3 decades. According to the results obtained by Rcp4.5 and Rcp8.5 outputs, in both scenarios significantly earlier flowering and ripening phenophases over the study area during 2006-2039 periods are estimated.

P-2223-12

High temperature stress on agricultural crops due to climate change

L. Kyoungmi (1) ; HS. Kang, (1) ; JY. Kim, (1) ; C. Chunho (1) ; CH. Park (1)
(1) National Institute of Meteorological Research, Jeju, Republic of Korea

Temperature variability is an important determinant of the yield of annual crops, particularly when high temperature episodes coincide with flowering. Under climate change an increase in the frequency of such episodes may occur. Hence temperature variability could become a major yield-determining factor for some regions in the decades to come. The magnitude of the impact will depend upon the level of heat stress tolerance in the genotypes grown.

Mean temperature affects yield by determining the duration of developmental stages. The impact of high temperatures, particularly near flowering, is primarily on the setting of fruit or grain. Most crops are currently grown in regions where current temperatures are already close to optimum for crop production. Any further increases in mean temperatures or of short episodes of high temperatures during sensitive stages, may be supra-optimal and reduce grain yield.

In this study, we performed a spatially explicit assessment of heat stress at the global scale, considering these environmental and management aspects, to identify hot-spots of risk for four important food crops (wheat, rice, maize and soybean). We used the Global Agro-Ecological Zones Model (GAEZ v3.0) to simulate the risk of heat stress for these four crops for a 30-year baseline historical climate (1961-1990) and an alternative future climate scenario (2071-2090) considering climate change.

There was a consistent increase in the intensity of heat stress from the baseline climate to the future climate change scenario for all crops. Rice showed high heat stress intensity already for the base climate, particularly in South Asia. The main hot-spots of heat stress occurred in the continental parts of Central Asia, East Asia, South Asia and North America.

In contrast, only little heat stress was predicted for maize under the base climate. However, the intensity increased highly under RCP8.5. Northern India, the Sahel region, Central South America and Eastern North America were hot spots of heat stress for maize.

A moderate heat stress intensity was predicted for soybean for the base climate with a considerable increase in intensity and extension for RCP8.5. Compared with the other crops, there was less change in spatial pattern and intensity of heat stress for wheat from the Base to the RCP8.5.

The percentage of days with heat stress events increased from the base to the RCP8.5 climate scenario. This increase was most evident for rice in suitable areas of Central Asia, South Asia and Central North America where a high prevalence was predicted. On the other hand, wheat had a less pronounced change in the frequency of stress in RCP8.5.

Mainly tropical agriculture will suffer from climate change. Our results indicate that global food supply may also be affected by heat stress in temperate and sub-tropical regions. Without mitigation measures to combat climate change or the implementation of local adaptive technologies, countries with extensive agricultural landsin continental regions at high latitudes may experience significant crop losses.

P-2223-13

The impact of high temperature on land values in Europe

E. Massetti (1) ; PS. Van (2) ; R. Mendelsohn, (3)
(1) Georgia Institute of Technology, School of Public Policy, Atlanta, GA, United States of America; (2) Hasselt Univeristy, Diepenbeek, Belgium; (3) Yale University, School of forestry and environmental studies, New Haven, United States of America

In Ricardian studies the relationship between climate and land values is conventionally assumed to be nonlinear. This nonlinearity has traditionally been captured using a quadratic model of temperature and precipitation (Mendelsohn, Nordhaus, and Shaw 1994; Schlenker, Hanemann, and Fisher 2005; Massetti and Mendelsohn 2011; Massetti and Mendelsohn 2012). This assumption has been supported by the data as the squared terms on climate have generally been statistically significant. Schlenker and Roberts (2009) have suggested that the effect of temperature on agricultural productivity may be not captured by a quadratic functional form because it is highly non-linear at the high temperatures. Schlenker and Roberts found a temperature threshold at about 30°C. Beyond this threshold agricultural productivity plummets.

Schlenker and Roberts (2009) limit their analysis to crop yields and use yearly data. Thus, they focus on short-term weather fluctuations and they neglect the possibility that farmers switch crops to avoid the harmful thresholds. Massetti and Mendelsohn (2014) is the first study that uses flexible functional forms to estimate the effect of growing season temperature on American farmland values and crop yields. The paper finds evidence of the hill-shaped response function for both farmland value and crop yields. But there is no evidence of temperature thresholds whether temperature is measured at 3 hour intervals, daily, or for multiple days.

With this paper we test if the relationship between temperature and land values in Europe is characterized by temperature thresholds. This is a relevant research question because if thresholds exist the increase in mean temperature will cause sizeable damages to the European agriculture. Thus, our study has direct policy implications for both mitigation and adaptation policy.

We use a flexible specifications for temperature in a Ricardian setup replicating the method of Massetti and Mendelsohn (2014) and following in spirit the method developed by Schlenker and Roberts (2009). With our method we are able to detect if farmland that is more frequently exposed to the right tail of the temperature distribution is also consistently traded at lower value than other farmland. If the Ricardian relationship is characterized by temperature thresholds we expect to find that the effect of additional warming at the highest temperatures is significantly negative and much larger than at lower temperature levels.

This paper uses a unique dataset obtained by merging farm-level data for more than 37,000 farms derived by van Passel, Massetti, and Mendelsohn (2014) from the Farm Accountancy Data (FADN) with daily temperature data from the ERA-INTERIM dataset over 1981-2010. The rest of the paper is structured as follows. Section 2 illustrates the method used for the analysis. Section 3 describes the dataset used. Section 4 illustrates results and presents robustness tests. Conclusions follow.

Building a statistical emulator for prediction of crop yield response to climate change: A global gridded panel data set approach

M. Mistry (1) ; E. De Cian (2) ; I. Wing (3)
(1) Ca' Foscari University and FEEM, Department of economics, Venice, Italy; (2) FEEM, Venice, Italy; (3) Boston University, Dept. of earth & environment, Boston, United States of America

There is widespread concern that trends and variability in weather induced by climate change will detrimentally affect global agricultural productivity and food supplies. Reliable quantification of the risks of negative impacts at regional and global scales is a critical research need, which has so far been met by forcing state-of-the-art global gridded crop models with outputs of global climate model (GCM) simulations in exercises such as the Inter-Sectoral Impact Model Intercomparison Project (ISIMIP)-Fastrack.

Notwithstanding such progress, it remains challenging to use these simulation-based projections to assess agricultural risk because their gridded fields of crop yields are fundamentally denominated as discrete combinations of warming scenarios, GCMs and crop models, and not as model-specific or model-averaged yield response functions of meteorological shifts, which may have their own independent probability of occurrence. By contrast, the empirical climate economics literature has adeptly represented agricultural responses to meteorological variables as reduced-form statistical response surfaces which identify the crop productivity impacts of additional exposure to different intervals of temperature and precipitation [cf Schlenker and Roberts, 2009]. This raises several important questions: (1) what do the equivalent reduced-form statistical response surfaces look like for crop model outputs, (2) do they exhibit systematic variation over space (e.g., crop suitability zones) or across crop models with different characteristics, (3) how do they compare to estimates based on historical observations, and (4) what are the implications for the characterization of climate risks?

We address these questions by estimating statistical yield response functions for four major crops (maize, rice, wheat and soybeans) over the historical period (1971-2004) as well as future climate change scenarios (2005-2099) using ISIMIP-Fastrack data for five GCMs and seven crop models under rain-fed and irrigated management regimes. Our approach, which is patterned after Lobell and Burke [2010], is a novel application of cross-section/time-series statistical techniques from the climate economics literature to large, high-dimension, multi-model datasets, and holds considerable promise as a diagnostic methodology to elucidate uncertainties in the processes simulated by crop models, and to support the development of climate impact intercomparison exercises.

P-2223-15

Climate Sensitivity of Rice Yields: An Agro Climatic Zone Analysis in Andhra Pradesh, India

SR. Padakandla (1)
(1) Centre for Economic and Social Studies, Division for Sustainable Development Studies, Hyderabad, India

Observational data confirm that there have been significant regional variations in climate change patterns across India. This paper examines the effect of rainfall and temperature on rice yields of different climatic zones in Andhra Pradesh using district level panel data from 1981-2010. Analysis of data shows that the degree of impact of climate on yield of rice is varied across different climatic zones. Climatic zones which have traditionally higher temperature and less rainfall are more susceptible to variations in climate. Similarly impact of irrigation is more significant in traditionally drier zones than others.

P-2223-16

Widespread vulnerability of current crop production to climate change demonstrated using a data-driven approach

TAM. Pugh (1) ; C. Müller (2) ; J. Elliott (3) ; A. Arneth (1)
(1) Karlsruhe Institute of Technology, IMK-IFU, Garmisch-Partenkirchen, Germany; (2) Potsdam Institute for Climate Impact Research, Potsdam, Germany; (3) University of Chicago and Argonne National Laboratory Computation Institute, Chicago, United States of America

The projected increase in global population suggests that, among a range of measures, an increase in food production will likely be necessary to achieve food security. A great deal of effort has been focused on the so-called "yield gap", the difference between actual and potential yields. The closing of this yield gap would bring about massive increases in production. Intensification actions such as irrigation, fertilisation, and better farming practices can bring the actual yield closer to the potential yield, although such actions may not be practical everywhere. Yet climate change greatly complicates this picture; crops are sensitive to their growing environment, and it is therefore inevitable that climate change will impact upon potential crop yields, changing the target for which intensification measures are aiming, and meaning that significant intensification may be required just to hold actual yields constant. Global crop models give some insight into such changes, but huge uncertainties in their process representations make even the direction of future change uncertain. We demonstrate a complementary data-driven approach, based on observations of current potential yield and climate analogues, to assess the vulnerability of yields of the three major cereal crops, wheat, maize and rice, to climate change. We find that huge swathes of current cropland show strong reductions in their potential yields of major cereal crops by the mid 21st century, indicating a large vulnerability of crop production in these areas to climate change, and greatly reducing the capacity for intensification of yields. These reductions are predominately in tropical or arid areas, and include current high-productivity areas like the North American corn-belt. Conversely, however, we also find large areas where potential yields increase substantially under climate change. These areas are most prominent in the northern temperate zone, and include areas not currently under cropland. Our approach is independent of the crop modelling methodologies previously used for future yield projections, however we find our results to be consistent with those from an ensemble of process-based global crop models, providing an important additional constraint on projections of future yield under climate change. Adaptation measures based on intensification of yields must consider the change in productive potential due to climate change.

P-2223-17

Biophysical modeling of climate change impacts on crop yields in Europe by 2030-2050 and socio-economic implications

F. Ramos (1) ; M. Blanco (2) ; B. Van Doorslaer (3) ; D. Fumagalli (1) ; A. Ceglar (1) ; F. Dentener (1) ; L. Stanca (2)
(1) European Commission, Joint Research Center, Institute for environment and sustainability, Ispra, Italy; (2) Technical University of Madrid, Madrid, Spain; (3) European Commission, Joint Research Center, Institute for prospective technological studies, Sevilla, Spain

An impact assessment of climate change scenarios on agriculture was run covering the EU-28 region and focusing on 2030 and 2050 time horizons. To assess the impact of model uncertainties, three model realizations of the Intergovernmental Panel on Climate Change (IPCC) climate scenarios were used as the input of the analysis, based upon the Representative Concentration Pathway (RCP) 8.5 from the runs of global circulation models (GCM) HADGEM2-ES, IPSL-CM5A-LR and MIROC-ESM-CHEM, all bias-corrected at 0.5°x0.5° resolution.

The WOFOST (World Food Studies) model has been used within the BioMA (Biophysical Model Application) platform to simulate the impacts of climate change on crop yields at EU-level. The crop yield simulations were performed at 25x25 km resolution using the soil and crop parametrization of the MARS Crop Yield Forecasting System (MCYFS) that provides the European Commission operational seasonal forecasts of crop yields in Europe. The crops covered by this study were wheat, maize, barley, rye, rice, field beans, rapeseed, sunflower, sugar beet and potato. For each of these ten crops, simulations were performed under water limited (rainfed) and potential (fully irrigated) conditions. Uncertainties are associated with the effect of CO2 on plant growth which were assessed by simulations considering or not the CO2 fertilization effect. The simulated yields were aggregated at regional, national and EU28 levels, using regional statistics on crop areas.

The crop growth simulations show in most of the cases a stagnation or a moderate increase in the potential yields of most of the crops with the notable exception of maize, sunflower and at a lesser extent potato. Under water limited conditions the picture is slightly different with more pronounced negative effects for maize and sunflower. The greatest decreases in the water limited yields occur with HADGEM2-ES GCM that simulates a drier future climate than the two other GCMs. The actual crop yields, estimated by a weighted average of potential and water limited yields using data on European irrigation shares (EUROSTAT), show an overall moderate increase for the three climate models under RCP 8.5 scenario when the CO2 effect is taken into account but a decrease when it is not.

The spatial distribution of the yield changes is crop specific with for instance an overall increase in winter wheat yields for most of the EU 28 regions and an overall decrease of maize (summer crop) yields, with in both cases a reversed result for northern Europe.

Focusing on the year 2030, a bio-economic approach was proposed to jointly assess biophysical and socio-economic effects of climate change on agriculture, providing both global level analysis as well as regionalised for the EU. The global agro-economic model CAPRI (Common Agricultural Policy Regionalised Impact) has been used to assess the effects of climate induced yield changes on agricultural production and prices. The future quantitative societal developments were introduces in the model by means of an intermediate Shared Socioeconomic Pathway (SSP2).

The results suggest that agriculture markets projections to 2030 are sensitive to changes in crop productivity and, therefore, to the uncertainties linked to climate change. They show as well that market forces can reverse the effects of climate induced yield changes with a decrease (increase) in production when yields increase (decrease). The price changes will induce adjustments both on the intensity of production and on crop areas. A sectorial analysis indicates that the regional variability in prices and areas is greater for oilseeds than for cereals. Overall the modelling exercise estimates a moderate decrease of the EU agricultural income for all the scenarios with the CO2 fertilization effect simulated and a moderate increase when the CO2 fertilization effect is ignored. The limitations of these conclusions will be explored.

P-2223-18

Interactions of Mean Climate Change and Climate Variability on Food Security Extremes

A. Ruane (1) ; S. Mcdermid, (2) ; C. Rosenzweig (3)
(1) NASA Goddard Institute for Space Studies, Climate Impacts Group, New York, NY, United States of America; (2) New York University, New York, NY, United States of America; (3) NASA Goddard Institute for Space Studies, New York city, United States of America

The Coordinated Climate-Crop Modeling Project (C3MP) has conducted a common set of sensitivity tests on more than 1100 simulation sets representing different farm systems in more than 50 countries, with carbon dioxide, temperature, and precipitation change sensitivities gauged for ~20 crop species and ~20 crop models. Here we present an analysis of C3MP results indicating how mean climate changes are likely to affect variability and extreme events within future time periods.

Recognizing that climate change will affect agricultural systems both through mean changes and through shifts in climate variability and associated extreme events, C3MP can elucidate several aspects of these changes. First, mean climate changes can affect yields across an entire time period. Second, extreme events (when they do occur) may be more sensitive to climate changes than a year with normal climate. Third, mean climate changes can alter the likelihood of climate extremes exceeding critical biophysical thresholds, leading to more food security extremes. Finally, shifts in climate variability can result in an increase or reduction of mean yield, as extreme climate events tend to have lower yield than years with normal

climate. This presentation will demonstrate each of these effects and illustrate the potential implications for future food production and associated agricultural economies under climate change.

P-2223-19

Past and future changes in climate of rice-wheat cropping zone in Punjab, Pakistan

B. Syed Ahsan Ali (1) ; G. Rasul (1) ; A. Ruane (2) ; G. Hoogenboom (3)

(1) Pakistan Meteorological Department, Research and Development Division, Islamabad, Pakistan; (2) NASA Goddard Institute for Space Studies, Climate Impacts Group, New York, NY, United States of America; (3) Washington State University, Washington, United States of America

Agriculture is ranked Pakistan's top among economic sectors vulnerable to the potential impacts of climate change. The agricultural production system is directly affected by weather inputs (temperature, solar radiation, and rainfall) that are projected to change in the future (following increases in carbon dioxide and other greenhouse gases). Climatic extremes such as drought, floods and heat waves, are expected to increase with detrimental consequences for agriculture and livestock production, but changes in mean climates also pose challenges to sustainable development. This study presents climate change results for five districts within the major rice-wheat productivity zone of Punjab province in Pakistan. The results are focused on RCP8.5 mid century (2040-2069) scenarios derived from five global climate models (GCMs) output and the Kharif (June-October) and Rabi (November-April) seasons. Analysis of recent historical weather data of Sialkot and Sheikhupura districts shows an increase in minimum temperatures and maximum temperatures and a large variation in rainfall. This temperature change and variability in rainfall is expected to enhance further as we approach the 2050s. Mean maximum temperature is projected to increase by 2-2.5°C during rice growing (Kharif) season and 2.4-2.7°C during the wheat growing (Rabi) season. Rainfall during rice growing season is more uncertain, with projections indicating an increase of 25%-35 % in the study region, while a minimal change is expected during the Rabi season. The projected increase in monsoon intensity corresponds with the climax of the rice season, leaving no doubt about the crop water demand satisfaction. However, simultaneous increase in day and night temperature may affect the growth and development at some critical phenological stages.

P-2223-20

Economic Impact of climate change and benefits of adaptation in maize production in Southern Africa: Case study from South Africa, Namibia and Botswana

M. Teweldemedhin (1)

(1) Polytechnic of Namibia, Agriculture, Windhoek, Namibia

The paper applied the Trade-Off Analysis-Multi-Dimensional (TOA-MD) model to evaluate the economic impacts of climate change and benefits of adaptation strategies for maize-based agricultural production systems in Southern Africa. The analysis was based on data collected from three countries, South Africa, Namibia and Botswana. The empirical analyses combined simulated baseline and future simulated yield from the Decision Support Systems for Agro-technology Transfer (DSSAT) crop model, under five different climate scenarios selected from 20 Global Circulation Models (GCMs). The paper focused on analysing three main objectives: (a) the sensitivity of current crop production systems to future climate change, (b) the sensitivity of future crop production systems to future climate change and (c) the benefits of adaptation in the future. The empirical results show that current and future crop production systems in the three study countries are sensitive to future climate change and yields would decline if no adaptation strategies are implemented. The results with the adaptation package show positive gains in yields, farm net returns and marginal reductions in poverty. In addition, the percentage of vulnerable farmers decrease for the scenario with adaptation compared to the other two scenarios without adaptation. Since various assumptions and uncertainties are associated with using the proposed approach, the results should be interpreted with caution. Despite these limitations, the methodology presented in this study shows the potential to yield new insights into the way that realistic adaptation strategies could improve the livelihoods of smallholder farmers.

P-2223-21

Modelling of Climate Change Impact on Maize Yields in Croatia

V. Vucetic (1)

(1) METEOROLOGICAL AND HYDROLOGICAL SERVICE, AGROMETEOROLOGICAL DEPARTMENT, ZAGREB, Croatia

Analyzing agricultural systems and modelling the potential impact of climate change on crop production is a very important topic, particularly nowadays as food supplies are becoming scarcer in many parts of the world and the need for all people to have sufficient food. As climate changes of different intensity in various regions were detected, there is a need for researching them at regional and national levels. The main application of the crop models is in climate change impact research on agriculture. Maize, winter wheat and spring barley are very often used for scientific investigations in the central and southeastern Europe using the different crop-weather models. Maize is one of the most important agricultural crops in Croatia and its vegetation period coincides with the warm season, from May to October. Therefore, it was decisive factor in the crop type choice for the research of climatic changes impact on maize yields in Croatia. The meteorological data of the Zagreb-Maksimir station, which is situated in the central Croatia, and pedological data, physiological and morphological data obtained in the field maize experiment in Zagreb have been analyzed. The Decision Support System for the Agrotechnology Transfer (DSSAT) model, as one of the most applied crop model in the world, has been used for the investigation of maize production in the present climate since 1949. The linear trends of model outputs and Mann-Kendall test indicated a significant earlier onset of silking by 1.4 days/10 years and physiological maturity by 4.5 days/10 years in the central Croatia which started in mid-1990s. Moreover, a significant decrease in maize yields by 216 kg/ha in 10 years is also obtained. The yield trend became significant at the beginning of the 21st century. There was a slight decrease in kernel mass (0.01 g/10 years) and aboveground biomass (122 kg/ha in 10 years). A positive trend in evapotranspiration and soil evaporation (around 3 mm/10 years) and in runoff (0.6 mm/10 years) has been noticed during the vegetation period. Thus, significant shortening the vegetation period by 5 days and reduction in maize yield by 2% have been estimated in the present climate. Further investigation involved the generation of synthetic meteorological series representing the changed climate by stochastic weather generator Met&Roll and different climate change scenarios. The climate change scenarios were prepared by the pattern scaling technique using the following global climate models: ECHAM, HadCM and SCIRO. The middle climate sensitivity is a 2.5°C increase in global temperature to equilibrium doubled carbon dioxide. When the three climate change scenarios had been prepared, the stochastic weather generator Met&Roll was applied to generate a 99-years synthetic meteorological series. Using the synthetic meteorological series in the DSSAT model, the indirect effect of increased carbon dioxide on maize yields in the central Croatia has been estimated for different climate change scenarios for years 2050 and 2100. All climate change scenarios for the 21st century projected a shorter growing season and a reduction in maize yields. The maize vegetation period in the central Croatia would be 39 days shorter for ECHAM, 42 days for HadCM and 34 days shorter for CSIRO, which would result in 14%, 25% and 22% smaller yields for maize, respectively, at the end of the 21st century. Both shifting planting date and using hybrids with longer growing season would be beneficial for maize productivity in the changing climate. The experience of farmers and agronomists in the central Croatia shows they have already been adapting maize production to the warmer weather conditions in the last decade. The usual hybrids in the central Croatia were hybrids with a medium growing season, but nowadays hybrids with a longer growing season are increasingly used. In the future, thus, Croatia could belong to the area of decreased maize yields. Some adaptation options like shifting to an earlier sowing date and selecting hybrids with longer growing season and resistant to drought could be an appropriate response to offset the negative effect of an increase in temperature. The present study could help in optimizing and improving agricultural management in order to adapt to changes in

climate and weather conditions in Croatia.

Two possible future climate scenarios for AgMIP-GGCMI – Sulfate Injection Climate Intervention and Regional Nuclear War

L. Xia (1) ; A. Robock (2) ; J. Elliott (3)
(1) Rutgers University, Department of environmental sciences, New Brunswick NJ, United States of America; (2) Rutgers University, Department of Environmental Sciences, New Brunswick, NJ, United States of America; (3) University of Chicago, Chicago, United States of America

Climate is one of the most important factors determining crop yields and world food supplies. To be well prepared for possible futures, it is necessary to study yield changes of major crops under different climate scenarios. Here we propose two possible future climate scenarios for the global crop modelling community: stratospheric sulfate climate intervention and regional nuclear war. Although we certainly do not advocate either scenario, we cannot exclude the possibilities: if global warming is getting worse, society might consider deliberately manipulating global temperature; if nuclear weapons still exist, we might face a nuclear war catastrophe. Since in both scenarios there would be reductions of temperature, precipitation, and insolation, which are three controlling factors on crop growth, it is important to study food supply changes under the two cases. There have been 12 general circulation modelling groups participating in the Geoengineering Modeling Intercomparison Project (GeoMIP) and three modeling groups have conducted the same regional nuclear war simulations, with fires from targets injecting 5 Tg soot into the upper troposphere. We are approaching a robust understanding of climate changes under the two scenarios. We have conducted simulations for China, because of its high population and crop production in the world and we have been working on global agriculture impact under those two scenarios using the crop model in the Community Land Model (CLM-crop). Also, we are preparing protocols and datasets for the Gridded Crop Modeling Initiative (GGCMI), which will conduct a multi-crop multi model assessment of crop yields under the above two simulated climate scenarios. Preliminary results indicate significant changes in patterns of global food production, with substantial losses in major bread baskets around the world under the simulated regional nuclear war scenarios. Here, we would like to invite more global crop modelling groups to be involved in this project, and hence to gain a better understanding of global agriculture responses under the two possible but unpleasant future climate scenarios.

Climate Compatible Development in Mongolia: analysis of vulnerability and adaptation response to global changes

D. Ojima (1) ; C. Togtokh (2) ; K. Galvin (3)
(1) Colorado State University and Future Earth US Hub, Natural Resource Ecology Laboratory, Fort Collins, United States of America; (2) Institute for Sustainable Development, National University of Mongolia, ULaanbaatar, Mongolia; (3) Colorado State University, School of global environmental sustainability, Colorado, United States of America

INTRODUCTION: Climate change and variability, market and policy changes are shaping pastoral communities' decisions on what pathways their future livelihoods will take and how the steppe landscapes and river basins, are managed. Recent droughts and damaging winter storms (zuds) of the past two decades have exacerbated the situation and undermined the natural capital on which the pastoral livelihoods depend.. River basins are critical natural resources for well-being of the social and ecological systems in Mongolia. River basins provide the ecosystem services which support pastoral communities, and industrial and urban development. Green development strategies are strongly dependent on water resources.

For this study our team worked in nine «sums» (i.e., county level administrative areas) in three river basins in two provinces (aimags) to collect household data from 144 households. We selected three sums in each river basis, representing forest steppe, steppe and desert steppe regions for comparison across river basins and ecological zones. We also collected census data from the «aimags» and national level to understand trends at the level of regions and river basins.

FINDINGS:
Drought management. Unlike for «zud», people report very few sources of help with drought beyond their household and kin relations. By far the most frequently cited strategy for coping with drought is to do «otor» - long distance movements with livestock.

Cooperation. The most frequently listed "best coping strategy" across all ecosystem types was for herders to have better cooperation, both among themselves and with administrators. They frequently expressed the idea that people working alone cannot accomplish much compared to when they work together. Furthermore, one herder said that in the past, "we deeply understood that the most important thing is cooperation during natural disasters." Herders also want improved education and training to cope with climate and market changes.

Protection and management of pastures, and support to do «otor» were next set of important strategies after cooperation. Protection of otor pastures by local governments is an important strategy for protection from mining expansion in addition to improved management of seasonal pastures.

ADAPTATION ACTIONS:
Integrated river basin management plans. Develop cross ministry and cross-sectoral working groups to develop and implement plans and actions which cut across land, water, livelihood resource needs. Incorporate assessment and monitoring of natural resources. Integrate climate change impact analysis, especially droughts on natural capital, ecosystem services, and livelihood needs. Create governance structures which incorporate both technical and stakeholder perspectives.

Monitoring and Assessment. Establish indicator metrics for multiple water, land and livelihood resources and outcomes. Evaluate vulnerability and adaptive capacity taking into account natural capital, ecosystem services, and livelihoods. Provide early warning for zud, based on summer drought and grazing conditions, and also zud forecasting.

Training and capacity building. Provide training for integrated management which provides tools and skills for assessing and monitoring natural capital, ecosystem services and socio-economic conditions across the river basins. The training tools would include geospatial data gathering on climate, natural resource distribution and usage, land use patterns, community-based planning and management practices, sum, bag and other informal boundaries. Provide adaptation and green development courses for local communities and school systems. Also provide training to resource managers on how to access and communicate information on climate change, natural resource management, adaptation and green development opportunities. For example, develop a webinar program to learn and disseminate skills.

K-2224-02

Innovative adaptation of pastoral systems to climate change: - Case study in Mongolia -

C. Togtokh (1) ; M. Watanabe (2) ; S. Watanabe (2)
(1) Institute for Sustainable Development, National University of Mongolia, ULaanbaatar, Mongolia; (2) Chuo University, Research and development initiative, Tokyo, Japan

Synergy of scientific, technological, governance and financial dimensions is required for adaptation of pastoral social-ecological systems to climate and global changes.

- Scientific understanding of vulnerability and adaptive capacity of local and regional social-ecological systems is the basis for success of response actions.
- Application of advanced technologies with co-benefits for mitigation and adaptation is one key for responding to climate change;
- Without financial mechanism, which enables application of innovative technology, there will be no technological advancement with improved adaptation and mitigation;
- Governance for sustainable development, integrating environmental, social and economic dimensions, is another key for adaptation towards sustainability;

We will demonstrate a case study in Mongolia, integrating all four dimensions.

Permafrost melting due to global warming impact is likely to be critical slow variable leading towards desertification of rangelands in Mongolia, reducing water availability for plant growth in the spring – critical season for pastoral systems. Pastoral systems are becoming vulnerable because of interacting dynamic factors such as drought, overgrazing and "zud" (severe winter condition for livestock).

Improved early warning systems with ICT technology based on drought/grazing impacts and winter forecasting are critical for early harvesting of livestock and preventing of livestock loss during "zud". Innovative meat storage systems with application of renewable energy-based freezing system is going to be demonstrated in Mongolia which will be co-benefiting mitigation and adaptation.

The Government of Japan and the Government of Mongolia signed the agreement on Low Carbon Development Partnership, using the Joint Credit Mechanism (JCM). The Parliament of Mongolia passed Green Development Policy in June 2013, which serves bases for governance towards sustainability. Climate compatible development, integrating adaptation, mitigation and sustainable development, was a core of the policy document.

It is a challenge to demonstrate and observe how technological, governance, financial and scientific factors will work at local community level. Management of innovative technology as new commons by local pastoral community is critical for strengthening the traditional adaptive capacity and resilience of pastoral systems in Mongolia.

Coupled Biological and Cultural Systems under Himalayan Climate Change: Perceptions, Adaptations and Mitigations

J. Salick (1)
(1) Missouri Botanical Garden, William L. Brown Center, Saint Louis, MO, United States of America

Recent, rapid Himalayan climate change includes rising temperatures, increasing and unpredictable precipitation, glacial retreat, glacial lake formation and outburst, and altering natural resources. Our 1500 km transect across the eastern Himalaya, with intensive, longitudinal ecological alpine plant monitoring (4-5000 masl), shows gradually increasing plant richness, biodiversity and endemism, especially at higher elevations. Comparatively, participatory methodologies of mapping, calendars, photographs and interviews with Himalayan peoples indicate their keen perceptions of and dramatic adaptations often based on traditional ecological knowledge both to climate change and to interacting socio-economic changes. Himalayan peoples recount rapid changes in Himalayan environments, agro-pastoralism and cultural adaptations, indicating dramatic tipping points of production and land-use systems, of subsistence and cash/tourist economies, and of traditional and contemporary cultural contexts . New fruit and vegetable crops are grown, but mostly for tourists, while locals retain their traditional diets. Yak herding now takes time from lucrative tourism. Lucrative chung cao (Ophiocordyceps sinensis) harvesting, once traditional, now commercial, dominates the early spring calendar. Both traditional spiritualism and tourism are threatened by snowless mountains, diminished glaciers and the disappearance of sacred cranes. With increased precipitation, traditional mud roofs are collapsing and being replaced by economical corrugated coverings. Traditional yak robes are too warm, while contemporary, light weight hiking gear is nationally produced and inexpensive. Road incursions into the Himalaya bring more tourists, tourism conglomerates and commercial goods, while undermining traditional ways of life and increasing carbon footprints. Traditional ecological knowledge and economic savvy prescribe rival adaptations for Himalayan peoples; traditional culture and economics become competing paradigms for the Himalayan climate change. Local mitigations of climate change are varied and potentially generalizable, but contextually in decline. Systems dynamics between biological and cultural diversity – models of biocultural diversity and interrelatedness – are transforming and potentially threatening the remarkable Himalayan biocultural diversity. While Himalayan plants seem to be adapting slowly to climate change, Himalayan peoples struggle. Climate change policy needs to incorporate indigenous peoples and their knowledge to support sustainable livelihoods and food sovereignty.

K-2224-04

Climate variability as experienced by farmers

C. Leclerc (1) ; C. Mwongera, (2) ; V. Moron (3)
(1) CIRAD – UMR AGAP, Crop Diversity Dynamics, Societies and Environments, Montpellier, France; (2) International Center for Tropical Agriculture (CIAT), Nairobi, Kenya; (3) Aix Marseille Université, and CEREGE, Aix en Provence, France

The typical approach of estimating crop response to future climate scenarios may be inappropriate in the case of smallholder multi cropping rain-fed agriculture. Indeed, a crop-by-crop simulation, based on current varieties, cannot take into account the dynamics among crops as well as within crops i.e. among varieties, in time and space. We implemented a comparative study to understand interactions between cropping system dynamics and past climate variations, taking into account the diversity of farmers' experiences and socio-cultural organization.

In Kenya, farmers who adopted maize a few years ago are still cultivating traditional sorghum and pearl millet varieties, while others abandoned them earlier in favour of maize. Farming systems were thus dynamic, with different crop assemblages over time. Thus, retrospectively, farmers' capacity to mitigate crop failure risk due to extreme rainfall events has never been constant. Has the farming system lost part of its capacity to cope with climate variability, as maize is known to be less resistant to drought than sorghum and pearl millet? While this is usually demonstrated using yield parameter, we used seed losses, which is consistent with a multicrop system.

Combining ecological anthropology and climatology, we confronted the results of a retrospective survey of farmers' seed loss reminiscence about the period 1961-2006 and climatic records for three altitudinal levels on the eastern slope of Mount Kenya were analysed. Over the period, 3204 seed loss events were reported independently by 208 farmers, for eight main crops of their rain-fed farming systems. The causes given for these losses according to farmers' experience and knowledge were recorded yearly. We first assessed whether these causes were related to recorded rainfall values, and, second, analysed the proportion of lost seed on a yearly basis, crop by crop and on the whole farming system, using logistic regression.

Drought was mentioned 73.5% of the time whereas 8.5% of the losses were attributed to heavy rainfall. Farmers recalls coincided on drought years associated with crop diversity losses: conditional Chi-square tests based on Monte Carlo

simulation clearly rejected independence (p = 0.001) between climatic reasons given by farmers and recorded rainfall, for both droughts and heavy rainfall. Farmers' retrospective perception of drought corresponds to major droughts reported for Kenya.

By favouring maize at the expense of sorghum and pearl millet, cropping system dynamics have promoted an increasing risk of drought-associated seed loss. The probability to lose sorghum seed (0.056- 0.065) was significantly lower than the probability to lose maize seed (0.071-0.087). All crops were affected more by droughts than by heavy rainfall. Seed loss probability increased for a rainy season shorter than 50 days, with less than 28 rain days, and with a precipitation under 400 mm. Logistic regression confirmed that a change in cropping systems increased the risk of seed losses due to drought over the 46-yr period.

Farmers experienced climate variability differently, with greater negative impact on farmers cultivating maize. Ecological and social components thus cannot be analytically isolated but have to be considered as parts of a socio-ecological system. While usual approaches consider present-day characteristics of agricultural systems to assess their adaptability to hypothetical rainfall variability (projection into the future), our study used farmer experiences to look into the past. In our approach, past rainfall variability is already known, not hypothetical, while farmers' experiences can allow assessment of the evolution of their agricultural systems, which can be monitored over time, and related to climate variability.

The cropping system dynamics, by favouring maize at the expense of sorghum and pearl millet are partly related to agricultural policies that positively valued maize, whereas sorghum and pearl millet were devalued, being perceived as ''poor people crops''. The current dynamics of agricultural systems thus imply many dimensions, not only economical, political, and agronomical, but also cultural.

K-2224-05

Adaptation of Irrigated agriculture to climate CHAnge: trans-disciplinary modelling of a watershed in South India

L. Ruiz (1)

(1) Institut National de la Recherche Agronomique, Sol agro et hydrosystèmes spatialisation (sas), Quimper, France

In the context of climate change and of agriculture increasingly relying on groundwater irrigation, it is crucial to develop reliable methods for sustainability assessment of current and alternative agricultural systems. The awareness that prediction of impact of climate change for water resource management must account for interactions and feedbacks between biophysical processes determining movement of water, and human behavior in a given socio-economic context has gained significant recognition among scientists in the past few years, including the recent advocacy for the development of the new science of "socio-hydrology", dedicated at studying the "co-evolution of coupled human-water systems". Recently, "Change in hydrology and society" was proposed by IAHS as the main research theme for the decade 2013-2022.

In this talk, we introduce the Indo-French CEFIPRA project "AICHA" (Adaptation of Irrigated agriculture to climate CHAnge, 2013-2016), based on the analysis of an agricultural watershed in South India, where a long term environmental observatory has been setup. We describe the trans-disciplinary approach that is developed to analyse the agro-hydrological and socio-economic drivers of groundwater sustainability and farmer adaptation, using integrated modelling.

In the studied watershed, spatial heterogeneity in groundwater gradients has resulted from intensive groundwater pumping in the villages in valley that started in the early 1990s. The decline in groundwater level provoked the disconnection between the groundwater and the river bed, and the main permanent rivers turned into ephemeral streams. Wells are being recently drilled in the upland areas and groundwater irrigation is increasing. Our analysis suggests that these contrasted evolutions are closely linked to the spatial distribution of soil types and groundwater availability, besides access to market and knowledge.

We hypothesize that feedbacks between the biophysical-social system and spatial interactions must be accounted for in order to be able to study scenarios of agricultural evolution and water management policies, not only in terms of sustainability at the scale of the watershed but also in terms of spatial variability of both the groundwater resource and the evolution of socio-economic inequity over time. Consequently, we propose to develop a model framework that combines hydrology, agronomy and economy.

We will also insist on one of the critical challenge in implementing such integrated models, which is to develop the human component of this framework to account for farmer decision that occur at different time scales. We propose to base this module on decision rules to allow the representation of farmer adaptation to a changing environment.

K-2224-06

Adaptation of Irrigated agriculture to climate CHAnge: Retrieving relevant information for distributed modelling of impact of Climate Change of water resources

S. Muddu (1)

(1) Indian Institute of Science, Civil Engineering Department, Bangalore, India

Developing integrated assessments of the sustainability of irrigated agriculture is critical in the context of ever growing pressure on water resources. A wide variety of models have been developed for simulating future scenarios of land-use change, climate change or ex-ante evaluation of management policies. Such models usually fail to account for feed backs of shrinking water resources on farmer strategies, and tend to neglect the biophysical and socio-economic interactions spatially and temporally within the watershed.

In this talk, we will present innovative approaches that are conceived and tested within the Indo-French CEFIPRA project "AICHA" (Adaptation of Irrigated agriculture to climate CHAnge, 2013-2016) based on a watershed in South India where a long term environmental observatory has been setup.

One of the critical challenge is to implement the integrated agro-hydrological model in a distributed way over the whole watershed. We propose to use methods based on remote-sensing to collect data on land use and soil properties.

One of the challenges of using such models for scenario testing in a distributed way is the need for accurate knowledge, for example for soil and crop parameters (Launay and Guérif, 2005) which are scarcely available for tropical conditions. As an example of the development of innovative methodologies fostered by the project, we present a method to retrieve soil parameters using remote sensing and crop model inversion (Sreelash et al., 2012; 2013).

Further, another challenge is for developing future projections of water balance components based on such an integrated agro-hydrological model would be the choice of the climate model forecasts to drive the model. This is commonly achieved by driving the agro-hydrological model with the bias-corrected precipitation data from the GCMs. The approaches that are being used for disaggregate and bias-correct the precipitation from the GCMs of CMIP3 will be presented.

P-2224-01

Strategies of farmers to rainfall variations in the municipality of Zè in Benin

VN. Adjahossou (1) ; SB. Adjahossou (2) ; FE. Dovonou (3) ; DF. Adjahossou (4)

(1) Université d'Abomey-Calavi, Géographie, Cotonou, Benin; (2) Université d'Abomey-Calavi, Génie de l'environnement, Cotonou, Benin; (3) Université d'Abomey-Calavi, Faculté des sciences et techniques, Calavi, Benin; (4) Université

d'Abomey-Calavi, Faculté des sciences agronomiques, Cotonou, Benin

Current climate change in several parts of the world are real obstacles to the development of agricultural activities. This change is characterized by irregularity and bad distribution of rainfall along the year. Sometimes rainfall occurs in abundance during a short period when crops don't need a lot of water. These difficulties are greater for farmers in developing countries as those in South-Benin practicing for the most part, highly dependent on rainfall agriculture.

Documentary research, observation and investigation in a real area have permitted to collect the necessary data during this research. The surveys were conducted with 202 farmers living and operating in the Municipality of Zè. This area is located in Atlantique department. It is situated between 6° 32 and 6° 87 N latitude and between 2°13 and 2° 26 E longitude. It covers an area of 653km², Zè is the largest municipality in the department represents 19.88% of the territory.

The climate is sub-equatorial and is characterized by rainfall amounts higher or lower, a relatively small annual thermal amplitude (less than 5 ° C) and the succession of four distinct seasons: a long rainy season from mid - March to mid - July; a short dry season from mid - July to August; a small rainy season from September to November and a long dry season from December to mid - March. The frequencies of rainfall and water levels are experiencing more and more disturbances in recent years. The hydrographic system is not dense. Only the northern part of the municipality is watered by the tributaries of the river Oueme mainly Sô River.

It appears from the use of the data collected that people (more than 84% rural) of the Zè municipality develop strategies to cope with climate change. In general, the agricultural calendar is modified to comply with new rainfall rates.

The combination of cultures and multiple or replanting seedlings are practiced in place to reduce the impact of rainfall variations on Agriculture in Zè. Changing the cropping calendar

Crop calendar takes account of the seasonal precipitation. Land preparation takes place in the late dry seasons. From the first rains, the farmers start planting. To the rainy season, sowing takes place from mid-March to mid-April and early rainy season, from mid-August to mid-September for maize. Currently, with late rains, sowing takes place later. Generally, farmers expect three to four rains before planting when they consider soil humidity is sufficient to favor seed germination and seedling emergence. But some farmers take the risk of planting after heavy rain and other precipitation when not following the operation, they resume planting.

In localities of great pineapple productions like municipality of Zè young farmers interested in increasingly pineapple production at the expense of maize production. Pineapple, CAM plant (Crassulacean acid metabolism), tolerates, breaking to sudden stops rain (Degras, 1986). This is not the case of maize which performance may drop drastically when drought occurs in the critical period of 15 days to 20 days during which occurs grain filling (Vieira da Silva, 1984). There is therefore, according to farmers, less likely to produce pineapples to produce maize.

The combination of cultures is to produce two or more crops simultaneously in the same field (Steiner, 1985). It contributes to reduce natural risks that could affect crop yields including breaks rain. Trenbath, (1993) showed that species that grows in association with other cultures is less attacked by pests that in mono culture and improves productivity per unit area (Adjahossou, 2005 and Adjahossou, 2012). According to some farmers, the association of cultures would better conserve soil humidity. This could be explained by the limitation of evapotranspiration due to the microclimate created by the combination of two or more cultures. In the study area, commonly associated crops are maize-cassava, maize-cowpea and corn-pineapple.

It should be noted that these strategies have many limitations and need to be improved significantly.

P-2224-02

Spatial Information Technology (SIT) based Land Sustainability Management through Suitability Analysis in Kansachara Sub-watershed, Bankura and Puruliya district, West Bengal, India

K. Bera (1) ; J. Bandyopadhyay, (2)
(1) Vidyasagar University, Remote Sensing & GIS, Midnapore, India; (2) Vidyasagar University, Remote sensing & gis, Kolkata, India

Soil is one of the most important non renewable natural resources and soil fertility is its crucial component for land sustainability. Now it is being increasingly emphasized for village level planning. Prosperity of agriculture of any region depends on physical and chemical properties of soil. SIT can play a very effective role in soil fertility analysis for land sustainable management.

The study is an attempt to identify the suitability areas of some alternative crops namely Maize, Barley, Millets, Paddy (Upland and Bunded), Potato, Papaya, Sunflower, Groundnut, Sorghum, Pigeon, Chickpea and Sesame etc. The suitable land were identify based on the land capability. Land capability area ware identify proposed by Tejwani et al. (1976) method. The land capability is categorized into two sub class i.e. i) Land fit for cultivation ii) Land not suitable for cultivation. Both the land is management by different ways.

The study concluded that the cultivable land management is done on the basis of knowledge of crop suitability followed by SYS method for maximum benefit of the farmers. On the other hand non cultivable land is management by applying 1. Grass Land, 2. Conservation Forestry, 3. Horticulture and 4. Animal husbandry.

P-2224-03

Develop a web service portfolio to support the adaptation of agriculture, forestry and water management to climate change

N. Breda (1) ; A. Chénot (2) ; T. Caquet (2) ; C. Gascuel-Odoux (3) ; JF. Soussana (4)
(1) INRA, Umr 1137 inra-université de lorraine «forest ecology and ecophysiology-eef», Champenoux, France; (2) INRA, Uar 1275 ecology of forests, grasslands and freshwater systems division, Champenoux, France; (3) INRA, 1069 inra-agrocampus ouest "soil, agro and hydrosystem-sas", Rennes, France; (4) INRA, Collège de direction, Paris, France

The adaptation to climate change of agriculture and forestry as well as water management requires tools to predict the effect of multiple scenarios combining agronomy, forestry, water management and climatic components in any physical environment, in order to anticipate negative effects of climate change, and to test and choose the most relevant strategies anywhere. A project is currently developed for building integrated tools and delivering services, encouraging midterm and strategic adaptation over France, by coupling agronomy, forestry and hydrology models. This project presents two main aspects: 1) an analysis of stakeholders demands, which has already shown that different spatial levels (territory, hydrological basin and whole France) would have to be considered, that demands are multiple and multiform, declined according to different levels of information (general information on the effect of climate change on agriculture and forestry, site vs. crop rotation modeling, up to totally distributed spatiotemporal agro-hydrologic modeling including economic dimensions); 2) an inventory of the currently available databases and models (climate, soil, crop and hydrology) and an analysis on how to couple them and overcome sectorial vision. The objective of a first step is to elaborate the specifications of one or several detailed integrated model(s), taking into account the demands of the stakeholders. Indeed, they request several innovations for the dissemination of research on adaptation: sharing knowledge and concepts, web mapping tools to display and examine maps or databases computed by modeling coupled water-agriculture-climate, or the making available models online at allowing the user to test by himself adaptation's options. Such a portfolio of services requires calculations

in the past climate, present and future, with combination of emission scenarios, climate models and downscaling methods to achieve a spatial resolution consistent with the decisions of farmers and foresters to adapt production and the corresponding economic sectors. Several crop and forest models should also be used in order to take into account the uncertainty related to the ability of impact models to reproduce all the processes. Such a portfolio of services requires calculations in the past climate, present and future, with the combination of emission scenarios, climate models and downscaling methods to achieve a spatial resolution consistent with the decisions of the farmers and foresters to adapt production and related economic sectors. Several agricultural and forestry models should be proposed to represent the uncertainty due to the vide range of impact models, reproducing more or less processes. Finally, multi-criteria evaluation (economic, social, biotech) adaptation options will be made possible. This project is developed by Inra and partners (Irstea, BRGM, CEA, CNRS, Universities, Météo France, ...) under the umbrella of Allenvi, the National Research Alliance for the Environment.

The INRA metaprogramme on Adaptation of Agriculture and Forests to Climate Change (AAFCC)

T. Caquet (1) ; N. Breda (2) ; JP. Amigues (3) ; C. Gascuel-Odoux (4) ; K. Chalvet-Monfray (5) ; P. Debaeke (6) ; JM. Touzard (7) ; JF. Soussana (8)
(1) INRA, Uar 1275 ecology of forests, grasslands and freshwater systems division, Champenoux, France; (2) INRA, UMR 1137 INRA UL Forest Ecology and Ecophysiology, Champenoux, France; (3) INRA, SAE2, Toulouse, France; (4) INRA, 1069 inra-agrocampus ouest "soil, agro and hydrosystem-sas", Rennes, France; (5) INRA, Ur 346 animal epidemiology-epi-a, Saint Genès Champanelle, France; (6) INRA, Umr 1248 inra-inpt agroecologies innovations ruralities - agir, Castanet Tolosan, France; (7) INRA, Montpellier, France; (8) INRA, Paris, France

The metaprogramme on Adaptation of Agriculture and Forests to Climate Change (AAFCC) has been launched by the French Institute for Agricultural Research in 2011. It aims at coordinating, promoting and integrating the research activities to overcome the scientific and societal barriers that could restrict adaptation. This proactive and pluridisciplinary strategy involves cooperation with French and foreign academic and socioprofessional actors. It should ensure rapid results and progress, for example in multi-criteria assessment of adaptation options. Favouring the dialogue between disciplines, AAFCC provides a framework for the various research projects on adaptation of agriculture and forests to climate change. Discipline-related skills in human and social sciences, agronomy, ecology, genetics, ecophysiology, animal sciences, economy and modelling are mobilised to cover the range of questions raised by adaptation to climate change. The chosen strategy focuses on integrated approaches at the sector or territorial level. The issues and general objectives of the programme can globally be ordered according to the increasing response times of the systems, from short- to long-term, and the intensity and 'active' nature of the adaptation: from palliative or support actions, to innovation and technical or collective organisational breakthroughs. Such breakthroughs require strong innovations and a thorough socio-economic assessment.

AAFCC is fully in line with the European Joint Programming Initiative on "Agriculture, food security and climate change", initiated to enhance coordination of national research programmes. Research projects address annual and perennial crops, livestock, forests, biodiversity or water and soil resources. AAFCC has also promoted training of young scientists through PhD grants and postdoctoral fellowships. Since 2011, AAFCC has supported more than 25 national research projects and international actions and networks. It supports various European-level initiatives through funding of some ERA-NETs. It also supports international (for example cooperative projects with India or south Mediterranean countries) or global (for example ensemble crop modelling) projects. International actions increase the range of climate conditions and model species under investigation. Considering the issues at stake, international cooperation is undoubtedly, along with pluridisciplinarity, the most important issue in this domain. This is the reason why AAFCC supports various European-level initiatives and international or global projects in addition to national projects. The general objectives of AAFCC and its main achievements are presented and discussed.

P-2224-05

Adaptation of smallholder farmers to climate change in the tropical Andes

O. Dangles (1) ; C. Carpio (2)
(1) IRD, Quito, Ecuador; (2) ESPOCH, Cedeterra, RIOBAMBA, Ecuador

In recent years, the precarious state of food production systems has become a focus of attention of scientists, policy bodies, and corporations face to a growing number of challenges including uncertainties and risks associated with climate change, unprecedented price hikes for basic food, and agricultural intensification. In the tropical Andes, climate and habitat changes are considered to be one of the most serious threats to sustainable development, with adverse impacts expected on the environment, human health, economic activity and food security. Over the last decade, the Andes have also experience socio-economic and institutional changes that have increased the pressure on natural resources, weakened the internal social organization and caused cultural erosion in the Andean society, reducing the capacities of populations to overcome them.

Global climate change represents a major threat to sustainable farming in the tropical Andes. Farmers have used local ecological knowledge and intricate production systems to cope, adapt and reorganize to meet climate uncertainty and risk, which have always been a fact of life. Those traditional systems are generally highly resilient, but the predicted effects, rates and variability of climate change may push them beyond their range of adaptability.

This presentation summarizes 10 years of studies performed by our group within a transdsciplinary (from social sciences to ecological sciences to earth sciences) and multi-methodology frameworks (from landscape suveys by drones to agent based modeling to participatory research). It examines the extent of actual and potential impacts of climate variability and change on small-scale farmers and describes how climate change impacts agriculture through two main study case: 1) the consequences of deglaciation and changes in hydrology on biodiversity and land users in high altitude pastures (bofedales) of Bolivia (see www.biothaw.ird.fr) and 2) the effect of temperature variability on the control of pest and disease populations in crop lansdcapes of Ecuador (see www.manpest.ird.fr).

The presentation highlights some promising adaptive strategies currently in use by or possible for producers, rural communities and local institutions to mitigate climate change effects while preserving the livelihoods and environmental and social sustainability of the region. In particular, it presents how the concept of adaptive management, «a systematic process for continually improving management policies and practices by learning from the outcomes of previously employed policies and practices», may provide mechanisms to adjust to change and uncertainty related to climate change.

P-2224-06

Farm level adaptation to drought: the case of maize production in Shanxi province, China

K. De Bruin (1) ; S. Glomsrød (1) ; T. Wei (1)
(1) CICERO (Center for International Climate and Environmental Research - Oslo), Climate economics, Oslo, Norway

Changes in temperature and precipitation will impact food production across the global. The latest IPCC AR5 WG1 assessment report states that although there is low confidence in global-scale observed trends in drought, there are regional changes, such as the weakening of the East Asian summer monsoon which in turn has led to increasing drought in northern China. Shanxi province, located in the north of China, is one of the most vulnerable provinces to be impacted by drought, especially impacting maize production.

Within the research programme on climate change and

Chinese agriculture we assess the impacts and costs to agriculture associated with expected change in risk of extreme events on maize production in Shanxi province. We investigate how local adaptation to climate change through the implementation of adaptation options reduces the vulnerability of farmers. Uncertainty about the extent of the impact of climate change on drought risk calls for flexibility regarding the implementation of adaptation options. Where one should avoid over-investment in case damages increase less than expected while at the same time facilitating proportionate adaptation if damages become higher than expected.

The objective of the paper is to show how drought risk affects the decision to invest in adaptation options. We conduct an extended cost-benefit analysis to address adaptation challenges of farmers in Shanxi province by simulating farmer's investment decisions on resources allocation and adaptation options under uncertain climate change impacts in order to maximize income and reduce the impact of an extreme event on crop production. The costs and benefits of three different adaptation options are considered, namely the implementation of drip irrigation, change of crop variety, and change of crop. Our case study of adaptation at the farm level in Shanxi province provides insights into the nexus between economic decision-making, climate change and adaptation in the agricultural sector.

P-2224-07

Increasing within-field diversity to foster agro-ecosystem services and cope with climate change

J. Enjalbert (1) ; X. Le Roux (2) ; V. Allard (3) ; B. Andrieu (4) ; S. Barot (5) ; J. Borg (6) ; D. Descoureaux (7) ; C. De Vallavielle-Pope (4) ; A. Gauffreteau (4) ; I. Goldringer (6) ; S. Lemarié (8) ; S. Saint-Jean (4) ; T. Wheatamix Consortium (6) ; E. Porcher (9)

(1) INRA, Plant Breeding, Gif sur Yvette, France; (2) INRA, Ea, Lyon, France; (3) INRA, Bap, Clermont-Ferrand, France; (4) INRA, Grignon, France; (5) IRD, Paris, France; (6) INRA, Gif sur Yvette, France; (7) Chambre d'Agriculture du Loir-et-Cher, Blois, France; (8) INRA, Grenoble, France; (9) MNHN, Paris, France

During the 20th century, agriculture experienced major gains in productivity via homogenization and intensive use of inputs. This model is jeopardized by the awareness of rapid global change, in particular climate change, and the need for greater agricultural sustainability. Crop genetic diversity should play an essential role in this context, as it could promote various ecosystem services essential for adaptation to climate change. Increasing within field diversity through the use of cultivar mixtures is a timely option, testified by with some significant "success stories" in the past. Despite the abundant bibliography demonstrating the interest of intra-specific crop diversity, cultivar mixtures are poorly developed worldwide. In this context, the WHEATAMIX project studies the interest of mixing wheat genotypes to reinforce the sustainability and resilience of agricultural production and the provision of various ecosystem services. Based on a highly multidisciplinary approach we analyze the interactions among genotypes and with the environment, to develop new methods for breeding and/or combining wheat varieties to obtain performing blends in a global change context. Complementary experimental approaches are being deployed: i) a main diversity experiment (Eighty-eight wheat plots with 1, 2, 4 or 8 varieties, under low input) to quantify over several years the variety diversity effects on ecosystem services; ii) replicates of the same diversity experiment in 4 sites across France, to test the robustness of wheat diversity effects under a wide range of soil and climate conditions; iii) a network of 50 farms, encompassing agro-climatic variability in the Paris basin, to compare the ecological and techno-economic performance of blends with that of monocultures, using direct links with key stakeholders. The first results provide a comprehensive characterization of the multiple ecosystem services provided by genetic diversity (yield stability; regulation of foliar diseases; insect pest and weed biocontrol; maintenance of soil fertility; biodiversity conservation), and the trade-offs and synergies that exist among ecosystem services. The result also guide the selection of variety mixtures and corresponding bundles of functional traits that can deliver particular groups of services to tackle the climate change issue.

P-2224-08

Assessing the determinants of alternative adaptation strategies at farm level: the case of wine growers in South-East France

N. Graveline (1) ; M. Grémont (1)

(1) BRGM, Environnement, Water & Ecotechnologies, Montpellier, France

Climate change is expected to have a double effect on water resources, directly, by potentially reducing the recharge of water resources and, indirectly, through an increase of water demands and uptakes, mainly through irrigated farming. Understanding the rationale leading farmers to adapt to climate change is thus a major challenge for water management because one of the strategies to adapt to increasing crop water requirement is irrigation. This will induce new water demands, thus understanding the determinants of irrigation choice is a challenge for robust water planification both in terms of water conveyance infrastructure planning and environmental impacts on water resources. It is also a central issue for agricultural economics and policy. One of our main assumptions to this analysis is to state that climate change is just one of the multiple changes farmers are facing together with regulatory changes (right to irrigate on a regular basis since 2006), economic changes linked to the changes in consumers demand and wine market in general, and technical changes. Adaptation must be seen as a response to all the perceived changes and not to a particular one, apriori. Also, adaptation has always been at the core of farmer's experience.

In order to explore these questions, we concentrate on the case of wine growers in South-East France (Languedoc-Roussillon) where the context is changing: irrigation is authorized on a regular basis since 2006 only and a large water conveyance infrastructure is being constructed enabling for new water resources. We surveyed wine growers in Languedoc-Roussillon via a detailed Internet questionnaire sent to more than 3000 winegrowers to understand the determinants of agricultural practices and strategic choices (planting, structural size change, commercialization). The diffusion of the questionnaire was realized via the mail listings of professional organisms (Chambre d'agriculture, cooperatives...). We collected data on current and future practices relative to soil-plant water management, perceptions of past economic, regulatory, technical and climate changes and social and economic characteristics such as objectives that wine growers are pursuing with their activity (improving wine quality, preserving tradition, etc.). For all completed and validated survey variables characterizing the terroir are systematically associated to each farm: rain, temperature, soil water capacity, elevation.

A representative sample of 363 wine growers is used for a descriptive and econometric analysis. 30% of our sample is already irrigating vine while up to 28% is considering this option. When facing a climate change scenario by 2050, 57% of those not currently irrigating say they would implement irrigation. This illustrates the importance of anticipating future demand for water irrigation. We consider two main types of determinants and explore their relative contribution in explaining the adoption of water management practices at farm level. Terroir-like variables and socio-economic variables, including main objectives that vine growers are pursuing with their activity are explored as determinants. The results confirmed that both terroir and socio-economic determinants play a significant role in the implementation of adaptation actions among which irrigation. Perceptions of past changes are determinants of adaptations: for instance perceptions of regulatory changes are determinants of existing irrigation whereas perception of climate change is a determinant of having the project to irrigate in the future. Results suggest that having its own cellar (wine transformation), increasing its size, being part of professional networks, producing wine of good quality and developing commercial strategies are determinants of resilient farms.

P-2224-09

Combining crop physiology, breeding, socioeconomics and modelling to the targeting of genotypes to "wheat hotspots" in Mexico

J. Hellin (1) ; G. Molero (2) ; P. Alderman (2) ; K. Sonder (1)
(1) International Maize and Wheat Improvement Center, Socio-economics program, Mexico, Mexico; (2) International Maize and Wheat Improvement Center, Global wheat program, Mexico, Mexico

Climate change is a global problem but its potential effects on crop production, as well as appropriate adaptation strategies and stakeholders' adaptive capacity, will differ by region. Mexican agriculture is particularly vulnerable to climate change with models projecting a reduction in national productivity of almost 30%. The main cereal crops such as wheat and maize will be particularly affected. Research in Mexico's main wheat production area, the Yaqui Valley, has shown that an increase of minimum temperature by one degree in the crucial growing period reduces yields by 10%. In order to assist crop breeding programs to select and target wheat genotypes, it is important to identify current and future agro-ecological zones for wheat production in Mexico and, subsequently, appropriate wheat genotypes for these zones. Already established networks for multi-environments trial evaluations worldwide (such as the International Wheat Improvement Network IWIN)) can be used to identify widely or specifically adapted wheat genotypes in order to recommend which ones could have greater impact in different agro-ecological zones in Mexico. This is particularly relevant to rain-fed areas of Mexico where scarce information on genotype performance is available. To complement this approach, detailed studies on the same genotypes evaluated for physiological traits during different years can help to determine which specific traits confer to the genotypes an advantage under given environmental conditions.

We focus on appropriate climate adaptation strategies for wheat in rain-fed areas in Mexico. We use a bio-economic modeling framework involving crop, spatial and economic variables to identify "wheat hotspots" i.e. areas in Mexico which are particularly vulnerable to increased drought and heat stress. Drawing on data from international wheat trials at 25 sites worldwide, we identify wheat lines than could be released as varieties most suited to these predicted wheat hotspots. Additionally, combinations of crop simulation models together with geographic information systems (GIS) help us to understand spatial and temporal aspects related with Genotype-by-Environment (GxE) interaction and can be used to support geographic targeting of genotypes to environments. Wheat breeding and seed supply is dominated by the public sector. The socio-economic analysis focuses on the implications of our results for agricultural policies in Mexico to ensure that farmers have access to seed of locally adapted wheat genotypes. Our cross-disciplinary approach that draws on plant physiology, crop breeding and socio-economics, provides a framework for policy-makers, researchers and development practitioner to identify where climate adaptation efforts should be directed. It is a framework that can be adapted to other regions and crops such as maize in sub-Saharan Africa.

P-2224-10

Farming Adaptation to the Impacts of Climate Change and Extreme Events in Pacific Island Countries

V. Iese (1) ; J. Maeke (1) ; M. Wairiu (1)
(1) The University of the South Pacific, Pacific Centre for Environment and Sustainable Development, Suva, Fiji

Farmers in Pacific Islands' communities are considered to be most vulnerable to the impacts of increased temperature, sea-level rise, droughts, cyclones, and heavy rainfall. Farmers living on a raised atoll in the Solomon Islands (Bellona) were interviewed to understand their perceptions and experiences on the impacts of climate change and extreme events on their crops. Some examples of damage and impacts according to the farmers included rotting of roots, damage to leaves and branches, and destruction of fruits and valuable yields. Interviews also revealed that the ability of farmers to recover after disasters was dependent on their pre-disaster conditions, number and varieties of crops they had planted, type of cropping system in use, and consistent use of simple, traditional, and innovative adaptive techniques. Such techniques included crop rotation, change of planting and harvesting dates, and the planting of new resilient varieties.

P-2224-11

Agricultural adaptation to climate change-assessing adaptive decision-making of Indian farmers

C. Jha (1)
(1) National Institute of Industrial Engineering (NITIE), Economics, Mumbai, India

Global climate change threatens natural and human systems and is expected to cause food insecurity, rural poverty, malnutrition and dreadful environmental conditions, especially for developing countries like India. Agriculture being the primary economic activity of developing countries, linkages between climate and agriculture are expected to be more prominent and vulnerable to erratic disturbances in near future. In this respect, adaptation is considered as a sustained approach to adjust agricultural system to changing climatic conditions. Agricultural adaptation involves local adjustments to climate variations and helps in reducing the vulnerability of agro-ecosystem to climate variations and extremes and ensures long-term resilience to future climatic turbulences.

Farmers being the key actors in agricultural sector; assessment of farmers' decision making, their willingness to adapt, adaptive capacity and the likely responses to climate stimuli are crucial to ensure sustainable agricultural management. The critical question underlying farmer's responses is how do farmers decide when and how to adapt and what determines their ability to adapt. Farmers usually choose from a set of adaptation strategies such as crop diversification, crop switching, altering area under cultivation, managing crop sowing and harvest timings, increased irrigation and soil and water conservation techniques; best suited to their local agronomic conditions. Farmers' adaptation initially depends on their perception on changes in climatic conditions which are usually based on their past experiences of climate variability and extreme events and their future expectations of climate change which in turn is based on prevailing climate scenario. Although farmer's perception to climate change might be a necessary condition it is not a sufficient condition to adapt as adaptive responses of farmers are finally determined by their incentive and ability to adapt. Farmer's incentive to adapt is driven by their risk taking behavior and their expectations of earning sustained higher economic returns. Farmer's ability to adapt might defer in terms of managerial and entrepreneurial capacities and farmer's household and socio economic characteristics (Bryan et al., 2000; Nhemchena and Hassan, 2007; Deressa et al., 2008; Below et al., 2010; Falco and Veronesi, 2013). Farmer's in developing countries usually try to maximize their net returns subject to their socio economic constraints, access to information and credit availability. Farmer's decision making is often affected by complex set of socio-economic factors such as household size, age, gender, education level, off-farm income, farm size, access to extension services and credit availability etc. which are beyond farmer's control.

Against this background, this study tries to hypothesize the possible effects of key socio economic variables on farmer's ability to adapt and adaptive choices under differing local conditions for Bihar district in India. Agriculture serves to be the chief economic activity of Bihar which lies in the Indo-Gangetic plain of India and is divided into three agro-climatic zones based on soil characteristics, rainfall and temperature. Through quantitative and qualitative analysis of survey data on farmer's responses, the study finds that socio-economic factors are key determinants of farmer's adaptive capacity and adaptation decisions are outcome of interactions between these factors. Large household size can ease farm labor supply and assist in non-farm income. Also, educated farmers with large household size help in creation of intra-household social network which eases flow of information and helps in framing farmer's perception. Young and educated farmers are more ready to adopt new and advanced technology and also ensure usage of appropriate amount and quality of seeds, fertilizers, pesticides and thus increasingly adopt soil and water

conservation through crop switching and mixed farming practices. The magnitude of effects of these interlinked factors is however difficult to assess as it depends on socio-cultural, economic and political status which varies across spatial and regional scales and are often complex in nature especially for developing countries. The results of the study can be helpful in assessing vulnerability of farmer's to climate change in developing countries and help in reducing barriers to climate change adaptation.

P-2224-12

Vulnerability assessment of commercial & small scale farmers to flooding and its impact on biodiversity from 1940 to 2010 in the Duiwenhoks and Goukou catchments Western Cape, South Africa

Z. Jonas (1)
(1) South African National Biodiversity Institute, Climate Change BioAdaptation, Cape Town, South Africa

South Africa is a water scarce country and the resources are unevenly distributed across the country's landscape. The majority of the exploitable water is found in sparsely populated mountain catchment areas. Demands in terms of quality and quantity of water differ across sectors, water users and ecological requirements. For the Western Cape for example, a strong seasonality and micro-regional differentiation determines the balance between availability of water and the demands from water users. As a result the pressures and the impacts associated with water use are diverse in composition and intensity and affect the resilience of the province's water resource situation and subsequent resource management. Major threats to both commercial and small scale farmers are as a result of water scarcity, which in turn directly affects the delivery of ecosystem services to the poor of the poorest. South Africa's biodiversity and ecosystems are increasingly under pressure from accelerated climate change ranging from temperature increases, changes in rainfall patterns and flooding. In Duiwenhoks and Goukou catchment there is evidence of increased floods from 1940 to 2010. This has resulted to severe catchment degradation which compromises the delivery of ecosystem services that poor people depends on. The large parts of these wetlands are destroyed, and wetlands are good ecosystem services to prevent flooding and ensure good water quality. The major problem currently is the over-extraction of water for various activities within the catchments such as water for vineyard farms, dairy farming as well as other commercial developments. In Goukou the inappropriate development in the estuarine space is hindering the ability of estuaries to buffer the surrounding landscape against floods. Flow reduction is increasing mouth closure and thereby increasing the risk of floods. This study is aiming at conducting thorough vulnerability assessment of both catchment and develops flooding response measures, where we will look at the land management practises using the existing spatial developments plans and integrated development plans and others in order to assess who is hit the hardest by flooding for both commercial and small scale farmers. The vulnerability assessment data will be integrated with spatial data related to ecosystem service delivery and translated to the local level, based on catchment vulnerabilities and needs to inform local adaptation plans.

P-2224-13

Influence of climate change on nitrogen-fixing bacteria and its use as bio-fertilizer for crop production

M. Karim (1)
(1) University of Dhaka, (and Global Young Academy), Microbiology, Dhaka, Bangladesh

Increasing rates of sea level rise in the mainland of the coastal areas of the Bay of Bengal is thought to have one of the many effects of climate change and global warming afflicting developing countries of South Asia. Bangladesh, in particular has already been affected through land erosion and salinity intrusion in its broader coastline, and is expected to suffer further setback in the form of damage to infrastructures, crop failure, fisheries destruction and loss of biodiversity. The coastal area covers about 20% of Bangladesh and over 30% of the net cultivable areas. Such a vast area is feared to be affected with varying degrees of salinity intrusion, with the consequent reduction of normal crop production. This study attempts to isolate and identify agriculturally-important microorganism (AIMO), Azotobacter spp which play a predominant role in maintaining soil arability by fixing atmospheric nitrogen. They are Gram-negative and aerobic soil bacteria which meet about 70% nitrogen demand in soil. In addition to nitrogen fixation, these bacteria are able to solubilize phosphates, produce plant growth hormones and vitamins. Overall, they are renewable, yet a cost-effective source of the major plant nutrient to supplement the nitrogen-containing chemical fertilizer. In the light of Rio+20 earth summit, it can be said that their effective use could ensure sustainable agriculture as they are economically profitable, socially responsible, and environmentally acceptable.

In order to understand how long these bacteria will remain proactive under the climate change effects, soil samples from rice fields were collected in order to isolate and identify Azotobacter spp based on microscopic, cultural and biochemical properties. Sixteen and four strains of Azotobacter spp were isolated from salinity-prone southwest coastal districts, and non-saline midland areas of Bangladesh respectively. Their survival response in selective media, Azotobacter broth, supplemented with varying concentrations of NaCl was studied. Isolates were found to adapt and grow even at 20% salt concentration indicating their phenomenal tolerance to withstand salt stress. As they continue to grow in medium devoid of nitrogen, understandably they fix nitrogen. Most of these isolates harbor single and one very large plasmid (>50kb), as opposed to isolates recovered from non-saline zones. High salt tolerant, Azotobacter spp were then characterized for their drug resistance, and were tested to twenty six antimicrobial drugs, belonging to fifteen different antibiotic groups. Isolates from saline zones showed shear resistance to most of the drugs (estimated 94%), while the isolates from non-saline zones exhibited 39% resistance only. The presence of high molecular weight plasmid therefore is assumed to be correlated with the multidrug resistance pattern of the isolates. Genetic fingerprinting of the studied bacteria revealed that twenty isolates belonged to five different Azotobacter species. Overall, these salt-tolerant species have the ability to counteract salinity stress, yet fixing atmospheric nitrogen; therefore have the potential to be applied as bio-fertilizer in the coastal agriculture.

P-2224-14

Reducing fungal infestaions in growing groundnuts through biocontrol methods that can increase crop safety by deacreasing Aflatoxin content

M. Kifle (1)
(1) UKZN, Plant Pathology, Pietermaritzburg, South Africa

Peanut (Arachis hypogaea L.) is an important food crop in sub-Saharan Africa and also an important oilseed and food crop around the world. In most of sub-Saharan Africa, the consumption of peanut and peanut products is high because of their affordability and adaptability to a variety of culinary uses. Peanut consumption has been linked to the reduction of cardiovascular disease including coronary heart disease, Alzheimer's disease, malnutrition as well as cancer. However, peanut is highly susceptible to the growth of mycotoxigenic fungi and hence it is prone to aflatoxin contamination. Pre-harvest infection of groundnuts by Aspergillus spp. is of great food safety concern due to their ability to produce secondary mycotoxins, called aflatoxins. Aflatoxins cannot be readily removed from contaminated foods by detoxification. Members belongs to the genus Asperigillus are most abundant in the tropics and as such, are major food spoilage agent in warm climates. Therefore, there is a need to develop biocontrol methods that will increase crop safety by preventing the infection of the groundnut seeds by these pathogens, and hence to stop the contamination of the seed by these toxins. Prior research in glasshouse trials suggests that this approach works and can increase yields by 50%, as a bonus.

P-2224-15

Sustainable Agriculture a An ecosystem based approach for climate change adaptation for food security- a case study from an Afican Small island Developing State

B. Lalljee (1)
(1) University of Mauritius, Agriculture and Food Science, Moka, Mauritius

Sustainable Agriculture as an ecosystem based approach for climate change adaptation for food security – case study from an African Small Island Developing State

Climate change is undeniably affecting all spheres of human life including food security. The impacts of climate change are felt more by the Least Developed Countries and Small Island Developing States (SIDS). SIDS are considered as special group of countries as per the United Nations, because their smallness and remoteness makes them more vulnerable to food insecurity issues, which are compounded by the adverse effects of climate change. Livelihoods and food security of small farmers in sub-Saharan Africa are seriously threatened by climate change and this is negatively impacting on agricultural production and productivity. Climate change is not limited only to increasing temperature, rainfall pattern, soil water availability, intensity and frequency of extreme events, but also encompasses overall perturbation of the ecosystem, all of which influence food production.

The ecosystem based adaptation (EBA) approach to food production and food security assumes greater importance in the SIDS, which have very fragile and unique ecosystems. The use of sustainable agricultural technologies represent one such EBA approach, and which includes measures such as mulching, minimum tillage, multiple cropping, use of soil conditioners such as compost, use of agroforestry systems, etc. Adaptation is not to be considered as a stop-action, but rather as a process. Adaptation of agriculture to climate change is adjustments of the agricultural system to reduce vulnerability and increase resilience. The agricultural system has to undergo continuous changes.

This paper discusses the positive effects of a package of sustainable agriculture technologies, composed of mulching, minimum tillage and use of compost as plant nutrient sources, to food production. Three locally available mulches were investigated, namely banana leaves, coconut leaves and vetiver leaves, at three different rates. Minimum tillage, use of compost, and reduced fertiliser application were the other components of the package. The package was tested and validated in farmers' fields in the island of Rodrigues of the Republic of Mauritius. The beneficial effects were increase in soil moisture, a more uniform and stable soil temperature, improvement in soil biodiversity, control of weeds and other pests, increase in the yields of maize and beans. Furthermore, soil health and fertility was enhanced, in terms of properties such as pH, electrical conductivity, organic matter, water holding capacity, porosity, NPK levels, bacterial and fungal counts.

The project also included an important aspect of capacity building. Farmers were trained on compost making from agricultural and kitchen wastes, on the use of cover cropping, for soil moisture, for weed and pest control, minimum tillage (time and frequency), soil and water conservation measures, rainwater and runoff water harvesting. The training also included an understanding of the barriers to EBA, in particular the multiple functions and services of ecosystems, ecosystem goods and services, ecosystem evaluation, as well as a lack of strong policy drivers behind EBA to climate change issues.

A stakeholder participatory approach was used, with the farmers, community leaders, and NGOs being actively involved right from the problem analysis stage. The project data and information was collected together with the farmers, and at the end of the project, all stakeholders exhibited a strong positive sense of ownership of the results. The participants then served as ambassadors for the popularisation of this technology among their peers, and has now been adopted by over 90% of the farmers in the community. This approach has a very high potential for replication in other SIDS as well as in the region.This project was funded by the European Union(EU)under the Decentralised Cooperatiom Programme (DCP)

Keywords : climate change adaptation, ecosystem based approach, mulches, tillage, compost, SIDS.

P-2224-16

Do agroecological practices decrease farmers' vulnerability to climate change? Insights from the Mediterranean wine industry in France and Australia

AL. Lereboullet (1)
(1) Université Paris-Diderot, UMR Prodig, Paris, France

This research aimed to determine factors that impact farmers' vulnerability to climate change with a focus on Mediterranean viticulture, a crop particularly sensitive to changes in climatic conditions and increasingly exposed to water stress. Vulnerability was conceptualized here as a function of exposure, sensitivity and adaptive capacity. In particular, we examined the role played by agroecological farming practices on farmers' sensitivity to recent climatic events and on their capacity to adapt to long term climate change. Agroecology can be defined as a set of practices that aim for sustainable productive systems in terms of environment (resource preservation), economy (income improvement) and society (rural development). Such practices are varied and context dependant, and generally include biodiversity preservation, increasing resource-use efficiency, and limiting chemical inputs. We formulated the hypothesis that agroecological practices could be a generic driver to reduce vulnerability, but implemented differently according to socioeconomic, cultural and political contexts. We thus compared two regions with a similar -Mediterranean- climate, Roussillon in France and McLaren Vale in Australia, but with contrasting production backgrounds, and we tested whether agroecological practices had an impact on their sensitivity and adaptive capacity to climate change, and to what extent their impact and implementation was dependent on the local context.

We used a mixed-methods approach combining analyses of discourse and of climate data. Between 2011 and 2013, we led 69 in-depth semi-structured interviews with producers and key regional stakeholders (37 in Roussillon, 32 in McLaren Vale). Interviews were designed to provide insights on the way producers had dealt with droughts and heatwaves in the last two decades, and how they perceived the future of their activity in a context of climate change. Interview results were confronted to climate data obtained from Perpignan (Roussillon) and Adelaide Airport (McLaren Vale) weather stations, and modeled for the future decades by ARPEGE-Météo France (Roussillon, SCRATCH10-RETIC V4 dataset, 8 km resolution) and CSIRO-Mk3.5 (McLaren Vale, 10 km resolution). Agroecological practices were evaluated as a gradient, from those following organic and/ or biodynamic principles, with (level 1) or without (level 2) official certification, those applying some principles according to their current objectives (agriculture raisonnée, or low-input agriculture) (level 3), to those applying little of these principles (levels 4 and 5).

We found that the use of agroecological practices was associated with a reduced vulnerability to climate change, through reduced sensitivity and increased adaptive capacity. Practices commonly implemented in the two vineyards studied were: the following of organic/biodynamic principles, the use of compost and tillage, the reduction or stop of herbicide use, and the use of alternative weed control such as sheep. Level 1 and level 2 producers showed a reduced sensitivity to extreme events from the last decade, such as the consecutively hot and dry summers between 2003 and 2009 in Roussillon, and the three heatwaves that hit McLaren Vale in 2008 and 2009. According to models used, such climatic conditions are likely to become the norm until the 2040's, and gain in frequency and magnitude during the second part of the 21st century. Those producers were also more personally involved in the development of their farm, which they tended to perceive as a component of a wider regional productive system. Their implication in transforming practices towards greater sustainability was associated with a long-term vision of regional development and with optimistic entrepreneurship, which often lacked among level 4 and 5 producers. Also, the close attention that levels 1 and 2 gave to their fields seemed to outgrow the fact that coping better with recent extreme events could minimize the motivation to envision climate change as a pressing issue. Despite the fact that agroecological practices tend to maximize the multifunctionality of the two areas studied -a principle valued by the European Union-, their implementation appeared easier in the Australian than in the French region, due a limitative economic, cultural and legislative context in the latter.

P-2224-17

Transhumant management in the context of climate variability in north east of benin

P. Lesse (1) ; J. Djenontin (2) ; I. Toko (3) ; M. Houinato (1)
(1) Faculty of Agronomics Sciences, Benin, Abomey-Calavi, Benin; (2) Faculty of Agromy, Parakou, Benin; (3) University of Abomey-Calavi, Abomey-Calavi, Benin

The W National Park and its surroundings are a privileged and concentration of the national herd where confront all the logical development of the transhumance. In a context where the Benin suffers directly from weather conditions less under control, it is essential to improve knowledge on transhumance, know the current rangeland management and coping techniques. To achieve these goals, 300 breeders were maintained according to the quantitative and qualitative method based on a questionnaire and processed using the Sphinx plus2 software. The results we found that the texts on transhumance are outdated, ambiguous and unknown key stakeholders. Drought, high winds, excessive heat, late and heavy rain are the major weather risks affecting animals. In response to the new climatic conditions, large farmers practicing transhumance pastoralism opportunism traveling great distances.La all surveyed farmers have noticed changes in their course. These changes may be due either to the plant populations on the old lanes (50%), invasion corridors by fields of crops (65%), the drying up a bit faster ponds and streams (32%). The effects of these changes between. It may be noted thereby lengthening the path of periods (65%), insufficient increasingly higher pastures (50%). The results allowed us to identify 12 transhumance routes in the neighboring municipalities of W Park, spatiotemporal dynamics showed that routes have also changed due to conflicts (68%). These changes are reflected in the reduction in grazing areas (58%), longer travel times (25%) and the emergence of new grazing areas (32%). The changes observed in the transhumance routes are part of the coping skills of nomadic herders face the difficulties they face in feeding their animals.

P-2224-18

Agriculture and conservation: agroforestry biodiverse systems as a adaptative strategy to climate change in the brazilian Atlantic Forest

G. Narezi (1) ; PJ. Sobral (2)
(1) Federal University of Southern Bahia, Center of Studies in Environmental Sciences, Porto Seguro – BA, Brazil; (2) University of São Paulo, Research program for the development of rural settlements and family farming, Piracicaba, Brazil

These analyses are focused on consensus possibilities regarding spatial planning solutions based on a perspective that overcomes the production/environment polarization and dichotomy. This study also found that transition to different agricultural models, which are more sustainable and biodiverse, can help family farmers achieve their goals. Thus, this research project is aimed at analyzing recent mediation strategies for social-environmental conflicts, addressing issues like the access to land, natural resources and life quality in the context of the in the brazilian Atlantic Forest. The objective of this research is to develop an analysis on the technical and methodological improvements and innovations applied to agroecological private and community production systems in these areas. The methodology adopted is based on bibliographic research and on the collection of primary data through field notebooks noting and oral reports gathering in participative spaces for use planning and land occupation in future rural settlements located in the southernmost region of Bahia, that has one of the largest continuous remnants of Atlantic Rainforest of the country. In addition, we are planning semi structured interviews with researchers who are working on themes related to adaptation and resilience in agricultural ecosystems regarding to climate change. The historical context of the region addressed in this research, including its economy cycles and social and environmental conflicts, must be considered. Specifically, the agendas brought up in negotiations between social movements, traditional indigenous populations, the state and forest companies are discussed here, in order to provide perspectives that enable an agricultural model that conserves the biodiversity of a massive part of the Atlantic Forest Biome. This paper also presents reflections regarding different management models designed for protected natural areas. From the data collected it was possible to characterize and interpret the social organization, the history of traditional agricultural production practices, of environmental conflicts related to the land management and intensive agricultural practices in degraded areas. In this context, it was possible to find evidence that the way of life and agricultural production of the area favor local sensitivity in regard of an agroecological transition process. However, the challenges over the implementation of the agroforestry biodiverse systems analyzed in this study, shows that the perspective of nature conservation along with development faces many obstacles to its propagation even though agroecology is in the forefront of the discussion. Even with the impact of successful agroecological experiences at brazilian Atlantic Forest, socio-biodiversity conservation initiatives and cultural valorization of sustainable development of traditional populations are still overlooked at public polices.

P-2224-19

Climate Warming and Rural Poultry Production in Southern Africa - A Review

N. Nyoni (1) ; S. Grab (1) ; VGE. Archer (2)
(1) University of the Witwtersrand, Geography an Environmental Studies, Johannesburg, South Africa; (2) CSIR, Climate change, natural resources and the environment, Pretoria, South Africa

Compared to other livestock types, poultry are more likely to be owned by most rural households in developing countries. Rural poultry production is not an occupation per se, but tends to comprise a supplemental household activity, primarily amongst poor rural families, and thus contributes significantly as a source of scarce animal protein and income. Rural poultry is, however, faced with several challenges such as inherent slow growth rates, high rearing mortalities and susceptibility to diseases, poor nutrition, housing, and lack of proper health care, which impede its productivity. At the same time, the unequivocal warming of climate is expected to compound certain of these constraints. The study described here seeks to establish the relationship between climate warming and rural poultry farming in southern Africa. This is envisaged to outline the impact of climate change on rural poultry, and create a platform for developing intervention strategies to improve and sustain rural poultry production. In the current paper, literature on the importance of rural poultry, rural poultry production challenges, and climate warming and poultry production is reviewed, and key knowledge and data gaps identified. Researchable issues on climate warming and rural poultry production are further suggested.

P-2224-20

The Important of Preservations and Distributions of Milk in respect to the Different Weather Changes in Federal Capital Territory Areas of Abuja, Nigeria

M. Oke (1)
(1) Michael Adedotun Oke Foundation, International Development, Federal Capital Territory, Nigeria, Federal Republic of

This paper look at the important of the preservation and the distribution of milk in respect to the different weather, during the dry and wet seasons and how does it affect the level of consumption , tastes , marketing strategies , mode of preservation and the different methodology being use in preservation's of the milk products and the various problems being encountered in the process . The research was conducted in two areas council of the Federal Capital Territory namely Gwagwalada and the Municipal . The Findings shows that weather changes have a great impacts in taste level of consumptions of an individuals that consumes it, it have impact in the areas of transportation during the raining seasons most Fulani's women finds it difficult to convey their milk products because of bad roads in most of the rural areas , cost price, the level of milking of animal is high in the raining seasons due to the much of grasses and indirectly affect the rate of measurement, cost reduces in getting ice blocks for preservation of the milk and during the raining seasons ,

less efforts is needed because of the cold weather , which serves as preservation's . Some industries make use of chemical, good bottling technology which they are using in the process and the use of ice block were done when about the point of sales to the people by the Fulani's women who sales to an individual's that consumes it. Oral interview were conducted, group discussion were made with the Different questionnaires which were administer and analyzed to the sellers of milk products and consumables respectively to ascertain the findings and pictures were taken to support.

Grapevine has been domesticated 8 to 10 000 year ago in Eurasia. From there, grapevine growing and wine making have expanded to the European-Asian-North African continents, and more recently to the so-called "new world". It is still one of the major high value fruit crops in the world. The capacity of this crop to colonize new spaces since ancient periods, facing a full range of climates, demonstrates its ability to adapt to various climatic conditions. In traditional growing zones, cultivars and human practices have been selected in order to take the best benefit from the environment to elaborate specific or unique wines. The balance between environmental conditions, cultivars and management practices within a specific location, referred to as the "terroir" concept (according to OIV definition), is used to market wines and increase their economic value. However current climate change may endanger this equilibrium. Considering these aspects, grape and wine industry may be considered as a model to study adaptation to climate change. It is the scope of a French project, named Laccave reported hereafter.

The close link of grapevine phenology with climate is demonstrated through successful reconstruction of past climate trends from harvest dates. Several studies show that process-based phenological models can accurately be used to calculate past temperatures and detect anomalies. Additional information on cultivars, wine styles and produced wine quality as well as viticultural in different wine regions may help to build more robust models at local scales. Phenological models have also been used to assess the future growing conditions by using climate simulations. For example, these studies show that an advance of 30 to 40 days for major phenological stages may be expected in France at the end of the XXIth century. Consequently, most varieties are expected to ripen at increasingly warmer conditions, impacting fruit composition and wine types elaborated from these grapes.

These changes are already noticeable in existing vineyards with a recorded advance of 2 to 3 weeks for harvest dates over the last 20 years. Increased sugar contents, lower acidity levels and modified aroma and polyphenolic composition have been observed. The suitability of actual growing zones may be seriously affected in the future and new regions may become appropriate. Cultivated areas in Great Britain have more than doubled in 25 years and vines are now grown in Sweden and Poland. Nevertheless the concept of suitability has to be taken with caution and large scale studies can lead to erroneous conclusions for local situations. Local climatic variability, adaptation of cultural and oenological practices and plasticity of cultivars may enlarge the limits of suitability. An international study is on the way to characterize and model thermal variability at local scale within grapevine growing regions in order to define the parameters of climate variability and the most suitable areas for the future.

It is clearly shown that local temperature variability within growing areas can be in the same range as variability between regions or several years and have to be taken into account for defining adaptation strategies. Altitude and exposition are key parameters. In each location, most suitable varieties to new climatic conditions can be chosen among traditional ones, but also within the large diversity existing among Vitis vinifera spp cultivars. Rootstocks bred from a larger range of Vitis spp background may also contribute to adaptation. Cultural practices such as canopy or soil management need to be taken into account as well as local variations in soil types. Irrigation can be an answer to severe water deficits but in the long run competition for water resources and increased soil salinity may become major problems. Alternative water sources, as retreated waste water, can be considered but their impacts on the environment and on wine quality have to be considered. Other disruptive innovations have to be invented. Growers and actors need to be associated to the process of defining strategies of adaptation. Their perception and the organization of innovation dissemination within the industry are key issues in this approach of adaptation. The research conducted within the Laccave project participates to the definition of these strategies and describes the mutual contribution of human and natural resources. It will be presented, based on examples from French vineyards.

P-2224-22

Investigating Climate Variability and Change and their Associated Impacts on Banana Productivity over Uganda

G. Sabiiti (1)
(1) Makerere University, Geography, Geo-Informatics and Climatic Sciences, Kampala, Uganda

Climate extremes associated with climate variability and change are on the rise both globally and regionally with far reaching impacts on socio-economic sectors particularly for countries like Uganda whose agriculture is largely rain-fed. Banana is a major crop that provides continuous cycles of harvests making it important for enhancing food security over most parts of East Africa. Studies have reported continuous decline in banana productivity due to biological and environmental factors including climate extremes. This study investigated pattern in climate and the effect of current and future extremes in rainfall and surface air temperature on banana productivity over L. Victoria basin of Uganda.

The study used observed rainfall, surface air temperature and banana productivity records spanning 1971-2009 for central and western regions of Uganda. Future climate change data from four Representative Concentration Pathways (RCP 2.6, RCP 4.5, RCP 6.0 and RCP 8.5) climate scenarios for the period 2021-2050 were also analysed.

In this study, seasonal climate data were subjected to time series analysis and Mann-Kendall tests for trend and change detection. The study employed correlation and polynomial regression analysis to identify linkage between current rainfall and surface air temperature variability and banana yields. The Food and Agricultural Organisation Crop Water Assessment Tool (FAO-CROPWAT) was used to estimate banana yield changes due to soil moisture variations for different parts of Uganda. The FAO Eco-crop tool and Geo-spatial Information System (GIS) techniques were used to identify suitable rainfall and surface air temperature conditions for banana production to map future (2021-2050) suitability of banana production.

The study results showed no significant trend in seasonal rainfall in most parts of the country except a notable rainfall decrease in the western regions and slight increase for stations around Lake Victoria region. The results indicated significantly increasing trends in surface air temperature. A faster increase is notable over the central than over western parts of Uganda. This is partly attributed to different rates of land-use changes from increasing urbanization and population pressure in characterizing the two regions. Polynomial functions of degree 1 (rainfall) and degree 2 (air temperature) were determined to fit a relationship between banana yield and climate variables. The regression results show that rainfall variability explained 26% and 14% of the variations in banana yields over central and western regions respectively. Variations in minimum (maximum) surface air temperature explained

31% (34%) and 26% (30%) of the variations in banana yields respectively.

The results indicated high likelihood of warming trends (2021–2050) with respect to the climate scenarios except RCP 2.6 simulation cooler (seasonal surface air temperature) and drier (seasonal rainfall) than current observations, seasonal surface air temperature and rainfall simulation of RCP 4.5 are slightly warmer and wetter than RCP 2.6 simulations. The projected seasonal rainfall and surface air temperature is more amplified in RCP6.0 compared with all other scenarios and only cooler than RCP 8.5 surface air temperature simulations (by ≈1.7 oC). Future banana suitability mapping indicate a larger (smaller) area suitable for banana production under RCP 6.0 and RCP 4.5 (RCP 2.6 and RCP 8.5) for the study period.

This study provides critical evidence of climate variability and change, establishes linkages between climate variability and banana productivity over Uganda that can used to develop coping and adaptation strategies to improve banana productivity and enhance food security over the region.

P-2224-23

Medicinal and Aromatic Crops: An alternate proposition for exploiting abiotic stresses

S. Singh (1) ; AK. Singh (1) ; N. Absar (1) ; R. Singh (1) ; NS. Sangwan (2) ; DD. Patra (1)

(1) CSIR–Central Institute of Medicinal and Aromatic Plants, Agro–technology, Lucknow, Uttar Pradesh, India; (2) CSIR–Central Institute of Medicinal and Aromatic Plants, Biochemistry and synthetic biology, Lucknow, Uttar Pradesh, India

The demand for herbal drugs, plant based aroma chemicals and natural products is increasing at a speeding pace owing to the uniqueness, diversity and effectiveness of the associated crops used for. The secondary metabolites synthesized in medicinal and aromatic crops (MACs) also protect them from challenging circumstances like defence against certain stresses. In some cases, stress has been shown to bear positive effects on the production of secondary metabolites. The unique features of these MACs are that, many of them have the potential to withstand abiotic stresses to a higher degree as compared to traditional crops. This is also due the fact that, unlike agricultural crops, the MACs are not so sensitive to availability of soil moisture / temperature/ photo–periodism etc. In many cases vegetative parts are the ultimate products. Hence, there are lot of flexibilities in adjusting the planting and harvesting time.

Many of MACs are considered as high value crops presenting higher returns to the growers. However, cultivation of these MACs may not be encouraged at the expense of traditional agricultural crops already growing on well managed fertile lands. While several attempts are being taken up using molecular and modern approaches to fulfil the impeding demands of natural products, yet still the commercial production of related crops under field conditions remains as major option. The attractive proposition, therefore, appears to evaluate and promote these crops on marginal lands which might be facing some kinds of abiotic stress. These crops can manage to improve productivity and economic output compared to traditional crops.

Various possibilities of growing medicinal and aromatic plants under different types of abiotic stresses and their evaluation in terms of imparting benefits over traditional food and agricultural crops being grown in tropical and sub–tropical regions of India will be deliberated at the meeting.

P-2224-24

Fighting food insecurity and alleviating poverty in the face of climate change through rice-growing in Tonga-Cameroon

C. Tchieudjo (1)

(1) The University of Yaounde I, The Faculty of Arts, Letters and Social Sciences, Department of Geography, Yaounde, Centre, Cameroon

This study focused primarily on the different actors involved in the rice production in Tonga (Western Cameroon) and strategies set to boost its cultivation, and it brought up some suggestions to the various problems that tend to weaken the activity. Preserving and enhancing food security requires agricultural production systems to increase productivity and to reduce output variability in the face of climate change and other agro–ecological and socio–economic risks. Cameroon, a low–income food–deficit country (LIFDC), has made agriculture a condition of its development. But the 2007's riots, coupled with the food prices soaring, deeply raise the double problem in the fight against food insecurity and poverty. The objective was to investigate the role played by the rice–growing activity in Tonga in the fight against food insecurity and poverty. Rice production in Tonga is on the rise because of its natural assets and good quality of the rice cultivated in the locality. To test our hypotheses, we used Quivy Campenhoudt and Van (2006) and Thiétart (1999) methods ranging from field investigation (enquiries to relevant stakeholders, on–the–spot assessment), sampling techniques, to data collection and processing. These methods have demonstrated that rice–growing contributes about 80% to the fight against food insecurity and alleviate poverty in Tonga. These findings could contribute to the improvement of the living conditions of rural populations in Tonga. However, to reverse the trend of rice consumption in Cameroon overall, it is necessary to move from family/traditional farming to industrial/modern agriculture on which the population could sustainably rely to improve their living conditions. The Cameroonian government through the Agricultural Sector Development Program (PADFA) provides different supports to farmers to eradicate hunger and poverty, and finally ensure a brighter future for rice growing. New challenges and technological opportunities for rice–based production systems for food security and poverty alleviation are then needed.

P-2224-25

Screening of Blackgram (Vigna mungo (L.) Hepper) genotypes for thermotolerance using Temperature Induction Response (TIR) technique

P. Theeban (1)

(1) tamil nadu agricultural university, crop physiology, tamilnadu, India

Temperature induction response was standardized for blackgram genotypes. A total of nineteen blackgram genotypes were screened and evaluated for thermotolerance. By using standardized optimum induction and challenging temperature, cellular level tolerance using TIR protocol was assessed in all the blackgram genotypes. The challenging lethal temperature was standardized as 50˚C at which 98 per cent of the seedling mortality was noticed. The induction temperature was standardized as 36 to 40˚C at which 46.4 per cent of growth reduction over control was noticed The Based on root length and shoot height of induced seedlings over control seedlings, the cellular level tolerance in terms of least reduction in growth and highest survival percentage was calculated. Also, the physiological basis of thermotolerance was assessed by measuring the proline content and antioxidant enzyme activities. The genotypes VBG–07–001, VBG–06–010 have intrinsic heat tolerance and they can be explored as donor source in breeding programme aimed for global warming.

P-2224-26

Does diversification in smallholder coffee landscapes help farmers to adapt to climate change? Answers from Nicaragua

M. Van Zonneveld (1) ; R. Guevara, (1) ; A. Fallot, (2)

(1) Bioversity International, Turrialba, Costa Rica; (2) Centre de Coopération Internationale en Recherche Agronomique pour le Développement (CIRAD, Turrialba, Costa Rica

Introduction: The Central American coffee production area is predicted to reduce substantially under progressive climate change. The livelihoods of many smallholders in these landscapes are threatened because they largely depend on coffee production. Despite the growing emphasis on on–farm diversification to manage climate risks and improve food security in coffee landscapes, there

are no criteria developed to quantify the status, need and outreach of diversification.

Objectives: We identified with community representatives and other local stakeholders in two contrasting coffee zones in Nicaragua (dry and humid): 1) the role of on-farm diversification in farmer strategies in climate change adaptation; 2) different dimensions of on-farm diversification; and 3) the need for specific measures to make use of the potential of diversification.

Methods: We carried out a literature review highlighting the different dimensions of diversification, and for each dimension, the benefits and drawbacks of diversification for smallholders of coffee landscapes. We consulted institutions and focal groups from ten communities in two contrasting coffee zones in Nicaragua about: 1) the vulnerability of their livelihoods to climate changes ; 2) existing and desirable strategies to adapt to these changes; 3) existing diversity in coffee farms; 4) what on-farm diversification would represent for them to be an effective way of adapting to climate change. Taken into account the gender issue, we conducted interviews in farm households to understand how actual diversification is related to climate risk management and food security status, and to identify specific needs to enable farmers making use of the potential for diversification. To embed our results in local development and research processes, our activities were linked to existing farmer initiatives and the local university agronomy faculty. In each coffee zone, phenological calendars for the principal crops were developed on the basis of the collected information to support farmers´ crop management under the existing climate variability.

Preliminary results and discussion: Farmer families in both coffee zones indicated crop diversification among adaptation options that they prefer, particularly enrichment with fruit perennials like plantain, banana and citrus. These crops provide cash flow through the year and can be used also for own consumption to enrich the diets of farmer families. Though a large diversity of agricultural species is grown in the landscape, most on-farm activities are concentrated around coffee, maize and common beans and take place between May and August, which coincides with the months of seasonal hunger. This suggests a high potential for diversification which is currently little utilized to improve food security, generate income and to adapt production systems to climate variability. The literature review allows us to draw a first typology of complementarity and competition effects amongst crops. Some farmers have already enriched their coffee farms with fruit perennials and other crops. Because of their experience, they are key persons to share knowledge about benefits and risks of crop diversification with other farmers. At landscape level, farmers stressed the importance of sufficient tree cover to ensure key environmental services like water availability. Restoration and conservation activities at landscape level will require coordination among farmer s and governmental organizations.

2225 - Climate Smart Agriculture: Propaganda or Paradigm Shift?

ORAL PRESENTATIONS

K-2225-01

From a global science conference towards UNFCCC negotiations: mobilizing science for transitions

P. Caron (1)
(1) Cirad, General direction, Montpellier

This presentation aims at presenting the main out comes from the 3rd Global Science Conference on Climate Smart Agriculture (CSA) in Montpellier, France, 16-18 March 2015 where more than 600 researchers and 150 stakeholders and policy makers from 75 countries and 5 continents convened. CSA is a framework that mobilizes synergies and can lead to innovative and comprehensive solutions at local, regional and global levels. Delegates also confirmed that CSA solutions exist and can be brought into reality provided favorable conditions.

Agriculture was acknowledged as a sector particularly vulnerable to climate change, which impacts the livelihoods of the world's poorest people. This places increased strain on global food systems, especially since expectations for meeting demand for food will change tremendously within the next 40 years. Agriculture has also a central role in strongly reducing greenhouse gas emissions and lies therefore at the heart of complex challenges to be addressed. CSA invites researchers, practitioners and policy makers to explore solutions combining three pillars, food security, climate change adaptation and mitigation, underpinning sustainable landscapes and food systems. This is essential since the sector is facing unprecedented uncertainty and risks: synergies have to be looked at and trade-offs addressed. Recognizing that agriculture is a pivotal sector for international negotiations on sustainable development and climate change, CSA therefore provides a framework for looking at necessary transitions.

The main recommendations were as follows: (i) agriculture in the future must also address the challenges of sustainable food systems and landscapes; (ii): based upon a renewed research agenda that addresses a more complex set of objectives, researchers and practitioners must engage to build evidence and design the trajectories for multiple transformative transitions of climate-smart agriculture; (iii) the future relies upon policy, institutional and financing decisions and particularly upon the involvement of policy makers, development agencies, civil society and the private sector with researchers and research institutions in innovation platforms.

The strengthening of CSA scientific community must be pursued and better engaged in interfacing with policy makers, promoting scientific diplomacy. Their capacity to develop relevant global research programs and joint initiatives to address as from now questions that will be key in the future should be supported and stimulated through international cooperation platforms.

Decision-support framework for targeting investment towards climate-smart agriculture practices and programs

A. Nowak (1) ; C. Corner-Dolloff, (1) ; AM. Loboguerrero, (2) ; M. Lizarazo (2) ; F. Howland (1) ; N. Andrieu (3) ; A. Jarvis (1)
(1) International Center for Tropical Agriculture (CIAT), Decision and Policy Analysis Research Area, Cali, Colombia; (2) CGIAR research program on Climate Change, Agriculture, and Food Security (CCAFS) , Ccafs latinoamerica, Cali, Colombia; (3) Centre de coopération Internationale en recherche agronomique pour le développement (CIRAD), L'unité mixte de recherche innovation et développement dans l'agriculture et l'agroalimentaire, Montpellier, France

Unprecedented impacts of climate change on agricultural systems around the world coupled with increasing food demand underlie the urgency of building a more productive, resilient, and low-emission agricultural development model – one that is climate-smart. Establishing climate-smart agriculture (CSA) systems requires investment in concrete on-farm practices and broader programs to establish implementation at scales that will transform systems to address food security and development goals in the face of climate change. The

CSA Prioritization Framework (CSA-PF) was designed by scientists at CIAT and CCFAS to guide actors at multiple levels in their effort to identify best-bet CSA investment portfolios through scientific and participatory evaluation of the broad set of applicable practices for a given context. The CSA-PF is a CSA implementation planning and policy support tool aimed at governments, donors, non-governmental organizations, and local actors. The framework explicitly targets investments that diminish trade-offs between productivity increases, gains in adaptive capacity, and lowering emissions contributions from agriculture. Given the various needs of potential users and investment targets, the CS-PF can be adapted to stakeholders' needs and resources. It has been designed as a four phase process, but current pilots has varied this approach, adding additional analyses and decision taking points as needed. The first phase leads the main user of the prioritization process, in collaboration with a team of experts, to identify the objectives, scope of the study based on vulnerable areas and production systems key for food security, and the associated climatic and non-climatic challenges to be addressed through CSA interventions. The process then continues with the development of a long list of CSA practices applicable to the selected region(s) and production systems, and the identification of indicators to assess the practice's impacts on productivity, adaptation and mitigation. In Phase 2, stakeholders validate these results through participatory workshops and select a shorter list of CSA practices for further investigation based on the analyses from the first phase. An economic analysis, most often a cost-benefit analysis, is conducted in Phase 3 for the short-listed practices. A second workshop for data validation is held in Phase 4, where stakeholders discuss strategies to minimize trade-offs, to increase synergies between practices, and to minimize barriers to adoptions. The process results in the collaborative development of CSA investment portfolios. Through a comparative case study approach, this paper also illustrates the results from implementing the CSA-PF in Colombia, Guatemala, and Mali, where the prioritization objectives vary from strengthening current national agricultural and climate change policy (Guatemala), to articulating governmental and non-governmental actors around CSA actions (Mali), to scaling out CSA initiatives with local community groups (Colombia). Opportunities and challenges related to the different approaches to using the framework are discussed and recommendations for down-scaling the CSA-PF and establishing multi-level planning platforms are formulated, thus contributing to the wider goal of informing agriculture and climate change policy and decision-making.

O-2225-02

The adoption of Climate Smart Agriculture innovations: a summary of an EU project

V. Blok (1) ; T. Long (2)
(1) Wageningen UR, Mst, Wageningen, Netherlands; (2) Wageningen UR, MST, Wageningen, Gelderland, Netherlands

Agriculture and its supply chains will be profoundly impacted by actions to mitigate against, and adapt to climate change. The emerging concept of Climate Smart Agriculture (CSA) is one response to this challenge, involving the simultaneous increasing of agricultural productivity and incomes, adaptation and the building of resilience, and the reductions of GHG emissions (FAO, 2010).

Whilst heavily advanced within developing country contexts, CSA is also forming a strategic priority within Europe. Technological innovations are signalled as playing a critical role in the transition towards CSA. However, the diffusion and adoption of technological innovations within OECD countries has been slow (del Río González 2005). This is due to the presence of social and economic barriers, including poor market incentives and low levels of awareness.

The development and refinement of appropriate business models for CSA, increasing awareness and the aligning of national and EU policies have been highlighted as responses to enhance the transition to CSA.

Results from a Climate KiC pathfinder project on CSA will be presented during this key note talk. This ongoing project seeks to increase the adoption and diffusion of CSA technological innovations across the EU by stimulating both supply and demand. The presentation will provide an overview of the projects approach and results to date, which will include consideration of:

- The role and form of inhibiting social and economic factors.
- The role of business models in enhancing CSA technologies, and identifying critical issues that shape successful CSA business models.
- Current policy and regulatory impacts, and how these could be altered in the future to further the diffusion of CSA technologies and practices.

The development of services to boost CSA in Europe.

P-2225-01

Trends and Spatial Analysis of Temperature and Rainfall Patterns on Rice Yields in Nigeria

C. Akinbile (1) ; O. Ogunmola (1) ; S. Akande (2)
(1) Federal University of Technology, Akure(FUTA), Agricultural & Environmental Engineering, Akure, Ondo, Nigeria, Federal Republic of; (2) Federal University of Technology, Centre for space research and applications, Akure, Nigeria, Federal Republic of

Due to the increasing decline in food especially rice production, a research to access the impact of climate variability on food crop in Nigeria was conducted. Trends and spatial analysis of the effect of temperature and rainfall on rice yield was carried out using 40 years climate and rice yield data. Past trends analysis was conducted with forty years (1971-2010) climate data obtained from the International Institute of tropical agriculture (IITA) Ibadan, Nigeria while rice yield data were obtained from the Food and Agriculture Organization (FAO) of the United Nations and the United States Department of Agriculture (USDA) respectively. Future trends for the next forty years (2011-2050) projections on the climate variability and trends on rice yields were also forecasted. Six cities, one in each of the six agro-ecological zones of Nigeria were selected for the studies which were Calabar in Mangrove forest, Enugu in wooded Savannah, Ikeja in tropical rain forest, Ilorin in Guinea Savannah, Kaduna in Sudan Sahel and Maiduguri in Sahel savannah. . Geographic Information Systems (GIS) software was employed to map out spatial analysis of temperature and rainfall over the entire country using the six cities in each of the six zones as nodal sampling points. Results and predictions were analyzed using Statistical packages such as Mann-Kendall and Sens' tests, multiple linear regression, cross-correlation analysis, Statistical Packages for Social Sciences (SPSS), Analysis of Variance (ANOVA), Duncan's multiple range test (DMRT) and Arc surfer software, all at 95% level of significance. Rainfall showed increasing trends in Enugu, Ilorin, Calabar, Ikeja, and Maiduguri but decreasing trends were observed in Kaduna while temperature showed increasing trends in all the cities considered in the last four decades. The future climate projections showed increasing rainfall trends in Enugu, Calabar, Ikeja, and Maiduguri while decreasing trends were observed in Kaduna and Ilorin while temperature showed increasing trends in all the cities for the next four decades. For annual rainfall, no significant trend was observed in Calabar, Ilorin and Enugu but a statistically significant negative trend was observed in Kaduna. Similarly, statistically significant positive trends of rice yield, rainfall, and temperature were observed in Ikeja and Maiduguri in the last four decades. Rainfall decreased at the rate of 4.706mmyr-1 (P) while rice yield increased at the rate of 0.052t/ha/yr (P) in Kaduna. In Maiduguri, temperature increased at the rate of 0.063°C/yr (P) while rice yield increased at the rate of 0.063t/ha/yr (P. Mann-Kendall tests showed that rice yield and temperature had generally statistically significant positive trends in Calabar, Ilorin, Kaduna, and Enugu. Pearson correlation also showed that the relationship between rainfall and yield is not significant in Calabar, Enugu, Ilorin, and Maiduguri while temperature against yield is significant at 0.01 in Calabar, Enugu, Ikeja, and 0.05 level of significance at Ilorin. The multiple linear regression models also showed that rainfall was insignificant in Calabar, Ikeja, Ilorin, and Kaduna while maximum temperature was insignificant only in Maiduguri. Adaptation strategies such as genetically modifying rice varieties to tolerate projected changes in

rainfall and temperature trends as well as effective water use strategies (supplemental irrigation) in areas of deficit rainfall are recommended to ensure food security and sustianble livelihoods in Nigeria.

P-2225-02

Salinity a Deleterious Impacts of Climate Change: Biochemical and Physiological indicators of adaptation of Vicia faba L. to Salt Stress

F. Anaya (1) ; R. Fghire (1) ; S. Wahbi (1) ; K. Loutfi (1)
(1) Faculty of Science Semlalia, University Cadi Ayyad, Biology/Laboratory of Biotechnology and plant physiology, Marrakech, Morocco

Plant physiological processes are invariably linked to the deleterious influences of climate change. Salinity stress is considered as one of the major abiotic stresses which strongly reduced crop productivity. In order to assess the effect of salinity constraint on some physiological and biochemical traits in broad bean (Vicia faba L.), two cultivars (Extra Hative and Lobab), originated from Morocco, representatives of two climatic zones were evaluated for their response to salt stress. In this study, the biochemical and physiological responses of two salt stresses levels (0 and 150mM NaCl) on V. faba L. and the effect of exogenous salicylic acid (0.5 mM) at 150mM salt stress were investigated. The irrigation with salt water (150 mM of NaCl) was applied after 15 days of sowing for 21 days. The biochemical and physiological characteristics of Vicia faba L. were measured including: leaf water potential, Stomatal conductance, membrane permeability, chlorophyll content and antioxidant activity (PPO, POD and SOD). The results showed that the physiological and biochemical parameters were affected by salt concentration and there were varying responses between varieties. Thus irrigation with saline water significantly reduced all plant biochemical and physiological parameters in comparison to the respective control. Indeed, Salinity affected leaf water potential, Stomatal conductance and perturbation of membrane permeability. However salt stress caused an activation of oxidative enzymes (PPO, POD and SOD). The increasing of the antioxidant activities was significantly ($p<0.05$) correlated with salt stress. These results suggest that antioxidant enzymes play an important role in reducing oxidative stress in the broad bean exposed to salt stress. Nevertheless the protein and chlorophyll content showed an increasing with salt stress. Alleviation of growth arrest was observed with exogenous applications of salicylic acid (SA) under salt stress conditions. Overall, the positive effect of SA towards resistance to the salinity of V.faba L. will provide some practical basis for V.faba L cultivation. Elsewhere comparison between cultivars resulted in significant difference of tolerance where the Extra hative present the better performance under salt stress. From these results, we conclude that High levels of salinity negatively affected growth parameters, although selection of tolerant cultivars is a viable solution as the case of Extra hative in this study.

P-2225-03

Fostering Climate Smart Agriculture : what role for voluntary sustainability standards?

G. Balineau (1)
(1) Agence Française de Développement, Paris, France

Greenhouse gas emissions are seen by economists and others as negative externalities of production (and, to a lesser extent, consumption, and trade. In this context, two ways of regulating "environment" are generally considered for public action: "command-and-control" orders (that is to say legislative and/or coercive regulation) and/or "market-based" instruments (for example creating a market for pollution rights). However, a "third wave of regulation" [Tietenberg, 1998, "Disclosure strategies for pollution control", Environmental and Resource Economics, 11, 587-602] has emerged since two or three decades, based on information provision. This is especially the case in agriculture, where smart consumers should be linked to smart producers: Eco-labels (aslo called «voluntary sustainability standards») such as "carbon free" or "environmental-friendly" assertions, which have proliferated since the 1990s are part of this third wave of environmental regulation based on information provision. What can be their role for mitigation and adaptation to climate change? How can we paradoxically solve production externalities through the so-called "responsible" consumption while consumers should be rational and free ride when they are told to contribute to common or public goods? To assess the efficiency of eco-labels in contributing mitigation and adaptation challenges, we have to answer 3 questions:

- First, do eco-labels explicitly include the objectives of mitigation and adaptation to climate change? Studying charters and standards for forest-based products and cocoa, we show that mitigation criteria are almost systematically included in eco-labels standards, whereas this is clearly not the case for adaptation ones.
- Second, why should eco-labels be successful in inducing consumers' behaviors' change when regulation and market-based instruments failed? We show that there are two hypotheses behind the efficiency of labels: i) consumers are willing to pay for contributing to common or public goods and ii) labels solve two types of asymmetry/uncertainty: the first is an asymmetry of information "a la Akerlof" [Akerlof, G. A.: 1970, 'The Market for ''Lemons'': Quality Uncertainty and the Market Mechanism', Quarterly Journal of Economics 84(3), 488-500], the second is an uncertainty "a la Darby and Karni" [Darby, M. and E. Karni: 1973, 'Free Competition and the Optimal Amount of Fraud', Journal of Law and Economics, 16(1), 67-88]. Research show that i) consumers are willing to pay for common goods, ii) asymmetry of information about the respect of standards is not a problem but that iii) uncertainty about the efficiency of standards (i.e. what criteria should eco-labels include) is still prevalent.
- Third, labels should not create new externalities or perverse effect, which could be the case if; for example, consumers do not consider the impact of their aggregated consumption but only by units consumed.

As a conclusion, we draw the lessons in terms of possible action for donors and public powers.

P-2225-04

Assessment of the olive tree adaptation to water stress and tool to increase crop performance in the context of climatic changes

D. Boujnah (1)
(1) Institution de la Recherche et de l'Enseignement Supérieur Agricole, Institut de l'Olivier, Sousse, Tunisia

Global climate change will introduce substantial changes to the agricultural ecosystems and consequentely will affect the agricultural productivity. Water stress is the most important factor limiting plant growth and production. Thus, monitoring of plant water status in field grown is considered of great interest, as it would allow the diagnoses of the onset and severity of water stress so as to optimise the cultural practices according to the actual plant needs. Changes in plant water status could be described by using a sensitive physiological indicator, which integrates both soil and climatic conditions. The aim of our study is to evaluate a quantitative direct relationship of the olive tree water status and the environmental conditions that might be used to evaluate the response of the tree to some unconventional cultural practices: use of hydro absorbent, increasing plantation density and supplement water of traditional olive tree grove. For online control two techniques was used: the sap flow measurement system and the leaf patch clamp pressure probe (LPCP) which give information about the relative changes in turgor pressure (Pc) of the monitored plant.

The results of the sap flow measurement show the direct influence of changes in environmental factors, water state and the physiological parameter of the tree on the sap flow level among the olive tree. For the LPCP the instantaneous data, provided by the probe, have allowed us to have accurate information on the hydraulic behavior of the olive trees and the efficiency of hydro absorbent injected in the soil to enhance the effect of the available water. Indeed, we found that the effect of the water provided by the hydro-absorbent doesn't act directly on the olive trees as is the case of direct water supply; its effect is delayed for a few days. This product can be used effectively to support the

tree during periods of intense biological activity. Also, the results confirmed some of the findings observed on olive tree particularly its high adaptability to environmental conditions, as after a period of stress observed in plants grown under rained conditions where an improved of turgor potential was recorded.

P-2225-05

Broadening the genetic base and knowledge of cultivated crops for climate adaptation: A citizen science approach

A. Gupta (1) ; S. Mittra, (1) ; EJ. Van (2) ; PN. Mathur, (1)
(1) Bioversity International, New Delhi, India; (2) Bioversity International, Turrialba , Costa Rica

Climate change has already started to roll and showing its effects on different aspects of today's world. Climate change affects crop production directly through the intensity and frequency of different types of stress, such as drought, heat stress, and flooding. One important adaptation measure is that farmers change to new varieties and crops. To make these changes, farmers first need information about new options and how they perform on their farms. This requires a massive effort in creating new information about crops and varieties in different contexts that is difficult to achieve with current approaches. Our work uses a novel citizen science approach to accelerate the creation of new information. We started in 2012 in the Indo Gangetic Plains of Bihar and Uttar Pradesh in India with rice and wheat. Since then, the approach has also been applied in Eastern Africa and Central America. This presentation focuses on India, where the application of the citizen science approach has advanced most.

The citizen science approach uses the farmers' views and preference in a participatory way using crowdsourcing to look for the best set of genotypes that can perform well under the changed climatic conditions of India. We first screened more than 300 varieties released from the National Agricultural Research System (NARS), selecting 12–20 varieties in each site through Participatory Varietal Selection (PVS) trials, comparing with current varieties. From this set, we distributed different combinations of 3 varieties to each of the farmers to be grown alongside their own regular crop. The variety names are not marked on the packages to avoid any bias based on previous knowledge or comparisons with neighbours during the crop cycle. We ask farmers 8–9 questions about their preferences. Farmers rank these 3 varieties evaluating various characters such as germination, yield, and resistance to pests and diseases. At the end of the season these data is compiled to see the overall performance of these newly introduced varieties as per the farmers´ verdict of different characters. We also did a set of carefully managed on-farm trials with quantitative evaluation of the full varietal set (15–20 varieties) and varieties currently grown in the area for agronomic performance. One or two of these trials are done per village and managed by leader-farmers who invite their neighbours to evaluate these varieties. We also record local weather conditions by using low-cost meteorological sensors. Every season, we repeat the process with a new set of varieties as we replace the varieties that received low marks from the farmers by a fresh set of varieties.

In wheat, the farmers of Bihar and Uttar Pradesh were growing only two varieties, UP 262 and PBW 343. Our evaluation shows that in three districts in Bihar the 12–20 varieties introduce by the project yielded more than the current varieties. Similar results were obtained for rice. Of the introduced varieties, 7 outyielded the 5 most popular hybrid varieties that the farmers are currently growing. This shows that genetic broadening and an increase in production can be combined and that the introduction of diversity can quickly close the climate adaptation lag.

Varietal evaluation data produced by the participatory variety evaluation done through on-farm plots with all varieties provided very similar results to the data provided by the crowdsourcing trials with 3 varieties per farmer. This was true for both wheat and rice. This indicates that crowdsourcing gives reliable results, while exposing the materials to a broader group of farmers with lower costs. We are analysing the feasibility of combining the variety evaluation data with the meteorological data to generalize variety recommendations to a wider area.

The impact that was noticed from the first season is farmers have started to save the seeds of the varieties that they like and find superior to the ones that they were already growing. The farmers are also trained in producing the seeds of these selected varieties and a number of groups are now producing and selling seed. Seed sales by farmer groups will help to make it financially sustainable to continue the introduction, testing and marketing of new varieties and adapt to new climatic conditions.

P-2225-06

Managing the biological function of N2O reduction for mitigating soil N2O emission

C. Henault (1) ; JPA. Cohan (2) ; GC. Le (3) ; M. Bardy (4) ; X. Galiegue (5) ; R. Philippon, (6) ; C. Revellin, (7)
(1) INRA, UR SOLS 0272, Orléans, France; (2) ARVALIS, Ferme expérimentale de la jaillère, La Chapelle Saint Sauveur, France; (3) CETIOM, Thiverval Grignon, France; (4) INRA, Us infosol, Orleans, France; (5) Université Orléans, Laboratoire d'economie d'orléans, Orléans, France; (6) AgroPithiviers, Pithiviers, France; (7) INRA, Agroecologie, Dijon, France

Human activities are currently considered to emit 5.3 Tg N-N2O per year, mainly from agriculture that accounts for around two-thirds of these emissions (UNEP, 2013). The atmospheric gas N2O is involved both in the greenhouse effect with a contribution on a molar basis of around 300 in relation to CO2 (Rodhe, 1990) and in ozone depletion (Ravishankara et al., 2009). The development of new approaches to increase agricultural efficiency and potential mitigation pathways are required in particular in the context of the continuing population growth.

In soils, N2O is mainly produced through the microbial processes of denitrification and of nitrification. The last step of the denitrification process (N2O → N2) is currently the only known pathway for the terrestrial removal of N2O. N2O reduction is catalysed by the N2O reductase enzyme encoded by the nosZ gene (Viebrock and Zumft, 1988). The efficiency of soils to reduce N2O to N2 is highly variable. Soils with low N2O reduction potential have also been observed to emit high levels of N2O on a field scale (Hénault et al. 2005). We developed strategies to mitigate N2O emissions from agricultural soils based on the stimulation of the microbial process of reduction of N2O to N2. We therefore developed two different approaches for promoting the biological reduction of N2O in soils.

The first one, is based on the results previously obtained by Sameshima-Saito et al., 2006 who had observed that Soybean roots nodulated with Bradyrhizobium japonicum USDA110, carrying the nosZ gene, were able to remove low concentrations of N2O. We studied the consumption of N2O by strains of Bradyrhizobium japonicum (USDA110 and MSDJ G49) on inoculated soybean plants cultivated in soil pots during a greenhouse experiment. During this experiment, we switched from a system acting as an N2O source (soil + soybean inoculated with a nosZ gene depleted strain) to a system acting as an N2O sink (soil + soybean inoculated with strains carrying the nosZ gene). Calculations using the obtained quantitative results clearly suggest an environmental benefit of nosZ+-nodulated leguminous on the field scale, with an assessed abatement of field emission of 60 % during the investigated period, (Hénault and Revellin, 2011).

The principle of the second approach is to understand the physico-chemical determinism of the N2O reduction in soils and then to manage these conditions to promote N2O reduction. Around 100 soil samples of the RMQS, the French Soil Quality Monitoring Network, were sampled and analysed for determining their physico-chemical conditions associated to their capacity to reduce N2O into N2. Soil pH was observed as an essential determinant of the capacity of soil to reduce N2O, this capacity increasing with soil pH. A field experiment was then set up on an acidic soil, receiving calcareous amendment. We observed a pH increase followed by an increase of the soil capacity to reduce N2O and at the same time a reduction of soil N2O emissions at the field scale, with an observed abatement of field emission up to 50 % during the investigated period.

The management of the biological reduction of N2O into N2 appears possible both by biological (inoculation of leguminous crops by strains having a functional nosZ gene) or physico-chemical (pH management) actions. A stimulation of the N2O reduction function in soil allows mitigating soil N2O emissions. These both approaches are very interesting because they don't create any transfer of nitrogen pollution in environment and because they do not compromise agricultural production of proteins. Their

economic aspects are currently investigated.

These studies are supported by the ADEME (SOLGES project), the Conseil Regional Centre Val de Loire (PUIGES project) and the Labex Voltaire (ANR-10-LaBX100-01).

P-2225-07

Climate Smart Adaptation on Lake Kariba: A Case Study of Siavonga District

M. Kabisa (1)
(1) University of Zambia, Geography and Environmental Sciences, Lusaka, Zambia

Siavonga district has for the last two decades experienced declining, unpredictable and poorly distributed rainfall and experiencing climate change impacts. Climate impact studies on Lake Kariba Kapenta fish stocks show increased temperature and reduced rainfall are the main climatic factors affecting fish catch. This has led to reduced primary productivity, fish productivity and resulted in reduced Kapenta fish catch. These studies however, have not considered resource users perceptions and their adaptation to climatic variability and change.

The adaptation strategies of Kapenta fishers to climate variability and their perceptions were investigated in Siavonga district, using primary data collected by a structured questionnaire, interview schedule and secondary data. A random sampling technique was used to select 90 Kapenta fishers on Lake Kariba. Descriptive statistics, Multiple Regression Analysis, Pearson Correlation Coefficient and a Likert scale were used to analyze the data collected.

Strategies employed by the Fishers to adapt to impacts of climate variability included no adaptation (9.5%), shifting fishing times (28.8%), fishing for longer time periods (38.4%), fishing in waters further away than before (69.9%), changing fishing gear (8.2%), catching smaller fish (8.2%), alternative livelihoods (5.5%) and 'Other' specified options (6.8%). About 64.3% of the strategies used have the potential to be climate-smart as they comply with Climate-Smart Agriculture Sourcebook by FAO (2010) and Principles of the Code of Conduct for Responsible Fisheries Management.

The fishers who were adapting did not all exclusively use one strategy. Based on the number of strategies employed, 36 respondents (44.6%) used a single strategy, 27 respondents (33.9%) used two, 12 respondents (14.3%) used three, 4 respondents (5.4%) used four and 1 respondent (1.8%) used five adaptation strategies. This implies that the fishers are diversifying ways to deal with climate impacts on the catch and use a variety of strategies depending on which option is available at the time.

The respondents noted that there were constraints to adapting to climate variability. A total of 66 (82%) of the adapting fishers stated that they faced some difficulties in adapting. Of these, 48 respondents (60%) cited a lack of money as being the main constraint to adaptation and 24 respondents (30%) cited other reasons.

A total of 79 Kapenta fishers (87.7%) were aware of climate variability. In terms of the amount of rainfall in the district, 44 respondents (49.2%) perceived a decrease and 25 respondents (27.9%) perceived an increase. In terms of temperature, 31 respondents (34.4%) stated there was an increase and 10 respondents (11.5%) perceived a decrease. About 15 respondents (16.4 %) perceived an increase in Kapenta catches and 53 respondents (59%) perceived a decrease in catches. The Regression model gave an R2 value of 0.195. Multiple Regression analysis showed that Age ($p \leq 0.01$), Years of Fishing Experience ($p \leq 0.024$) and Access to Extension services ($p \leq 0.054$) have the most significant relationship with perceptions as well as having the highest Beta values contributing to perceptions to climate variability. Pearson correlation coefficients showed that the independent variables are not highly correlated. They had a range of values between -0.273 and 0.066, which are below 0.3, indicating a small strength of association.

P-2225-08

Revamping Agriculture Sector through Sustainable method: Using Solar Water Pumps in Punjab state (Study of selected Districts)

R. Kaur (1)
(1) Panjab University, Public Administration Department, Mohali, Punjab, India

Abstract- Sustainable agriculture is the activity oriented concept to produce food in a suitable quality and quantity and guarantee food security for the world. Land use, crop choice, irrigation, and fertilization should be done in such a way that it should not lead to land degradation and desertification. India's irrigated agriculture sector plays a significant role in India's economic development as 28% of India's GDP and 67% of employment is based on agriculture. The reliable irrigation is a critical demand as farmers in India are facing issues like erratic grid supply, increasing unreliability on monsoon rains and high cost of diesel pumps. The availability of less than 1000 cubic metre per capita is considered as scarcity as per International Standards and remedial measures. Government of India at union level and State Governments had formulated certain policies and programmes to overcome this issue and launched Solar Water Pumps (SWP) as a solution to irrigate fields adequately as it is environmental friendly and cost effective. Presently, Punjab state food grain production has failed by 16.65 million tonnes to meet its target as Punjab face problem of less energy generation for farms. Ministry of New and Renewable Energy in coordination with other governmental agencies and state nodal agencies like Punjab Energy Development Agency (PEDA) have implemented SWP schemes for improving irrigation system to increase production of food grain.

An attempt will be made through this to analyse need and scope of the implementation of SWP scheme in state of Punjab for sustainable irrigation to increase crop production. The main objective of the study is to evaluate the extent of scheme in creating awareness among population involved in agriculture while considering the perception of beneficiaries towards their installation process to meet their requirement of energy. Paper will also discuss involvement of Government machinery involved in enforcement of scheme and will suggest measures to improve irrigation through SWPs. Primary and secondary sources will be used in the proposed research paper. The primary data will be taken from two districts, Gurdaspur (max, SWPs installed) and Fatehgarh Sahib (min SWPs installed). 100 farmers will be selected as sample size for survey (50 from each district). Secondary data will be collected from annual reports of PEDA, e- Journals and other Government documents. Paper is beneficial for Government agencies and Research Scholars.

P-2225-09

Barriers to linking mitigation and adaptation in smallholder farming systems: lessons from maize cultivation among Mayas in southern Belize

R. Kongsager (1)
(1) UNEP DTU Partnership, Copenhagen, Denmark

Linking of adaptation and mitigation in agriculture is proposed as a necessity, as the sector will need adaptation to resist future climatic changes, and because high emissions from the sector contribute significantly to climate change. This study investigate the barriers for making adjustments in the maize production among Maya communities in Southern Belize. It is an exploratory case study based on qualitative interviews and field observations, where four low external input adjustments that potentially will result in both adaptation and mitigation benefits were suggested. The findings show that adjustments to enhance the adaptation-mitigation link in small-scale maize production in Maya villages in Southern Belize are possible in principle, however several of the barriers can make the overall climate-smart objective difficult to implement in practice. The barriers are of proximate and indirect nature, exist at different spatial scales and involve various governance levels. Land tenure, market access, and changes in the traditional culture are shown to be some of the barriers, but it is also demonstrated that barriers are not homogenous across the villages in the region. An

overall district level strategy for enhancing the adaptation and mitigation link is possible, but the toolbox should contain a wide variety of approaches. Which could happen, for instance, through alterations of the land tenure and land taxation system at the national level, enhancement of the agricultural extension system to ease the access to knowledge and input at district level, and by supporting a less complex governance structure at village level.

P-2225-10

Tropical climate-smart soil conservation technologies for agro-ecosystem resilience

S. Mesele (1) ; H. E.j. (1) ; A. J.o. (2)

(1) International Institute of Tropical Agriculture, West Africa Soil Health Consortia, Ibadan, Oyo State, Nigeria, Federal Republic of; (2) Federal University of Agriculture, Soil science and land management, Abeokuta, Nigeria, Federal Republic of

Enhancing resilience in ecosystem changes for improved agro-ecosystem services is a prerequisite for sustainable land management. Sustainable land management in the context of climate change presents great potential for protection and enhancement of ecosystem services in all land use systems. The degradation of water, soil and vegetation, as well as greenhouse gas emissions contributing to climate change can be significantly abridged by climate-smart soil conservation technologies that simultaneously conserve natural resources and increase crop yields. These climate-smart soil conservation technologies are however scattered and poorly documented in the literature with varying levels of adoption among the smallholder farmers who are the backbone of tropical agriculture. This paper therefore reviews different soil conservation technologies that have been found effective in different agro-ecological zones, and with the capacity to enhance resilience in tropical agro-ecosystems. These technologies were grouped into improved farming system technologies, soil cover/residue management technologies, cropping system technologies, soil management technologies, soil fertility amendments technologies, and mechanical field technologies. The need for further research, extension and appropriate policy formulations on these technologies were further highlighted. It was concluded that no single technology is best for any particular area in the tropics but a combination of two or more technologies or systems within the technologies may be very effective and productive in terms of increased crop production and sustainable land management, particularly, within the socio-economic competencies of smallholder farmers.

Climate-smart agriculture and cocoa: engaging with farmers and their supply chains in Ghana

S. Muilerman (1) ; C. Bunn (2) ; H. Kirscht, (3) ; L. Jassogne (4) ; M. Lundy, (2) ; P. Läderach (5) ; P. Van Asten (4) ; G. Schroth, (6) ; R. Asare, (1) ; NA. Anyidodo, (7)

(1) International Institute of Tropical Agriculture, West Africa, Accra, Ghana; (2) International Center for Tropical Agriculture, Cali, Colombia; (3) International Institute of Tropical Agriculture, Yaoundé, Cameroon; (4) International Institute of Tropical Agriculture (IITA), Systems agronomy, Kampala, Uganda; (5) International Center for Tropical Agriculture (CIAT), Ciat - asia, Hanoi, Vietnam; (6) Rainforest Alliance, A, Brazil; (7) University of Ghana, Institute of statistical, social and economic researc, Legon, Ghana

Global demand for cocoa has been increasing 2-3% annually, especially due to growing demand in Asia. The cocoa industry is challenged to produce the additional million tons required over the next years. The historic growth model for cocoa, especially in the Upper Guinea Rainforest areas, was largely based on successive waves of migrant cocoa farmers moving into virgin forests. With less than 15% of the original forest cover remaining in West Africa, this model has collapsed. Recent studies have revealed that climate change further threatens the current production zones, negatively impacting production if nothing changes. Sustainable, profitable and climate-smart intensification is required, not only to sustain the global industry, but also the livelihoods of its smallholder producers. Previous recommendations to improve productivity, including full-sun or low shade intensified cocoa, today apply to an ever-decreasing group of cocoa producers who have the necessary resources for this type of farming; moreover, it may increase the vulnerability of cocoa farmers to climate change. Availability and access to the right agro-inputs is necessary but insufficient to prepare farmers for climate change. Success raising productivity has been achieved especially in Ghana's last cocoa frontier, the Western Region, which has been the prime focus of vast government subsidy and distribution schemes. However, demonstrated yield growth figures could not sustainably be scaled to a national level. This is also clearly demonstrated by the persistence of a 50 to 75 percent yield gap for cocoa under on-farm compared to on-station conditions. Climate-smart cocoa initiatives will not only need to look at the farming systems (incl. crop diversification to buffer farmers against market, policy and environmental risks), but will also need to take on an integrated value chain approach. Proposed solutions will need to be adopted at scale, based on real-world incentives and resonating with a diverse landscape of stakeholders. Awareness needs to be raised by the identification of exposure levels and ranking of potential impacts that may vary significantly across the country and region. Relevant climate smart practices will need to be disseminated using appropriate vehicles to reach scale, e.g. by linking with existing training programs and impact investors to reach producers and their organizations. With the age of the average cocoa farmer being about 50 years, adapting for the future will also require the industry to make smallholder cocoa farming more attractive and accessible for younger farmers with strong climate smart business models. To confront all these challenges we present an inclusive approach that unites stakeholders throughout the value chain and marries existing value chain interventions focused on changing farmer practices and the provision of innovative financial vehicles with climate science. Our approach tests new methods for identifying and scaling site-specific and appropriate CSA practices, assessed against the risks of exposure on a climate change gradient, which are then mainstreamed into voluntary certification schemes and linked to impact investment in producer organizations.

P-2225-12

Exploring socio-economic and bio-physical indicators for trade-offs in Climate Smart Agriculture adoption: a case study from Tanzania and Uganda

C. Mwongera (1) ; L. Winowiecki (2) ; K. Shikuku (1) ; P. Läderach (3)

(1) International Center for Tropical Agriculture, DAPA/Soils, Nairobi, Kenya; (2) International Center for Tropical Agriculture, Soils, Nairobi, Kenya; (3) International Center for Tropical Agriculture (CIAT), Ciat - asia, Hanoi, Vietnam

The contribution of climate smart agriculture (CSA) in the achievement of sustainable development goals under climate change cannot be overemphasized. CSA sustainably increases productivity, enhances resilience, lowers greenhouse gas emissions, and enhances achievement of national food security. In employing CSA, a critical gap lies in the understanding and correct representation of trade-offs across temporal and spatial scales to inform decision makers. The challenge is greater in smallholder farming systems in East Africa, implied by their highly diverse and complex bio-physical and socio-economic environments all of which produce multiple livelihood strategies, opportunities, and constraints for agricultural productivity. Unlocking the indicators for trade-offs in these production system is key in understanding prospective or ex-ante effects of technology changes and the bio-physical, social and economic outcomes under climate change.

We illustrate key bio-physical and socio-economic indicators for trade-offs in CSA adoption, across diverse landscapes drawing on household surveys in four districts in the Acholi sub-region of northern Uganda and four districts across the Southern Agricultural Growth Corridor of Tanzania in 2014. The data revealed key indicators include yield, input use, gender-disaggregated labor, off-farm employment, asset poverty, on-farm food security and soil health. The indicators varied across and between sites. In addition we use the indicators to show the tradeoffs in CSA adoption between economic outcomes (greater farm income) and environmental and social outcomes (increased environmental health, reduction in poverty levels, reduced labour demand) across landscapes and to determine the likelihood that farmers will adopt

new practices. For instance farmers are less likely to make changes during months of food insufficiency as they engage more in off-farm employment. In addition ownership of farm assets enhances the uptake of CSA. Some practices such as slash and burn, common in northern Uganda lower soil quality with negative impact on adoption of CSA practices. Engaging heavily in off-farm employment can be an indication of low farm income and willingness to change current practice. In other contexts CSA might require more time spent on the farm reducing the likelihood of engaging in off-farm activities. Farmers with better soil health were generally more willing to adopt CSA practices that in areas with high land degradation. Socio-economic attributes such as higher off-farm income, high education levels, good technical knowledge and high social preference also increase the likelihood of CSA adoption.

This analysis revealed key barriers for each of the communities that need to be overcome in order to implement and out-scale adoption of locally appropriate CSA practices as well as the importance of assessing the spatial and social context. The study highlights that assessing bio-physical and socio-economic trade-offs indicators across diverse environments could help to better target CSA farming systems to foster adaptation to climate change.

P-2225-13

Exploring solutions in response to Biosinvasions threatening agroecosystems under climate change scenarios: pest/predator adaptation and biodiversity management of acarofauna as an example

M. Navajas (1) ; MS. Tixier (2)

(1) Institut National de la Recherche Agronomique, Umr cbgp (inra / ird / cirad / montpellier supagro – centre de biologie gestion des populations, Montferrier-sur-Lez, France; (2) Montpellier SupAgro, Umr cbgp (inra / ird / cirad / montpellier supagro) – centre de biologie gestion des populations, Montferrier-sur-Lez, France

Under climate change scenarios, increasing ecological and climatic stresses create new conditions posing a major threat to global agriculture. Particular relevant are invasive alien species introduced into agroecosystems where they often grow into destructive pests. The examples of bioinvasions threatening agricultural systems are unfortunately frequent and their number is expected to increase. Processes of range expansion and adaptation of pests but also natural enemies are fundamental for understanding the impact these organisms have or will have on populations, communities and ecosystems under new climatic conditions. These issues are here addressed taken as an example the acarofaune in crop solanaceous systems in the Mediterranean region. A focus is done on an invasive spider mite, Tetranychus evansi. While considered to be native to South America this tropical species has emerged as a new damaging pest in more temperate areas of the planet, in Europe and in other continents. Population genetics approaches unrevealed that colonization routes of the mite are complex. By distinguishing among multiple pathways and timing of introductions, there is evidence for different genoyptes of T. evansi responding to climate in distinct ways, affecting the ability of populations to adapt and being invasive. The effect of climate change affecting future range shifts is taking in consideration by using niche distribution modelling under several climatic scenarios. By exploring plant protection strategies along with predicting pest adaptation, much effort has been done on classical biological control to find native predators (Phytoseiidae mite family) in the area of origin of the pest, but none are completely efficient. Also, the introduction of exotic natural enemies is more and more questioned, in an environmental side effects point of view. More relevant would be to explore how the agroecosystem diversification could be managed to limit pest species abundance (under the resource concentration hypothesis) and to enhance natural enemy diversity and abundance (under the natural enemy hypothesis). To exploit natural biodiversity but also predicting the species potential for range expansion under new climatic conditions, appear as highly informative to advance adapted strategies for climate-smart agriculture.

P-2225-14

The Dynamics of East African Climate and the Suitability of crop Mapping over the Mountainous Areas in a changing climate

G. Otieno (1)

(1) university of nairobi, meteorolgy, nairobi, Kenya

The East African region is bordered by mountains that are crucial in modulating the climate of the region. The current evidence of climate change and climate variability poses risks to the sustainable development of the society.

The study examined trends in projected rainfall and air temperature and suitability of growing major staple food under a changing climate around the mountainous areas of Kenya, Uganda, Tanzania and Ethiopia.

The data used were observed rainfall, temperature datasets, the second version of African Rainfall Climatology (ARC2) for the period 1981-2010 and future projection from 2011-2040. The downscaled model estimates of future climate scenarios under Representative Concentration Pathway (RCP 4.5) from Coupled Model Inter-comparison Project Phase 5(CMIP5). The Mann-Kendal test was used for trend analysis and the FAO ECO-crop model was used for suitability mapping of various agricultural zones for production of maize and beans at the lowlands and down slope of the mountainous areas.

At least ten stations indicated a temperature rise of 0.3 per decade. High seasonal rainfall variability was experienced during March-May and October-December seasons. The values of Mann-Kendal were in the range of 0.8 – 2.0. The projection showed that temperature will continue to rise by about 0.5 per decade.

There was marginal suitability for production of beans and maize over most parts of the four countries. Most of the western and central part of Kenya showed high potential for production of the two crops. This trend was also reported in central Part of Uganda and coastal area of Tanzania.

The future suitability mapping for crops production showed quite similar patterns as the current situation. The highland and rift valley regions would no longer be suitable for growing the crops. The increased human activities around these regions like deforestation probably could account for the decline in suitability of growing these crops.

The threats from climate change are likely to impact negatively on the agricultural activities around the mountainous areas. The farming community living around the slopes of the mountainous areas should diversify the farming activities and best practices to cope with current climate variability and adapt to future climate changes.

P-2225-15

Climate smart rice practice under drip irrigation

T. Parthasarathi (1) ; V. Koothan (2) ; S. Mohandass (3) ; V. Eli (4)

(1) Tamil Nadu Agricultural University, Crop Physiology, Coimbatore, India; (2) Tamil Nadu Agricultural University, Tamil nadu rice research institute, Aduthurai, India; (3) Tamil Nadu Agricultural University, Department of crop physiology, Coimbatore, India; (4) Netafim Irrigation Ltd, Agronomy chief, Israel, Israel

Drip irrigation studies were conducted in aerobic rice during Dry Season (DS), 2011 Summer Season (SS) 2012 and Summer Season (SS) 2013 in Coimbatore, Tamil Nadu, India. Drip irrigation treatments comprised of three levels of lateral distance (0.6, 0.8 or 1.0 m lateral distance) with the two discharge rates (0.6 or 1.0 L h-1 emitters) in DS 2011. In SS 2012, 2013 the micro irrigation treatments namely; surface, sub surface drip irrigation (SDI) and conventional aerobic rice practice. Among the lateral distances, 0.8 m lateral distance registered as the optimum spacing for the better performance in root characters, growth and yield attributes than rest of the lateral distances. From the surface-drip and sub-surface drip irrigation (SDI) treatments, the SDI performed better in terms of root character, growth and yield attributes. Interactively,

laterals spaced at 0.8 m with 1.0 L h-1 drippers laid sub surface-drip through fertigation exhibited better performance in terms of root parameters (such as root length, Root Mass Density, root biomass and root volume) along with growth attributes (Leaf Area Index, Specific Leaf Weight, Crop Growth Rate and Net Assimilation Rate), yield and its components (such as productive tillers, spikelet numbers, filled grain percentage and Harvest Index) along with water saving when compared with the conventional irrigation treatment. Drip irrigated plants emitted lesser methane over the others. Therefore, it is suggested that the lateral spacing of 0.8 m with 1.0 L h-1 drippers under SDI through fertigation is adjudged as a climate smart practice for enhancing the values for water productivity, grain yield and reducing methane emission in areas of limited water availability.

P-2225-16

Private Sector Actions to Enable Climate-Smart Agriculture in Small-Scale Farming in East Africa

S. Quail (1) ; L. Onyango, (2) ; J. Kinyangi (3) ; J. Recha (4)
(1) University of Florida, School of forest resources and conservation, Gainesville, United States of America; (2) Maseno University, Urban and regional planning, Maseno, Kenya; (3) ILRI, Ccafs east africa, Nairobi, Kenya; (4) International Livestock Research Institute, Climate Change, Agriculture and Food Security, Nairobi, Kenya

Climate change is projected to disrupt food production in East Africa, in particular for small-scale farmers; however, adoption of agricultural innovations is linked to improved food production and food security, which in turn, will help farmers adopt to altered weather patterns. Agricultural innovations are comprised of practices that increase crop productivity and improve the natural resource base that crops are grown on that improve the resilience of agricultural systems. Access to equipment, farm tools, tree seedlings, seeds, agrochemical inputs, etc. – all which are channeled through private sector entities – are needed for the realization of those innovations. Moreover, dissemination of climate information and improved farming practices needed for climate smart agricultural landscapes, which typically fall under the purview of government extension, may be more effectively diffused through the private sector.

The private sector plays the most important role in financing agricultural investments, innovation and information dissemination where constraints on government investment render private sector actions all the more important. In East Africa, little is known about the participation of small businesses, independent traders, farmer organizations, large-scale wholesalers, marketing boards and cooperatives in climate-smart agriculture (CSA) and its diffusion to small-scale farmers. In particular, small companies and the informal sector are out of view. Yet such information is critical in exploring how best to harness private sector comparative advantage to benefit the food security of small-scale farmers in East Africa impacted by a changing climate. This study is an attempt to fill this research gap and examines patterns of, and incentives for, private sector investments and activities in climate-smart agriculture at three pilot projects implemented by Climate Change, Agriculture and Food Security (CCAFS) in Nyando, Kenya; Hoima, Uganda; and Lushoto, Kenya.

This research uses social network analysis (SNA) to examine relationships between private sector actors and farmers to visualize and interpret patterns of networks for information services for the following areas: climate, crop and livestock extension, credit and banking, and legal. It also examines supply chains of agricultural inputs, as well as agricultural product value chains. Focus group discussions and surveys were administered to 289 farmers. Local businesses were also interviewed. This study also examines local-level linkages with national agricultural organizations to determine if the latter play a role in facilitating climate-smart agriculture.

Preliminary results suggest that independent traders dominate trade in all sites and that even though the supply of inputs is sufficient, farmers often lack access to credit. Also, distinctive differences exist in terms of the concentration of business activity amongst local actors and the diversity of marketable crops produced. The efforts of Kenya's National Farmer's Federation to establish locally based farmer's groups is reflected in its highly diversified groups that grade amongst themselves, in contrast to Uganda where a select few dominate locally traded agricultural output. Lushoto's proximity to Dar es Salaam is evidenced in its high number of independent traders, and to a lesser extent, locally registered businesses. Despite its high level of trade, it is also the least food secure of the three sites. The results indicate that while independent traders focus primarily on the trading of crops, they do disseminate information relevant to climate smart agriculture suggesting that efforts to strengthen this sector is important. Finally, the implications of these findings for food security are discussed. This study demonstrates that social network analysis is an important tool for identifying which private sector actors can be strategically targeted for strengthening efforts to scale up climate-smart agriculture and where weaknesses in input and output supply chains exist.

P-2225-17

Promoting Climate Smart Agriculture along the Coastal Belt of Bangladesh Using ICT

MA. Rahaman (1) ; MA. Aslam,s. (2)
(1) ADAMS, Climate Change, Khulna, France; (2) ADAMS, Executive board, Khulna, Bangladesh

Bangladesh is a small country and the highest densely populated country in the world which is vulnerable to different types of environmental disasters. The major disasters and environmental vulnerabilities are floods, water stagnancy, droughts, cyclone, tidal surge, river erosion, salinity, extreme temperature and low light intensity, pests and diseases etc. The vulnerabilities due to climate change are likely to aggravate more in the future. These catastrophic events significantly hinder the agriculture production systems, economic and social development of the country firstly, through damaging the crops, livestock, fisheries and agro-forestry, natural resources, establishments and infrastructures and secondly, pulling back the on-going developments, business and trade at local, regional and even global levels. Costal areas are mostly inhabited by the poor and disadvantaged groups. Usually coastal belt is flooded from May/June to November/December. Salinity also restricts agriculture in the coastal areas. In the Coastal Zone, crops are lost due to water stagnancy/standing flood water or tidal surge during July/August-November/December (5-6 months) in wet seasons. On the other hand, during winter salinity is major threat to agriculture in this area. During summer season, due to lack of irrigation availability, farmers can not produce crops in their lands. The aim of the action research is to ensure food security of ultra poor climate vulnerable farmers promoting climate-smart agricultural system using ICT in costal belt of Bangladesh. The study was conducted in flood and saline prone Bagerhat District of South-West Coastal region of Bangladesh adopting establishment of Climate-smart Agricultural Information Centre; generating local agro-meteorological, soil and hydrological information; developing and regular updating customized software on generated information; dessiminating seasonal agro-meteorolical, soil and hydrological informatinon relating to crop suitability using cellular phone, community radio message and mobile internet; educating farmers on ICT and climate resilient agricultural system, soil health, flood & saline tolerant varieties. Based on the empirical findings, the study reveals that ICTs are powerful tools in climate-smart agricultural development. Radio, cellular phone and mobile internet are strong platform in interaction between farmers and climate change experts. It made a tremendous improvement in climate-smart agricultural promotin in the study area.

Floating Vegetables Gardening: Climate Smart Agriculture Technology for Food Security in Tidal Flooded Area of Southern Bangladesh

MA. Rahman (1)
(1) Bangladesh Agricultural Research Institute (BARI), Division of Agronomy, Barisal, Bangladesh

Bangladesh is ranked as one of the most climate-vulnerable countries in the world, where agriculture is the most climate sensitive sector. The consequences of

climate change concerned here are: floods, intrusion of soil and water salinity, sea level rise and tropical cyclones, which are major constraints for sustainable agricultural production in Bangladesh. The coastal area covers about 23 percent of the country and lies on the 'front line' of climate change and sea level rise. Most of Bangladesh is less than ten metres above sea level, with almost ten per cent of the country below one metre, making it extremely vulnerable to increasing high tides. Intergovernmental Panel on Climate Change predicted that about 17% of the country's landmass could be inundated with a one metre rise in sea levels in Bangladesh (IPCC'S AR5, 2014). Therefore, climate change adaptation measures must be taken for improving the food security of the people. The coastal area adjacent to sea-bank in southern region of Bangladesh remain under submerge condition for a long period (generally from June to December) during monsoon season or even all the year round due to tidal flooding and erratic rainfall. As a result, there is no scope of crop cultivation on this land naturally that hampers the crop production as well as food security severely particularly for the vulnerable poor people. To cope with the situation, the farmers of tidal flooded area have been practicing a climate smart technology of soilless vegetables gardening since two centuries, which is locally known as "Vasoman or dhap chash," meaning "Floating Agriculture" (similar to hydroponics). In considering its innovativeness, a study was conducted using questionnaire tool among the randomly selected farmers (n=150) in three southern districts (Gopalganj, Pirojpur and Barisal) of Bangladesh during 2012-14 to assess the agro-economic performance of floating vegetables gardening and its potential for adaptation to climate change in the country. The floating bed is built up with various types of local materials and the single most important component is water hyacinth (Eichhornia crassipes), but topapana (Pista stratiotes), dulali lata (Potamogeton alpinus), son ghash (Imperata cylindrica), noll ghash (Hamerthria protensa), aquatic algae (Nitella sp.) wood ash, and dissected coconut fibres are also used for floating bed preparation. A large number of people are involved with this business for supplying the local materials to the farmers. Size of the floating bed varies over district ranges from 15-45 meter long, 1.2-1.5 meter breadth, and 1.0-1.2 meter height. The floating beds lift up with rising of tidal flood water level without any damage. Farmers of Gopalganj district usually grow different vegetable crops (okra, Indian spinach, bottle gourd, bitter gourd, tomato, brinjal, snake gourd, cucumber, ridge gourd, yard long bean, water melon, musk melon, chilli, etc.) on floating bed during monsoon season without using any fertilizers and pesticides. However, seedlings of above stated vegetable crops are produced on the floating bed in Pirojpur and Barisal districts. Seedlings of vegetables are grown for 3 to 5 times/bed/monsoon season (June-October), where 1000-1200 seedlings/bed are grown in a time. Before growing of vegetables and/or seedlings on floating bed, a series of backward tasks (media ball preparation, seed sprouting and set-up, primary nursing etc.) are done mostly by women at homestead nursery. After vegetables cultivation, the decomposed floating beds can be used as compost for succeeding crop production that saves the use of chemical fertilizers as well as environment. The seedlings are sold at local market of nearby districts for income generation (average net return USD 20/bed). Floating gardening provides fresh vegetables for household consumption of the local people and the surplus amount of the product are sold at the local market to earn some cash particularly for the women. Thus, the technology has the potential to provide a means of income and food security for the millions of small households who have no access to plan land but live close to large bodies of water in southern region. The local innovative technology (floating gardening) may be recognized as agricultural heritage as well as suitable adaptation option in considering its environmental and social aspects in Bangladesh. Therefore, the floating vegetables gardening have been considered as a climate smart agriculture technology for food security in southern region of Bangladesh.

Multi-Criteria Decision Analysis (MCDA) Technique a Tool for Assessing and Comparing Sustainability of Climate Smart Agriculture Systems with Conventional Agricultural Systems

B. Talukder (1) ; A. Blay-Palmer, (2) ; GW. Vanloon (3) ; KW. Hipel (4) ; R. Milne (5)

(1) Wilfrid Laurier University, Geography and Environmental Studies, Waterloo, ON, Canada; (2) Wilfrid Laurier University, Waterloo, Canada; (3) Queen's University, School of environmental studies, Kingston, Canada; (4) Waterloo University, System engineering department, Waterloo, Canada; (5) Wilfrid Laurier University, Department of geography and environmental studies, Waterloo, Canada

Assessing and comparing sustainability of climate smart agriculture (CSA) systems with conventional agricultural (CA) systems is essential for future policy and planning of CSA. In this paper we proposed a holistic approach based on MCDA methodological approach that helps to assess and compare CSA with CA. Through a case study from south west coastal region of Bangladesh the sustainability of CSA and CA are assessed and compared. To assess and compare of CSA and CA the indicators were developed based on productivity, stability, efficiency, durability, compatibility and equity categories of sustainability of agricultural systems. To develop indicators, data was gathered through questionnaire survey, secondary information, focus group discussion and key informant interview. The indicators of six categories of sustainability were assessed and compared through weighting and aggregation methods of MCDA. The findings of this research work demonstrate the overall sustainability status of CDA and CA. The results of the study show that this approach has the potential to become a useful framework for agricultural sustainability assessment of CSA.

The Future of Emerging Diseases Under Climate Change: Current Knowledge and Synergistic Solutions for Health and Sustainability

C. Machalaba (1) ; JF. Guégan (1) ; WB. Karesh (1) ; P. Daszak (1)

(1) Future Earth ecoHEALTH, New York, United States of America

Climate change is anticipated to pose serious threats to public health this century. Infectious diseases present an especially relevant health consideration, as they currently cause over one billion human cases and millions of deaths annually. In particular, in many cases emerging infectious disease (EID) outbreaks in humans, which may be novel or appear in a new region, are sensitive to climate variability. On a micro level, temperature and precipitation-dependent pathogen development cycles may affect the basic reproductive rates determining pathogen survival and spread in a population, and may similarly affect suitable habitat range of its competent host(s). On a macro level, however, EIDs are dependent on a wide range of factors, and thus climate cannot be viewed in isolation when assessing risks. Rapid changes to ecosystems and resulting alteration in composition and abundance of species, as well as anthropogenic practices that are facilitating increased and novel human-animal contact, pose complex biotic dynamics that interface with abiotic climate variability. Given that changes in land use (e.g. deforestation), agricultural production, and global trade and travel are among the leading causes of disease emergence, and overlap with the underlying drivers of biodiversity loss as well as the major direct contributors to greenhouse gas emissions, integrated solutions can be taken to address challenges of all three. From the work of the Future Earth ecoHEALTH project and its partners, we highlight findings from ecological niche modeling for disease such as Nipah virus and malaria to examine the different dimensions of EID risks over the coming century, and propose near and long-term solutions that can mitigate known risks and better anticipate future risks where research gaps remain. Given the high economic impact of recent EID outbreaks, we also identify priority areas of collaboration with other sectors, including on strategies for land use and agricultural production, to minimize future burden of EIDs while simultaneously promoting a sustainable future.

Introduction
Dengue fever (DF) is a serious and potentially life-threatening infection acquired through the bite of infected Aedes aegypti mosquitoes and responsible for major outbreaks in French Guiana. DF transmission is driven by complex interactions between hosts, vectors and viruses that are influenced by environmental, anthrogenic and climatic factors which results in annual seasonality and multiannual variability. Although the onsets of outbreaks seem to be associated with the start of the rainy season, the mechanisms involved in the occurrence of epidemics are not well understood. With the objectives of explaining and predicting DF outbreaks occurrence in French Guiana, we explored the impact of climatic factors on DF epidemics at different spatial and temporal scales in French Guiana.

Methods
For this analysis that covers the 1991-2013 period, we used biologically confirmed DF epidemiological data, climatological parameters including Niño and NAO indices, atmospheric reanalysis gridded data and meteorological stations record including rainfalls, temperatures, relative humidity, sunstroke average and wind force.

We sudied the association between incidence of DF and climatic variables to identify temporal predictors of DF outbreaks. Year-to-year disease variability was investigated by linking atmospheric and oceanic synoptic patterns to the epidemiological regional context. Finally, contextual sequential patterns extraction techniques were used at local scale and weekly time step to identify the most significant climatic factors influencing DF incidence dynamics.

Results
From 1991 to 2013, more than 23,600 biologically confirmed DF cases were recorded in French Guiana and 8 major outbreaks were identified. Annual activity was characterized by a seasonal increase of incidence levels during the first quarter of the year. We found that outbreak occurrence can be linked with summer Niño conditions, 6 months before the onset of the outbreak. Furthermore, a statistical model based only on climate indicators indicated that 30% of the disease variance from year-to-year is explained by the dry season rainfall, forecasting epidemic years with a hit rate of 75% and a positive predictive value of 75%.

At regional scale, the outbreak onset in specific areas was frequently associated with a 4-6 week lag with an increase in the relative humidity, high levels of rainfalls and a decrease of temperature. During epidemic period, local specific weather conditions were not predictive of the epidemic peak, where a predominance of the cumulative incidence occurred.

Conclusion
Using complementary approaches at different geographic scales we explored the role of climate conditions to understand and predict DF outbreaks in French Guiana. Our findings will be useful to timely target appropriate public health interventions to mitigate the effects of major outbreaks, particularly in areas where resources are limited and the medical services may become overwhelmed by large epidemics.

This first successful step opens new opportunities in the DF risk prediction. Future work will be a more in-depth focus on influence of future climate conditions according to different scenarios of climate change on epidemiologic patterns.

Emerging/re-emerging infectious diseases with high epidemiological potential risks, lead public health managers to adapt their policies. Adaptation includes early knowledge of risks. The latter requires new tools to prevent re-emerging risks.

Infectious diseases such as Rift valley fever or malaria are closely tied to climatic and/or natural and anthropogenic environmental factors among which some could be identified using remote-sensing. Then they can be assimilated into bio-mathematical models thus allowing re-emerging risks' assessment. The French Spatial Agency (CNES) with its partners has developed a conceptual approach so-called Tele-epidemiology based upon studying climate-environment-health relationships with applicable products.

This multidisciplinary approach is based upon the study of the key mechanisms favoring the surge and spread of those diseases. Analysis of those processes is a key step in the development of new and original risk mapping using Earth observation satellite data. The primary mission is to show how those adapted space products could contribute to diseases surveillance policy and improve Early Warning Systems (EWS). The overall objective is to attempt predicting and mitigating public health impacts from epidemics.

This approach has been applied with success for malaria in Burkina Faso through the Paluclim project. This project was to apply the Tele-epidemiology conceptual approach linking climate, environment and vector-borne diseases such as malaria in the Sahelian region of Nouna (Burkina Faso). It was proposed to study the impacts of environment/climate variability on malaria entomological risk, a first step for risks of malaria outbreaks and then to analyze impacts from risks' forecasting.

The project objectives were to provide and validate dynamic entomological risk maps, then to study adaptation processes for controlling management, i.e., addressing the predicted risk, and to study the impacts of climate variability (from seasonal to low frequency climatic signals, including tendencies and climate change) on risks' forecasting.

To achieve these objectives, the Paluclim project integrated efforts from several teams and partners: CNES, Météo-France, Public Health Institute of the University Hospital of Heidelberg (Germany), Centre de Recherche en Santé de Nouna (Burkina Faso) representing the Health Ministry. As such it benefited from previous expertise and results obtained by the different partners in entomology, climate, environmental sciences, and in Tele-epidemiology. In this work it was shown that:

- based upon satellite (SPOT 5) and in-situ data it was possible to build an operational model to predict location of larvae sites and distribute dynamic maps on larval productivity for local villages ;
- based upon the larval productivity maps for targeted larvicide strategy could be implemented.

The added-values from the use of entomological risk maps were obvious in terms of additional element such as economical savings for decision makers. The use of larval productivity maps for larvicide treatment was perceived locally as extremely positive.

As of today, rainfall is the main meteorological driving parameter for the knowledge of vectors' density (which is used for the evaluation of entomological risk maps). The malaria entomological risk as a function of the weather/climate spatio-temporal variability was undertaken. An impact model was developed based upon an existing model (Graig's model), particularly efficient when resources are limited. The climate analyses were done for different temporal scales (i.e., seasonal, quasi-biennial, inter-annual, low-frequencies and climate change). The model could thus be used immediately on an operational mode. It was found that the new main driving factor for the upcoming years will be the temperature increase leading to a decrease of malaria risks (for at least the next 50 years), knowing that models have a hard time to predict rainfall variability in the near future.

Will climate warming decrease winter mortality in Europe?

J. Ballester (1) ; JM. Robine (2) ; FR. Herrmann (3) ; X. Rodó (1)

(1) Institut Català de Ciències del Clima, Barcelona, Spain; (2) INSERM, Démographie et santé, Montpellier, France; (3) Department of Rehabilitation and Geriatrics, Geneva medical school and university hospitals, Geneva, Switzerland

The steady increase in greenhouse gas concentrations is inducing a detectable rise in global temperatures. The sensitivity and degree of adaptation of human societies to warming temperatures is however a transcendental question not comprehensively addressed to date. Recent studies have pointed to improvements in housing, standards of living and healthcare systems as primary factors explaining the progressively decreasing year-to-year association between excess winter deaths and winter temperatures in economically developed societies such as Europe and the United States.

Here we show the link between temperature and daily numbers of deaths in nearly 200 regions in western Europe, which are subsequently used to characterize the spatial picture of human vulnerability to climate conditions in winter. Our analyses show that only the United Kingdom, the Benelux and northern France have successfully taken steps towards the adaptation to harsh winters, and that the Mediterranean and eastern countries, including Germany, Austria and Switzerland, still remain sensitive to intense cold seasons. Results however reveal that the countries exposed to the most extreme climatological conditions in winter are the least vulnerable to cold spell episodes, while the incidence of these events is again particularly damaging in the temperate regions of southern Europe.

The different sensitivity of European regions to cold temperatures highlights the kind of adaptation strategies that each country has already implemented, and reveals the actions that could potentially be taken in order to increase the overall life expectancy. In the light of our results, the European society will remain exposed to the natural and anthropogenically-induced climate variability in winter unless a substantial degree of adaptation to both intense cold spells and harsh winters takes place.

Achieving Health Dividends from Climate Change Mitigation Policies

A. Haines (1) ; J. Milner (1) ; R. Green (2) ; A. Dangour (2) ; P. Wilkinson (1)

(1) London School of Hygiene and Tropical Medicine, Social and Environmental Health Research, London , United Kingdom; (2) London School of Hygiene and Tropical Medicine, Population health, London , United Kingdom

There is growing interest in the range of co-benefits from well designed policies to reduce greenhouse gas (GHG) emissions. Importantly, many mitigation-related health impacts may accrue sooner than the benefits projected from reducing the magnitude of climate change and are subject to less uncertainty because the pathways linking the policy measures, changes in exposures and subsequent health outcomes are quite well established from epidemiological studies. A range of studies published over recent years have suggested significant net health benefits across several mitigation strategies in both high and low income countries. Studies estimating the ancillary health effects of mitigation strategies (while acknowledging that co-harms also may result) use a range of modeling approaches, and draw expertise from public health, agriculture, environmental sciences, nutrition, urban planning, architecture and other disciplines to generate policy-relevant outputs. Reductions in fine particulate air pollution, with major benefits to health, result from policies to reduce fossil fuel use - particularly reduced coal and diesel combustion. In the transport sector, policies which increase active travel (walking and cycling) would also reduce CO2 emissions and lead to substantial benefits, including for cardiovascular health, which would greatly outweigh increased risk of road traffic injuries. Interventions which increase energy efficiency in the housing sector have the potential to lead to considerable health benefits through improved internal temperatures during winter and protection against outdoor air pollution, as long as compensatory ventilation is provided to reduce exposure to indoor-generated pollutants. Relatively modest changes to dietary patterns can lead to substantial benefits for health and also reduce GHG emissions. However, drastic GHG reductions may require unpalatable modification of current diets. This presentation will give an overview of recent studies that have estimated the magnitude of health co-benefits from strategies to reduce carbon dioxide and short lived climate pollutants in the energy, transport, housing and food and agriculture sectors in high and low income settings. It will also discuss key methodological issues in designing studies. It will outline how valuation of health and other co-benefits can help offset the costs of mitigation policies and potentially make them more attractive to decision makers. Finally it will also consider potential co-harms of poorly designed policies and how such risks can be minimised.

Urbanization, Climate Change & Human Health A Study on Four Megacities of Urban India

J. Basu (1)

(1) West Bengal State University, Economics, Kolkata, West

Bengal , India

The World Bank in 2002 reported that in poor countries as much as 80 per cent of future economic growth occurred in cities and 60 percent of the world's population will be residing in cities by 2030. The increase in the average temperatures in the megacities in India is accompanied by the increase in population. The Third Assessment Report of the Intergovernmental Panel on Climate Change (IPCC) has focused that by 2100 the global temperature would increase by 1.8 °C–4 °C and which has effect on increased heat-related mortality and morbidity and greater frequency of infectious diseases like diarrhea, cholera and other bacterial diseases. The paper attempts to address the impact of precipitation in relation to human mortality pattern in India and the distribution of disease vectors like malaria, dengue and diarrhea diseases at the four megacities like Mumbai, Delhi, Kolkata and Chennai of India. In addition, the paper also attempts to establish the impact of urbanization on climatic variables like temperature and rainfall. The objectives of the paper are four fold. First, is to examine trends in summer temperature, monsoon temperature, post monsoon temperature and winter temperature at four megacities like Mumbai, Delhi, Kolkata and Chennai of India. Second, is to examine the impact of precipitation on the disease vector like malaria in India. Third, is to examine how climate change affects the distribution of disease vectors in the four megacities of India. Fourth, is to establish the relationship between urbanization and temperature change at four mega cities of India.

The paper utilizes time series data on temperature and precipitation, number of malaria deaths from the various reports of Indian Metrological Department for period 1978 – 2008. The analysis of trends in temperature at four largest cities is based on data for the period 1901–1991. Regression analysis is done to estimate the effects of precipitation on malaria cases. As the data set comprises time series in nature, before doing regression analysis we have applied unit root test and the Augmented Dickey Fuller test (ADF test) is employed for this purpose. After conforming the data are stationary we have applied regression analysis to show the impact of precipitation on malaria death.

In the univariate case, it is possible to view the stationarity of { Yt } as being dependent on the magnitude (a1–1), that is,

$$Yt = a\,1\ Y\,t{-}1 + \epsilon\,t \quad \text{---------- (1)}$$

$$\Delta\,Yt = \gamma\,Y\,t{-}1 + \epsilon\,t \quad \text{Where } \gamma = a\,1 - 1 \text{ ----------(2)}$$

In the presence of trend of drift the Dickey and Fuller equation can be written as

$$\Delta\,Yt = a\,0 + \gamma\,Y\,t{-}1 + a\,2\,t + \epsilon\,t \quad \text{----------(3)}$$

where a 0 and a 2 t represent the drift and time trend component respectively.

The result of the unit root test shows that death due to malaria (MDt) and precipitation (Rt) are stationary at the first difference. After checking stationary test we have regressed death due to malaria on precipitation.

The regression equation is given below

$$Log\ Kt = b\ Log\ Z\,t$$

Where Kt = Log MDt – Log MD t–1

Zt = Log Rt – Log R t–1

The result shows that there is a positive and significant relation between precipitation and death rate due to malaria. The higher is the precipitation and higher is the death rate due to malaria. Most of the trends showed positive change in temperature with different rates in different seasons. In some cases, the trends showed asymmetry. The results of the impact of urbanization on temperature revealed that there is a positive relation between the increase in temperature change and the increase in population change on the annual scale. But on seasonal scale this is applicable for monsoon, post-monsoon and winter season and not for summer season. The paper has important policy implication for improving water quality.

P-2226-02

Scalling heat-mortality relationships recorded in cities to the global scale

L. Costa, (1) ; L. Krummenauer, (1) ; A. Holsten, (1) ; J. Kropp, (1)
(1) PIK, Potsdam, Germany

A large number of epidemiologic studies relating air temperature and mortality in cities have been conducted but they findings not generalized to continental scales. The studies usually culminate with the determination of a threshold-mortality temperature (TMTs), that is, a temperature value beyond which recorded mortality in a city deviates from the normal expected.

In this work we have compiled and homogenized threshold-mortality temperatures (TMTs) found in peer-reviewed literature for circa 90 cities worldwide. The chosen unit for homogenization was mean apparent temperature, since it is a composite measure of temperature and humidity. A multivariate linear regression between TMT's and a set of 12 independent variables was preformed. The set included several measures of the climatologic features of a city, as well as physical urban features city density, size and fraction of urban spaces. The linear regression exercise returned 30-year mean amplitude and 30-year average temperature as the best explanatory variables (adjusted R2 = 0.66). Results point therefore for a significant role of climate alone in shaping the ability of urban population in sustaining heat-stress, while the remaining variability is likely attributed to factors such as demographics or health care standards.

In order to reflect the existence of a physiologic limit for temperature, a sigmoid function (S-shape curve) was fitted to the TMT's using the same set of independent variables as for the case of the linear regression. 30-year mean of the hottest month returned the fit with the lowest residual standard error. The saturation value for the sigmoid function, that is, an approximation of the physiological limit (or adaptability limit), was set and 45 degrees, in reflection to the upper limit of temperatures recorded at permanently habitable regions in the world and further evidences from literature. The robustness of the sigmoid function was tested for subsets of TMT's from different climatic zones. The fit preformed best at sub-tropical-wet climates, and worst at humid-continental climates. Climate projections of temperature were superimposed with the results of the sigmoid fit in order to highlight the regions where the largest deviation from air temperature to TMT's are expected. In particular, the function allows for the exploration of several «adaptability» scenarios by varying the speed with which a region can «move» along the fit function.

There is still a considerable amount of variance in TMTs not captured by our approach but we have successfully captured the role of climate in shaping the adaptive capacity of the urban population. We also moved closer into bridging the persistent gap between research undertaken at the case-study and the need for global generalizations of results. Finally, following the proposed function, first order approximations of TMT's can be made for regions where temperature-mortality studies are absent.

P-2226-03

Climate change effects on the erythemal and vitamin D weighted UV daily doses in South America and Antartica: Impacts on the health of populations

M. De Paula Correa (1) ; G. Moraes (1) ; S. Godin Beekmann (2) ; E. Mahé, (3)
(1) Universidade Federal de Itajubá (Federal University of Itajubá), Instituto de recursos naturais (natural resources institute), Itajubà, Brazil; (2) CNRS, IPSL/LATMOS, Guyancourt, France; (3) Centre Hospitalier Victor Dupouy, Departement de dermatologie, Argenteuil, France

Recent studies show that the ozone layer will be recovered until 2050. This is a significant result of the Montreal Protocol which points out the success of this environment protection agreement. However, climate change projections show that the total ozone content will have a relevant increase until the end of this century, mainly at higher latitudes. On one hand, this increase can reduce the

adverse effects of UV radiation overexposure. On the other hand, the decrease of UV availability at the surface can reduce the synthesis of vitamin D among the inhabitants of these regions. In this study, we provide erythemal (DoseE) and vitamin D (DoseD) weighted UV daily doses estimates for ten different sites of South America and Antartica. Our calculations are based on the ozone forecasts provided by four climate models reported on the last IPCC report. Unlike previous works, our study evaluates the impact on the daily dose of radiation received. Thus, these results can be used as an important tool for the health studies on the excess or lack of sun exposure. The first results show significant UV attenuation at Southern sites. At 30°S, DoseE and DoseD can be reduced between 5 and 7%, respectively, until the end of this century if the anthropogenic emissions continue to rise throughout the time. At 50°S, these reductions increase to 12 and 21%, respectively; and, in Antartica they will possibly exceed 15 and 30%, respectively. We did not observe significant variations at the equatorial sites. In this talk we also discuss the impact of these UV availability reductions on the population's health.

P-2226-04

Evolution of surface UV radiation in relation to ozone depletion and climate change

S. Godin Beekmann (1) ; M. De Paula Correa (2) ; E. Mahé, (3)
(1) CNRS, IPSL/LATMOS, Guyancourt, France; (2) Universidade Federal de Itajubá (Federal University of Itajubá), Instituto de recursos naturais (natural resources institute), Itajubà, Brazil; (3) Centre Hospitalier Victor Dupouy, Departement de dermatologie, Argenteuil, France

Exposure to ultraviolet (UV) radiation is known to be a risk factor for several diseases such as skin cancers and cataracts. On the other hand, a number of studies have described the benefits of UV exposure in relation to the synthesis of vitamin D and prevention of several diseases. The evolution of surface UV radiation has been under scrutiny in the last decades due to the discovery of ozone depletion in the middle atmosphere. Atmospheric ozone is the main atmospheric absorber of UV-B radiation (280 – 320 nm spectral range) and its depletion has raised concerns about the protection of human populations, living organisms and ecosystems against dangerous UV radiation. The rapid understanding in the 1980s of the main processes involved in stratospheric ozone destruction, which incriminated halogen substances emitted by human activities, led to the regulation of the emission of these ozone-depleting substances (ODS). Since then, ODS abundances have continued to increase up to the mid or end of the nineties, depending on latitude, and have now started to decrease slowly. As a consequence, the ozone layer has stabilized and shows signs of recovery. While the decrease of ODS content is expected to be the dominant cause of the future long-term evolution of stratospheric ozone, climate change effects and natural variability of the atmosphere still hinder the unambiguous detection of the recovery expected from ODS decrease.

Chemistry-Climate models indicate that minimum levels of stratospheric ozone have been reached in the early 21st century. The recovery of the ozone layer is forecasted in a period ranging between 2015 and 2030 in the northern hemisphere and between 2030 and 2040 in the southern hemisphere, with a disappearance of the Antarctic ozone hole after 2050. Due to climate change induced effects on transport processes and temperature climatology in the middle atmosphere, models simulate a super-recovery of ozone in the polar and mid-latitude regions and an under recovery in the tropics. The future evolution of ozone will thus have an impact on surface UV at global scale and on the health related UV doses.

This presentation will review the latest results on the past and future long-term evolution of global ozone and surface UV. Projected changes in clear-sky erythemal and vitamin D effective UV doses for Europe over the period 2006 to 2100, based on CMIP5 simulation of total ozone and aerosols will also be presented.

P-2226-05

Planning for the Impacts of Climate Change on Human Health: A Focus on Cities

K. Haddadimoghaddam (1)
(1) International Sturgeon Research Institute, Marine Ecology, City:Rasht , Province:Guilan, Islamic Republic of Iran

Cities are faced with the task of planning for the present and future growth needs of their citizens. Climate change places pressure on cities ranging from rural to urban migration causing increased demands for housing, to physical changes from flooding and heat waves that challenges the ability to plan. Research and practice have demonstrated the capacity of cities to address the economic and physical impacts of climate change. Less understood is how cities can address the impacts of climate change on human health and well-being; which ranges from death and injury caused by extreme temperatures and weather events, to malnutrition caused by drought. Cities have role in reducing the impacts on human health and well-being. In the 1980s, the Healthy Cities movement aimed to make cities supportive of human health but success was inhibited by a lack of coherence. However, the core ideas of cities: developing action strategies to promote health, being centers for human action, and having an unmatched potential for producing healthy human beings hold today. The challenge for cities now is identifying the causal relationships between human health and climate change; for which there are many. Thus it is the objective of the research that is to be undertaken to conduct a critical analysis of the policy actions of cities in their efforts to address the impacts of climate change on human health through policies and plans.

Seasonal Variations in Emergency Department Visits of Schizophrenic Patients in Sofia, Bulgaria

Z. Spasova (1)
(1) National Center of Public Health and Analyses, Health Policies Analyses, Sofia, Bulgaria

Climate change is making hot summer days hotter and stretching their numbers into heat waves. And the heat is causing more than just discomfort – as temperatures rise, so are the number of illnesses, emergency room visits, and deaths. Among the risk groups are young children and elderly people, people with chronically diseases especially of the cardiovascular and respiratory system, the poor, people who are working at open environment and those living in big cities where the effect of "heat island" makes the heat waves more severe.

It's little studied the effect of hot weather and the effect of the season on people with mental disorders and specifically schizophrenia (as one of the mostly common and severe mental disorders). Schizophrenia is characterized by enormous societal and economic costs due to the extensive therapeutic care and loss of economic productivity, as well as personal suffering and stigma which often affect the patient and his/her family for most of the patient's life. As for schizophrenia patients, there is still no cure, the research of etiologic factors, particularly environmental ones that could be avoided and used in effective prevention programs, is essential.

Many studies have demonstrated evidence of seasonal patterns in the incidence of psychotic disorders, and schizophrenia in particular. It is known since the time of Esquirol (1838) that the number of patients admitted in mental hospitals increases in summer months and decreases in winter. Most of the studies for seasonal distribution of hospital admissions in schizophrenia also report summer peaks, some of these for female patients only. With respect to the factors responsible for the summer excess of admissions, Myers and Davies have suggested a rise in ambient temperature; Parker and Walter, the increasing luminance; and Carney et al., the length of day. Social factors, such as summer holidays, "are unlikely to have an effect" (Takei et al.).

While the problem of seasonal admissions of patients with schizophrenia has been widely discussed in Western Europe, America and Australia, in Eastern Europe it

has been neglected. We are not aware of any published research on this subject in Bulgaria, which makes the present study important as a contribution to the scientific literature on the problem in the country and in the South East Europe region. Its findings could also raise the awareness of the problem of health care management for psychiatric patients in SEE countries besides Bulgaria.

The purpose of this study was to reveal the seasonal distribution of emergency department visits of schizophrenic patients in Sofia, Bulgaria.

We collected daily data for visits of patients with schizophrenia, schizotypal and delusional disorders in the emergency center of the regional dispenser for mental disorders in the city of Sofia for the period 1998–2003. The total number of emergency visits was 5723 (mean daily visits: 5.04±2.4). T-test was used to compare the monthly and seasonal distribution of visits.

The season with the highest levels of emergency visits was summer, and the lowest levels were observed in winter ($P<0.0001$). Spring and autumn had intermediate values close to the mean value, and significantly differentiated from winter values. The month with the highest admission rates was September, followed by May and the three summer's months. The lowest levels were observed in December, October and January, with statistically significant differences observed between the values of all the three months. Differences between July values compared with December and October values were significant, but not with January values.

The study showed significant seasonal and monthly differences in emergency schizophre-nics' visits. The data confirm the outcome of similar studies conducted in countries with temperate climate in the Northern Hemisphere. The results are particularly relevant against the backdrop of rising ambient temperatures and the tendency of increasing of the frequency of heat waves, observed in recent decades in Bulgaria. These results could prove useful for psychiatrists, public health specialists, and governmental authorities dealing with team planning and prevention programs in the field of public health.

2228 - Removing Barriers to Climate Change Mitigation at City Level

Making Cities Resilient to Climate Change: Identifying 'win-win' interventions

H. Dulal (1)
(1) Abt Associates, International Economic Growth, Bethesda, Maryland, United States of America

Urbanization has truly become a global phenomenon. From a mere 10 percent in 1900, thepercentage of global population living in urban areas now exceeds 50 percent. With rapid urbanization, urban emissions have also increased over the decades. Cities currently account for about 75 percent of global energy consumption and 80 percent of global greenhouse gas emissions. Even though the greenhouse gas emission footprints of cities have been increasing over the years, for the cities in developing countries, greenhouse gas (GHG) mitigation is still not the priority. It is a «low-priority» issue, if anything. Given the resource constraints and competing local priorities, developing countries' cities are more interested in dealing with rapidly deteriorating air and water quality than use their scarce resources for urban climate change mitigation. The existing reluctance, however, can be overcome if cities are made aware of the fact that bundling of policy tools can actually help them overcome their perpetual struggle against increasing urban environmental externalities and contain rising urban greenhouse gas emissions. The proposed paper intends to identify sectors and policy instruments, adoption of which, will not only ensure the reduction in rising urban environmental externalities in developing countries, but also help contain rapidly growing urban greenhouse gas emissions and provide climate change adaptation co-benefits.

O-2228-02

'Nudging' the city towards sustainability; analysis of leverage points for reduction of urban footprint

FM. Khan (1)
(1) WWF Luc Hoffman Institute, Lund, Sweden

Since 2010 the Earth Hour City Challenge (EHCC) has been encouraging cities to submit data on carbon reduction commitments, strategies and investments that allow assessment of urban governance vision and impact over the years, and has been collecting this data through the Climate Carbonn Registry. Cities meeting certain criteria of data availability and reduction commitment become Earth Hour City Challenge candidates and the most ambitious cities compete for the title Earth Hour Capital of the year. In the 2014 iteration of the challenge more than one hundred and sixty cities from seventeen are reporting on hundreds of reduction commitments and thousands of mitigation actions from all sectors of urban governance. As the primary habitats of human beings and one of the two most important governance units of our civilization along with the nation state, cities must take a leading role in the transformation towards sustainability and reduction of human footprint. However as complex systems, cities exhibit both, a behavioral inertia that is borne of the dense network of interactions between people, infrastructure and intangibles that define the city, as well as the ability to undergo a rapid transformation akin to a face change in complex systems when faced with the right intervention at the right leverage point. In order to navigate a successful transformation to sustainability, meet the relevant targets such as sustainable development goals and stay within the planetary boundaries while improving standards of living for the global poor, we need to identify these points at which a phase change can be triggered in urban systems; these would be the leverage points where large gains in footprint reduction can be obtained with minimum effort interventions. These high leverage points emerge from research in unexpected disciplines as well from investigations at the interaction of disciplines that do not traditionally converse as these points lie concealed in latent correlations. To identify these points thus a multi-disciplinary, consultative, framework approach is needed. The EHCC data has been analyzed to identify high leverage opportunities for reduction in urban footprint. The research uses the framework and data collected as an objective function to identify leverage points for maximizing footprint reduction using various strategies. Various stakeholders from practice and academia have been consulted to provide a survey of strategies for urban footprint reduction from various disciplines. This has included evidence collected from practical policy and technological implementations in the disciplines of transport, housing, waste management, local food production and energy, summary of theoretical and empirical findings from behavioral economics and psychology that can help devise policy interventions to

'nudge' citizen behavior towards footprint reduction, and analysis of theoretical developments in the science of urban complexity that can inform identification of high impact leverage points. A framework has been developed and correlations explored using a preliminary network mapping exercise.

Urban and peri-urban forestry in the face of climate change in Cameroon: challenges and new perspectives for sustainability

GH. Chekuimo (1)
(1) Centre for Research in Economics and Sustainable Development, Yaounde, Cameroon, Agriculture and Sustainable Development, Yaounde, Centre, Cameroon

Urban forestry is a relatively new, multidisciplinary approach in international forest research. Rapid urbanization and climate change raise several issues for those who are responsible for developing policies and making decisions at local, national and international levels. Urban trees provide a significant contribution to building resilient cities and improving health and well-being, such as through mitigating natural disasters, providing ecosystem services, reducing energy costs or increasing property values. However, urban and peri-urban forest ecosystems in Cameroon are steadily increasingly under pressure from their city populations. This study assessed the status of urban and peri-urban forestry, evaluated the effect of population growth on urban forests landscape and designed innovative strategies that will ensure sustainability and improvement of urban living environment. It was investigated through secondary data, field investigation, enquiries to relevant stakeholders, direct assessment and observations of urban and peri-urban forest landscapes in Cameroon. These analyses highlight the extreme diversity of environmental resources from urban forests in Cameroon. Rapid urban population growth, limited land area, and poor implementation of government policies are some factors affecting urban forests development and are responsible for vicious cycle of environmental degradation in urban areas in Cameroon. The results contribute elements for strategic and operational planning. Urban forestry management is an important strategy to improve urban living and working environments. There is a need to highlight successful strategies and actions concerning the management of urban and peri-urban forests. Involvement of all stakeholders and users in reflections and in the implementation of policies concerning the management of the urban and peri-urban forests should be adopted and advocated, to ensure sustainable development and to ensure that cities, trees and forests grow together to meet the needs of urbanized societies.

2229 - Cities and their environments: Assessing Climate Change Impacts, Adaptation and Mitigation strategies across scales from rural to urban

ORAL PRESENTATIONS

Sustainable Futures in Rural and Peri-Urban Areas

D. Purnamita (1) ; J. Morton (2)
(1) Institute of Economic Growth, Environmental and Natural Resource Economics Unit, Delhi, India; (2) University of Greenwich, Greenwich, United Kingdom

This keynote will focus on the possible impacts from climate change on rural areas and rural-urban continuums, with special emphasis on the implications for human settlements. It will consider alternatives for building resilience for the future in recognition of a two-way relationship between sustainable economic development and climate change. A wide range of human and ecosystem interactions define the risks from climate change, in many parts of the world, including the developing and the least developed, where multiple stressors co-exist. Illustrations to highlight these aspects will be drawn from material from the AR5 report of the IPCC. The opportunities and challenges in bridging the gaps between quantitative and qualitative dimensions, of integration across scales and timelines is also to be discussed given the multiple sources of vulnerability and differences in development across regions of the world. In this context, the presentation will dwell on the economic valuation of climate change impacts which requires moving from pure cost benefit analysis to multi-metric evaluations with consideration of the risk and uncertainty dimensions. Non-market values, inequities, behavioral biases, ancillary costs and benefits of response options and aggregation of values across multiple contexts call for innovative and less conventional approaches.

K-2229-02

Cooling Our Cities: International efforts to implement heat island countermeasures

H. Akbari (1)
(1) Concordia University, BCEE, Montreal, Canada

As the threat of climate change becomes more pronounced, a number of scientists have proposed supplementing the full range of mitigation efforts with geo-engineering (manipulation of the Earth's environment) to quickly respond to this threat. Many proposed geo-engineering techniques are novel and unproven. One simple technology has been in practice for thousands of years: changing the solar reflectance (albedo) of the built surface. "Cool roofs" and "cool pavements" should be among the first geo-engineering techniques used to combat global warming.

Increasing the solar reflectance of the urban surface reduce its solar heat gain, lowers its temperatures, and decreases its outflow of thermal infrared radiation into the atmosphere. This process of "negative radiative forcing" can help counter the effects of global warming. We estimate that resurfacing conventional dark roofs with a cool white material that has a long-term solar reflectance of 0.60 or more increases its solar reflectance by at least 0.40. Retrofitting 100 m2 of roof has an effect on radiative forcing equivalent to a one-time offset of 10 tonnes of CO2. Similarly, the solar reflectance of pavement can be raised on average by about 0.15, the equivalent of a 4 t reduction in CO2 per 100 m2.

In addition, cool roofs reduce cooling-energy use in air conditioned buildings and increase comfort in unconditioned buildings; and cool roofs and cool pavements mitigate summer urban heat islands, improving outdoor air quality and comfort. Installing cool roofs and cool pavements in cities worldwide is a compelling win-win-win activity that can be undertaken immediately, outside of international negotiations to cap CO2 emissions. We review the status of cool roof and cool pavements technologies, policies, and programs in the U.S., Europe, and Asia. We propose an international campaign to use solar reflective materials when roofs and pavements are built or resurfaced in temperate and tropical regions.

This presentation will discuss the technologies and international policies related to development and utilization of cool construction materials.

K-2229-03

Towards an integrated model for more sustainable urban (re-)planning

D. Robinson (1)
(1) University of Nottingham, Architecture and built environment, Nottingham, United Kingdom

Sustainability has become a byword. Whilst it is understood that we are now mainly an urban species, that the overwhelming majority of economic activity and associated resource use takes place in cities, some surprisingly basic questions remain unanswered: How do we define city sustainability? How do we then measure it to determine how sustainable a city is? Which are the most effective strategies and policy measures to bring about positive change? How do we model them to evaluate their effectiveness? How do we then implement them? These are some of the questions currently being tackled by the Laboratory of Urban Complexity and Sustainability (LUCAS) at Nottingham. Positioned within this landscape, I will focus in this talk on the challenges we face in developing a platform for modelling the principle urban resource flows, in a sufficiently spatially sensitive manner to support the testing of scenarios to minimise these flows (or some measure(s) of them) in the future and how cities might transition to these target future states.

Climate Change in Rural Areas: Reflections

J. Morton (1)
(1) Natural Resources Institute, University of Greenwich, Livelihoods and Institutions, Chatham, Maritime, Kent, United Kingdom

The Contribution of Working Group 2 to the IPCC Fifth Assessment Report (2014) included for the first time a Chapter on Rural Areas. This presentation will be a reflection on the writing of that chapter by one of its two Co-ordinating Lead Authors. Some of the questions posed will be as follows:

- Is there something specific about rural areas (or "rurality") that can make them an object of study in the context of climate change, along the continuum from low-income to high-income countries?
- How can the different experiences of poverty and ill-being in rural and urban contexts, as they exist and as they will be exacerbated by climate change, best be compared in a non-reductionist manner?
- How best can we conceptualise and research interactions between adaptation and mitigation in rural areas?

How best can we conceptualise and research linkages between rural and urban areas and the ways they will be impacted, and will adapt, under climate change?

O-2229-02

Efficiency of Waste Management of Different Cities in the Philippines: Assessment and Its Implication to Climate Change Mitigation and Adaptation Policies

J. Pagunsan (1) ; K. Shimada, (2)
(1) Office of the Ombudsman, Field Investigation Office II, Quezon City, Philippines; (2) Ritsumeikan University, Economics, Kusatsu City, Japan

Rapid increase in the emission of greenhouse gases (GHGs) particularly in the waste management processes resulted in socio-economic changes and various environmental issues in major cities of the world. Increasing trends of GHGs emission was due to the rapid urbanization and booming economic development in these cities particularly in developing countries like Philippines. Globally, the risks and uncertainties of climate change tend to be more complex and costly which can aggravate the threat to human civilization and economic development of a particular country. This pressing issue at hand calls for a comprehensive evaluation and consideration for the progressive and sustainable future in a more globalized society. Hence, this paper evaluated the efficiency of waste management of different cities in the Philippines towards climate change mitigation and adaptation. The two-stage approach was utilized in quantifying and understanding the efficiency of different cities in the Philippines. First, efficiency of every city was done using Data Envelopment Analysis. Having the efficiency scores at hand, efficiency measurement was expanded using Tobit Regression Analysis to further analyze the potential influence of environmental factors such as land area, number of barangays (villages), poverty incidence, environmental governance and presence of disposal facility in the implementation of waste management in different cities. Finally, this paper will conclude with the analysis and discussion on its implication to climate change mitigation and adaptation policies.

O-2229-03

Responding to Changing in Climate : Who Act The Most in Greater Jakarta

SA. Dalimunthe (1) ; IA. Perdana Putri (1)
(1) Indonesian Institute of Sciences, Research center for Population, Jakarta, Indonesia

Over the past decade, increased knowledge coupled with economic incentives, subsidies and related interventions has raised awareness and concern about climate change in vulnerable Greater Jakarta. This paper will analyze index and status of responsiveness of each region within Greater Jakarta towards climate change by means of Climate Change Effectivity Response Assessment (CCERA) using multidimensional scaling technique (MDS). Total data used is 1261 respondent. Overall, the index shown Bogor responding the most to climate change. Looking through each dimension, it is likely Bogor is the highest in knowledge dimensions (61.14), community resources (63.72) and level of alertness (87.26). While Bekasi holds the highest index in individual resources (71.47). The most influencing attribute regarding to index and status response are willingness to take out insurance, willingness to change lifestyle (knowledge); sign up for early warning alerts and disaster preparedness plan (individual resources); talk to other about taking action and feel involved in decision making (communal resources) and don't know to response and care about natural environment (level of alertness). The result of this study will provide evidence based to support more ambitious regional response to climate change based on the status of responsiveness of each region in Greater Jakarta.

Continued Growth, Sustainability and Climate Change in America's Energy Capital

K. Lester (1)
(1) Rice University, Shell Center for Sustainability, Houston, TX, United States of America

Planners are uniquely situated to contribute a comprehensive approach to evaluating and solving development issues (Myers, 1997). Many of the less discipline specific issues in addressing climate change such as understanding long-range consequences of present actions; understanding needs for disadvantaged populations; and managing the exchange of confluences between the built environment and natural environment fall naturally under the toolbox of planners. Methods and tools in planning are robust enough for this challenge (Talen, 1996). New research is taking a critical look at what approaches should and are being conducted across the US (Jepson & Haines, 2014). This is exactly the type of environment that fosters more integration of planning for climate change into the routine high visibility planning products developed for and by cities. This presentation will deliver findings from a study addressing the question of limits to growth and climate change impacts in America's largest energy metropolis.

The City of Houston, Texas is the 4th most populous city in the United States, with a population of 2.1 million persons as of the 2010 US population census. Houston is the most sprawling city of the top 5 most populous, with a land area of approximately 600 square miles, which is larger than New York and Chicago combined. Less than 10% of the workers use public transportation to get to work. Houston has only 7.5 miles of passenger rail, while New York has 2,047 miles and Chicago has 224 miles. This sprawling city is also home to the Port of Houston, which is the largest port in the US for foreign trade and imports. It supports the largest petrochemical manufacturing area in the world. It is estimated that 1 million jobs are supported by port activity and approximately $178 billion in economic activity in Texas (Port of Houston Authority, 2013). This evidence shows that Houston is a sprawling city, with a dependence on private automobiles and an economy heavily influenced by development and trade in petrocarbons. This city is a challenge to planning for climate change and an ideal

environment to evaluate the impacts of projected major growth inducing forces into the future.

A comprehensive suite of sustainability indicators from the Houston Sustainability Indicators project (HSI), will serve as the base measures to characterize Houston and its environment in this study. The HSI project has reported on the sustainable development of the City of Houston for the past four years and produced four (4) reports showing dynamics at various spatial levels (Blackburn, 2011; King, 2014; 2013; 2012). Indicators will be projected to 2030 and 2050 and multivariate analysis will be conducted on the indicators and communities across the city to support identification of major development factors ongoing at these two times (2030 and 2050). Specifically, this exploratory research will seek to identify factors explaining limits to growth around the stress nexus issues of energy, water and food in addition to land use constraints among communities in Houston in 2030 and 2050. Houston needs to prepare for several climate change scenarios such as increases in temperatures, water scarcity, flooding, seal-level rise, droughts and increased storm frequency. However the political climate focuses more on current issues rather than medium term or long term ones. This study serves to examine one method in which cities can evaluate expected development conditions across many processes and identify congruent development trends that may help to explain environmental stress in energy, water, food and land use. Planning for climate change is essential in current times of uncertainty and this research contributes new findings towards this effort (Barth, 2011).

Barth, B., 2011. Planning for Climate Change: A Strategic, Value-Based APproach for Urban Planners, Nairobi, Kenya: UN Habitat. Jepson, E. & Haines, A., 2014. Zoning for sustainability: A review and analysis of the zoning ordinances of 32 cities in the United States. Journal of the American Planning Association, 80(3), pp. 239-252. Myers, D., 1997. Anchor Points for Planning's Identification. Journal of Planning Education and Research, pp. 223-224. Talen, E., 1996. After the plans: Methods to evaluate the implementation success of plans. Climate change and water management issues in megacities, the example of Paris metropolitan area

B. Nguyen (1) ; JP. Tabuchi (2)
(1) UNESCO, SC/HYD/GSS, Paris, France; (2) SIAAP, Direction santé environnement, Paris, France

Are the effects of the climate change at the dawn of the 21th century already visible at the operational water management level of Paris megacity? Some elements speak in favor of it. The scheme and the infrastructures of the drinking water supply system of the capital of France date back to 150 years; and the recording of the rainfalls in Paris began at the end of the 19th century. The gauging of the underground water springs, which supply even today half of the 2.3 millions of Parisians, also benefits from long and precise records since 1872. And one can note a concentration of rare events during these last years: 2001 was the record year of highest rainfalls in Paris with more than 1,000 mm of precipitation; 2003 was the year of the heat wave which killed 15,000 people in France; and in 2006-2007 following several years of droughts, the level of certain springs which supply Paris had never been so low. On the other hand, the modern tools for real time measurement of the consumptions allow to better understand the consequences of the exceptional climatic episodes which impact the water demand; and consequently to prepare for a more efficient management during these climatic constraints.

As for the future, 4 successive research programs (IGCC-Seine (2004) RExHySS (2009), Explore2070 (2012), Climaware (2013)) have shown, with a satisfactory level of probability, a number of effects of climate change on the hydrology of the Seine River catchment. These changes would be sensitive from the middle of the century.

According to these scientific works, the most significantly perturbed hazard is drought, not flooding. This is linked to the significant increase in temperature from the mid-century which is sufficient to increase evapotranspiration of about 15%. This increase is paired with a likely decrease in summer precipitation with as result a reduction in low flows. The average flow of the Seine River in Paris could fall between 20% to 40% and the five-year low flow return period between 30 to 60%. A significant decrease in the dilution capacity of the Seine River and its tributaries with regards to pollutants is likely then to arise within the next forty years.

At the same time, the Paris area should continue its development. This is certainly the ambition of policy makers. In this context the future of wastewater treatment will become very complex while being impacted by cumulated constraints: increased sensitivity of the Seine to discharges of pollutants, pollutant loads increase at the treatment plants inlet and less possibility for pollutants loads discharges in the Seine River.

In these circumstances, compliance with environmental standards will become more difficult and can lead to put into question improvements that were achieved in recent years. More general questions also arise on broader issues: the search for technical solutions to obtain high waste water treatment performances at affordable energy cost, the search for alternatives to conventional sanitation by implementing an extraction of the chemical elements C, N, P out of the water cycle, or the possibility of lowering thresholds for environmental indicators before returning the treated water into the rivers; the latter issue if implemented being a real regression and a terrible failure.

This example is an illustration of the problems that the megacities will face. But, if the improving knowledge of water resources and the changing needs of the population are keys from promoting new solutions, it will also be necessary to analyse the way how political decisions are being taken.

These issues and many more will be the subject of an international scientific symposium dedicated to water management in megacities and global change (particularly climate change), held from December 1st to 4th 2015 in Paris and organized by ARCEAU-IDF with the support of UNESCO (http://eaumega2015.sciencesconf.org/)

O-2229-06

Assessment of climate change mitigation and adaptation strategies at the district scale

M. Musy (1)
(1) ensa Nantes, IRSTV FR CNRS 2488, Nantes, France

The urban climate is on average warmer than its rural counterpart. This urban heat island (or UHI) is influenced by the corresponding urban form and materials and their impacts on radiative exchanges and heat storage, by vegetation and byanthropogenic heat gains. In summer, heat rejection from air cooling systems can represent a substantial share of these anthropogenic gains and this is itself exacerbated by the urban heat island, since this diminishes systems' performance. On the other hand, in climates in which buildings' energy use is dominated by heating demands, the UHI reduces demands for applied energy and may, on the whole, improve pedestrians' comfort. These climate-energy-comfort relationships are complex and intertwined. Furthermore, as cities become denser, the magnitude of this UHI increases and this can have significant implications for building energy use and greenhouse gas emissions, comfort and indeed for mortality; as the influence of heat waves isintensified. Solutions to climate change mitigation, energy transition and climate change adaptation must thus be tackled simultaneously. The effectiveness of these solutions requires, in addition to knowledge of the relationships between climate and the thermal behaviour of buildings, the development of approaches that support predictions of energy use in the urban context and its impacts on the urban microclimate. In that context, policymakers face an increasing need to improve knowledge of environmental impacts from city layouts and uses on the urban climate, in order to assist with planning climate change mitigation and adaptation measures. This proposed contribution aims to gather and debate the state of the art regarding assessment of UHI reduction strategies, with a particular emphasis on the district scale, which is the usualurban planning and design scale.

O-2229-07

A 'Sustainability Window' of Urban Form

S. Lohrey (1) ; F. Creutzig (2)
(1) Mercator Research Institute on Global Commons and Climate Change, Land Use, Infrastructure and Transport, Berlin, Germany; (2) Mercator Research Institute on Global Commons and Climate Change, Land use, transport and infrastructures, Berlin, Germany

Climate change mitigation becomes an important policy goal for cities worldwide, but local environmental objectives are equally important in policy-making. This study investigates the impact of urban form and modal shares on air pollution, greenhouse gas emissions, congestion and cost of living by using both empirical data from a number cities, as well as a straightforward urban economics model. Denser urban form would nearly unambiguously mitigate climate change, but also translate into a higher proportion of air pollution affecting citizens. We introduce a window of most sustainable urban form to highlight trade-offs between the externalities of urban form. Only a combination of transportation policies, infrastructure investment and progressive public finance enables the development of cities that meets all sustainability dimensions simultaneously. We identify a minimum urban density of 50 persons/ha to meet sustainability goals.

Promoting Sustainable Human Settlements and Eco-City Planning Approach: Southeastern Anatolia Region and Southeastern Anatolia Project (GAP)

B. Acma (1)
(1) Anadolu University, Economics, Eskisehir, Turkey

In the recent years, there have been many opportunities flourishing through the development of Turkey. One of these is unvalued rich agricultural and hydro-sources in the Southeastern Anatolia Region. The Southeastern Anatolia Project (GAP), one of the most important projects to develop the remarkable natural resources of the world, is considered as a chance to make use of rich water and agricultural resources of the Southeastern Anatolia Region.

In the recent years, the concept of promoting sustainable human settlements and eco-city planning approach has been included into the GAP Project. And, by applying these concepts in real projects caused remarkable results through development of the region.

The aim of this study is analyze the concepts of promoting sustainable human settlements and eco-city planning approach in the GAP Project that has been still processed.

In the first section, the region of Southeastern Anatolia and the GAP Project will be introduced briefly. In the second section, the stages of GAP Project and the project existing will be analyzed. In the third section, the projects and sub-projects used for promoting sustainable human settlements will be introduced.

In the last and fourth section, a series of policies and strategies for providing the process of settlements which is optimal and harmonizes with eco-system will be given.

Producing nature for public: panel data analysis of public green spaces provision in Chinese cities

W. Chen (1)
(1) The University of Hong Kong, Department of Geography, Hong Kong, Hong Kong

The landscapes and infrastructures of cities have long been viewed as products of human-nature interaction. This study sheds new light on how a critical constituent of urban landscape and infrastructure, urban public green spaces, has been produced in China's ongoing profound urbanization process. Over the past decade, China's urbanization has been characterized by a land-based pattern centered on the commercialization and capitalization of urban land induced by the decentralization of state power. The non-budgetary revenues generated from urban land leasing hold the promise to empower local governments' fiscal capacity and flexibility in financing various urban infrastructures aiming to enhance local amenities and attract external investment. This paper investigates the impact of land-based urbanization on the provision of urban public green spaces, an integrated part of urban public infrastructure, using panel data across 285 Chinese prefecture cities from 2002 to 2009. The results reveal a negative relationship between the reliance on land finance and the amount of urban public green spaces, indicating that local governments' pursuit of maximizing land lease revenue will not be able to finance more public green spaces, and may even cause the loss of public green spaces. The regional variations amongst the eastern-coastal, central, and western cities confirm that an initially positive relationship between land finance and the provision of urban public green spaces at the early stage of development would reverse to a negative relationship with the increasing pace of urbanization and economic development, which may lead to a social inequity pertaining to public accessibility to urban green spaces. A balance amongst economic growth, environmental concerns, and social equity is very much needed in the quest for sustainable development.

P-2229-03

Green roof cooling effect as climate-adaptation tool for tropical cities

CY. Jim (1)
(1) University of Hong Kong, Department of Geography, Hong Kong, China

Global warming has accentuated the urban heat island (UHI) effect in cities. Urban green infrastructures can provide ecosystem services and attendant climate-change adaptation. Compact cities have urban green space (UGS) deficit due to deficient ground-level sites. Numerous building envelopes, including rooftops, facades and walls, furnish ample yet largely untapped greening opportunities. Their efficacy in mitigating climate-change impacts deserve to be investigated by empirical experiments. In compact humid-tropical Hong Kong, two green-roof and a control bare-roof plots were installed on a high-rise building. Precision temperature sensors were installed in a holistic vertical profile extending from outdoor air to roof surface, green-roof material layers, and indoor ceiling and air. The apartments under the plots were kept unoccupied to monitor air-conditioning energy consumption. The comprehensive-systematic data allowed in-depth analysis of thermal performance of vegetation (Sedum and Perennial Peanut) and weather (sunny, cloudy and rainy) in summer. Intense solar radiation at Control plot triggered significant material heating, which in turn warmed near-ground air to intensify UHI effect and indoor space to lift energy consumption. Sedum plot with incomplete plant cover, low transpiration rate and limited substrate moisture experienced feeble evapotranspiration cooling. The warmed roof passed heat to near-ground air and subsurface layers to impose an indoor cooling load. Peanut plot with high transpiration rate can significantly cool foliage surface and near-ground air to ameliorate UHI. Its high moisture-holding capacity, however, can generate a heat-sink to push heat downwards and increase indoor cooling load. Practical hints on green roof design and management were derived from the findings for application in tropical region to contribute to climate-resilient cities.

P-2229-04

Building Urban Climate Resiliency and Adaptation Strategies: A Case Study of an Indian Mega Cities

S. Mandal (1)
(1) National Institute of Technology Patna, Department of Architecture, Patna, Bihar, India

India is experiencing rapid urbanisation, and consequently water demand in urban areas is escalating rapidly. Many megacities of India are located in the central part of the

Gangetic plains. The Indian mega cities are amongst the oldest surviving urban centres in the world, with a continuous recorded history dating back to the fifth century BC (Ramchandran 1999). The Indian cities are one of the fastest growing urban centres in the world. Despite the fact that cities are located on the banks of the river, residents are primarily dependent on groundwater aquifers for domestic water supply. Increasing pressure on groundwater supplies is exacerbated by the unregulated construction of deep tube wells, along with the development of apartment complexes to accommodate a mushrooming urban population. For example, an overall comparison among data sets for the periods 1960–1967, 1977–1986, and 2008–2010 reveals a decline in the level of the deeper aquifer, in the range of 2–10 m (Saha et al 2013), The decline in the piezometric head of the deeper aquifer (13 cm/year) during the previous two decades is another concern (CGWB, 2011). This raises concerns about the security of Indian mega cities water supply, and, hence, the economic vitality and sustainability of the city.

In this environment, with already existing pressures on water availability and use, climate change puts further stress on water management and the sustainability of water supplies. Climate change is already having impacts on temperature. Observed average minimum temperatures (annual temperature Jan–Dec) have increased from 19.00C to 20.50c over the period from 1989 to 2009. These changes are associated with the changes in population, which has increased from 0.5 million in 1971 to 15 million in 2011). Trends in temperature also interact with non–climatic factors, such as the removal of natural vegetation drainage patterns, loss of rainfall absorbing capacity of soil due to urbanisation and the provision of man–made drainage systems. These interactions complicate planning for water supply and demand and increases water insecurity. Moreover, regional annual average monthly maximum temperatures are projected to increase 2.5°C by 2049, based on the ensemble average of 41 CMIP5 models and assumptions of moderate future increases in greenhouse gas emissions (i.e., RCP 4.5; data source: http://climexp.knmi.nl). These projected increases in temperature will put further stress on water supplies, through increased demand for water, and through increased evapotranspiration. In addition, the increasing exposure to climate change, described above, will be superimposed on existing vulnerabilities, which include a lack of groundwater regulation and monitoring. Currently, Indian mega cities lack building by–laws to encourage water conservation. Furthermore, based on informal interviews with water management personnel, it is clear that they lack information on and understanding of projected climate change impacts.

The present study examines the nature of the aquifer system within the urban areas, the temporal changes in the water level and the recharge mechanism of the deeper aquifers. It also looks at associated dialogues and actions related to climate adaptation strategies about water sector in urban areas.

The purpose of this research is to understand the complex dynamics of the water sector and ultimately to suggest the resilience interventions to address these vulnerabilities and tools to support overall resilience, which are needed just to address Indian mega cities non–climate water management concerns, are necessary as a stepping–stone to transformative pathways for addressing the uncertainties associated with our common future under climate change.

P-2229-05

Urban land-cover types, thermal differences and relative vulnerability to climate change: quantification of South Africa's coastal metropolitans using remotely sensed data

J. Odindi (1) ; O. Mutanga (1) ; E. Abdel-Rahman (1) ; A. Elhadi (2) ; V. Bangamwabo (1)
(1) University of KwaZulu–Natal, School of agriculture, earth and environmental sciences, Pietermaritzburg, South Africa; (2) University of The Witwatersrand, Johannesburg, School of Geography, Archaeology and Environmental Studies, Johannesburg, South Africa

Coastal landscapes have historically attracted a larger number of settlements than inland. This trend is expected to continue. Commonly, increase in coastal settlements has been accompanied by growth of existing urban areas, particularly coastal cities. Such growth is characterised by transformation from natural landscapes to impervious surfaces associated with thermal elevation. These result in urban micro and macro climate alteration and vulnerability to climate change and associated impacts. In this study, we determine the relative vulnerability of the eThekwini, Buffalo City and Mandela Bay metropolitan areas on South Africa's eastern seaboard using remotely sensed thermal and multispectral datasets. Duncans post–hoc one–way analysis of variance, multispectral Landsat 8 scenes and Terra Moderate Resolution Imaging Spectroradiometer (MODIS) were used to determine differences between the major land–use–land–cover (LULC) mosaics and their respective surface skin thermal values. Based on each of the metropolitan's LULC proportions and their respective thermal values from MODIS imagery, the Contribution Index (CI) was used to determine the source/sink contributions within each metropolitan area. The eThekwini metropolitan area, due to its dominant impervious surfaces proportion, was more vulnerable to elevated urban heat and therefore higher relative vulnerability to climate change than the Buffalo City and Nelson Mandela Bay metropolitans. Results in this study show the value of remotely sensed datasets in determining inter and intra urban landscape matrix, thermal elevation and relative vulnerability to climate change. Such findings are particularly valuable for sustainable coastal urban landscape planning and mitigation of climate change related impacts at local, regional and even global scales.

Trapped in a flood-prone zone: Poverty and policy in a Tanzanian slum

L. Stark (1) ; L. Tiina-Riitta (2)
(1) University of Jyväskylä, Department of History and Ethnology, Jyväskylä, Finland; (2) University of Jyväskylä, Dept. of history and ethnology, Jyväskylä, Finland

Dar es Salaam is a coastal city with more than 70 per cent of its five million residents living in informal settlements that lack adequate infrastructure and services. Here climate change is expected to exacerbate the vulnerability of poor communities located along stormwater drainage channels through sea level rise, increased rainfall variability, and possibly more intense coastal storms. In mid–April of 2014, heavy rainfall led to the worst flooding since Tanzania's independence in 1961 and left at least 15 people dead. It also caused devastating damage to private property and public infrastructure, leaving thousands stranded and without shelter. Apart from significant loss of property and risk to human life, floods pose widespread health risks for poor residents due to pit latrine overflow.

Not all areas of the city are vulnerable to flooding, however. This paper will explore why the residents of the most flood–prone zones are unable to leave and move elsewhere. Our focus is on the subward of Tandale, located five kilometres from the centre of Dar es Salaam and bordering the Ubungo–Ng'ombe river system. This river system experiences severe annual flooding during the long rainy season, and both informal home owners and renters living along its banks find themselves 'trapped' by chronic poverty, lacking the means to rent or purchase homes in other central urban areas (necessary to livelihood) due to rising land values elsewhere. Moreover, disaster risk in this area is exacerbated by the practice of creating landfill from solid waste along river banks to increase space for home construction. Government programs to upgrade infrastructure and formalize land tenure through residential licenses so far do not apply to flood–prone areas, and thus cannot help these residents. Our ethnographic research into residents' experiences of flooding and the reasons for their immobility is based on in–depth, thematic interviews and observation carried out during 2010 – 2014.

2230 - Transport and climate change: mitigation and adaptation measures for transport infrastructures

Climate change mitigation and adaptation strategies in the transport sector

A. Leuxe (1)
(1) French Ministry of Ecology, Sustainable Development and Energy, Paris, France

International scientific works confirmthat climate changes (IPCC, 2007). Climate change already impacts our society and economy in different sectors: energy, infrastructures, agriculture, etc. Tackling climate change is complex, as it requires anticipation; transversal cooperation between elected representative, scientists, the civil society, etc.; and both adaptation and attenuation strategies.

Greenhouse gazes emissions from transportation are likely to increase in the coming years. Thus, international policies have been decided to limit greenhouse gazes emissions due to the transport sector. The French Ministry for Ecology has applied these policies and also introduced proactive policies,e.g.to better understand and quantify greenhouse gazes emissions and to encourage stakeholder cooperation to reduce there emissions.

All forms of transport are affected by the impacts of climate change on transport networks. Adaptation has become vital due to the long functional lifespan of networks and transport equipment. Four actions toadapt transporthave been decidedin the French Climate Change Adaptation Plan. This plan, set up in 2011 and available for 5 years, results from a consultation of various stakeholderat national and local scales and then, an administrative production. Itsfourtransport actionsareaimed atanalysing the impact of climate change on transport infrastructures and networks, anticipating transport system vulnerabilities and making preparations to improve the resistance and resilience of existing and future infrastructures to ensure the continuity and safety of transport services for goods and passengers:

- action 1: review and adapt technical standards for construction, maintenance and operation of transport networks (infrastructures and equipment) in continental France and French overseas territories
- action n°2: study the impact of climate change on transport demand and the consequences for reshaping transport provision
- action n°3: define a harmonised methodology to diagnose the vulnerability of infrastructures and land, sea and airport transport systems
- action n°4: establish a statement of vulnerability for land, sea and air transport networks in continental France and in French overseas territories and prepare appropriate and phased response strategies to local and global climate change issues

O-2230-02

Adaptation of transport infrastructures and systems to gradual climate change and to extreme climate events

M. Colin (1)
(1) CEREMA, Île de france, Sourdun, France

There is no remaining scientific doubts that climate changes (IPCC, 2007). First impacts of climate change are already being felt in numerous sectors, such as energy, agriculture, transport, etc. These impacts are predicted to increase in the coming years. The French Climate Change Adaptation Plan, implemented in 2011 and covering a five-year period, has identified actions and measures to tackle impacts of climate change in these sectors. Since transport infrastructures and systems are vital for economic and human activities and requires long-lasting investments, there is a high need of adaptation solutions. Thus, transport adaptation actions have been identified in the French Climate Change Adaptation Plan. These actions are aimed at improving resistance and resilience of transport systems to climate change. Therefore, a transversal working group with experts of various transport systems was established in 2011. The group met numerous times, among other things, to review and adapt technical standards for the construction, maintenance and operation of transport networks (action 1) and to develop a methodology of risk analysis (action 3).

A diagnostic of impacts due to long-term evolution of climate on infrastructures and on technical and normative reference documents for infrastructures conception, maintenance and operation has been done. Experts representative for all transport modes - road, bridge, rail, aeronautic, waterway, maritime mode, etc. - worked together to understand climate scenarios and to screen major long-term impacts of gradual climate changes and gradual changes of extreme weather events on infrastructures. Hundreds of technical and normative reference documents have been analysed. Documents that may be impacted by climate change have been listed and classified in categories which reflect their priority of adaptation. Climate variables that are required to adapt documents have been identified. The way forward will be to make climate projections to adapt documents and then, construction, maintenance and operation standards.

Adaptation of transport infrastructures to extreme events has also been addressed by the working group, through the development of a methodology for risk analysis. Extreme events are defined here as not easy to anticipate, localized and with high impacts on transport infrastructures and system - networks deficiency or failure and then, environmental, societal and economical impacts. The methodology comprises three main stages:

- analysing past and future extreme climate events - intensity, occurrence and spatial distribution, to identify climate events that are likely to impact transport,
- analysing infrastructure vulnerabilities of extreme climate events to build impacts scenarios
- analysing system functional vulnerabilities - mobility devices, accessibility, access for rescue services - to identify consequences of network disruption.

O-2230-03

A review of adaptation practices in Europe and challenges ahead

A. Aparicio (1)
(1) European Environmental Agency / Technical University of Madrid, Madrid, Spain

This presentation makes a summary of recent adaptation initiatives in the transport sector in Europe, and discusses

the key challenges ahead, based on the recent report of the European Environment Agency (http://www.eea.europa.eu/publications/adaptation-of-transport-to-climate). The factual information collected was based on data available in the Climate-ADAPT information platform, a literature review, case studies provided by many stakeholders, and a questionnaire on transport and adaptation addressed to EEA member countries in 2013. A total of 23 countries answered this questionnaire. Although the results obtained reflect the perceptions of a limited number of respondents, they provide interesting insights and encourage further analysis and discussions.

The review of experiences in Europe shows that mainstreaming adaptation into regular transport planning, and into other policies and plans, is not yet common. For example, measures planned in the context of low carbon transport like improved inter-modality offer also options for adapting transport to climate change but currently do not include it. Many tools developed for natural disaster risk management or contingency plans can easily be made relevant for climate change adaptation too. Meanwhile the adaptation focus is mostly on transport infrastructure, with little attention given so far to proof operations for future climate impacts.

Attention to adaptation remains relatively low in the transport agenda, particularly when compared to action in mitigation. Current action focuses on early, conceptual stages and less, so far, on implementation in spite of the urgent need to consider climate change impacts in those infrastructure investments being made now. Measures mostly follow a piecemeal and spontaneous approach, and are often organised autonomously by the different stakeholders. This fragmented approach is unlikely to be efficient or to guarantee the necessary consistency to address long-term challenges. Effective adaptation of the transport system requires moving from isolated and spontaneous adaptation to integrated, complementary and mutually supportive action of the many different stakeholders involved in and outside the sector.

Climate change mitigation is strongly influencing contemporary long-term visions on transport. Future transport systems (2050 and beyond) could be quite different from today's concepts: economic and social changes may alter current transport needs and transport generation patterns; technological and operational innovations may phase out currently dominant mobility solutions; governance reforms could provide more participatory and transparent decision making approaches, better balancing accessibility needs and environmental footprints. In such a dynamic environment, efforts focusing merely in adapting today's transport systems to future changes in climate could result in dedicating resources to problems that may no longer remain a priority in the long-term future, when adaptation may actually be needed. Ironically, adaptation actions with a narrow approach on today's systems could jeopardize the transition towards low-carbon transport concepts. It cannot be taken for granted that the transport system in 30 years from now will basically remain the same we know today: in fact, influential actors, including many national governments and the European Union (e.g. in the 2011 White Paper on Transport) are actively pushing to achieve a low-carbon transport system in the long term.

Significant changes are expected within the coming years in the transport sector. These are the combined result, among alia, of changes in the root causes of transport demand, changes in accessibility needs, and the implementation of innovative concepts. Although this long-term thinking has been largely influenced by climate change mitigation considerations, adaptation has largely been absent. Integrating adaptation objectives within these concepts could help to better identify the adequate policies, and could also help to properly assess and select the adequate adaptation actions to undertake in the short, medium and long term.

O-2230-04

Cross-border cooperation on adaptation strategies for roads in Europe

M. Grauert (1)
(1) CEDR, Copenhagen, Denmark

CEDR (Conference of Directors of Roads) is a European confederation of national road authorities (NRAs) that works on facilitating the exchange of experience and information and to analyse and discuss all road-related issues, especially infrastructure, infrastructure management, traffic and transport, financing, legal and economic problems, safety, environment, and research in all of these areas.

Road directors of Europe (CEDR) are aware of the importance of improving European cooperation. This is a key element for making progress in the road and road transport sector and strengthening the relationship with other modes of transport and with society at large.

Addressing climate change adaptation is becoming a very important task in CEDR, as road owners see the consequences of changes as an increasing matter. Cross-border cooperation in an appointed "Task group on climate change adaptation and mitigation" has become a valuable tool to facilitate National Road Administrations outline a strategy for adapting roads to climate change.

The strategy is centered on management, improvement, prevention and cooperation, and provides specific examples on areas to consider. These include examples of information to road users, incident management, implementation through planning phases, tools for risk analyses, legislative work, research and information sharing and many others.

Likewise, a template for an action plan is provided, giving examples on how to ensure responsibility and anchor climate change adaptation in the organization and create awareness in order to actually direct the organization towards a more climate-resilient profile.

The work of the CEDR-task group is a sound example in the context on how cross-border collaborations between NRA's can yield more than merely networking for enhanced means of climate change adaptation. A key outcome of the CEDR-work group on climate change is to provide a paradigm on composing a directly implementable strategy and action plan to every road organization, a plan which likewise will be applicable to other modes of transportation, e.g. railroads.

O-2230-05

Adaptations of road infrastructure to climate change - Selected examples from around the world (session 2230 - Transportation)

T. Dubreucq (1)
(1) Ifsttar, Departement for geotechnics, environment, natural hazards and earth sciences, Nantes, France

To adapt a road to a new and specific climate affecting one country, there is first need to investigate if it is observable elsewhere in the world. And owing to exchanges in the World Road Association, geotechnical engineers can determine rules to be taken to preserve the existing road network and the precautions to design a new road. We illustrate below some specific actions of five countries: Australia, Mexico, Morocco, Malaysia and South Korea.

Unsealed roads account for most of the roads linear in the world. To climate change, better maintenance is expected to ensure their durability. Australia has produced a guide for non-specialists which contains the technical maintenance of unpaved roads, in accessible terms. The guide introduces a wearing course instead of the surface layer of a paved road. Speed limits and maximum loads are indicated. A chapter is devoted to measuring the damage of unpaved roads by an original measure of dust which is produced in traffic. After the rain falls, barriers are put in place on the roads, for the drying time. The life service of Australian unpaved roads is thus to twenty years if the quality of building materials is respected and if the periodic road maintenance is followed (every three months in wet weather).

To repair the degradation of unpaved roads after the water floods, the Mexico infrastructure Institute has also made large-scale projects to test new soil treatment products, mainly based geopolymer. Geosynthetics can also be associated.

In the South, Morocco faces at an increasing silting of its road network. All forms of silting are encountered, and decrease the road safety. An analysis about road network and actions over several decades has been conducted.

Unfortunately it appears that this natural phenomenon is complex, non structurable and difficult to model or control.

The practices in stormwater management on the roads in Malaysia are very interesting. Malaysia is a tropical country which receives up to 2.5 m of water mainly between November and February. The return period of rainfall for network design does not exceed ten years. The road drainage follows the «Guidelines for the design of the road drainage» produced by the Department of Public Works and the Road Association of Malaysia. These recommendations are drawn from various repositories (AASHTO, British Standard, ...) but applied to local conditions. Malaysia has also dug in its capital Kuala Lumpur a tunnel of 9.7 km in length and 13.2 meters in diameter. The tunnel comprises a highway pavement in its upper half and a channel in its lower half. During thunderstorms, the entire tunnel can be flooded to drain all the water that flooded the city so far, of course after banning the traffic of vehicles.

South Korea has established for all its highways a national risk map and defined the types of landslides encountered. Torrential rains can reach more than 110 mm per hour. Global warming seems to cause an increase in the intensity of rainfall and mudslides and rocks on the slopes. Each highway drainage system (hydraulic structure, surface sanitation, drainage slopes, drainage trenches) has a return period well defined by geography (mountains, plains rivers). A drainage class and a flow rate calculation mode are assigned to each portion of highway depending on the extent of the watershed. Drainage system are adopted. To prevent the solid thrust (blocks, uprooted trees), many dams have been built.

O-2230-06

Assessment of the impact of La Niña phenomenon over the infrastructure of transport in Santander-Colombia

J. Gutierrez (1)
(1) Universidad de Santander, Environmental Engineering, Bucaramanga, Colombia

Extreme meteorological events associated with climate change are a real issue and have important impact over the economy of infrastructure sector, including high ways, hydrocarbon transport by pipelines, mines, etc., because saturation of soils by water can produce landslides and it could produce the fracture of pipelines or other kind of tangible assets. For example, an assessment of historical geotechnical failures in Ecopetrol (Colombian Oil Company) vs. extreme meteorological events shows that during La Niña (extreme rainfall period) geotechnical failures are three times greater. This work shows a method to identify places of risk by extreme meteorological events, mainly La Niña phenomenon, with focus in most probably alteration of rainfall. Our results illustrate the hot spots where there is a high probability of slight excess (120-160% of average rainfall) and high excess (>160%) of average rainfall. The results have been intersected in a GIS whit pipelines and highways with mass movement risk maps to identify the places of high risk along Santander region Colombia.

2230-POSTER PRESENTATIONS

P-2230-01

Socio-technical transitions to low-carbon consumption: Developing markets for electric mobility

J. Axsen (1)
(1) Simon Fraser University, Schoole of Resource and Environmental Management, Burnaby, BC, Canada

Societal transitions to low-carbon consumption require substantial changes in technological development and consumer behavior. This study applies a socio-technical perspective to study transitions—assessing opportunities and obstacles that are political, technological and social, and how they develop and influence one another. The present focus is the deployment of plug-in electric vehicles (PEVs) in Canada, a technology that is powered by electricity solely or in part. PEVs could reduce greenhouse gas (GHG) emissions in the transportation sector, which currently accounts for 28 percent of Canada's emissions.

The goal of this research is to characterize Canada's readiness for a socio-technical transition to PEVs and inform national and provincial GHG policy. Key uncertainties include Canadian consumers' awareness, perceptions, attitudes and values relating to PEV technology. Uncertain technical constraints include consumer driving patterns, access to PEV recharge infrastructure, and the GHG-intensity of electricity sources.

Data were collected via an in-depth, multi-part consumer survey completed by representative samples of vehicle buyers in Canada (n = 1,754), as well as electric vehicle owners in British Columbia (n = 112). Social readiness is assessed via questionnaire scales of awareness, attitudes, values and lifestyle. Consumers' technical readiness is assessed via a diary of driving behavior, and a questionnaire assessing home electrical infrastructure. Consumers' PEV design preferences were elicited via an innovative series of design exercises and discrete choice experiments. We then constructed regionally and temporally explicit models of PEV market penetration and use from disaggregated consumer data. These demand models are matched with provincial electricity generation data to estimate energy and GHG emissions impacts.

Results highlight opportunities and barriers for a transition to electric mobility. Opportunities includes findings that most car buyers already have access to some form of home based charging for these vehicles, and awareness of existing public charging infrastructure is not required to build consumer demand. Further, at least one-third want to buy some form of PEV under realistic price conditions, though patterns of preference, willingness-to-pay, and motivations differ substantially across segments of potentially early market buyers (as identifed through latent class analysis).

Potential barriers include a broad lack of familiarity with PEV technology, and controversies about the true (lifecycle) environmental impacts of PEV usage. Most important is the role of strong climate policy, such as carbon pricing or regulations such as a Zero-Emissions Vehicle mandate (as implemented in California and several other U.S. states). Without such supply-focused policies in Canada, it is unlikely that a substantial transition to electric mobility will occur in the coming decades.

Knowledge of PEV impacts, readiness and policy priorities is highly valuable to policymakers considering PEV deployment to meet GHG goals, as well as electric utilities, urban planners and automakers. These results also enhance knowledge regarding the social and technical challenges of low-carbon societal transitions.

P-2230-02

Science-policy-stakeholder dialogues about Low Carbon Strategy in the Colombian Freight Transport Sector

A. Cadena (1) ; R. Delgado (1) ; M. Espinosa (1) ; C. Garcia (2) ; C. Obando (2) ; F. Marquez (3) ; JM. Sandoval (4) ; R. Suarez (4)
(1) Universidad de los Andes, Bogotá, Colombia; (2) Unidad de Planeación Minero Energética, Bogotá, Colombia; (3) Ministerio de Transporte de Colombia, Bogotá, Colombia; (4) Ministerio de Ambiente y Desarrollo Sostenible de Colombia, Bogotá, Colombia

Colombia as other southern countries has undertaken a serious process for the statement of national post 2020 mitigation scenarios. We have identified and evaluated a package of more than 100 mitigation options by estimating abatement potential and costs. We have proposed sectorial mitigation plans finally adopted by government. A delightful dialogue process has been undertaken with a wide participation of industry, academy and government in order to get appealing and engaging mitigation scenarios and targets. Mitigations Actions Plans were adopted by government ministries.

This process was conducted under the Colombian Low Carbon Development Strategy (CLCDS). The dialogue was part of the MAPS project (Mitigation Action Plans and Scenarios), coordinated by SouthSouthNorth (SSN). Similar processes were adopted in the Long Term Mitigation Scenarios project in South Africa, as well as in the Low Carbon Strategies in Brazil, Chile, and Peru.

Commitments have been achieved in almost all sectors with modest but tangible results in agricultural, power end energy, and industry sectors.Transportation of passengers and freight have showed huge difficulties to decouple their growth from energy use and emissions. Energy demand in Colombia was 1331 TJ in 2010 and transportation sector accounted for 38% of final energy demand. Total GHG emissions were 218 Mton CO2e and transportation sector accounted for 10,5% of total emissions.

Diesel and gasoline are the main fuels used in road transportation. Either fuels account for more than 85% of the total consumption in this sector. The National Energy Plans signals the importance of diversify the transportation basket (as well as the power generation one and the oil and gas sources). Due to national regulations, diesel and gasoline contain a percentage of biofuels (ethanol for gasoline and biodiesel for diesel). Compressed natural gas (CNG) was initially used only by public urban passenger transportation vehicles (taxi cabs and buses). In recent years there has been an increasing number of vehicle conversions (automobiles and small trucks) from gasoline to CNG due mainly to high oil prices. As a result, CNG consumption has increased. Right now the country has a huge availability of Liquefied Petroleum Gas and representatives of the industry are looking for opportunities to increase its participation in the transport business.

We discuss the following questions in this paper: Why Colombia should change its energy matrix in freight transportation? How we succeed in introducing microLNG, GLP biofuels and electricity in the energy basket)? Could we introduce new vehicles and logistic technologies? Could Colombia made changes to river and rail transportation or any attempt will be defeated by stakeholders, reluctant to new technologies and sinked in the comfort of current affairs? How likely appear in the 2050 energy and emissions scenarios these changes? What barriers we have to overcome to get a more efficient transport of freight and finally a more productive economy? Which organizations and what regulations we need to achieve the cleaner and diversified 2050 scenarios?

This kind of issue is culming the analytical corridors in planning offices in Colombian think tanks and research centers. Colombia changed its main fuel for freight transportation from gasoline to diesel, from 1985 until 2000, following the global trends. Colombia has tried to scrappage the old trucks. Colombia has tried to foster cleaner fuels. Colombia has tried to renewed train and river. Little effects out of this strategies. One less unsuccesful than others.

After measuring the benefits, co-benefits, implementation and transaction cost, sectorial and economy wide, we propose a bundle of recommendations to get the energy efficiency and mitigation goals we aimed to achieve. These recommendations are oriented to solve market coordination and government failures.

P-2230-03

Challenges and Opportunities in Climate Change Adaptation of Coastal Cities: Lessons in the Adaptation Road Maps of Metro Manila and Singapore

PM. Paje (1)

(1) University of Asia and the Pacific, Asia-Pacific Studies, Pasig City, Metro Manila, Philippines

The Guide to Climate Change Adaptation in Cities (2011) published by the World Bank considers a city resilient if it is able to respond quickly and effectively to climate change impacts. The same guide contends that a resilient city's adaptation strategies should be integrated into its own disaster risk reduction and sustainable development policies. To get the public engaged and committed to embrace the concept of adaptation however is fraught with difficulty. As Coleman, Offenheiser, and Waskow (2009) argue in the book Climate Change and Global Poverty: A Billion Lives in the Balance, the concept of adaptation is a tough one to sell and remains something incomprehensible to the public. How can one convince people to segregate and recycle garbage when most people find it convenient to just put all things inside one garbage bag and throwing it anywhere? How can state policymakers promote that walking is both a healthy activity for both humans and the environment when they themselves don't even take public transportation? How can environment advocates teach that air conditioning is a source of CFCs when people congregate to the malls to take advantage of free air conditioning to escape the perennial tropical heat?

The road to climate change adaptation indeed is long and winding. Dessler and Parson (2010) consider climate change to go beyond the issue of the environment making it a serious and difficult matter to manage. But, as climate change poses inevitable challenges, it also offers opportunities in carbon trading through the Clean Development Mechanisms. This is the context that frames this policy analysis of the roadmaps of Metro Manila and Singapore in climate change adaptation towards their goals of becoming resilient cities in Southeast Asia. This analysis presents the challenges as well as the opportunities that these two coastal mega-cities in Southeast Asia have. The rate of a city's expansion in terms of territory and population is directly proportional to the increase in the risks it could face against climate change impacts especially if city residents are clueless about what possible hazards they are faced with. The wrath of super typhoon Haiyan in 2013 mirrored in the storm surge devastation of Tacloban City in the Philippines has been a tragic remembrance of a worst-case scenario to date if and when the next bigger storm hits major metropolises. Most people in Tacloban prepared for the usual strong winds but overlooked the enormous storm surges that did the worst damage. As cities are in themselves complexes, coastal cities are in a more precarious situation considering the millions of lives and resources that can be affected by the rise in sea-level and the threat of storm surges.

Adaptation of cities involves initiatives and measures whether formal or informal that leads to resilience against climate change impacts. Singapore is quite unique being an island city-state in itself. Metro Manila on the other hand is a microcosm of the nation-state it serves as a capital and major city. A glaring disparity exists between the two in terms of political regimes, economic and social development. In terms of climate change issues however, both cities have witnessed unusual flooding in the past five years. It is thus fitting in the context of climate change adaptation to examine the strategies that these coastal cities are undertaking how they address old environmental issues such as land use, energy conservation, and sustainable development to the emerging ones like E-waste disposals and Clean Development Mechanisms.

P-2230-04

A Study on Climate Change Impacts Adaptation Measures for the Hilly Road construction: Case of Nepal

N. Pokharel (1)

(1) Tribhuvan University, Environmental Science, Lalitpur, France

Nepal encompasses 85% of its land as hilly and mountainous area. Out of total 80,000 km road construction within the country only 18000km is with blacktopped. The steep slopes with fragile geology are the characteristics of the hilly region. Geologically Nepal lies on Himalayan area with the mobility of Tibetian and Indian Plate. So the vulnerability seems higher. The Impacts of climate change focused on water resource. The Himalayas towers are the source of rivers and rivulets in the country. 6000 rivers and rivulets are flowing from north to south up to Gangas River in India. The road and transportation sector requires to cross the rivers and return periods for the floods and extreme rainfall. The trend of extreme events seems changing. To cope with such events and impacts it requires some techniques. The Climate change may cause more flooding of roads, bridges and airport runways, especially in low land areas as a result of erratic rains. A range of adaptation responses can be employed to reduce risks through redesign or relocation of infrastructure, increased redundancy of critical services, and operational improvements. Roads, bridges, tunnels and railway lines will be vulnerable to increased precipitation, groundwater levels, temperatures and winds.

The road transport sector is a key area that contributes to climate change by way of greenhouse gas emissions. However, the transport sector is in turn itself affected by climate change. Higher groundwater levels associated with extreme precipitation will mean an increased risk of landslides on excavated slopes. There is a risk that the bearing capacity of bridge and tunnel foundations,

supporting walls and sheet pilings will be reduced by increased groundwater levels. This can be found in number of ways, especially for foundations on sand. Modern safety installations are significantly more sensitive to temperature increases than older installations and this may presents a particular problem. Autonomous adaptation to climate change is important because of the complexity and long lifetime of road. Furthermore, improved maintenance in the form of cleaning existing road drainage systems can retain drainage capacity corresponding to that of a new installation.

Whilst, transport systems and infrastructure designed to withstand typical weather patterns, climate change impacts arising in the near and longer-term can have an impact on the efficiency of transport operations and ability of infrastructure to withstand extreme events.

The designs of project road have been done considering the potential effects of climate change. From a road development perspective in Nepal, impact of climate change mainly takes the form of concentrated high rainfall resulting in the accelerated surface run-off from slopes and increased flows in gullies, drainage channels, streams, and rivers. These phenomena have a consequent effect on the stability and performance of road sections, bridges, and other structures.

Is electric mobility a driver to climate mitigation in the EU-27 countries? Myths and realities from energy systems analysis

J. Seixas (1) ; L. Dias (1) ; S. Simões (1)
(1) Faculdade Ciencias e Tecnologia - Univ Nova de Lisboa, Caparica, Portugal

In many research and policy fora, electric vehicles (EV) are considered effective alternatives to passenger mobility due to their contribution to CO2 mitigation, when compared with internal combustion engines, mainly if the power comes from renewables. Recent research [1] showed that for an EU-wide greenhouse gas emission reduction cap of 40% and 70% by 2050 vis-à-vis 1990 emissions, battery electric vehicles (BEVs) are cost-effective in the EU only by 2030 and only if their costs are 30% lower than currently expected. Vehicle costs and the capability to deliver both short- and long-distance mobility are the main drivers of BEV deployment. Other drivers include national mobility patterns and the cost-effectiveness of alternative mitigation options, both in the transport sector, such as plug-in hybrid electric vehicles (PHEVs) or biofuels, and in other sectors, such as renewable electricity.

A bottom-up partial equilibrium 36 multi-region model (PET36) representing these countries' energy systems linked through trade of the main energy forms was used. PET36 is driven by exogenous country-specific energy services demand, and it takes into consideration the evolution of energy prices, endogenous energy potentials and policy assumptions. Its main output is the cost-effectiveness mix of energy supply and demand technologies for the seven sectors: primary energy supply (e.g., oil and bio refineries, natural gas distribution pipelines), electricity and heat generation, industry, residential, commercial, agriculture and transport. This model allows us to get in-depth insights on the energy system transformation of each EU-27 country to deliver cost-effective BEVs for passenger mobilityup to 2050. We use two families of scenarios, shaped by varied EU level emission caps and BEVs cost curve.

Our presentation relies on results just published [1] and goes a step further, focusing on:

- (a) confrontint the national plans of each EU country on EV adoption with current status (actual deployment) and the results from our analysis, aiming to discuss the expectations and failures of electric mobility deployment in each EU country and the current and future role of public policy to overcome current barriers and risks;
- (b) assessing the reduction of greenhouse gas emissions in each EU country due to adoption of BEVs and PHEVs taking into account the whole energy system, i.e., not only the shift from internal engine combustion to electric engines, but also the shift in the power sector and refineries. The goal is to discuss the impact of electric mobility policy measures on the transformation of energy system, including trade-offs, co-benefits, risks and feedbacks.

We argue that the energy system analysis used in this research is the appropriate approach to discuss the impact of mitigation policies. Across Europe, as well as in other regions, electric vehicles are seen, both by climate policy makers and car markets, as a panacea for the mitigation of a significant share (up to 40%) of greenhouse gas emissions. However, detailed analysis at EU member state level shows that the adoption of this technology is far from expectations due to vehicle costs, charging constraints and the mobility model still in place based on individual ownership. We argue that radical mitigation in Europe will rely in electric mobility (including trucks) but there is the need to look across the whole energy system, to prevent risks and undesired feedbacks (e.g. increase of new fossil based power plants) and to expand co-benefits (energy efficiency and foreign oil dependency). Policy initiatives must be designed to make EVs' cost evolution cheaper for consumers than what is currently expected, while looking at risks of such pathway.

2231 - Cultural Heritage facing up to Climate Change, Sea Level Rise and Pollution

ORAL PRESENTATIONS

O-2231-01

Creation and evaluation of future indoor climate and risk maps for European cultural heritage buildings and their interior

M. Winkler (1) ; F. Antretter, (1) ; R. Kilian, (2) ; J. Leissner (3)
(1) Fraunhofer Institute for Building Physics IBP, Valley, Germany; (2) Fraunhofer Institute for Building Physics IBP, Cultural Heritage Reserach, Valley, Germany; (3) Fraunhofer Gesellschaft zur Förderung der angewandten Forschung, Brussels, Belgium

In the EU-funded Climate for Culture (CfC) project, an interdisciplinary research team of 27 partners investigated the impact of climate change on Europe's cultural heritage buildings and their interior collections. Thereby regional climate models and building simulation tools were coupled to assess the outdoor and indoor implications. Two different climatic scenarios, A1B and RCP 4.5, from the 4th and 5th IPCC-report were used as baseline for the projection of future outdoor climate data. The regional climate model REMO was applied for high-resolution simulations of outdoor climate over Europe and the Mediterranean for both climatic scenarios. These calculated climate indices were used as input for hygrothermal building simulation tools allowing a prediction of future indoor climate and its risk potential to interior objects.

To investigate the long-term impact of climate change on a variety of historic buildings the CfC project used the so-called "Generic Sacred Buildings": 16 fictitious but representative building models of unconditioned buildings like churches or monasteries, which are based on measurements of existing buildings collected during the CfC project. These Generic Sacred Buildings were placed on 474 locations all over Europe and the Mediterranean and building simulation tools were applied to simulate indoor climate for three time-windows: 1960 - 1990, 2020 - 2050 and 2070 - 2100. Afterwards, each indoor climate, in particular temperature and relative humidity, was evaluated by using a newly developed automated method which assesses nearly 200 parameters, like for example

temperature, relative humidity, deterioration rates or various damage risks. All results of this assessment process were collected and visualised as pan-European maps. Also the differences between the three time-windows were calculated for every parameter allowing the identification of changes from past to future periods.

Because of the sheer amount of available data, more than 52.000 maps were produced, the here presented evaluation of future indoor climate projections focuses on some selected parameters. A common insight from the maps is that mean indoor temperature will increase all over Europe for all investigated building types. As a result of the temperature development, frosting time inside the buildings decreases, mostly in Northern and Eastern Europe. An often inquired damage process is mould growth on collection objects. The maps hint, that mainly in Northern and Eastern Europe possible risks of mould growth will increase in future periods. Furthermore insect growth conditions inside the buildings were evaluated by calculating degree-days. Favourable growth conditions can be found around the Mediterranean and with increasing temperature in future time-windows these will also increase in Northern and mostly in the middle parts of Europe. The assessments also include risks for mechanical damages of wooden objects like panel paintings, statues or furniture. These damage risks were evaluated by analysing long- and short-term changes in relative humidity and show mostly a stable risk classification during the time-windows. Also chemical degradation processes were evaluated by using Lifetime-Multipliers. They indicate increasing damage risks mostly around the Mediterranean.

Long-term damage of climate and pollution on the stone and glass in Paris

RA. Lefèvre (1) ; P. Brimblecombe (2) ; M. Déqué (3) ; C. Grossi (4) ; A. Ionescu (5)

(1) Université Paris-Est Créteil, LISA, Paris, France; (2) City University of Hong Kong, School of Energy and Environment, Kowloon, Hong Kong; (3) Météo France – CNRS, Centre national de recherches météorologiques, Toulouse, France; (4) University of East Anglia, School of environmental sciences, Norwich, United Kingdom; (5) Université Paris-Est Créteil, Certes, Créteil, France

The urban fabric is affected by both climate and air pollution, but the magnitude of their impact varies over time. The effects of air pollution on the degradation and soiling of materials were particularly noticeable during periods of rapid urbanization, while the late 20th century has seen a reduction as a result of the decline in the aggressive pollutants such as sulfure dioxide. Soiling is more complex as there have been changes in the nature of the deposited particles over time, but as with the gaseous pollutants there have been improvements that accompanied more stringent regulations designed to improve air quality. Over the centuries there has been an increase and subsequent decrease in the rate of damage to building materials which can be interpreted in terms of the environmental Kuznets curve. The decline in the aggressiveness of pollutants in Paris makes it likely that climate driven processes will on balance play a bigger role in the future. Historically frost damage was important, but it is hardy likely to be relevant in a warmer future. This presentation attempts to estimate the rates of recession and soiling of calcareous stone and damage to glass and stained glass in Paris over many hundreds of years and understand how these processes will change through to the end of the 21st century. The long term variation of air pollution is assessed on the basis of past observations and estimated for the future from likely regulatory trends. Meteorological input derives from historical data and some non-instrumental weather records, while future climate is adapted from the Hadley Centre and Météo-France models under a2, RCP2.6 and 8.5 scenarios for the 21rst century. Converting this environmental input to long term change in damage has used dose-response functions from a range of sources to estimate the magnitude of the changes and where possible compare these with historical observations of the state of buildings made by architects and other observers.

Quantitative Nuclear Magnetic Resonance Imaging, Profiling and Diffusometry on Fluorinated Compounds to Preserve Cultural Heritage Porous Media and Safe for the Environment

L. Brizi (1) ; M. Camaiti, (2) ; P. Fantazzini, (1)

(1) Centro Fermi, Roma, Italy, University of Bologna, Department of Physics and Astronomy, Bologna, Italy; (2) Centro Fermi, Roma, Italy, National Research Council, Institute for geosciences and hearth resources, Florence, Italy

The preservation of historical buildings and outdoor cultural heritage is a necessity to hand down to the posterity works of art, as well as to guaranty an economic resource. The main causes of degradation of stones, one of the most important porous materials of these artifacts, are related to the chemical-physical processes that influence the ingress and diffusion of water (liquid or vapor) into the pore space. It is well known that water dissolves CO2 and pollutants from the atmosphere, causing acidic corrosion of the stone or the binder, and it is responsible of internal mechanical stresses due to freezing-thawing cycles or salt crystallization.

For the treatments, usually hydrophobic compounds (typically synthetic polymers) are applied, with performance (efficiency and durability) that depends on the compounds used, the treatment procedure and the chemical-mineralogical nature of the substrate. Many are the characteristics of the products to guaranty good performance: high stability (chemical, thermal and to photo-oxidation), high adhesion to the mineral substrate (interaction but not reaction with stone), low surface tension and suitable molecular dimensions which allow a uniform distribution, good penetration into the porous structure, and low propensity to pore blockage. Very important is the solubility of the product in solvent safe for man and environment. Perfluoropolyethers, applied on some historical buildings since the 1980s, have high stability, water repellency and low surface tension, but the protective treatment showed a low durability. Perfluoropolyethers containing polar groups able to give better interaction with stone, typically ester and amidic groups, were developed. Unfortunately, these compounds are soluble only in CFC and in supercritical CO2, therefore their use as protective agents for historical stone artifacts was abandoned since the 1995.

This work was focused on the preparation of a new protective agent with low average molecular weight containing short pendant perfluoropolyether segments linked to an oligosuccinamide chain in order to achieve: (i) high hydrophobic effect and photo-stability, (ii) good adhesion to the rock through the polar amidic groups, (iii) excellent distribution on the pore walls surface without their blockage, (iv) solubility in environmental friendly solvents.

Hydrophobic penetration and distribution properties of the compound applied on a biocalcarenite (Lecce stone), have been investigated by Nuclear Magnetic Resonance (NMR) Imaging, Profiling and Diffusometry of 1H nuclei, and compared with a perfluorinated commercial product. These NMR techniques has been proved to be a valid non-destructive and non-invasive technique for monitoring the conservation state and water absorption in materials and objects of interest to cultural heritage, as well as for evaluating the efficiency and distribution of protective or consolidation treatments.

The results obtained by Imaging were compared with those obtained by single-sided NMR apparatus. This last instrument, that allows for in situ non-destructive analyses, was equipped with a lift for automatic shift of the NMR sensor and allowed us to obtain high spatial resolution profiles of the NMR signal inside the samples. Two-dimensional correlations maps of the two parameters self-diffusion coefficient and NMR relaxation time gave further information on the performance of the treatments. The results demonstrate that the partially fluorinated oligoamide satisfies the main properties required to a protective agent (no color changes of the treated surface, high residual permeability and high photo-oxidation stability), and improves the water repellency of treated stone surfaces in respect to a fluoroelastomer, frequently applied as protective agent and here used as reference.

Urban planning and design to mitigate climate change impact: the role of heritage conservation in a dense urban city

EHK. Yung (1)
(1) The Hong Kong Polytechnic University, Department of Building and Real Estate, Hong Kong, China

Climate change and global warming has made urban heat island effects become more severe in cities facing rapid urbanization. The urban heat island phenomenon is even more severe in urban cities with the tall and massive high-rise building morphology. In contrast, built heritage sites consist usually of low rise buildings located in city centres. The conservation and adaptive reuse of historic buildings can provide potential breathing space among the high rise blocks to generate air paths and minimize the heat island effect. Thus, the careful planning and design of heritage sites can enhance human thermal comfort and mitigate the adverse impact of climate change in the dense urban cities, whilst preserving historic pride and cultural spot.

Climate change also alters the way that people live, work, worship or socialize in public space. What role can built heritage play in minimizing the adverse impacts of climate change on the microclimate of the urban environment? Conservation and Planning considerations should emphasize more on clusters of heritage sites in urban districts which can provide much greater impact on the overall urban environment than a single building.

This paper explores the relationship between climate change mitigation and built heritage conservation in a dense urban city.

It is proposed that a robust database of spatial maps will be constructed, of an urban districts in Hong Kong with the aid of GIS. The study maps will display the urban fabric including the locations of heritage sites, building height and mass, building footprint, land use, open space, and topography. Micro-climate environmental maps which include temperature, and wind velocity will also be compiled. Field measurements of the meteorological parameters at the selected studied heritage sites will provide supplementary data for the spatial maps.

Despite the robust maps and measurement are important, the ways in which conservation of heritage buildings can influence the social experience of adapting to climate change would be worth for investigation. The impact of climate change should not be limited to physical and environmental impacts, in fact, the socio-economic changes due to climate change will have also have a great impact on the conservation of cultural heritage. On one hand, climate change alters the ways that people, in relation to the environment they live, work, worship and socialize in buildings, sites and landscapes with heritage values. For example climate change modifies the social interaction patterns in public spaces. On the other hand, heritage can also affect the social experience of climate change. Heritage conservation can have a positive effect on the lives of people in a changing climate and how they perceive climate change. For example, a green common space in a heritage site can provide the community with a pleasant breathing space in the middle of high rise buildings.

Thus, it is of paramount importance to examine the extent to which the adaptive reuse of heritage buildings can also incorporate design considerations which mitigate the physical and social effects of climate change. This proposed research will help towards responsive and innovative solutions to the UHI effects and climate change with the conservation and reuse of heritage buildings. A better understanding of the links between built heritage, urban morphology and the surrounding microclimate is essential to create successful climate change mitigation strategies for dense cities.

The study will provide useful reference data for urban planners and urban designers helping them to incorporate environmental and social considerations on the conservation of heritage buildings, and most importantly, help to ensure the better use of heritage sites to mitigate climate change adverse impacts in dense urban cities.

O-2231-05

Towards a Framwork for Evaluating Existing International Best Practices on Climate Change and Heritage

A. Potts (1)
(1) International Council on Monuments and Sites (ICOMOS), United States National Committee, Washington, DC, United States of America

This presentation examines the response of the heritage sector to climate change with an emphasis on the key themes and theoretical frameworks that have been adopted by major organizations to date. It finds that a formal concern for the impact of climate change on heritage sites is increasingly being complemented by a broader concern for the impacts on social sustainability from the degradation of intangible heritage and "a sense of place" attendant to climate change. Attention is also increasingly being paid to the ways in which cultural heritage is a solution to climate change, for example offering lessons in past human successes and failures in adapting to environmental changes, and providing insight into the origins of the modern climatic situation.

It has now been almost a full decade since the issue of the impacts of climate change on natural and cultural heritage properties was formally brought to the attention of the World Heritage Committee. This resulted in an expert meeting in March, 2006 at the UNESCO headquarters in Paris which issued a joint report on "Predicting and Managing the Effects of climate change on World Heritage" as well as a "Strategy to Assist States Parties to the Convention to Implement Appropriate Management Responses." The World Heritage Committee endorsed these two documents at its 30th session (Vilnius, 2006) and requested all States Parties to implement the strategy so as to protect the outstanding universal values, integrity and authenticity of the World Heritage properties from the adverse impacts of climate change. In 2007 climate change and heritage experts, including ICOMOS, issued a Policy Document on the Impacts of Climate Change on World Heritage Properties which among other things identified future research needs. Broadly speaking these documents provide guidance on (1) Monitoring and reporting; (2) Mitigation; (3) "Corrective actions" including management, adaptation, and risk management and (4) Collaboration, cooperation, and sharing best practices and knowledge.

As the world approaches the 10th anniversary of these reports, this presentation would examine the climate change strategies from major cultural heritage organizations around the world, using the 2006 and 2007 guidance documents as touchstones. Two examples of these heritage responses are those of the United States National Park Service (NPS) and the International Trust Organization (INTO).

INTO represents national heritage trust organizations in over 40 countries and has been represented at 4 of the last 6 COPs. INTO views climate change through the lens of the Victoria Declaration on the Implications for Cultural Sustainability of Climate Change which was adopted by INTO at its 14th International Conference of National Trusts held in 2011. The Victoria Declaration focuses on the capacity of climate change to undermine the integrity of the world's cultures, and the resulting social dislocation and social instability likely to follow, framing these issues in terms of intergenerational equity.

The NPS is the lead US federal agency for the management of cultural heritage. In 2014, it signed a policy memo Climate Change and the Stewardship of Cultural Resources, which set out a leadership role that looks at both the impacts of climate change on heritage and the capacity to learn from these over time, and applies those to the four pillars of climate change response that NPS established in its 2010 Climate Change Response Strategy: science, adaptation, mitigation, and communication. While focusing on impacts, the Policy includes the science of learning from cultural heritage about climate and environmental change, for example, learning about human adaptation to climatic variability through time from cultural heritage and learning from heritage to reacquaint ourselves with energy-saving practices and methods that have become less used.

O-2231-06

Multi-Criteria Accuracy Assessment for Indoor Climate Change Projections of Historic Buildings

R. Kilian, (1) ; H. Brandl, (2) ; F. Antretter, (3) ; M. Krus (3) ; K. Sedlbauer, (4)

(1) Fraunhofer Institute for Building Physics IBP, Cultural heritage research, Holzkirchen, Germany; (2) Fraunhofer Institute for Building Physics IBP, Preventive conservation and heritage preservation, Holzkirchen, Germany; (3) Fraunhofer Institute for Building Physics IBP, Hygrothermal building analysis, Holzkirchen, Germany; (4) Fraunhofer Institute for Building Physics IBP, Director, Holzkirchen, Germany

Recently hygrothermal building simulation has been applied for the projection of damage risks from future indoor climate in historic buildings. This has been done using generic weather data obtained from dynamic downscaling of regional models with different global climate change scenarios (A1B and RCP4.5). The objective of this paper is the development and definition of new concepts to assess the accuracy of hygrothermal simulation models for indoor climate of historic buildings in the contexts of climate change and preventive conservation. Preventive conservation is aimed at the permanent conservation of works of art and objects of cultural value by improving ambient conditions and by reducing or minimizing relevant risks. The quality of simulations is of significant importance especially when assessing climatic risks in historic buildings with precious interieur and works of art, since misjudgements of planned measures can result in irreversible damages. Moreover, hygrothermal simulations offer new opportunities in calculating the effect of different measures to improve indoor climate. But also for the assessment of future risk it is important to know how reliable a simulation model is for the present. Therefore, it is important to develop criteria to assess the results of simulation with regard to preventive conservation, and to verify them by means of case studies. The indoor climate of the small village church St. Margaretha in Bavaria is characterized in detail by means of measured data and reproduced by means of simulation models. For this case study a new approach was developed using multiple criteria in the form of different damage functions for accuracy assessment. This assessment is only one important element in the chain of uncertainties that applies when using projected future climate data from global climate change projections. Therefore also the measured long-term outdoor climate from a weather station nearby has also been compared to the generic weather data for the recent past (1960–1990) for different climate change

O-2231-07

The balance of air pollution and climate as drivers of damage to heritage

P. Brimblecombe, (1)

(1) City University of Hong Kong, School of energy and environment, Kowloon, Hong Kong

It has been well known from classical times that weather and smoke cumulatively damage buildings. The shifting climates of the past had an impact and historic exposure to aggressive air pollutants, especially those from coal which caused not only blackening, but led to surface recession and crust formation that resulted from high sulfur dioxide concentrations. The situation has changed as air pollution is more effectively regulated. Our understanding of the impact of climate on heritage assets requires the development of material or heritage climatologies that recognise the role of the combination of meteorological factors, cycles of climate and the long accumulation of damage. Although controversy surrounds long-term climate predictions, there seems little doubt that the world will become warmer and rainfall patterns will change, even if we cannot be sure of the magnitude. The changes are often quite small, just a few degrees change in temperature or percentage changes in rainfall or relative humidity. This means amplification is often necessary for the effects to be significant. Phase changes (freezing or salt crystallisation) can be important amplifiers, while biological effects (changing insect numbers or rapid fungal growth) can also enhance the outcomes from small temperature changes. The impact of changed rainfall can be increased by a larger number of wet days or longer times of wetness. The frequency of extreme events may also alter the rate of material damage. Air pollutants will doubtless be more regulated in the future, but new problems may arise through the presence of ozone and diesel particles in the air and novel pollutants might also have an impact.

O-2231-08

Socio-cultural implications of Climate Change for Cultural Heritage

M. Cassar (1)

(1) University College London, UCL Institute for Sustainable Heritage, London, United Kingdom

When considering the interaction between cultural heritage and climate change, the most media-visible effort on climate change is undoubtedly scientific research. Yet society requires science to have wider context and meaning. It needs to be relevant. Therefore the socio-cultural impact of climate change must be part of any discourse on the implications of climate change for cultural heritage.

Not only would this inform our understanding and influence our response to climate change impacts, it can also make our response more resilient and sustainable. There are inherent cultural and social dimensions to climate change. Artists and sculptors, writers and poets, performances and exhibitions engage the public with climate change in ways that are necessary and important. They provide critical pathways for adaptation. The arts and humanities, social sciences and economic disciplines provide different lenses through which to develop new responses to life-changing events. By developing a range of perspectives, we improve our chances of co-creating sustainable survival strategies.

Cultural heritage research until recently, has been largely concerned with the impact on ancient and historic materials and assemblies such as those caused by increasing sea levels and floods, changes in the moisture contents of the air and in the conditions of soil (especially for archaeological sites) and migration of pests. Yet cultural heritage is more than stones, bricks and mortars.

In addition to these impacts, climate change can severely affect the sustainable conservation of cultural heritage places by altering the traditional way of life of communities. The relationship of communities to their landscape, their work and social habits, can be affected by the rapid deterioration of physical assets and loss of authenticity[i].

In 2008, World Monuments Watch and the World Monuments Fund provided dramatic evidence of these consequences when it listed a number of places at high risk of loss due to the effects of climate change. These included:

Herschel Island, Canada (from rising sea levels, eroding coastline and melting permafrost);

Scott's Hut and the Explorer's Heritage, Antarctica (from warming triggering large amounts of precipitation leading to microbial infestation and decay);

Sonargaon-Panam City, Bangladesh (from the low-lying terrain making it especially vulnerable to flooding and rising sea levels);

Leh Old Town, India (from changing weather patterns in the Himalaya bringing more rain in the summer thus creating problems for the flat mud roofs designed for the originally dry climate);

Kilwa Historic Sites, Tanzania(from serious rapid deterioration of the archaeological and monumental heritage due to erosion and vegetation caused by rainwater wash accentuating the risks of collapse of the remaining structures on the edge of the cliff); and

Chinguetti Mosque, Mauritania (from effects of the expanding desert, changing rainfall patterns, vegetation loss, soil erosion and extreme temperatures).

If scientific research is to understand deeply the cause and effect of change on cultural materials, and if it is to develop sustainable adaptation strategies, the values associated with these places need to be integral to the solution. This

contribution will focus primarily on the language that is used to highlight the significance of these endangered sites in order to evaluate the extent to which the socio-cultural impacts of climate change are integrated into scientific studies of cultural heritage.

[i] UNESCO World Heritage Centre (2006) World Heritage Paper No. 22. page 10. Available at: http://whc.unesco.org/en/climatechange/ and published in English and French.

Protecting coastal heritage from coastal rapid events: Epistemological issues

H. Regnauld (1)
(1) Université de Rennes 2 et Institut Universitaire de France, Laboratoire costel, umr letg, Rennes, France

Coastal heritage is comprised of many different types of artefacts. Some of them are located along the coast but have no direct relation with the sea (such as tombs, stones circles). Others (for example harbours, fisheries, dykes, shell middens...) do present a deep relation with the sea level, the wave directions, the local winds and possibly with sediment movements. The first group of heritage site may, today, be concerned by relative sea level rise and/or coastal retreat and beg for a protection. Though these archaeological objects may be moved inland and still keep most of their scientific value and cultural interest. In this case their land ward shift and protection is not vey different from their possible inclusion into a museum collection.

The other set of heritage sites is totally different. Most of their scientific value depends on their precise relation with the "natural" environment at the moment of their building. As objects they can be deconstructed and stored in a museum but as a site they cannot be understood outside of the very precise geomorphological setting where they were built. In these two cases the epistemological issues are clearly different. Though a large part of the scientific value is located inside of the object itself (it is a real property of the object, as realists philosophers have often explained it) some other dimension of the scientific knowledge is not in the object but in the relation it has with the local passed environment, and especially with the local ancient morphodynamic condition. Therefore what should be protected (or reconstructed) should not only be the object but the natural ancient environnement (the local site when sea level was different) and the ancient events which may have taken place such as storms or human induced soil erosion. The context of the object is as important as the object itself. This rises new questions about heritage and cultural approaches of heritage conservation. How can climatic events be understood as heritage ? How can ancient human induced erosion processes may be included into the wide and general notion of heritage? Our scientific knowledge about ancient processes is limited and new dating techniques regularly appear and help to produce new information. So there is an always wider range of objects which can be dated : with Pb 210 muds may be dated even when they do not contain organics. The question of how large is the accommodation space around the artefact is totally opened: how far from the object may the environnement provide relevant information? How far should the protected area be extended? Is this protected space compatible with other activities on the coast?

This speech present some pre roman examples in Brittany and some post cold war examples in Taiwan.

Outdoor-Indoor climate relationships for Cultural Heritage

D. Camuffo (1) ; J. Leissner (2) ; C. Bertolin (3) ; F. Antretter, (4) ; M. Winkler (4) ; L. Kotova (5) ; U. Mikolajewicz (6) ; A. Van Schijndel (7) ; H. Schellen (8) ; T. Broström (9) ; G. Leijonhufvud (10) ; J. Ashley-Smith (11) ; D. Jacob (12)
(1) Consiglio Nazionale delle Ricerche, Istituto di scienze del clima e del atmosfera, Padua, Italy; (2) Fraunhofer Gesellschaft zur Förderung der angewandten Forschung, Brussels, Belgium; (3) Institute of Atmospheric Sciences and Climate (ISAC) – Italian National Research Council (CNR), Padova, Italy; (4) Fraunhofer Institute for Building Physics IBP, Hygrothermal building analysis, Valley, Germany; (5) Climate Service Center 2.0, Helmholtz center geesthacht, Hamburg, Germany; (6) Max Planck , Institute fur meteorologie, Hamburg, Germany; (7) Technical University, Einshoven, Netherlands; (8) Technical University, Eindhoven, Netherlands; (9) Uppsala University, Gotland, Sweden; (10) Uppsala University, Department of art history, Uppsala, Sweden; (11) JAS, Cambridge, United Kingdom; (12) HZG/ Climate Service Center 2.0, Hamburg, Germany

Not only historical buildings and outdoor monuments are exposed to climate changes and related risks. The exchanges of air, heat and moisture through the building envelopes will affect the indoor climate too, with potential risks to collections, paintings, furniture etc. The potential impact of mechanical, chemical and biological agents will depend on the outdoor climate change, the building structure and the material type. In order to know the expected changes and assess risk factors, the EU funded «Climate for Culture» Project has investigated the problem and produced thematic maps over Europe, using the REMO regional climate model at 10 km ´10 km space resolution. Two moderate IPCC emission scenarios have been considered: A1B and RCP 4.5. The former to make comparisons with previous studies easier; the latter as updated reference. The situation has been calculated for two future time windows, i.e.: 2021-2050 near future and 2071-2100 far future. Changes have been highlighted calculating and mapping the difference between each future map and the related situation in the 1961-1990 past reference period.

The first step has been to calculate the outdoor climate (e.g. precipitation, dryness, temperature, humidity, time of wetness, repeated freezing thawing, salt crystallization cycles), then the indoor climate and finally the potential damage and risk factors. To this aim, it has been necessary to assess the impact of climate change through an improvement of the prediction models; then to develop a methodology to assess the climate-induced risks on materials and building envelopes. The study has been based on some 120 case studies plus 16 classes of generic building types, each class being characterized by a different building volume (small/large), structure (heavy/light weight), moisture buffering performance (low/high) and window area (small/large). A number of key materials (i.e. stone and masonry, metals, wood and veneers, painted wood, paper, silk and colour photographs) have been considered, either because they are commonly used in this field, or for the potential risk that may derive under certain unfavourable circumstances. The relevance of deterioration mechanisms and the risk factors have been calculated using specific damage functions, either known in literature or tested in laboratory within this Project. Damage functions and/or thresholds link the changes of the climate variables to a specific risk of damage. The level of risk has been defined according to the number of events that have exceeded some specific thresholds, or the time elapsed above them. A traffic light code (i.e. green colour: safe; orange colour: attention; red colour: risk) has been used to express the risk levels. At the end, a total of 55,650 high-resolution thematic maps over Europe have been produced.

The uncertainties related to the project outcomes include the uncertainty band in risk maps, forcing conditions and the used climate model, significance of the climate change pattern, building simulation, damage functions. The above uncertainties have been analysed to assess the confidence limits of the future scenarios that should be considered in view of any decision support/making system. Although the study has been focused on cultural heritage conservation, some outcomes might be useful for other social application fields, e.g. temperature changes and increased number of tropical days may be related to health, cultural tourism and energy consumption; mould growth and pest infestation to sick buildings. The recovery of early instrumental observations and various proxies has also been considered to produce long-term urban outdoor and indoor historic climate series (e.g. 1500-today), or to reconstruct the sea level in Venice (1200-today). This has been useful to improve understanding and to refine future simulations.

The analysis of the results shows that climate change may have negative, neutral or positive effects (e.g. faster or slower deterioration rates, more or less need for heating, cooling or humidifying) depending on specific problems, aims, solutions, and building use. These results offer a timely information to prepare adaptation and mitigation strategies, or to take advantage from the positive aspects, when possible. In this sense, this project provides an informative tool aimed to assist policy makers, conservators, architects and other users, in view

of an efficient strategy for management and preventive conservation of the European cultural heritage.

In the times of climate change, a global imperative is to save energy and reduce our carbon footprint. Museums and other cultural institutions are deeply implicated in these concerns as major consumers of energy, particularly heating and ventilation systems often housed in modern buildings. The demand for a better understanding of the interactions between cultural heritage collections and the climate and future perspective of energy consumption are pressing. The current state of knowledge highlights the need to develop strategies for protection and adaptation which requires specific risk assessment not only in the short but in medium and long term. Above all such risk assessment shall be focused on the correspondent building type and geographic location of the end user to provide a scientific support in planning target interventions in terms of lower energy consumption and cultural heritage protection.

This intervention exploits and analyzes the data developed within the EU-funded research project Climate for Culture (CfC) (www.climateforculture.eu) active 2009-2014 to assess, in the Alpine region, the future energy consumptions of HVAC systems as well as the specific risks of mould, pest infestation and freezing-thawing cycles looking at several building types different in level of control, quality of envelope, windowed area, thickness and construction materials.

The CfC project, over the past five years, has investigated the influence of current and future climate change on cultural heritage objects [Kilian et al. 2013; Leissner et al. 2013 and 2014]. This large scale EU research project has now made available for a wide community of stakeholders scientific knowledge, technological innovation and new data concerning future indoor projections of thermo-hygrometric variables and HVAC energy consumption from regional climate models in a range of generic and exemplary buildings. In particular the data which generate the Climate for Culture maps, supported by other CfC outcomes as recommendations to minimize energy consumption, preservation strategies and the exDSS software for implementing the decision support system, provide unique and useful tools for helping stakeholder in planning energy saving and preventive conservation intervention strategies in their area of interest in advance.

The purpose of this work is to create an exemplary data analysis focused on the Alpine region, to help final users in exploiting CfC results as tool to assess in which extension the impact of the ongoing climate change will affect a specific geographic area over the near (2021-2050) and the far future (2071-2100). The results will be analyzed in term of energy saving and risk management strategies.

Present and future salt climatology in France

B. Menéndez (1)

(1) Université de Cergy-Pontoise, Géosciences et Environnement Cergy, Cergy-Pontoise cedex, France

Following the concept of "salt climatology" introduced by Grossi et al. (2011) which deals with the knowledge of environmental parameters conditioning salt weathering of cultural built heritage, our objective in this work is to compare the spatial salt weathering distribution in France in the near past (1971-2000) to the one predicted in the future (2071-2100).

To quantify salt damage, different methods are used depending on the salt type. For some salts the number of phase transitions is estimated from meteorological data, temperature (T) and relative humidity (RH). For other salts the damage is estimated just from the environmental conditions. In this study we took into account three different salts: Sodium Chloride, Sodium Sulphate and Calcium Sulphate. For NaCl we estimate the number of times salt can crystallise from a solution. To do that we consider the number of times that daily relative humidity crosses the deliquescence value of 75.3%, from RH higher than 75.3% to RH lower than 75.3%, and for temperatures above 0°C. To estimate the weathering produced by Na2SO4 we count the number of times the equilibrium line between thenardite and mirabilite has been crossed in the phase diagram temperature - relative humidity. On this phase diagram for Na2SO4 we assume that the line separating thenardite and mirabilite domains is a straight line for the temperature range between 0 and 35°. For gypsum, it is assumed that when relative humidity is higher than 80%, gypsum will precipitate on the inner part of the rock inducing important damage, whereas it will precipitate on the surface when relative humidity is lower than 80%, with less damage associated. Therefore the number of days with relative humidity higher than 80% has been considered as an estimator of gypsum weathering. In this way we calculate the number of transitions of Sodium Chloride and Sodium Sulphate and the number of days with RH higher than 80% for two locations in the North-West of France, Rouen and Caen.

To estimate salt weathering distribution in France we use the methodology presented in Grossi et al. (2011). To obtain a "simple" way to estimate salt transitions in different locations, we plotted the number of monthly salt transitions calculated for the period 1960-2008 in Caen and Rouen data as a function of the difference between mean relative humidity and the equilibrium relative humidity for each salt. For sodium chloride the relative humidity equilibrium is equal to 75.3% and it is independent of temperature, in the range 0 to 40°C. For sodium sulphate we obtain the equilibrium relative humidity for each temperature from the phase diagram. For calcium sulphate we consider the 80% relative humidity threshold. By a regression fit of this plot we can associate a number of monthly transitions to the mean relative humidity for the month by a polynomial function. This methodology allows estimating the salt damage from simple data as the mean monthly relative humidity.

We estimate the salt weathering in 44 locations uniformly distributed in France, applying the obtained regression to meteorological data from 44 stations and to future model data at the same locations obtained from climate models. All the past data come from Météo-France stations from 1971 to 2000 and future data from simulations of Arpege model for 2071 to 2100, A1b scenario. The final goal was to classify the different salt weathering behaviours in different regions. For each station we calculate the mean, max, min and standard deviation of the number of transitions (NaCl and Na2SO4) or the number of days (CaSO4) obtained from the polynomial regression functions. After that we apply an Ascending Hierarchical Classification to the data to classify the different locations.

The results show that for past data 3 different "salt behaviour" classes are well differentiated but for future data the classification is more complex and does not correspond to the actual one. In general, we can distinguish three geographic areas in a N-W to S-E direction. In the Northern part weathering by NaCl and Na2SO4 will remain constant or slightly decrease but gypsum effect will be more important. In the central part, covering most of the France, salt weathering will increase for the three salts and in the southern part, NaCl and Na2SO4 salt weathering will increase but gypsum weathering will decrease.

2232 - The Copernicus Climate Change Service : an European answer to Climate Change Challenges

ORAL PRESENTATIONS

K-2232-01

Europe's Eyes on Climate Change

P. Brunet (1)

(1) European Commission, Dir. of aerospace, maritime and defence industries of dg grow, Bruxelles, Belgium

Climate change is a major global challenge with a range of potential social and economic impacts and the need for accurate information about the impacts of our changing climate is growing increasingly urgent.. Copernicus, through its new thematic service, will support policy-makers and relevant public authorities in monitoring the changing climate in order to better understand its potential effects and take appropriate actions. To illustrate the effort dedicated to this operational programme, a a total budget of EUR 4.3 billion has been allocated to the Copernicus programme (including the satellites), EUR 900 million thereof are dedicated to the six services. The importance of the climate change is reflected by the allocation of EUR 215 million (almost a quarter of the services budget) to the Copernicus Climate Change service (C3S). This service will bring together and integrate many different sources of information about the Earth, including data from the dedicated and operational Sentinel satellites and information from the other Copernicus services monitoring our oceans and ice masses, our atmosphere, and the Earth's land surfaces. The study of climate change involves a wide range of stakeholders and different scientific disciplines. Consequently, the C3S will be inherently cooperative, collaborative and international. Copernicus aims at becoming a trusted reference source for climate-related information and will become Europe's main contribution to global efforts to better understand and monitor our planet's natural systems. The C3S products will comprise ECVs (Essential Climate Variables), a set of key variables identified by GCOS for monitoring and predicting climate change, as well as Climate indices and Indicators required to address sector specific issues. Amongst the first sectors to be taken up by the pre-operational service are domains of particular interest, for instance water management and energy. Based on the ECVs and the indices and indicators tailor-made products will be developed integrating geophysical data with ancillary data on population, infrastructures, industrial assets, transport, etc. These products will support the holistic assessment of proposed climate policy measures for different possible scenarios for future developments. The Copernicus Climate Change service is ready to begin operations in a phased approach, starting with a proof-of-concept and the pre-operations. The service is implemented by the European Centre for Medium-range Weather Forecasts (ECMWF) [cf. Jean-Noel Thepaut «The Copernicus Climate Change Service», same session] The service will embody a comprehensive operational climate change monitoring system, which will continue to evolve in light of, and in close cooperation with, existing European and international initiatives, projects and activities, which it will complement with integrated modelling, reanalysis and observation capabilities.

O-2232-01

The Copernicus Climate Change Service (C3S)

JN. Thepaut (1)

(1) ECMWF, Research, Reading, United Kingdom

This presentation will provide an overview of the C3S:

This service will combine observations of the climate system with the latest science to develop authoritative, quality-assured information about the past, current and future states of the climate in Europe and worldwide. The service will benefit from a network of observations, both from in situ and satellite sensors, and modelling capabilities. Moreover, it will provide key indicators on climate change drivers (such as carbon dioxide) and impacts (such as reducing glaciers).

The service will deliver substantial economic value to Europe by (1) informing policy development to protect european citizens from climate-related hazards such as high-impact weather events, (2) improving planning of mitigations and adaptation practices for key human and societal activities, (3) promoting the development of new services by providing datasets and tools following an free and open data policy.

The talk will review the expected portfolio of C3S products and datasets which include consistent estimates of multiple Essential Climate Variables, global and regional reanalyses (covering a comprehensive Earth-system domain: atmosphere, ocean, land, carbon), products based on observations alone (gridded; homogenised station series; reprocessed Climate Data Records), a near-real-time climate monitoring facility, multi-model seasonal forecasts and climate projections and scenarios at global and regional scales.

This wealth of climate information will be the basis for generating a wide variety of climate indicators aimed at supporting adaptation and mitigation policies in Europe in a number of sectors including (but not restricted to) energy, water management, agriculture and forestry, insurance, health, tourism, infrastructure, disaster risk reduction, coastal areas). The service will be fully operational by 2018, and continually and independently evaluated and improved, to ensure that C3S represents the latest developments in climate science and that innovative service elements are introduced reflecting current research. Appropriate channels and interfaces with Research and Innovation activities in Europe will be established to ensure an efficient transfer from research to operational climate service related activities.

O-2232-02

How is the climate changing? Climate monitoring based on observations

D. Dee (1)

(1) ECMWF, Reanalysis, Reading, United Kingdom

Earth observations, recorded over time by a multitude of instruments ranging from early mercury barometers to synthetic aperture radars and other advanced satellite sensors, contain the fundamental information at our disposal to describe in detail how the climate has changed

since the pre-industrial age. Observations contain the evidence that the Earth surface is warming, glaciers are melting, sea-level is rising and the oceans are acidifying. Observations allow us to monitor and assess more subtle changes taking place in our environment related to air quality, regional rainfall patterns and the occurrence of extreme events. Observations provide the foundation for developing and testing the Earth-system models and prediction systems that are needed to help us understand our common future.

An important challenge for the Copernicus Climate Change Service therefore is to improve access to observations and to the tools needed to render them useful for climate science and climate services. A dedicated Climate Data Store is being developed for this purpose, with a catalogue that includes in-situ observations, measurements from space, homogenised and reprocessed climate data records, model-based climate reanalyses and information about data quality and uncertainties. The reanalysed data sets, constructed by combining climate observations from multiple sources with state-of-the-art models, provide the most comprehensive view of the changing climate. They contain time series of many essential climate variables, pertaining to the atmosphere, land surfaces, oceans and cryosphere, that extend back by decades or more. Continual improvement of climate reanalyses with complete and consistent descriptions of the Earth system at global and regional scales will be key to the success of the Copernicus programme.

O-2232-03

Climate prediction and projections in support of climate services

S. Planton (1)
(1) Météo-France, CNRM, Toulouse, France

One main basic component of climate information disseminated by climate services are future climate predictions and projections. Either used directly or through sectoral impact analyses, future climate simulations are needed to develop adaptation strategies or to evaluate the efficiency of climate policies. Long-term forecasting is already developed at the European and at the international level with some applications that are already useful in different socio-economic fields, like in the energy sector either at mid or tropical latitudes. Climate projections, from global to regional scale, are already feeding services within the context of national climate services all around the world with a very large spectrum of potential applications. We will give some insights on the usefulness of climate predictions and projections within the context of evolving requirements coming from the user community. We will give specific attention on the uncertainty issue with the common practice for climate prediction and climate change projection consisting in using multi-model ensembles of simulations putting some constraints on the climate services construction.

O-2232-04

The impacts of climate change - Sectoral applications

R. Vautard (1)
(1) Laboratoire des Sciences du Climat et de l'Environnement, Saclay, France

Climate change, its current and future foreseenable impacts have been assessed in the 5th IPCC report. Beyond mitigation, necessary to keep climate warming at a manageable level, the report pinpoints the need for adaptation for coping with unavoidable consequences. However most damageable impacts are expected in several decades, which is sometimes too far a horizon, with a number of uncertainties, to easily foresee businesses in a sustainable market for adaptation.

The talk will present exemplified areas where impacts of climate change present sufficient evidence and challenges to be implemented in a public service like de Copernicus Climate Change Service. It will also review, for a few cases, new challenges for science, and the need for even basic science to support climate change services. These exemples will cover classical sectoral areas such as water, energy and health. It will also develop from a few examples how extreme events and their impacts, as a consequence of climate change, and their attribution could, after overcoming several scientific and communication challenges, be fully part of a public climate change service.

The presentation will also develop the challenges for modelling but also for monitoring the earth, and particularly the impacts of climate change.

O-2232-05

How to inform policy-makers ? Supporting and enabling evidence-based policy-making

G. Barker (1)
(1) Department of Energy and Climate Change, Former minister of state for climate change (2010-2014), London, United Kingdom

As we get closer to the UNFCCC legally-binding international climate change agreement set to be agreed in Paris in December 2016, policy-makers need to be equipped with evidence-based information to assist them in determining future strategies to address climate change challenges.

Developing and improving the science is one thing; making it available to its intended users and presenting it in a format and language which will actually assist policy-making are today's challenges. We have identifies three main areas to discuss:

- Language and visualisation - though the evidence is scientific, the language should be adapted to its intended users -how science-literate are policy-makers anyway?
- How to translate uncertainty in policy-making? One of the UNFCCC core principle is that national governments should err on the side of precaution in the face of scientific uncertainty. How do we justify this approach to citizens?

Policy-making cannot satisfy itself with a 'one size fits all' approach and needs a sectoral approach to help target strategies and policies to each specific industry.

2232-POSTER PRESENTATIONS

P-2232-01

Time course of weather variables in malaria-related mortality in Sub Saharan Africa rural population

E. Diboulo, (1)
(1) Swiss Tropical and Public Health Institute, Epidemiology and Biostatistics, Basel, Switzerland

The current and potential future impacts of climate change on human heath have attracted increasing attention in the recent years and it is expected to significantly affect the spatial distribution as well as intensity of infectious diseases. Changes in climate are likely to lengthen the transmission seasons of important diseases and to alter their geographic range, potentially bringing them to region which lack either population immunity or strong public health infrastructures as it is the case in most of SSA.

The relationship between human health and weather conditions has been extensively studied although mostly focused on urban settings. Therefore little is known about the effects and associations between human health and weather conditions in rural populations of SSA hitherto. Studies on these associations are rather limited and scarce due to scarcity of good quality data.

Malaria features among the infectious diseases whose impacts are expected to exacerbate under future climate change scenarios in SSA. However, despite an apparent ostensibly simple association between particular weather conditions and increased abundance of mosquitoes, there still remains a lack of information on the relative importance of the different weather variable in the occurrence of the disease Indeed both the mosquito development and survival as well as incubation period before an infected human develops symptoms of malaria

strongly depend on prevailing climatic conditions. Furthermore there is always a lag time between climate suitability and change in mosquito's population and both the temperature-dependant sporogony within the mosquito and the incubation period in human add an additional complexity and uncertain lag time.

The lagged effects of weather on daily deaths are believed to dissipate with distant lags. However choices of the different lag structure in earlier studies have been usually motivated by model adjustment parameters that reduce serial correlation and confounding.

In this study, we set out to model flexibly lagged effects using fifteen years of weather variables namely temperature and rainfall on malaria related daily mortality counts using distributed lag non linear models.

Distributed lag models (DLMs) allow for a flexible estimation of the time course of the effect size of weather variable over time on the outcome.

The results show a harvesting effect of high temperatures on malaria-related mortality with an increased relative with the rising temperatures; while mortality show a steady and linear increase with high rainfall.

P-2232-02

Modeling of the vulnerability of «biomass energy» sub-sector to climate change in Togo

K. Kouami (1)
(1) Faculty of Sciences, Botany, Togo, Togo

Biomass energy accounts for 80 % of total energy consumed in Togo. But its potential decreases exponentially as a result of population growth and the fact that the techniques of production and consumption are still archaic and climate change. The aim of this work is to contribute to the assessment of vulnerability and adaptation to climate change in the sub-sector of biomass energy in Togo by a modeling approach. Specifically, it is i) to study the evolution of the household demand for fuelwood and ii) to analyze the vulnerability to climate change of sub-sector of biomass energy (mainly charcoal and firewood) in Togo. Demand scenarios of fuelwood were developed from the LEAP model. The vulnerability analysis is made by coupling the demands and the potential of fuelwood and by taking into account the parameters of climate change. At the end of this study, it appears that the fuelwood demands evolve exponentially and that the sector is vulnerable to future climate change. In addition, the potential of fuelwood is very deficient compared to the demand for years to come and will be exhausted before the year 2025. The current energy and forestry policies are far from fill this gap.

P-2232-03

Seasonal Rainfall Forecasts and Climate Change Adaptation Among Smallholder Farmers in South West Region of Nigeria

A. Onwuemele (1)
(1) Nigerian Institute of Social and Economic Research, Social and Governance Policy Research, Ibadan, Oyo State, Nigeria, Federal Republic of

Climate change is undoubtedly one of the most serious environmental threats facing mankind worldwide. It affects almost all sectors in agriculture (crop, livestock, pastoralism, fishery, etc) due to the high reliance on weather and climatic elements in agricultural practices. In the south west Nigeria, crop production is the dominant agricultural enterprise among smallholder farmers and is the primary means of their food security. This enterprise is currently faced with the challenges of changing climatic conditions. The smallholder farmers in south west Nigeria are highly vulnerable to climate change due to their general weak capacity to adaptation and this vulnerability is worsened by their heavy practice of rain fed agriculture. Recent evidence from the Nigerian Meteorological Agency [NIMET] (2008), indicates that the climate of the south west region of Nigeria is already changing based on the assessment of the climate over the period 1941 to 2000. This is manifested in changes in seasonal rainfall patterns and more unpredictable, severe and frequent extreme events like floods and droughts threatening livelihoods among smallholder farmers in the region. This scenario is having significant impacts on crop yields and product quality as a result of changes in temperatures, moisture, air and soil. To a large extent, the smallholder's farmers in the region have continuously been adapting to varying weather and climatic conditions; however, the increasingly erratic climate variability and the rapid pace of other drivers of change are overwhelming their capacity to adapt. Consequently, the need to explore new methodologies to endure the climate uncertainty and variability in the region have become more critical more than ever before among smallholder farmers. The use of seasonal rainfall forecasts may be an important adaptation to a more dynamic climate as it can provide valuable insight into future weather and climate variability. While seasonal rainfall forecasts can serve as a potential tool for adaptively managing agricultural systems in response to climate change, it is not clear whether smallholder farmers in south west Nigeria are receptive to innovations such as the use of seasonal rainfall forecasts in planning for adaptation activities. This paper evaluates the applicability of seasonal rainfall forecast in climate change adaptation as well as the determinants and constraints to application of seasonal rainfall, forecast in climate change adaptation among smallholder farmers in South West Nigeria. Simple purposive sampling was used to select Oyo State out of six states in the south west Nigeria while agricultural communities that are prone to climate change in the state were also purposively selected. Primary data were obtained from 425 farmers using questionnaires while two Focus Group Discussions (FGDs) were conducted for men and women smallholder farmers in the communities. The data obtained were organized in Microsoft Excel, cleaned and analyzed on the Statistical Package of the Social Sciences (SPSS) using descriptive and inferential statistics while the FGD were content analyzed. Results indicate poor understanding and little or no application of seasonal rainfall forecast in planning for adaptation in the study area. Results further shows that only 12.7 per cent of respondents had access and utilize seasonal rainfall forecast in planning adaptation activities. It further identified the main constraints to the non application of seasonal rainfall forecast to include poor access to seasonal rainfall forecast, lack of information on its content as reported by 49.8 per cent of the respondents. Finally, results show a high positive correlation between usage of seasonal rainfall forecast and educational attainments, income, ownership of ICT facilities as well as membership of local community groupings. The paper calls for greater enlightenment programmes and the integration of local medium in the communication of seasonal rainfall forecast in the region for effective access and utilization of seasonal rainfall forecast by small holder farmers in the region.

P-2232-04

From weather to climate: responding to climate risk across timescales

J. Slingo (1)
(1) Met Office, Exeter, United Kingdom

Weather and climate risks occur on a range of timescales, from severe weather to extreme seasons to centennial changes, all of which require a response. Over the coming century we will need to mitigate and adapt to these risks, taking into account additional challenges posed by rising population levels, increasing urbanisation and associated increases in demand for water, food and energy.

Forecasts and early warnings are both critical contributors to climate change adaptation across a range of timescales: at decadal timescales, they enable introduction of adaptation policies and planning of major infrastructure changes on appropriate timescales; at monthly to annual timescales, they enable planning of public and business preparedness; at hours to weeks timescales, they enable emergency managers and individuals to protect communities and themselves through defence and evacuation measures.

Recent advances in weather and climate forecasting capability by advanced weather and climate services have shown remarkable skill in providing valuable advice at each of these timescales. They have also demonstrated substantial benefits of working in a seamless manner across these different timescales. Investment in building the capacity of less developed National Meteorological and Hydrological Services to make use of these new advances is a highly cost-effective way of reducing the impact of climate change across timescales.

2233 - Climate Change Adaptation and Disaster Risk Reduction: International and Urban approaches

PLACARD: building a platform for CCA and DRR cooperation by 2020

M. Pulquerio (1) ; T. Capela Lourenço (1) ; P. Pringle (2) ; R. Schwarze (3)
(1) Faculty of Science, University of Lisbon, Lisbon, Portugal; (2) UK Climate Impacts Programme , School of geography and the environment, Oxford , United Kingdom; (3) UFZ, Leipzig, Germany

Significant challenges exist towards strengthening the Climate Change Adaptation (CCA) and Disaster Risk Reduction (DRR) communities for coherent, mutually and pragmatic planning and action. While efforts to increase complementarity continue, much work is still required to coordinate and integrate the two domains. Within the complex landscape of research and policy initiatives of these two areas various international and European efforts have been undertaken to better integrate CCA and DRR, and thus minimize the current and future risks presented by climate change in the context of extremes. Paradoxically, the past decade has seen a major fragmentation of CCA and DRR agendas, particularly at the level of research, policy, knowledge and practices. International frameworks, political processes, funding mechanisms, information exchange fora and practitioner communities have largely developed separately and operated in isolation from one another.

PLACARD is a newly funded Horizon 2020 European project that seeks to support the coordination between these two communities. PLACARD will tackle current challenges by 1) providing a common 'space' where CCA and DRR communities can come together, share experiences and create opportunities for collaboration; 2) facilitating communication and knowledge exchange between both communities; and 3) supporting the coordination and coherence of CCA and DRR research, policy and practice. PLACARD's approach to achieving these goals is to establish a strong and operational network of networks by connecting to existing networks and boundary organisations, to foster dialogue among stakeholders (e.g. researchers, research funders, policymakers, practitioners) engaged in CCA and DRR at the international, European, national and sub-national scales. This overarching network will enable these communities to share knowledge, to discuss challenges and to jointly co-produce options to bridge the gaps they experience. It will support the development and implementation of a research and innovation agenda to make better use of research funding, as well as to develop guidelines to strengthen relevant institutions in their efforts to mainstream CCA and DRR.

O-2233-02

Adoption as Adaptation! Long-term consequences of cyclone disaster in coastal Bangladesh

Z. Sultana (1) ; B. Mallick, (2)
(1) Coastal Research Foundation (CRF), Environmental science discipline, khulna university, Khulna, Bangladesh; (2) Vanderbilt University, Political science, Nashville, United States of America

Disaster risk reduction strategies and adaptation practices vary from region to region and community to community, for example, the practices of southern part of Bangladesh are different from the northern part. The sustainable disaster risk reduction strategies or adaptation practices of one region may be not be replicable to another region or community but the learnings from each strategies can introduce a new one that is adoptable to the other region. Therefore, this research aimed at to identify the short-term and long-term adopted strategies that are practicing after a devastated cyclone in southwest coastal Bangladesh. It is given that, in coastal areas people live under the constant threats of natural hazards. Thus raise the questions: how they react to the risk of those natural calamities and how they adapt with the adverse situations that derived by those calamities. Particularly, this research has empirically explored community level practices in agriculture, housing, water resources, communication and employment generations in Bangladesh.

The empirical research was designed with a mixed-methods approach: (1) content analysis of face-to-face interview of 145 respondents by using semi-structured questionnaire with selected social groups and their households' assistants; (2) contingent debates concerning the local attitude and perception for the improvement of their livelihood, which was understood as a case-study of livelihood complexities in coastal areas. Therefore, Focus Group Discussion (FGD) was conducted with three different groups: farmers, fishermen and general people. Key informant interviewers (KII) were: chairman of the Union, Upazila Agricultural officer, Upazila Fisheries Officer, NGO Representatives. Sector wise disaster risk reduction strategies and adaptation practices are recognized by the discussion with the FGD participants.

Results show that people have to start cultivating saline tolerant rice and vegetables on raised homestead instead of traditional rice varieties, as a consequences of saline intrusion after cyclone Aila. They were using dripping irrigation methods and rain water harvesting and artificial aquifer tube-well were introduced for water management. Mud wall of the houses were replaced by or even built newly with Goran wood or bamboo sticks. They have to start forming groups to save money for next disaster and taking credit for small entrepreneurship. Due to the crises of fodder, pastureland and freshwater people was forced to rear small animals and birds like sheep, goat and pigeon instead of cow and buffalo rearing. New technology based shrimp farming also has been started.

Besides, an external aid must not be the only solution to increase the coping capacity of a community, and thus to develop a resilient one. Likewise, the measures/strategies are identified that were taken by various actors based on their existing socio-economic conditions and both positive and negative consequences of those adopted strategies are discussed. The pros-and-cons of each adopted strategies states the interests of the different actors behind the respective strategy. It also explore that such adopted strategies in the long-run will be seen as traditional form of adaptation option for them. This study is therefore be of importance for regional planners and policy makers help to develop a comprehensive disaster management plan that is helpful in building resilience in the affected communities.

Early Warning Systems - seamless between Disaster Risk Reduction and Climate change Adaption

J. Thielen-Del Pozo (1) ; P. Barbosa, (1) ; L. Feyen, (2) ; P. Salamon, (1) ; MJ. San (1) ; J. Vogt, (1)
(1) European Commission Joint Research Centre, Institute for Environment and Sustainability, Ispra, Italy; (2) JRC, Ispra, Italy

Our climates change continuously, due both to natural causes and as a result of human activities. There is a growing consensus in the scientific and policy communities that the consequences of worldwide industrialisation and rapid urbanisation are also affecting our climates. Increase in global temperature may have impact on frequency and intensity of extreme weather events, sea level rise, as

well as shortages of food and water, just to name a few examples. Consequences of climate change constitute, under present and future climates, a threat to the more developed countries such as Europe, but even more so an obstacle to poverty reduction and stability in less developed countries. In already fragile regions and countries, climate driven disasters can negatively influence development, security and stability and thus reduce resilience.

Therefore, joint efforts between scientists and policy makers are needed to find feasible solutions to keep climate change within manageable limits, to assess adaptation strategies to minimise negative impacts, and to develop early warning systems to reduce the residual risks associated with extreme weather events. Early warning systems contribute to anticipation of the event, allow decision makers to take appropriate actions to reduce the impact.

The JRC has been developing continental systems for monitoring and forecasting floods, droughts and forest fires which will be illustrated in the presentation: the European Flood Awareness System (EFAS) has been developed since 2003 following the devastating Elbe and Danube floods which highlighting the need for European solutions to be prepared for cross-border events. EFAS provides twice daily information on ongoing and expected floods up to 10 days in advance to the Emergency Response Coordination Centre (ERCC) of the European Commission and the National Hydrological Services. The European Forest Fire Information System (EFFIS), initiated in 1998, aims at providing harmonized information on forest fires in Europe. EFFIS provides the European Commission services, the European Parliament and the forest fire services in the countries with harmonized information on forest fires. Both EFAS and EFFIS have become integral part of the COPERNICUS emergency management service, one of six operational services under the EU Copernicus space programme. Furthermore, the JRC has been developing a prototype of a European Drought Observatory (EDO) which is to providing in pre-operational timely and consistent information on droughts in Europe. EDO allows to monitor, detect, forecast, and assess drought situations throughout Europe, serving as a platform for information exchange between various stakeholders. After all systems have demonstrated their added value for cross-border management of severe events, they are now being expanded experimentally to global scale.

While the focus of the systems is to monitoring and forecast floods, droughts and forest fire events in Europe and globally they also represent a framework for further studies on assessing past and future trends, scenario modelling with regard to different drivers, management plans and potential adaptation measures. By promoting seamless forecasting from now-casting to seasonal and longer time scales the systems can be useful for both climate change adaptation as well as disaster risk reduction at different levels. The presentation will illustrate how these systems, in partnership with leading organisations and international initiatives and programmes, have the potential to contribute to both disaster risk reduction and climate change adaptation studies in a multi-hazard framework.

O-2233-04

Participatory socioeconomic scenario development as building block of a local risk management tool to climate change adaptation - an Alpine test-site in the East-Tyrol, Austria

I. Meyer (1) ; B. Eder (2) ; AM. Hama (3) ; M. Leitner ()
(1) Austrian Institute of Economic Research - WIFO, environment, energy, agriculture, Vienna, Austria; (2) AIpS, Innsbruck, Austria; (3) alpS Centre for Climate Change Adaptation, Innsbruck, Austria

In Austria as elsewhere, extreme events such as heavy precipitation, storms, debris flows and floods are expected to show fundamental changes with respect to magnitude, frequency and duration caused by climate change. Today, risks associated with climate change are mostly still understood and analyzed in a sector- and hazard- specific and rarely in a dynamic, scenario-based manner. The project ARISE (Adaptation and Decision Support via Risk Management Through Local Burning Embers) develops a decision support system for climate-sensitive iterative risk management as a key adaptation tool for the local level. One of the building blocks of ARISE are socioeconomic scenarios that capture main features of the future local economy. Regional socioeconomic scenarios are the pillars to identify future climate related risks and thus to shape disaster risk reduction and risk management which support the building of resilience and adaptation capacities at the local level. The scenarios are based on the current state and trends of sector developments in employment and value creation in the test-site City of Lienz and its surroundings in the East-Tyrol. They include drivers such as demography, a story line and a vision into the future. Scenarios were developed using a participatory approach. Participatory approaches are increasingly recognized as an important element of management and decision-making. There are various reasons why to pursue a participatory approach. For instance, problems in today's world are complex and require knowledge from many different domains and disciplines; participation is said to be a process of collective learning that changes the way people think and act. The paper presents results of two socioeconomic scenarios that were developed using insights from stakeholders and decision-makers of the City of Lienz as well as scientific findings from available data sets and the literature, i.e. a "boom" and a "bust" scenario. Categories of drivers of socioeconomic scenarios discussed during the scenario workshop cover inter alia institutions and socio-political frameworks, demographics, production and demand, markets and trade, scientific and technological innovations, and value systems. Based on empirical data on local employment we identified 6 relevant sectors of the local economy with specific trend developments that served as framework to discuss scenarios: 1) infrastructure and natural hazards, 2) tourism, 3) industry and manufacturing, 4) agriculture and forestry, 5) politics and the administration, and 6) health, education and other services. As the City of Lienz is situated south of the main Alpine ridge in the East-Tyrol it is characterized as peripheral region with population loss in the recent past. One of the major challenges for conceiving a "boom"-scenario was thus to imagine the region to become attractive for well educated people. Last but not least, another feature of the participatory scenario workshop was to communicate knowledge from science to local decision-makers. Regional climate scenarios, socioeconomic data and projections as well as a summary of perceived current climate-related risks were presented. The latter were gathered by subjective expert reasoning (personal interviews) with stakeholders from the region. Participation thus incorporated a two-way information exchange, from science to practice and from practice to science. The presentation will finally give a perspective on the development of the climate related risk management tool.

O-2233-05

GIS-based Climate Change Vulnerability Assessment of the Municipality of Del Carmen, Surigao del Norte Province, Philippines

D. Racelis, (1) ; E. Racelis (1) ; A. Limpiada (1)
(1) University of the Philippines Los Banos, College of Forestry and Natural Resources, College, Laguna, Philippines

A GIS-based mapping and assessment was conducted to determine the vulnerability to the impacts of climate change and climate risks of ecosystems, communities, and infrastructure in the municipality of Del Carmen, Surigao del Norte Province, Philippines. The study involved collaboration with bio-physical and socio-economic survey teams in undertaking qualitative and quantitative assessment of resources and their capacities against climate-related hazards. It also included assessment of past and present impacts of climate change vulnerability in the project areas and assessed and prioritized adaptation strategies, and identified gaps/needs in the implementation of the selected strategies.

Approximately equal number of hectares are exposed to either high (6,340 ha) or low risk (6,039 ha) to drought. In particular, Brgy. San Fernando has the largest area exposed to high risk with 1,186 ha of uncultivated lands. For cultivated lands, Brgy. Bagakay has the largest area exposed to high risk with 232 ha. In terms of exposure, Brgy. Mahayahay has the highest with 100% of its land area exposed to high risk. In contrast, Brgy. Caub and Brgy. Lobogon have the lowest exposure to the risk.

Further, analysis shows that around 137 ha of populated areas which is about 1% of the total land area of the municipality of Del Carmen are exposed to very high risk to rain-induced landslide. These areas are mostly located in Brgys. Caub, Mahayahay, Quezon, San Fernando, and Tuboran. Likewise, about 1,644 ha (14%) of unpopulated areas are also exposed to such risk. Further, around 31 ha and 79 ha of populated areas have moderately high to moderately low risk to landslide, respectively. However, it should be emphasized that more than 8,792 ha (71%) have no risk to landslide. Further, the safest area as far as risk to landslide is concerned is Brgy. Del Carmen with virtually no areas exposed to the hazard.

Moreover, around 143 ha (1.1%) of the municipality are exposed to low to medium risk to storm surge. These are obviously confined to coastal areas. Brgy. Del Carmen has the largest populated area exposed to medium risk with 49.3 ha while Brgy. San Fernando has 1,024 ha of unpopulated areas exposed to the same risk. Spatial analysis also shows that Brgys. Concohoy, Lobogon, Mahayahay, Quezon and Tuboran are virtually free from risk to storm surge. The condition is due to the fact that these barangays are mostly located in the higher elevation section of the municipality

A model of choice under uncertainty for flood preparedness intention in Brazil

G. Guedes (1) ; R. Raad (2) ; L. Vaz (3) ; M. Araujo (4)
(1) Federal University of Minas Gerais, Department of Demography, Belo Horizonte, Minas Gerais, Brazil; (2) Federal University of Minas Gerais, Department of economics, Belo Horizonte, Brazil; (3) Federal University of Rio de Janeiro, Department of economics, Rio de Janeiro, Brazil; (4) Federal University of Minas Gerais, Department of statistics, Belo Horizonte, Brazil

This paper performs an econometric analysis based on selected dimensions of the Protective Action Decision Model (PADM) for Brazil. We empirically estimated preparedness determinants by using Seemingly Unrelated Regression models. PADM survey instrument validation was based on Cronbach alpha, inter-rater agreement index, factor analysis, and mean-comparison tests. The PADM was applied to a representative sample of 1,200 households in the municipality of Governador Valadares, State of Minas Gerais. The site was chosen because river floods are recurrent in the area, reaching thousands of households along the river. Its urban environment has undergone dramatic change in the last decades, creating an ideal scenario for flooding: riparian deforestation, river silting, unplanned occupation of riverbanks, and garbage and sewage discharge into the river. In addition to the econometric analysis, event calendar of major floods in the area, also collected in the survey, allows for comparison between intended and actual preparedness behavior. Building on models of private insurance, we provide a theoretical framework stating that risk aversion is a key factor affecting the directions of influence given by the price and resource effectiveness on the probability of adopting preventive behavior. Thus, for a given nominal budget constraint an increase in insurance price could change one's risk aversion, leading to a higher propensity to buy insurance. We found that, under certain conditions on risk aversion, hazard-related attributes (HRA) positively affect propensity to take protective actions. This was confirmed by our regression results. In contrast, resource-related attributes (RRA) positively or do not affect propensity to adopt protective actions. This non-intuitive finding can be justified by our theoretical framework: risk averse individuals would feel relatively deprived with increase in the opportunity costs of action, leading to additional effort to take protective actions against flood hazard. Finally, the impact of HRA was empirically higher than RRA on preventive behavior since the effective cost of preventive actions is low relative to a person's budget constraint. These findings suggest that public action should promote educational campaigns aiming the reduction of subjective uncertainty on resource effectiveness.

P-2233-02

The Power of Communication in Post Disaster Reconstruction and the Implication for RIA: A Cross Country Synthesis

EKH. Lin (1)
(1) Academia Sinica, Research Center for Environmental Changes, Taipei, Taiwan

This research presents a research project funded by International START secretariat, and earlier co-sponsored by International Social Science Council and Integrated Research on Disaster Reduction (IRDR). The project is built on the RIA model developed by Risk Interpretation and Action working group of IRDR and further examines the effects of communication across scales and social entities that might influence personal RIA in the arena of post disaster reconstruction and resettlement phases. The ontology of the conceptual framework pertinent to this project views risk interpretation and decision making as dynamic and interactive. Based on the rationale, we develop an analytical framework to investigate the higher level of legislative, institutional and political structures that determine the scope of engagement and the relationships among the governed stakeholders in the policy making processes, with the lower level of norms and values that not only frame the essence of the society but also inherent in the personal interpretation about certain risk of interest. We also examine the factors addressed in RIA model in the cross scale communication dynamism. A three-staged hierarchical research design is thus developed corresponding to these research inquires in the case studies across five countries, namely Taiwan, Philippines, Uganda, Honduras, and India. The research results of the cross country synthesis are displayed at governmental and institutional level and at the community or individual level that finally come along with the provisional pathologies for analyzing communication influences throughout the processes.

At the governmental and institutional level, it is found that the robustness of the legislative and institutional framework to regulate engagement and participation of civil society is fundamental for strengthening the influences of communication on policy making. Taiwan and Philippines, followed by India, have shown the higher standard of the trajectories, while Uganda and Honduras display weak or absence of the related legislation and thus the least strength of communication waged with higher social conflicts and instability. At the community and individual level, the RIA factors are examined including experiences, trust, culture, social norm, rational choices and uncertainty. Dramatically this research finds that risk interpretation and decision made for taking action are two different things. The interpretation of risk has deep rooted in the population's cultural basis, which is not easy to be changed. Moreover, people's decision for risk reduction does not singly reflect their interpretation of the certain risk of the physical hazard as narrowly defined by scholars or experts; it actually builds on the interpretations of enormous uncertainties relating to any socio-economic and cultural changes following the possible action. Thus risk interpretation is multidimensional, reflecting people's social, cultural and institutional embeddedness, far beyond the theoretical debates between rational or irrational discourses. The decision made for taking certain action usually reflects the net outcome of factor competitions behind the embeddedness. Communication thus brings imperative functions for sharing the interpretation of the risks and the concerned uncertainties; and obviously as revealed in the study, shared rights for local people to participate in the policy making processes could bring positive effects on formulating more desirable and acceptable policies for post disaster reconstruction and resettlement that would reciprocally influence personal decision making towards a more mutually desirable solution.

Modelling Agricultural Risk in India from an Insurance Perspective

T. Osborne (1) ; R. Hohl, (2) ; A. Boissonnade, (3)
(1) Asia Risk Centre, Reading, United Kingdom; (2) Asia Risk Centre, Singapore, Singapore; (3) Asia Risk Centre, California, United States of America

After China, India is the second largest agriculture producer globally where over 120 million farmers with an average farm size of only 1.3 hectares produce a large variety of crop types in two main growing seasons. With only 30% of the arable land being irrigated, India's agriculture sector relies heavily on the timely onset and spatial distribution of monsoon rainfall for successful cultivation of summer (Kharif) crops. Breaks in monsoon rainfall can trigger severe droughts as experienced in 2002 where rainfall deficits reached 21% over the growing season and a drop of 18% in nationwide grain production resulted. Conversely, particularly active periods within the monsoon can lead to flood damage to Kharif crops. The winter (Rabi) crops are sensitive to prolonged cold spells, frost events and abnormal heat.

As part of measures to cope with severe droughts, cyclones and floods, the Indian government has implemented and supported a variety of national crop insurance programs which entirely rely on weather and yield indices. The current insurance schemes include the Weather Based Crop Insurance Scheme (WBCIS) and the yield-based modified National Crop Insurance Scheme (mNAIS). With the anticipated growth, annual agriculture insurance premiums are likely to reach USD 1 billion making India the third or fourth largest agriculture insurance market globally.

With the increasing complexity of the weather and yield indices pricing WBCIS and mNAIS portfolios has become a challenge for insurers. Key constraints for robust risk modeling and exposure management are i) the lack and accessibility of weather station data and ii) the short and often incomplete time series of historical yield data which often show strong trends depending on the crop type, region and season. For mNAIS, insurance terms are based on only 11-15 years of historical yield data and payouts are triggered if actual yields are 10%-20% below expected (insured) levels. In areas where larger yield shortfalls have not been observed in the last 11-15 years, insurance terms might not adequately reflect the risk potential, especially for systematic events such as droughts, floods and cyclones. Based on the short historical time series, extreme events such as the 1987 or 2002 droughts cannot be consistently assessed and insurers are concerned about spatial correlations of such events and resulting financial losses.

This paper presents results of research undertaken by Asia Risk Centre to assess insurance losses of mNAIS portfolios in India. A crop model is developed using key parameters such as high-resolution gridded weather data, soil types and structures, slope coefficients, irrigation levels and crop-specific growing season parameters. To generate synthetic yields for the last 45 years the model is then driven with historical climate variations. The model resolution is set at 25 x 25 km which approximately corresponds to a sub-district ("block") on which triggers for mNAIS insurance products apply. Following market practice, other insurance terms such as premium rates and indemnity levels are used at a district level. The synthetic yields are processed to calculate insurance losses to mNAIS portfolios after consideration of original policy terms and conditions.

This paper reveals how synthetic yields allow a quantitative and robust assessment of i) the profitability levels of a given mNAIS portfolio and growing season and ii) the expected losses from historical extreme events such as the 1987 and 2002 drought events. Synthetic yields of wheat and rice in Uttar Pradesh are compared to historical to determine the model's ability to accurately represent climatically-driven variability in yield. Further, outputs of crop models in general are discussed in terms of benefits for the insurance sector including improved risk assessment, risk pricing, risk transfer and risk management and how simulated weather events can be used in crop models to generate several hundreds of years of synthetic yield series.

P-2233-04

Government-NGO Collaboration for Disaster Risk Reduction in India: A SWOT Analysis

J. Parida (1) ; N. Mishra, (2)

(1) National Institute of Technology,, Dept. of Humanities and Social Sciences, Rourkela, Odisha, India; (2) National Institute of Technology, Dept. of humanities and social sciences, Rourkela, India

Effective and meaningful collaboration between the two stakeholders: Government and Non-governmental Organizations (NGOs) is imperative to attain the goals of Disaster Risk Reduction (DRR). The involvement of NGOs in all phases of DRR programmes is very crucial because of their grass-root presence and community-focussed approach. Literature documents GO-NGO partnership is a harmonious and constructive approach with mutual respect and recognition based on four aspects such as co-operation, co-option, complimentary and confrontation (UNESCO, 1989; the World Bank, 1990; Nazam, 1999). Though lots of studies have been carried out on GO-NGO collaboration, but on the aspect of disaster management is not explored much. Over the last couple of years, a paradigm shift in the approach to disaster management has been carried out by the Government of India. National policies and Acts like Disaster Management Act, 2005; the National Policy on the Voluntary Sector, 2007 and National Policy on Disaster Management, 2009 emphasize the proper coordination of actions of Government and Non-governmental Organizations in a holistic and proactive manner. However, the study is an attempt to identify the Government and Non-governmental Organizational relationship in disaster risk reduction programmes particularly at district and panchayat level. To accomplish this objective, this study has attempted to find out the answers of certain questions like i) how far the existing GO-NGO collaboration is effective in managing disasters, ii) what are the strengths, weaknesses(internal factors), opportunities and threats (external factors) affecting to achieve the policy-goals of DRR.

In this paper, the study was carried out in Balasore and Kendrapara districts of Odisha, India which are more prone to disasters like floods. Respondents from both Government Organizations and NGOs engaged in disaster management directly or indirectly were interviewed in order to have broader views and opinions on policy matters, problems and potentials and to evaluate their roles in that particular area. Open and close- ended questions were used for this purpose. A SWOT analysis was used to focus on the strengths and weaknesses of collaboration in relation to efficiency, capacity building, quality and accountability. The study found that the effective collaboration is lacking between Government and NGOs at local level. Majority of the respondents were not satisfied with the existing mechanism of collaboration because of more control and authority over NGOs. There is irregularity of interaction between Government officials and NGOs which makes the collaboration weak. It is recommended that mutual respect, trust, transparency and accountability should be present between both the stakeholders.

P-2233-05

Community based disaster risk reduction practices in Bangladesh

A. Rahman (1)

(1) Khulna university, Urban and Rural Planning, KHULNA, Bangladesh

Bangladesh is one of the most disaster prone countries in the world. Conversely, this country has proven superb experienced for disaster risk management as the disaster and relief ministry of Bangladesh has envisaged long term risk reduction strategy through community involvement instead of relief distribution. To explore the best practices for sustainability of community based disaster management (CBDM) in Bangladesh is the prime aim of this study. Qualitative approach was adopted to conduct the research. The activity of Disaster risk reduction and emergency management is managed and implemented by disaster management regulatory framework. The active bottom to top level disaster management committee (DMC) headed by elected person in every administrative tier is the main actor for disaster management. According to disaster order, the local level DMC develops risk reduction action and disaster management plan periodically with community involvement aiming to reduce risk during disaster cycle. Following this, district level Risk Reduction action plan and contingency plan has developed and implemented with the active people's participation and then incorporation Disaster Risk Reduction (DRR) into sectoral and local level development plan. Local level disaster management fund creation is another milestone for effective local risk reduction and emergency management. It is also found that the people are placed

in central for planning, implementation and monitoring in the risk reduction interventions which creates community ownership and it increase their resiliency to disaster. Social, economic and environmental considerations are also focused in the CBDM. Disaster management network and information center, DRR issues incorporated into text books, school based preparedness programme and capacity building of different stakeholders are the major ongoing initiatives to enhance knowledge and skills for CBDM. In conclusion, community involvement in both software and hardware DRR interventions make sure the sustainability of CBDM in Bangladesh.

P-2233-06

Multi-Hazard Early Warning Systems for Effective Disaster Risk Management

X. Tang (1)
(1) World Meteorological Organization, Weather and Disaster Risk Reduction Service Department, Geneva 2, Switzerland

Every year, disasters related to meteorological, hydrological and climate hazards cause significant loss of life, and set back economic and social development by years. Over the past decade (2005–2014), 3 253 hydrometeorological hazards were reported around the world, resulting in 283,035 deaths and economic losses amounting to US$ 983 million. From 1970 to 2012, storms and floods accounted for 79 per cent of the total number of disasters due to weather, water, and climate extremes and caused 55 per cent of lives lost and 86 per cent of economic losses, while droughts caused 35 per cent of lives lost. Climate change is exacerbating the impact of hydrometeorological hazards and compounding disaster risk. Disaster risk reduction is one of the effective ways of climate change adaptation.

According to the Hyogo Framework for Action (HFA), effective disaster risk management calls for a paradigm shift from emergency response to a more proactive, holistic and systematic approach with strong focus on risk reduction. This paradigm shift requires meteorological, hydrological and climate services to support science-based risk management decisions, as well as investments in Early Warning Systems (EWS) which are well recognized as a critical life-saving tool for floods, droughts, storms, bushfires, and other hazards. The National Meteorological and Hydrological Services (NMHSs) who are members of the World Meteorological Organization (WMO) made considerable advances in EWS in the recent years, which are characterized by better observation and monitoring of hazards and improved forecasting and warning services. Also, risk assessment and hazard mapping have been of assistance in development planning and increased the awareness and understanding of risk by the people. However, the societal benefits derived from this progress in EWS have been uneven among countries and communities. Significant gaps remain, especially in servicing the grassroots communities and benefiting poor and vulnerable families.

The global changes in societal structures, rapid urbanization, growing exposure of populations and assets, and climate change, altogether result in a highly dynamic and complex state of disaster risk. This situation, together with the increasing globalisation of risk, calls for strengthened EWS at all levels. It also calls for an integrated and holistic approach to early warnings for multiple hazards and risks tailored to user-needs across sectors. In this regard, international and regional collaboration as well as multi-stakeholder partnership at all levels is critically necessary, given the borderless nature of most natural hazards.

At the Third United Nations World Conference for Disaster Risk Reduction (WCDRR), Member States of the United Nations, through the post-2015 framework for Disaster Risk Reduction (DRR), agreed on the necessity of enhancing multi-hazard early warning systems (MHEWS). In response to this call, the multi-stakeholder partnership – International Network for Multi-Hazard Early Warning Systems – is forged to facilitate and make available to governments and key stakeholders the necessary technical support for strengthening MHEWS as a national strategy towards building disaster and climate resilience. The network embodies the commitment of its partners to act and work together in advancing MHEWS and to foster multi-stakeholder partnership in DRR for promoting societal resilience. A comprehensive description of the International Network and its operational procedures to promote effective disaster risk management are presented.

P-2233-07

Hurricane Sandy and the Prospects for Climate Resilience and Transformative Adaptation in New York's Jamaica Bay Urban Communities

S. William (1)
(1) City University of New York – Hunter College, Geography, New York NY, United States of America

Climate change resilience and transformative adaptation requires a greater understanding of how current extreme events influence local and regional development trajectories. Within the New York–New Jersey Metropolitan region, Hurricane Sandy and the immediate response to the storm have created conditions for a potential large-scale transformation with respect to settlement of the coastal zone. While the vulnerability of this region to climate change has been well-documented, Sandy's impact has placed this issue into the forefront of public and private discussions about the appropriate response at every level from individual homeowners who are contemplating whether and how to rebuild after devastating losses, to small coastal municipalities which are considering construction of protective engineering structures and changes in zoning laws, to the City of New York, the states of New York and New Jersey, and the federal government which are engaging in discussions about how to better protect the region's population, property, and vital infrastructure from future storms. These discussions are particularly complex given that they are now beginning to be discussed within the context of emerging and potentially intensifying climate change.

This paper presents results of a research study that entailed documentation of the initial phases of a transition in coastal communities and neighborhoods in the Jamaica Bay region of New York City that were heavily impacted by Hurricane Sandy's storm surge and flooding. Drawing upon results of stakeholder and community-based organization interviews, we explore: 1) evidence of socio-ecological system stress and crisis; 2) associations between stress and crisis, the resilience of local stakeholders, and shifts in system-level equilibria; and 3) cross-scale connections between stakeholder responses, socio-ecological system transitions, and broader-scale, community level transformations. The results indicate the conditions of resilience practice and tranformative adaptation are highly contested and spatially and societally uneven. This unevenness reveals emerging equity and justice implications within and across the impacted communities.

The Contribution and Centrality of Indigenous Knowledge Systems to Developing Sustainable Adaptation Strategies

KAS. Kassam (1)
(1) College of Agriculture and Life Sciences, Cornell University, Natural Resources & American Indian Program, Ithaca, NY, United States of America

All over the world, communities that contributed least to the increase in greenhouse gas concentrations are facing their harshest impacts. At the vanguard of climatic variation are indigenous communities at high altitudes and latitudes as well as coastal regions. Increasing climate variability

means that these communities cannot simply adapt to a 'new normal'; they must prepare for a broader range of possible conditions and patterns. In its Fifth Assessment Report, the Intergovernmental Panel on Climate Change identifies the urgent need to 'downscale' climate model projections in order to anticipate climate change impacts. The difference between predictive capacity and anticipatory capacity is that the former presumes knowledge of future outcomes whereas the later involves being prepared for the future under varied outcomes. Developing anticipatory capacity of communities drastically affected by climate change is not only an intellectual challenge but an ethical imperative.

Applied transdisciplinary research is best suited to meeting these challenges. This means active engagement of the biophysical and social sciences as well as the humanities with indigenous knowledge. Indigenous knowledge not only contributes valuable context-specific insights but also facilitates the mooring of adaptation strategies within the local sociocultural and ecological milieu. The cornerstone to resilience is socioculturally and ecologically grounded approaches to climate change adaptation. These approaches contribute to long-term sustainability and dynamism of collaboratively generated knowledge and solutions.

In this presentation, we will illustrate how ecological calendars represent such a collaborative transdisciplinary approach to anticipating climate change in the Pamir Mountains of Central Asia. Calendars are knowledge systems humans use to synchronize activities with seasonal changes in our habitat. Calendars are essential to food systems, because hunting, fishing, gathering, producing crops or rearing livestock all depend on the ability to anticipate patterns of temperature and precipitation and plan accordingly. Ecological calendars are based on phenological indicators, such as the last day of snow cover, the first flowering of a plant, the emergence of an insect, or the arrival of a migratory bird. By keeping track of time in relation to such events, communities are better able to align their livelihood activities with the weather. Ecological calendars could play a critical role in building anticipatory capacity for climate change, because they are able to account for new trends and variability. Furthermore, they are grounded in local ecological knowledge and embedded in cultural values.

Economic Resilience to Natural Disasters: Application to 87 Countries and Mumbai

S. Hallegatte (1) ; M. Bangalore (2) ; A. Vogt-Schilb (2)
(1) Climate Change Group , Washington , United States of America; (2) World Bank, Washington, DC, United States of America

With disaster losses increasing globally, it is ever more important to measure the ability of a country or city to cope and recover. This ability, often termed "resilience", is complex. At its core, resilience is about the welfare loss from a disaster, and how to reduce it (i.e. increase resilience). In this paper, we estimate welfare impacts (and resilience) of 87 countries to a flood/storm that affects 1% of the population. Our contribution is that we account for distributional impacts, examine outcomes, and that our paper is based on a welfare analysis. We develop a model which includes the hazard, exposure, and vulnerability, and also the impacts on household assets and income, and the ability to bounce back (or be trapped). Economic resilience for each country, as we calculate it, is the ratio of a "reference" welfare loss (e.g., in a country with no inequality and with perfect loss sharing) to the welfare loss from a flood/storm. We also go beyond assessing resilience and evaluate a series of country-specific policy options (e.g. reducing exposure, increasing social transfers) and the benefits each policy produces (in terms of increasing resilience). All data used is open-source and our methods fully transparent. The approach is also validated ex-post using detailed data after a specific event, the 2005 floods in Mumbai.

Resilience to extreme weather: using science to inform policy

E. Woods (1)
(1) The Royal Society, Science Policy Centre, London, United Kingdom

Extreme weather can have a devastating impact on people's lives and livelihoods. It represents a major obstacle to development, often preventing people from escaping poverty or pulling them into it. Societies are not well adapted to the extreme weather being experienced today. Compounding this, future climatic and demographic changes will increase the exposure of people and their assets to this threat.

In this presentation, Professor Georgina Mace CBE FRS will outline the findings of the Royal Society's 'Resilience to extreme weather' report (see royalsociety.org/resilience). The culmination of 18 months' evidence gathering and analysis, this policy report examines not only the risks posed by extreme weather, both now and in the future, but also the range of ways in which people can adapt and become more resilient to these risks.

Resilience-building solutions range from specific physical defences (ecosystem-based approaches, engineered approaches, and hybrids of the two) to more general principles and processes for building resilience globally, nationally and locally.

The use of scientific evidence to inform which solutions are most appropriate in which circumstances is crucial. In the context of this year's international agreements on disasters (March), sustainable development (September) and climate change (December), ensuring that efforts to build resilience are joined-up across different policy frameworks is also important.

Climate Change Resilience and Vulnerability Analysis of Indigenous Community in Western Himalaya

BW. Pandey (1)
(1) University of Delhi, Department of Geography, Delhi, India

Present research is an attempt to investigate the impact of microclimate change on agro horticultural crops, water supply and vulnerability of livelihood security among the local community in Upper Beas Basin of Western Himalaya. Study is based on both the Primary as well as Secondary sources of data. To collect the primary data, twenty two hamlets of the Valley between the elevations of 2000-3000 meters were surveyed on the basis of Stratified Random Sampling (SRS). Two hundred questionnaires were fulfilled along with the physical investigations of quality and quantity water and land use changes between 1954 to 2014. Attempt has been made to assess the changes in food availability, quality and quantity measurement and analysis of changes in method and mode of food supply. At the end, effort has been made to analyse future vulnerability and changes in the nature of occupations and household economy due to local climate change.

The research findings highlight that the number of livestock has been increased in the valley, while the areas under grazing land has been reduced. This is because of the privatization of the land and closing the forest area. Consequently more pressure has been exerted on agricultural land. The number of households of the nomadic herders has been considerably reduced, as the new generation is migrating towards plain for job in metropolitan areas like Delhi and Mumbai. Agricultural practices have been shifted upwards 400 meter to 1000 meter between 1954-2014. Another finding highlights that there were less than 10 hotels in Manali in 1975, which has increased to more than 1500 in 2014. Land Use Land Cover Changes, Urbanization and vehicular pollutions are the principal factors for local climate change. Growth of

Tourism based urbanization has taken place on agrarian land in the Himalayan geosystem is economically lucrative today, but can pose a risk of food crisis tomorrow as non agricultural uses of the land is increasing in the interest of the outside population on the cost of the local farmers. A planned land use from the government is of dire need to save the livelihood security and vulnerability of food supply to the local community of the Western Himalaya.

P-2234-02

Public policies and risk management in extreme hydrological events in Southeast Mexico

F. Tudela (1)
(1) Centro del Cambio Global y la Sustentabilidad en el Sureste A.C., Climate Change, Villahermosa, Tabasco , Mexico

Extreme hydrological events have already jeopardized development in Southeast Mexico. Their economic impacts have been regularly assessed and exceed by far any other socio-economic aspect. A clear example may be found in the floods that affected the State of Tabasco in October-December 2007, when nearly one million inhabitants -more than half the State´s population- was severely affected, and 80% of Villahermosa, the capital city, was underwater. Attribution issues- natural variability / climate change superimposed effects- remain uncertain, but some statistical data, some of them included in this presentation, point at the increasing relevance of anthropogenic factors. Not only the vulnerability of socio-environmental systems has been aggravated, but the hazards themselves are apparently gathering momentum. Current public policies dealing with risk management are considered now inadequate, and will be even more defective as climate change progresses.

This contribution focuses on these policies, which neglect to a large extent the preventative measures and adaptation approaches. It includes a comparison between the expenditures from FONDEN (Fondo de Desastres Naturales) and those from FOPREDEN (Fondo para la prevención de desastres naturales). Land use planning tools are also questioned in terms of their effectiveness. An in-depth revision of the risk management policies, that should pave the way for new systemic approaches, will be spurred by an increasing recognition of climate change as a process that brings about a new sense of urgency.

P-2234-03

Cost-benefit analysis of flood resilience strategies to cope with global change impacts. Application to the Barcelona case

M. Velasco (1) ; R. Beniamino (2) ; A. Cabello (3)
(1) CETaqua, Global Change Impact Programme, Cornellà de Llobregat, Spain; (2) Aqualogy, Urban drainage direction, Barcelona , Spain; (3) cetaqua, Sustainability department, Cornellà, Barcelona, Spain

Urban areas are, due to the concentration of population and economic activities, one of the most sensitive regions to natural hazards. This work presents the results of a flood damage assessment taking into account the effects of drivers such as socio-economic trends and climate changes. This work is part of the FP7 CORFU project (Collaborative Research on Flood Resilience in Urban areas) focusing in the Raval district of Barcelona.

The first stage of this work consisted on creating a detailed flood damage assessment for the case study area. The implementation of a new 1D-2D coupled model was used to obtain flood depths (Russo et al., 2014), and new stage damage curves were developed to estimate the direct tangible damages (Velasco et al., 2015a). The curves were validated using data from surveys and actual reported damages to the Spanish re-assurance. Then, combining the hazard and vulnerability levels by using a GIS-based toolbox, the expected annual damages (EAD) of the area was obtained. This enables the determination of the critical points of the district in terms of flooding impacts, and highlights the need to implement strategies to cope with these impacts.

For a time horizon centered in the year 2050, several future scenarios of climate and socio-economic changes were created. Using the previously developed tools, the EAD values of the several future scenarios were obtained for the Raval District (Velasco et al., 2015b). The comparison between future and current damages presented increase ratios that ranged between 1.5 and 4. This highlighted the need of implementing adaptation strategies to cope with possible future impacts.

Finally, different measures were modelled so the corresponding damages could be calculated. Three different levels of adaptive capacity were studied:

- Low: measures implemented should be non-structural, and only focusing on vulnerability and risk reduction. In this case, local protection measures (flood board) linked to an early warning system were analysed
- Medium: it consists of SUDS (Sustainable Urban Drainage Systems), and specifically green roofs
- High: it considers classical structural measures, which were 6 new pipes upstream the Raval district, and one storage tank in this area

By undertaking a cost-benefit analysis, the effectiveness of the strategies was assessed, and a prioritization of the most adequate ones for each scenario was done.

The non-structural strategies presented higher net benefits than the structural ones, due to their low cost. However, the structural strategies could better cope with flood impacts, but at higher costs. Nevertheless, the economic benefits of these strategies were only related to the Raval District. By extending the domain analysed, the results would be different.

P-2234-04

Medium-term effects of early-life weather shocks on cognitive and health outcomes

M. Vicarelli (1) ; A. Aguilar (2)
(1) University of Massachusetts, Economics department, Amherst, United States of America; (2) ITAM, Economcis department, Mexico City, Mexico

This paper investigates medium-term consequences of negative weather extremes experienced during early stages of life on children's physical and cognitive development. In rural, rain-fed agricultural settings, rainfall shocks are often cited as the most important risk factor faced by households (Progresa-Mexico 1998-99; Fafchamps et al. 1998; Gine, Townsend and Vickery 2008). Young children and pregnant women represent particularly sensitive populations to events of this nature.

The idea that stimuli or stressful conditions during critical periods in early life can have lifetime consequences is well established in developmental biology (Barker 1998). Previous work in the economics literature has also shown how pervasive conditions (e.g. malnutrition, sickness, pollution, etc.) in-utero and during the first years of life have considerable long-term consequences. Some of these studies identify effects of early life conditions on outcomes at adulthood, such as income, health, educational attainment, and physical and mental disabilities (Alderman et. al. 2003; Almond 2006; Almond and Mazumder 2011; Maccini and Yang 2009). In this study we shed light on medium term impacts: test scores for language development, working and long-term memory, and visual-spatial thinking provide information about specific dimensions of cognitive development. This information, added to objective anthropometric measures (like height and weight) and gross motor skills, has been

proven as a strong predictor of success later in adulthood (Case and Paxson 2006; Grantham-McGregor et al. 2007).

El Nino Southern Oscillation (ENSO) is a recurrent climatic event that causes severe weather shocks. This paper employs ENSO-related floods at the end of the agricultural season to identify medium-term effects of negative conditions in early child development (in utero and up to two years of age). The socio-economic and health data used in this study comes from a rich longitudinal household dataset gathered as part of Mexico's PROGRESA randomized poverty alleviation program. This database is exceptional for size and data quality and data includes valuable information for children aged 2 to 6, namely, specific indicators of cognitive development, motor skills, as well as objective anthropometric and health indicators.

Our analysis shows that, four to five years after the shock, children exposed to floods in early life have test scores in language development, working-memory, and visual-spatial thinking abilities that are 11 to 21 percent lower than same aged children not exposed to the shock. Negative effects are also found on anthropometric characteristics: children exposed in early life exhibit lower height (1.07 to 1.803 cm), higher likelihood of stunting (11 to 14 percentage points), and lower weight (0.381 kg) than same aged children not exposed to the shock. Negative effects of weather shocks on income, food consumption, and diet composition during early childhood appear to be key mechanisms behind the impacts on children's outcomes. Finally, no mitigation effects were found from the provision of the Mexican conditional cash transfer program Progresa on poor rural households with children exposed to ENSO-related shocks. This might suggest that children were not prioritized in distributing resources within the household or that the cash transfer was not sufficient to buffer the liquidity constraint faced by the household and generated by the weather extreme.

Climatologists indicate that ENSO cycles will continue to affect global climate, and events might become more frequent and intense with global warming (Vecchi and Wittemberg 2009). ENSO-related studies are therefore relevant from an economic, climatic, and public policy perspective. To the authors' knowledge this is the first study to investigate the impact of ENSO-related weather shocks on human capital formation. More broadly, this study represents an important test bed to further understand the possible impacts of weather extremes associated to climate change on human capital formation (i.e. child cognitive and physical develpment). These types of impacts are still vastly underestimated in the economics literature.

P-2234-05

Early warning systems for climate related extreme events: The development of an ICT based multi-hazard and multi-sector early warning platform in Kenya

E. Vogel (1) ; A. Kooiman (2) ; Z. Zommers (3)
(1) University of Melbourne, School of earth sciences, Melbourne, Australia; (2) Geo Enviagro Solutions International, Nairobi, Kenya; (3) United Nations Environment Programme, Division of early warning and assessment, Nairobi, Kenya

The Fifth IPCC Assessment Report on climate change shows that the frequency and/or intensity of different types of weather extreme events is likely to increase in a number of regions across the globe. Additional pressures on socio-economic and environmental systems due to population growth, rapid urbanization, conflicts and environmental degradation, particularly in developing countries, are likely to further increase the vulnerability of populations and to exacerbate the risks of severe impacts from climate hazards. Early Warning Systems (EWS) form an important part of national disaster risk management (DRM) strategies and are important to protect communities against the immediate threat and consequences of climate-related extreme events.

However, although great efforts have been made to improve EWS worldwide, many of the existing systems have important shortcomings: Often, EWS focus on one hazard type only, ignoring interactions between concurrent hazards. Many fail to provide estimates of climate impacts in a standardized way and taking into account all sectors that are vital to the functioning of societies and relationships between sectors. Furthermore, the communication of warnings is not always adequate, either by not reaching affected populations or by not providing timely and reliable warning. Finally, in many cases early warnings are not sufficiently linked to rapid response measures.

The aim of the United Nations Environment Programme's CLIM-WARN project was to review the current state of multi-hazard Early Warning Systems in three African countries (Kenya, Ghana and Burkina Faso), to identify capacity gaps, to assess the needs of vulnerable communities, to review best practices for early warning communication and response and to develop a set of recommendations for decision makers to improve existing Early Warning Systems which are applicable beyond the case study countries. An important gap that was identified by stakeholders is the lack of a central platform which integrates hazard warnings from relevant national agencies and provides a visual interface for accessing hazard risk data and which facilitates the communication of warnings to vulnerable groups. These findings resulted in the development of a prototype of a multi-hazard and multi-sector Early Warning Platform in Kenya, building on collaborations with partners and using information and communication technologies (ICT). This talk will present the methodological framework which underpins the development of this prototype platform and will demonstrate the web-based tool which integrates hazard data from different data sources, automatically calculates hazard impacts and disseminates subscription-based warnings and response recommendations to users, based on their data needs and preferred communication channels.

The combination of multiple forecasting datasets in one platform has several benefits: It ensures a comprehensive assessment of impacts in all major sectors, taking into account relationships between hazards and sectors; it facilitates the creation of integrated response plans and the exchange of data and knowledge between different stakeholders. Furthermore, it enhances the visibility of risk and hazard data and by this, helps to raise awareness. Remaining gaps and challenges are related to data availability and accuracy as well as to the creation of a national, legislative and institutional framework with clear roles and responsibilities. The development of an Early Warning platform requires strong partnerships with and the support of regional, national and subnational governmental and non-governmental institutions to ensure that the platform will be used by disaster managers in the long term.

Tree-based energy for resilient livelihoods and ecosystems under climate change in Kenya

M. Njenga (1)
(1) ICRAF, Nairobi, Kenya

Kenya has a population of 39 million people with 68% of the population living in rural areas and half of her population lives below poverty line. Kenya has a land area of 580,728km out of which approximately 85% is arid and semi-arid land (ASAL) and support 30% of the population and 70% of the livestock production. Agriculture is the backbone of the Kenyan economy directly contributing 24% of the GDP valued at KSh342 billion in 2009 and another 27% indirectly, valued at KSsh.385 billion. The country is experiencing climate-related impacts such as prolonged droughts, frost in some of the productive agricultural areas, hailstorms, extreme flooding, receding lake levels, drying of rivers and other wetlands, leading to economic losses and environmental degradation. For instance the floods of 1997/98 affected 1 million people

and cost the economy US$ 0.8-1.2 billion.

Trees provide various ecosystem services that build resilient social-ecological systems through (i) providing biological products such as fruit, browse for livestock, medicines for human and livestock, oils, construction materials, woodfuel and gums and resins, (ii) supporting services of soil fertility management, soil moisture and biodiversity, (iii) regulating services on macro and micro climate, air quality, soil erosion and water regulation and (iv) cultural services. The loss of trees under climate change is of great concern to the country which has retained only 2% forest cover.

One of the drivers of tree loss is the unsustainable woodfuel sector. Over 80% of households in rural areas and 70% of households nationally depend on firewood. Charcoal ranks second as a source of cooking energy in Kenya and is used by 82% of urban and 34% of rural households; and most of it comes from the drylands. Trees on-farm provides cooking energy hence saving women and girl's time and drudgery in traveling long distances in search of firewood and reduces household expenditure. Recycling organic by-products into briquettes generate income and employment for women and youth and the product burns cleaner and longer. Improved cook stoves generate income from sales of stove, save fuel and time, reduce emissions and some produce charcoal as by-product. As such scaling-up the following local innovations will reinforce resilient livelihoods and ecosystems through tree-based energy; (i) wood energy production through short rotational forestry, farmer managed natural regeneration, coppice management, intercropping trees with crops or pasture, (ii) briquetting agricultural, tree and municipal organic by-products, (iii) improved cooking technologies (iv) large-scale gasification of biomass, for instance of invasive tree/shrub species, for electricity production and briquetting of by-product -charcoal dust and (v) policy framework that supports and creates awareness on growing of trees for energy and resilient livelihoods and ecosystems and regulate tree-based energy trade.

O-2235-02

A Community based initiative of afforestation for charcoal production: Case study Siaya County, Kenya

N. Oduor (1) ; J. Maua, (2)

(1) Kenya Forestry Research Institute, Forest Products Research Centre, Nairobi , Kenya; (2) Kenya Forestry Research Institute, Kakamega sub-centre, Kakamega, Kenya

It is estimated in Kenya that about 90% of rural households use fuelwood either as firewood or charcoal with firewood meeting the energy needs of over 93% of rural household, and the charcoal being the dominant fuel in urban households. Besides being the most common cooking fuel for the majority of Kenyan households, fuelwood is also an important energy source for small-scale rural industries such as tobacco curing, tea drying, brick making, fish smoking, and bakeries, amongst others. The principal sources of fuelwood are agro-forestry (84%), biomass in trust lands (8%) and gazetted forests (8%). Kenya is a relatively dry country, with approximately 80% of total land area defined as arid and semi-arid. The current status of much dry land forest resources is the direct result of wasteful practices and degradation, from overgrazing, overexploitation of trees for the acquisition of firewood and charcoal particularly in the close vicinity of towns and refugee camps.

Currently, there is a growing imbalance between supply and demand of biomass energy. In 2012, the firewood and charcoal demand stood at 18,702,748m3 and 16,325,810m3 respectively against an estimated supply of 13,654,022m3 and 7,358,717m3. The principal drivers of biomass energy demand are population growth, lack of access to energy substitutes and the growing incidence of poverty among Kenyans. This biomass energy supply and demand imbalance is exerting considerable pressure on the remaining forest and vegetation stocks, thereby accelerating the processes of land degradation and desertification. In addition, the production of biomass energy poses a threat to competing land use systems such as agriculture, forestry and human settlements.

Initiatives of reforestation and afforestation are being carried out to mitigate this deficit, mitigate the effects of climate change and to raise the total land area in Kenya under forest to 10%. This paper gives the experiences of a community afforestation project in Siaya County that was started in 2002 using Acacia xanthophloea and A. Polyacantha species. Research was carried out on the optimal tree spacing, wood yields, efficient production of charcoal and the optimal age for charcoaling. Spacing trials of 1m X 1m; 1.8m X 1.8m; 2m X 2m; 2.5m X 2.5m, 3m X 3m up to 4m X 2m and 4.5m X 1m were set up. Three efficient charcoal kilns were used (half orange kiln, drum kiln and Casamance kiln) and lastly the optimal age for charcoaling was determined by charcoaling the two Acacia species aged 4 and 6 years old.

The optimal tree spacing (where it allowed selective harvesting - not clear felling) was 2.5m X 2.5m. The total biomass estimation based on diameter and height was calculated as Y= 0.0006x where x is (dbh2 * ht), R2 =0.8374. The optimal age was found to be six years, where the weight of the same volume of charcoal increased by 10kg.

The current estimated area of land under acacia is 240 hectares with an estimated yield of 100 tons of round wood or 30 tons of charcoal per hectare under six years rotation. The number of farmers who have set aside land sizes ranging from 0.5 - 3 acres (0.21 - 1.25 Ha) for wood lots, now stand at 545.

O-2235-03

Are we ready to scale-out climate-smart agriculture in South Asia?

P. Aggarwal (1) ; KC. Arun (1) ; B. Paresh (1) ; M. Jat (2) ; P. Thornton (3) ; A. Jarvis (4)

(1) CCAFS, IWMI, New Delhi, India; (2) CIMMYT, New Delhi, India; (3) ILRI, Nairobi, Kenya; (4) CIAT, Cali, Colombia

Recent IPCC report and several other studies indicate a probability of 10-40% loss in crop production in India and other countries of South Asia with increases in temperature by 2070-2100 and decrease in irrigation water unless steps are started now to increase our adaptive capacity. There could be significant losses in some crops such as wheat even in short-term. Droughts, floods, tropical cyclones, heavy precipitation events, hot extremes, and heat waves are known to negatively impact agricultural production, and farmers' livelihood. The projected increase in these events will result in greater instability in food production and threaten livelihood security of farmers. Increased production variability could be perhaps the most significant impact of global impact change. Early signs of decrease in yields due to changing weather have started becoming visible.

Several technological, institutional and policy interventions have been proposed that can help us adapt to climate change as well as to current and future weather variability. These include simple adaptation practices such as change in planting dates and crop varieties. Additional strategies for increasing our adaptive capacity include bridging yield gaps to augment production, deployment of adverse climate tolerant genotypes and diversified land use systems, the use of solar irrigation, assisting farmers in coping with current climatic risks through providing weather linked value-added advisory services to farmers and crop/weather insurance, and improved land and water use management and policies. It is interesting to note that most of the proposed adaptation options, if implemented scientifically, come with large mitigation co-benefits.

CCAFS is scaling out the Climate-Smart Villages (CSVs) model in several countries, including in South Asia, to promote climate-smart agriculture (CSA). Climate Smart Villages are sites where a portfolio of the most appropriate technological and institutional interventions, determined by the local community, are implemented to increase food production, enhance adaptive capacity and reduce emissions. Interventions are bespoke to each village but the concept lends itself to be applied in any region under the right circumstances. Initial results suggest a large potential to maximize synergies among different interventions in order to scale out CSA.

While most of these interventions have indeed shown increased production, resilience and even mitigation, their area coverage is still small. This paper argues that evidence base for many of these interventions is still limited and we need enough context specific targeted knowledge about them before they can be applied on a large scale. In addition, lack of appropriate 'business models' around

these interventions limits scaling-out efforts.

O-2235-04

The impact of bioenergy development on the climate resilience of vulnerable communities in Kenya

S. Abrar (1)
(1) Edinburgh University, Edinburgh, United Kingdom

The purpose of this project is to examine whether bioenergy developments have an impact on the climate resilience of vulnerable communities in Kenya. Interviews were conducted with professionals and several projects and programmes were visited on site. The research, based on evidence, shows that traditional use of solid biomass, which is the most popular source of energy in Kenya, is believed to have a negative impact on climate resilience. However, most of the interviews and projects visited have also demonstrated that, in certain conditions and under specific circumstances, bioenergy developments can reveal strong climate resilience characteristics. If they cannot by themselves improve considerably the resilience to climate change, some of them, when combined with measures and initiatives aimed at improving the life of the most vulnerable, do achieve this purpose. This study also demonstrates, once again, how important it is for any project, programme or technology to address the specific needs and tastes of the populations they intend to serve and how engagement, empowerment and ownership by the communities is key to achieve success. A higher consideration and respect for local cultures and ways of living, promoting a grass-¬-root approach, encouraging collective actions through capacity building and awareness raising, and finally providing financial and political support, will help generate more suitable and targeted technologies and programmes, including those related to bioenergy, that would improve the climate resilience of vulnerable communities in Kenya and elsewhere.

O-2235-05

Multiple benefits of biochar: Synergism or trade offs

E. Yeboah (1)
(1) CSIR-Soil Research Institute, Microbiology, Kumasi, Ghana

Poor soil fertility is a key constraint to improving farm productivity and farmer livelihoods in sub-Saharan Africa. The search for sustainable soil management practices is still on. Biochar, a pyrolysed biomass in recent years has gained international recognition to improve soil productivity.There are however limited research on biochar in Ghana to warrant government policy. A field study was conducted in the major season of 2012 in the semi-deciduous forest zone and the Guinea savanna agroecological zones of Ghana. The objective was to determine soil management scenarios that will enhance the beneficial effect of biochar application to soils. The treatment were control no amendments, 2 t/ha biochar and 4 t/ha biochar. Each main treatment received 0, 30, 60 and 90 KgN/ha. The test crop was maize. 4 t/ha biochar + 90kg N/ha increased maize yield indices across sites. Biochar increased N use efficiency and improved gravimetric soil moisture contents across sites. The synergistic effect rather than tradeoffs of the biochar technology to address energy use of the smallholder farmer through the use of efficient cookstoves, the bio-physical constraints in the context of soil improvements to increase food security, soil carbon sequestration for climate change mitigation as well as the socioeconomic constraints of the smallholder farmer needs to be explored for wider adoption of the biochar technology.

O-2235-06

Moving from climate vulnerability to Resilience: a case study of Bangladesh

S. Huq (1)
(1) International Center for Climate Change and Development (ICCCAD), Dhaka, Bangladesh

Bangladesh has been identified well over a decade ago as being one of the most vulnerable countries to the potential adverse impacts of human induced climate change . Over the last decade the country has been one of the first of the Least developed Countries (LDCs) to carry out their National Adaptation Programme of Action (NAPA) as mandated by the United National Framework Convention on Climate Change (UNFCCC) as it's 7th Conference of Parties (COP7) held in Marrakceh, Morocco in 2001 under the Marrakech Accords, which provided technical assistance and financial support to the LDCs for carrying out the NAPAs.

Subsequently the Government of Bangladesh built on the NAPA which was only meant to identify urgent and immediate adaptation actions, to develop a more elaborate and longer-term Bangladesh climate Change Strategy and Action Plan (BCCSAP) which has six pillars and forty actions. These actions have been funded by creating two Climate Change funds, one with the Government of Bangladesh's own finances and the other with donors contributions. Both the funds together have now funded over three hundred projects to tackle climate Change . While most of them are adaptation related a a few are also mitigation. Related as mitigation was one of the six pillars of the BCCSAP.

Thus over the last decade Bangladesh, including the government as well as other stakeholders such as civil society, universities, media and private sector have already invested in various activities to tackle climate Change and as a result have climbed up a knowledge ladder that enhances the collective understanding of what is needed. The latest development in this journey of tackling the adverse impacts of climate Change is to focus on Resilince as opposed to Vulnerability, so, while the focus until now had been on identifying vulnerability and helping to build adaptive capacity it has now moved to identifying underlying characteristics of resilience and building on them. This is a much more positive agenda and enables all the relevant actors to focus on their strengths and build on those strengths rather than focus on vulnerability and only invest on risk management alone. This is also in many ways a transition from investing in incremental adaptation to transformational adaptation using the climate change challenge as opportunity.

O-2235-07

Building resilience in dryland Africa

C. Toulmin (1)
(1) IIED, London, United Kingdom

This presentation outlines IIED's experience on building resilience in dryland Africa. Drawing on a range of field sites, we show the timeframe and process for strengthening local capacity in decision-making, in ways which provide sound public investment choices. Between 1980 and 2012, it is reckoned that the annual damage from extreme-weather related events rose from $20b to 150b, totalling close to US$2 trillion, of which only 1Ż4 was insured. Examples include floods in Bangladesh and Thailand, typhoons in the Caribbean and droughts in the West African Sahel and Horn of Africa. Poor people and nations have been particularly vulnerable to the impacts of these events; people living in countries with a low Human Development Index make up only 11% of those exposed to hazards but account for 53% of disaster mortality.

Even if we manage to cut greenhouse gas emissions rapidly and effectively from today, we must anticipate 20-30 years of growing impacts from climate change due to lags in the global atmospheric system (IPCC, 2014). Drought, floods, and heat waves are all likely to increase in both frequency and intensity. The impact of tropical storms and associated sea surges will be amplified by sea-level rise. Disaster preparedness is key to help minimise loss of life and property, as well as speeding recovery post-disaster. "Resilience" has become a widely used term to describe the quality of human-environment systems and their response to disaster. In the recent study by the Royal Society of building resilience to extreme weather events, resilience is taken as "encompassing more than merely coping with individual extreme weather events; it means looking at the capacity of individuals, communities and systems to not only survive, but also adapt and grow in the face of stress and shocks." While "resilience" has spawned an increasing number of definitions, essentially it refers to our ability to deal with changes, in terms of reducing the risk of a hazard, and minimising the subsequent impacts.

Building resilience to extreme weather needs a systems approach, which involves investing in a combination

of technical, economic/financial, and institutional dimensions. When faced with a threat such as drought or flooding, the first instinct is to invest in hardware – such as dams to capture and store water for dry periods, or sea-walls to protect from floodwater. And such tangible infrastructure is clearly very important. But alongside such investment in the physical hardware of protection, there are a range of vital intangible investments needed in the software of institutions for managing variable resources, and sharing risk. Institutions may be invisible, but their strength can make a big difference in how societies cope with disaster. Building resilience also requires shared action and responsibility at local, national and international levels, by the public and private sectors, local communities and non-governmental organisations. We will use the case of northern Kenya, Mali and Senegal to illustrate this systems approach, and the role that different actors need to play.

Nowadays, many ecosystems are affected by multiple kinds of disturbances and changes on different time scales: one might be the strong disturbance by land use (e.g. harvest of the woody biomass in forests, grazing) or land use change (mainly conversion to agricultural land); the second, slower and more a change than a disturbance is climate change, caused by rising concentrations of greenhouse gases in the atmosphere (Higgins et al. 2010). Climate change results in a variety of changes in temperature and precipitation patterns, but also higher probability of extreme weather events. These changes may massively influence biogeochemical cycles as well as the balance between species.

Based on this, it can be hypothesized that many ecosystems, even if they are very resilient, may not return to their initial state after disturbance, but will rather adapt to a new steady-state (e.g. associated with the intermediate change in climate). We can name this phenomenon «Adaptive Resilience of Ecosystems». It can be used as a further development of classical resilience concept and use it as base for integrative research and management concepts. This is outlined with the example of semi-arid savanna ecosystems.

Climate vulnerability of the supply chain: methodological review

A. Miola (1) ; A. Valeria (2)
(1) EU Joint Research Center Institute for Environment and Sustainability, Climate risk management unit, ispra, Italy; (2) Liverpool Hope University, Business school, Liverpool, United Kingdom

The increasing complexity of the present economic system and the strong interdependencies existing between production activities taking place in different world areas make modern societies vulnerable to crisis. The global supply-chain is a paradigmatic example of economic structures on which the impacts of unexpected events propagate rapidly through the system. Climate change, which affects societies all over the world, is one of the most important factors influencing the efficiency of the present economic networks. During the last decades a large set of studies have been oriented to investigate the direct impacts generated on specific geographical areas or productions. However, a smaller number of analyses have been oriented to quantify the cascading economic effects generated all over the world. The great complexity of the global economic system, coupled with methodological and data gaps makes it difficult to estimate the domino effects of unexpected events. A clear understanding of the possible consequences generated all over the world is, however, a fundamental step to build socio-economic resilience and to plan effective adaptation strategies. Within this context, the main objective of the present report is to provide an overview of the main studies, methodologies and databases used to investigate the climate vulnerability of the global supply chain. This information can be useful to i) support further studies, ii) to build consistent quantification methodologies, and iii) to fill the possible data gap.

Testing and Piloting Climate Smart technologies in Pastoral and Agro Pastoral systems; The case of Ijara sub-county, Garissa County in Kenya

E. Okiri (1) ; M. Okoti (2)
(1) Kenya Agricultural Livestock Research Organization, Environment and Climate Change, NAIROBI, Kenya; (2) Kenya Agricultural and Livestock Research Organization, Environment and Climate Change Research, Nairobi, Kenya

Ijara is one of the six sub-counties that form the Garissa County in North-Eastern Kenya; it falls into agro-ecological zone V-VI: temperatures range from 15°C – 38°C and rainfall is bimodal ranging between 700–1000 mm per annum. The average relative humidity is 68%. The sub-county covers an area of 10,000 km², with more than 90% of the land as trust land. The population within the sub-county was estimated at 100,000 during the 2009 national population census, with a population growth rate of 3.7%, while the poverty index stood at 63% with over 90% of households depending on pastoralism. The main economic livelihood of the inhabitants of Garissa County is livestock keeping. The pastoral households face a number of challenges that constrain their ability to employ productive systems effectively. These include among others population growth; the allocation of land for other purposes such as agriculture and wildlife conservancies; inadequate maintenance of infrastructure such as roads and earth dams; poor planning resulting in haphazard creation of water points; insecurity in Somalia; unsustainable management of land, water and other natural resources; and deteriorating livestock management practices. These issues are exacerbated by climate change, which has led to environmental degradation such as loss of biodiversity and soil erosion. Climate change is also a driver of poor resource management, as people resort to increasingly unsustainable coping strategies such as charcoal production to manage recurrent shocks to their livelihoods. To deal with challenges affecting major livelihoods in the county and to reinforce the resilience of the community, the Kenya Agricultural Livestock Research Organization (KALRO) and International Development Research Centre (IDRC) project used various approaches including reconnaissance surveys; Risk and Vulnerability Assessment, including downscaling of climate information; and participatory identification of viable adaptation options. These adaptation options were piloted through farmer field schools. The project also organized field days and exchange visits in fodder production and livestock management as part of stakeholder capacity building, with a mix of adaptation options to establish pastures at the individual farm level. The downscaled climatic information indicates that Ijara sub-county is getting warmer. This coupled with increased climate variability implies that planning for appropriate adaptation options is mandatory. In order to counter the expected loss of livestock and subsequent livelihoods, a mix of adaptation options needs to be put in place in the sub-county. A key option is the establishment of pastures at the individual farm level. Results from the project's fodder component showed that the establishment of rain-fed Sudan grass is feasible as both a short-term and a long term adaptation strategy. The grass is highly adaptable in the region and gave an average yield of 24 tonnes/hectare/year. This can support up to 16 milking cows per year, and so can contribute greatly to food security at the household level. The benefit-cost ratio was 1.25. Socio-cultural and economic changes had negatively affected the traditional livestock management practices e.g. breeding

management. After a series of capacity building initiatives, households started putting in place measures to improve their livestock herd. These included selecting of breeding males and females; castration of excess males; avoiding the use of polled bucks; culling of one testicle males; taking care in the administration of drugs; adoption of camels as opposed to cattle – it was a cultural taboo for them to keep camels despite camels' better resilience to climatic shocks compared to cattle. Study/exposure tours had a strong positive influence on agricultural technology adoption among pastoralists. From the project initiatives, the farmers' ability to perceive climate change and related climate variability was a key precondition for their choice to invest in fodder production and conservation. Demonstration and information allowed the households, and also policy makers, to make rational decisions on investment options.

Three decades of changes in stream communities of France reveal ecosystem shifts and resilience mechanisms in temperate region freshwater ecosystems

K. Van Looy (1) ; M. Floury (1) ; M. Ferréol, (1) ; J. Piffady, (1) ; Y. Souchon, (1)
(1) Irstea Lyon, Milieux Aquatiques Lyon, labo hydroécologie quantitative MALY, LHQ, Lyon-Villeurbanne, France

Global warming is assumed to be a threat to temperate stream biodiversity. Still, many of the processes and mechanisms behind the predicted threats to diversity remain uncertain. We identified current trends and drivers of change for freshwater communities over a large spatial and temporal scale already revealing a strong ecosystem shift.

We analysed diversity and composition shifts in stream invertebrates communities during the last three decades in relation to geographic elements and human stressors over the French river network (circa 1000 km in longitude and latitude). We observed a 42% increase in the taxonomic richness of stream invertebrate communities, largely caused by climate change (23% purely climate-induced taxonomic richness increase). As a local mechanism, a bottom-up food web productivity response to rising temperature was responsible for this strong increase in diversity. Stochastic assembly processes (both environmental stochasticity and dispersal related stochasticity) increased the regional scale diversity, giving spatial insurance to biodiversity and lowering the risks of biotic homogenisation.

Thus, stream invertebrate communities show strong resilience to environmental changes thanks to local and regional responses of productivity changes (resource resilience), and thanks to landscape heterogeneity (refugia resilience) and dispersal processes (recruitment resilience). For the French stream invertebrate communities, up to now the resilience mechanisms seem to outweigh the predicted threats. From this knowledge emerge scenarios that enhance the temperate streams' resilience to cope with further global changes.

K-2236-02

Scenarios Emergent!

R. Lempert (1)
(1) RAND Corporation, Frederick s. pardee center for longer range global policy and the future human condition, Santa Monica, United States of America

Responding to climate change may require us to imagine future worlds, both good and bad, different than the one with which we are familiar and to take concrete steps now to shift towards more favorable pathways into the future. Scenarios can play an important role in such visioning and action. At their best, scenarios can effectively represent deep uncertainty; integrate over multiple domains; and enable parties with different expectation and values to expand the range of futures they consider, to see the world from different points of view, and to grapple seriously with the potential implications of surprising or inconvenient futures. These attributes of scenario processes can prove crucial in helping craft effective responses to climate change. But traditional scenario methods can also fail to overcome difficulties related to choosing, communicating, and using scenarios to identify, evaluate, and reach consensus on appropriate policies. Such challenges can limit scenario's impact in broad public discourse. In recent years, new decision support approaches employing new quantitative tools, now enable scenarios to emerge from a process of deliberation with analysis among stakeholders, rather than serving as inputs to it. Such approaches can significantly increase the impact of scenarios on decision-making. This talk will survey this emerging field of computer-assisted scenario design, describe some applications, suggest how the underlying concepts can inform a broad range of scenario activities, and help make scenario more impactful in shaping both incremental and transformative responses to climate change.

Building and analyzing large numbers of socio-economic scenarios for decision support under uncertainty: a modelling experiment to explore the main determinants of economic growth in a carbon-constrained world

C. Guivarch (1) ; J. Rozenberg (2)
(1) Centre International de Recherche sur l'Environnement et le Développement (CIRED), Paris, France; (2) World Bank, Climate Change Group Chief Economist Office, Washington DC, United States of America

Climate change poses a challenge to traditional decision making techniques due to long time scales, complex systems that couple human, technical and natural elements, and multiple uncertainties. Scenario technique is a key tool for decision making in such context. Here we demonstrate how building and analyzing databases of scenarios that explore the "uncertainty space" can bring novel insights for decision support. We do so in an illustrative study that focuses on identifying the main sources of technological and socio-economic uncertainty for indicators used for policy decision.

The relevant measure for the macroeconomic evaluation of mitigation pathways depends on the question at stake: deciding on the level of mitigation to target or choosing a strategy to meet an already fixed target. Choosing the level of greenhouse gases emissions reduction to target requires balancing mitigation costs against avoided costs from climate change damage. Both costs are usually measured by GDP or welfare losses compared to a baseline – a scenario with no mitigation and no damage. However, whether this balancing approach is appropriate for climate change is being increasingly called into question, in particular because estimates of the damage that can be caused by climate change are highly uncertain and possibly in the realm of the "unknowable". But when the stabilization target is already fixed, the design of the best strategy is better informed by absolute levels of GDP in pathways that meet the target.

We construct a modelling experiment to explore the role of a wide range of socio-economic uncertainties for the two metrics: absolute per capita GDP under mitigation scenarios and GDP losses with respect to the baseline. The modelling experiment takes the form of an analysis

of an ensemble of 648 scenarios, built with an Integrated Assessment Model that represents the intertwined evolution of technical systems, energy demand behavior and economic growth. The model parameters are grouped into six parameter sets: productivity growth in the leading country, productivity catch-up in other countries, energy demand behavior, end-use energy efficiency, availability of low-carbon technologies, and availability of unconventional fossil fuels. Combining alternative assumptions on the values of the parameter sets leads to 216 baselines. For each baseline, two mitigation scenarios are modeled. Both meet an exogenous emissions trajectory constraint leading to a 50% reduction in global emissions by 2050 compared to 2000. They differ in the use of the carbon tax revenues – revenues are either redistributed to households or used to reduce pre-existing taxes.

In the resulting ensemble of mitigation scenarios, we find that GDP losses and absolute GDP are not well correlated and are not determined by the same (uncertain) drivers. We identify the most important sources of uncertainty for absolute GDP in mitigation scenarios and for GDP losses with respect to the baseline, using a regression tree algorithm. We find that GDP losses against baselines are mainly determined by the design of the climate policy and the availability of low-carbon technologies whereas absolute GDP in mitigation scenarios is mainly determined by end-use energy efficiency and energy demand behavior. More generally, our modeling experiment shows that, in a context of uncertainty, GDP losses and absolute GDP are not well correlated and do not give the same insights for policy designs. Realizing the difference is important to focus on the relevant information for each type of decision.

Despite, and because of, the uncertainty surrounding future damage caused by climate change, decision-makers in many places around the world have set mitigation targets in terms of concentration of greenhouse gases or temperature (at the global level), or in terms of future emissions (at national or local levels). They are now designing strategies to meet these targets. In this context where mitigation targets are already fixed, our results challenge the practice of macroeconomic evaluations of mitigation pathways that mainly focus on investigating the role of technological uncertainties for GDP losses relative to baseline scenarios. Instead, analysts and decision-makers should to devote more attention to GDP levels under a carbon constraint on the one hand, and to uncertainties on energy demand behaviors and energy efficiency on the other hand.

Scenarios can be a powerful approach to exploring future climate and socio-economic uncertainties. However, scenarios are not strategies – instead, they provide challenging contexts for decision-making. In the face of pressing policy concerns around climate adaptation and mitigation, the need to integrate scenarios with governance and planning processes is high, and greater understanding is needed about how such links could be made effective.

We present a global research project that evaluates the use of scenarios for policy development in the context of climate adaptation, socio-economic development and food security through six case studies. First, regional scenarios were developed by stakeholders in six global regions: East and West Africa, South and Southeast Asia, the Andes and Central America. Participants used a novel method for the combination of many interacting drivers in the scenarios. The scenarios were then quantified using two global agricultural economic models, IMPACT and GLOBIOM, and linked to the new global Shared Socio-economic Pathways (SSPs). In each of these regions, dialogues with governments led to the identification of a number of specific national policy processes (Cambodia, Honduras, Peru, Bangladesh, Ghana, Uganda) where the process leaders welcomed the opportunity for scenario-guided policy design. For this purpose, those involved in the processes and wider groups of stakeholders used a method for re-imagining the regional scenarios to ensure a perfect fit with policy concerns. These adapted scenarios were used in detailed analyses of the policy drafts, and suggested changes were taken up into new policy drafts and taken forward toward finalization and implementation, supported by the project researchers.

To study these processes, hypotheses about best practice and indicators were formulated with regional partners. Research results show that 1) a focus on specific policies yielded the clearest impacts; that 2) the establishment of trust between researchers and policy makers was key to ensure an effective, open process; that 3) the scenarios had to be flexible enough to be adapted for specific policy concerns but credible enough to be seen as useful; 4) that challenges associated with government turn-over and re-structuring had to be overcome and 5) that scenario-guided policy processes have to be highly transparent for those not involved in them. We translate these lessons into recommendations to help respond to a widespread need for effective scenario-guided policy development.

O-2236-03

Social responses to climate change: What can participatory games and scenarios tell us?

J. Pardoe (1) ; M. Garschagen, (1)

(1) United Nations University, Institute for Environment and Human Security, Bonn, Germany

Climate change concerns are exceptionally pressing in agro-ecosystems, where social-ecological connections are particularly close. However, inherent climate uncertainties make anticipatory adaptation of agriculture-dependent communities particularly challenging. This paper draws on scenario analysis in order to understand how local level decision making processes in three rural communities in West Africa may unfold as climate change progressively reveals itself.

Empirical evidence was collected using a game designed around future uncertainty with climate change. Participatory games based on scenarios provide a safe space in which to explore potential futures and the respective patterns of individual and collective decision-making. The gaming method was used specifically to understand how the social actors might respond to climate change impacts on agricultural production, paying particular attention to the ability to maintain the fundamental functions of the agro-ecosystem. The method proved particularly valuable for eliciting information on potentially negative futures that participants are otherwise reluctant to consider and discuss, due to the predominance of inherently fatalistic worldviews in the case study region. The results have revealed important insights on the role of thresholds and tipping points in decision making. These can be reached through both sudden and gradual changes, yet with significantly different implications for adaptation decisions and the consecutive system configuration.

Based on this novel method, the paper is able to make a number of contributions to the empirical and conceptual understanding of adaptation decisions in coupled social-ecological systems. Lessons can in particular be drawn on the question which role different speeds and depths of environmental change have on triggering the level and type of adaptation action. The data suggest that sudden and extreme events are more likely to trigger more reflexive and more fundamental adaptation responses than gradual environmental degradation, with the latter implying a high risk or rigidity traps in the case study regions.

The research further allows drawing a number of methodological lessons, particularly with regards to the strengths but also weaknesses of participatory scenario methods. In order to arrive at wider conclusions, the lessons from the rural agricultural context in West Africa are juxtaposed with lessons learned in another project, where participatory scenario development has been applied by the authors in a very different setting, i.e. on adaptation trajectories in coastal megacities, jointly generated with adaptation and planning professionals. Recommendations for other researchers are formulated and amendments to the current literature discussed.

O-2236-04

In search of analytically sound and socially viable energy strategies: linking stakeholder narratives with energy scenarios

E. Trutnevyte (1)
(1) Swiss Competence Center for Energy Research-Supply of Electricity, ETH Zurich, Zurich, Switzerland

Climate change mitigation requires a rapid transformation of the energy sector. Energy strategies that are both analytically sound and socially viable can lay foundation for this transformation. I will propose a set of scenario methods that enable development of such strategies by linking narratives of stakeholders and the public (to capture the social viability component) with quantitative energy scenarios (to capture the analytical component). After discussing the limitations of the conventional story-and-simulation approach, where several narratives are represented by one quantitative scenario each (from one narrative to one scenario), I will propose three alternatives. The first approach translates normative narratives, or so-called stakeholder visions, into many scenarios (from one narrative to many scenarios). The second approach compares several narratives, based on multiple scenarios, in order to elicit commonalities and differences of the narratives (from many narratives to many scenarios). The third approach develops the narratives and scenarios simultaneously and then finds best matches (many narratives and many scenarios, side by side). These three methods will be illustrated with the cases of regional and municipal energy strategies in Switzerland, electricity system transition pathways in the UK, and risk governance process for deep geothermal power plants. I will close with reflections on the real-world impacts and stakeholder learning effects that were captured in the described studies.

O-2236-05

The IPCC narrative(s) – themes, actors, and storylines

K. Fløttum (1) ; Ø. Gjerstad, (1)
(1) University of Bergen, Department of foreign languages, Bergen, Norway

This abstract is submitted to the session «Scenarios, public deliberation and decisions»:

The IPCC has the challenging mandate to produce "policy-relevant and yet policy-neutral, never policy-prescriptive" reports related to climate change. The policy relevance, based on the most comprehensive assessment of climate change research undertaken, is condensed and presented in the IPCC Summaries for Policymakers (SPM). With this as a backdrop, as well as numerous previous studies undertaken on IPCC communication (e.g. Bowman et al. 2009; Budescu et al. 2009; Budescu et al. 2014; Harris et al. 2013; Hulme 2013; Jonassen and Pielke 2011), the current paper proposes to undertake a textual and narrative analysis of the SPM of the 2014 IPCC AR5-SynthesisReport (SYR). The chosen perspective here is particularly interesting since IPCC authors themselves now have started to characterise their documents as "narratives". We will examine to what extent the SYR-SPM corresponds to the typical narrative structure (Adam 2008), with a clear storyline or scenario comprising specific content components and actors. Our intention is to broaden the current discussion of language use in the IPCC assessment reports, by looking not only at the calibrated language for handling uncertainties set out for the IPCC authors, but also the contribution of other language and textual devices that may contribute to fulfil the communicative goals of the IPCC, which are to present a consensual message to be used by policymakers.

Narratives are crucial to people's understanding of the discourse and to their potential engagement with the challenge at stake (Jones 2011, 2013). The notion of narrative has been used in a somewhat loose sense to describe a variety of texts genres. However, some research has also been done on applying the notion in a more rigorous way in order to understand to what extent there may be a storyline in texts related to climate change (Fløttum 2013; Fløttum and Dahl 2012; Fløttum and Gjerstad 2013), with a point of departure in the hypothesis that such texts can be considered as climate change narratives. This expression refers to text and talk presenting climate change as a certain type of COMPLICATION, with implicit or explicit recommendations or imperatives for ACTION(S) taking place or that should take place in order to achieve some particular EFFECT(S) or FUTURE SOLUTIONS (Adam 2008).It is this last part of the narrative which is particularly interesting to the scenario focus given to the present session – the action(s) and effect(s) components. We will further investigate how the three SPMs from Working groups 1 – 3, representing to some extent three different worlds, are combined in a new narrative in the SYR SPM. What are the themes, scenarios and ways of thinking promoted, which could prime, guide and frame audiences' appropriations of the conveyed messages?

Narratives have plots with different actors involved, in the roles of HERO, VICTIM or VILLAIN. Recent research on the concept of narrative in the policy process (Jones 2010, 2013) has found that the use of "heroes" is "particularly powerful in shaping opinion about climate change" (Shanahan et al., 2013: 456). We investigate to what extent there may be room for heroes in the SYR SPM, or whether actors such as victims and villains are the only appropriate actors in the IPCC context.

Questions to be further discussed: To what extent is there a storyline structuring the SYR-SPM? Which scenario may best promote transformational policies?

Our findings will provide a basis for discussing the potential impact of texts such as the SPMs on target audiences and for discussing links between linguistic and scenarios research, public deliberation and decisions.

2236-POSTER PRESENTATIONS

P-2236-01

Scenarios Exploring Climate Change based on Soft Computing

A. Batisha (1)
(1) Environment and Climate Change Research Institute, Cairo, Egypt

The study presents an integrated view of soft computing to solve Climate Change problems. Having a collection of methodologies, soft computing may take advantage of tolerance for imprecision, uncertainty and partial truth to achieve tractability, robustness and low Climate Change solution cost. The focus is to apply the highest quality analysis in application and convergence of the areas of Fuzzy Logic, Neural Networks, Self-Organizing Maps, Evolutionary Computing, Rough Sets and other similar techniques to address Climate Change complexities that may affect Our Common Future.

Scientific communities should work more together on understanding of future climate risks, Disaster reduction and emergencies, and Hazard mitigation. Models and observations of the climate system play an important role in protecting our future climate. Especially extreme events can disrupt society. The impacts concern increased risks of coastal, river, surface water flooding and/or drought. Such issues may be considered by using Soft Computing Techniques: future sea level scenarios globally and regionally, future changes in storm surges, changes in precipitation regimes and associated river discharge, analyses of multiple threats to coastal areas and river delta due to climate change, measuring/recording climate change induced change, extremes and compound climatic events, and the role of adaptation in hazard mitigation and on possibilities to strengthen post hazard reconstruction with a long term adaptation perspective.

Climate change, socio-economic development, ineffective water policy and governance, and basin-wide

developmental interventions are causing increasing threats to the availability and access of fresh water for drinking, agriculture, ecosystem sustenance and industrial activities. Sea level rise, Stalinization and long periods of drought are posing challenges to optimization of freshwater supply and demand. Such issues may be considered by using Soft Computing Techniques: research on how river delta can be adapted to threats of Stalinization and increasing uncertainties in fresh water supply, including technical, economic, policy and spatial planning measures that can be applied for improved fresh water management.

Uncertainty about climate change increases the complexity of decision-making. Limits to the predictability of natural and societal processes prevent scientists from making firm statements about the possible consequences of adaptation decisions. This contrasts with the public's expectation that decisions will be based on sound science. Such issues may be considered by using Soft Computing Techniques: bridging the gap between science and decision-making; Better methods and tools for assessing; simulating and communicating climate risk and the environmental, social and economic costs and benefits of adaptation.

P-2236-02

Going beyond integrated assessment: big emitting nations and the 2°C target

A. Bows-Larkin (1) ; M. Sharmina, (1) ; J. Kuriakose, (1) ; K. Anderson (1)
(1) Tyndall Centre for Climate Change Research, University of manchester, Manchester, United Kingdom

This year, the United Nations Conference of the Parties in Paris is tasked with delivering a land-mark agreement on avoiding the 2°C warming associated with 'dangerous interference with the climate system'. If such an agreement is reached, it will re-invigorate analyses of how global and national energy systems can deliver the rates of mitigation accompanying the 2°C threshold. Commonly such studies rely on detailed integrated assessment models combining physical and economic relationships to postulate future climate and energy systems. Typically these models optimise on the basis of minimum costs in developing 'feasible' scenarios in terms of technology, infrastructure and efficiency change, as well as providing longitudinal outputs related to parameters such as capital costs, carbon tax rates, etc.

This paper reflects upon the reliance of decision makers on the outcomes of these models, and their suitability for producing plausible outcomes. One criticism is aimed at their limited ability to explore future societies under the pressures of climate change mitigation and adaptation, given that their economic parameterisations are underpinned by historical relationships fit for a world unperturbed by climate change. A second questions whether their theoretical basis is appropriate for articulating the outcome of non-marginal change, when the very futures they are set up to explore involve non-marginal rates of change; for example radical cuts in CO2, or severe climate change impacts. Quantifying societal responses within such models is a particular challenge. Finally, these models downplay risks through disregarding low-probability, high-impact events and their consequences, including wars and migration. It is argued here that as currently formulated these tools are unsuitable for modelling the revolutionary transformations necessary to stay within 2°C carbon budgets, or similarly, futures with higher levels of warming and subsequent impacts.

To address these deficiencies, this paper takes an alternative approach to contextually explore the 'possibility space' appropriate for avoiding 2°C. In contrast to exercises that build future scenarios using 'immutable' relationships within and between the energy and climate systems, a more transparent and dynamic framing based on highly constrained cumulative carbon budgets is proposed. Building on previous assessments that use a similar approach by authors Anderson and Bows, this analysis looks beyond the contested 'Annex 1' and 'non-Annex 1' division to backcast what the remaining CO2 budget implies for the world's top emitting nations. The analysis takes the top 25 nations, responsible for 85% of global CO2, and groups these nations on the basis of similarities within their energy systems. Using a range of explicit variables such as short-term CO2 growth, a suite of emission scenarios for these groups are developed, constrained within a range of 2°C carbon budgets. By varying the levels of near-term emissions from each group's energy system, under a highly constrained CO2 budget, important sensitivities are revealed. Results demonstrate the significance of the rates of CO2 growth in the highest emitting groups, the importance of short-term change and the relevance of bunker-fuel emissions in shaping our collective futures. They also illustrate that only non-marginal change resulting in radical transitions across all energy systems can now be reconciled with the 2°C policy objective.

P-2236-03

The Integrating Assessment Modeling Community: overview, structuring and interactions with the IPCC expertise

C. Cassen (1) ; B. Cointe (2)
(1) CIRED, PARIS, France; (2) CIRED, Nogent sur Marne, France

The intellectual debates expressed by the Club of Rome about the "Limits to Growth" (Meadows, 1972) and the oil crisis in the 70s have given rise to energy-environment-economy (E3) models to explore the feasibility of long-term development pathways. The rise of climate change on the public agenda since the late 80s has prompted the need for quantitative assessment of mitigation strategies, in particular in view of the IPCC reports. E3 models gather different types of models, in particular IAMs (Integrated Assessment models). IAMs are simplified, stylized, numerical approaches to represent complex physical and social systems, and the most relevant interactions among the systems (e.g., energy, agriculture, the economic system). From a set of input assumptions they produce outputs in the form of quantified scenarios: energy system transitions, land use transitions, economic effects of mitigation, emissions trajectories. These scenarios are central to the work of the IPCC "Working Group III" on mitigation of climate change, and play an increasingly important part in the negotiation and elaboration of climate policies.

In this paper, we investigate the conditions of the production of such scenarios and the diversity of the models behind them. These models have been developed by an heterogeneous, interdisciplinary community of research. This paper analyses the development and the evolution of this community since the early 90s and provides an overview of the main models and research teams. The climate debate fostered the rise of a new generation of models in the vein of the first global and technico-economic models developed in the 60s and 80s. A main divide in the 90s was between macro-economic models (top-down) and more engineer styles models (bottom up). Bottom-up models give the priority to a detailed description of technologies and sectoral systems, while top-down models represent macro-economic consistency but encapsulate a limited description of technologies. The gap between has narrowed and an increasing number of hybrid models now combine comprehensive top-down representations of macro-economic processes with a technologically explicit bottom-up representation of energy systems.

We explain this narrowing gap as a result of the structuring of the IAM community. How did these models emerge as unified – though diverse – category? How and where did the IAM community organise as such, and what is it made of? This paper stresses the role of intercomparison modeling exercises under the framework of key institutions (for instance the Energy Modeling Forum coordinated by Stanford University, European Framework projects…). It traces the development of an epistemic community which participates, through the production of socio-economic scenarios, to the framing of the assessment of climate policies in group III of the IPCC. This history of the development of IAM relies on a mapping of existing models and modeling team, on interviews, as well as on an analysis of the content of the research programs conducted in these forums, the material produced (reports, articles, IPCC assessment reports in particular AR4 and 5…).

Native American Vulnerabilities to Climate Change and the Emergence of Federal Mitigation Strategies

S. Day (1)

(1) University of New Mexico, School of Public Administration, Albuquerque, NM, United States of America

Native Americans in the United States face a variety of existential threats due to climate change. This paper presents a typology of the specific vulnerabilities these groups face, and explains why they are unique groups when it comes to programs to mitigate the effects of climate change. The variety of climate change vulnerabilities include the well-documented problem of sea level rise and its effects on coastal communities, impacts of drought on such things as water availability and agriculture, increased riparian flooding due to shifts in rainfall patterns and vegetation change, and cultural impacts stemming from the loss of hunting and fishing for migratory species. Vulnerability patterns are furthermore complicated by the fact that the 566 federally-recognized Native American tribes vary considerably in terms of their populations, land areas, and resultant population densities. As semi-sovereign governments with land assets held in trust by the federal government of the United States, these groups represent an interesting problem for climate change mitigation, in that the federal government has specific obligations towards the protection of these groups. What this means for climate change mitigation is unclear. What does the federal government "owe" to a tribe whose land base is under threat due to climate change? Do certain mitigation strategies pose threats to the cultural and/or social fabric of the group, particularly if mitigation involves relocation? After providing the basic typology of climate change vulnerabilities faced by tribes, this paper goes on to describe several mitigation programs currently in the implementation phase. These include federal-tribal land swaps and relocations, as well as renegotiation of water rights. Thus far, these programs have not been controversial due to the fact that the tribes involved were small in terms of population and land base. However, I argue that the political feasibility of these types of mitigation strategies are limited by several factors specific to the types of vulnerabilities being addressed. As an example, the successful negotiation of land swaps and relocation are fundamentally constrained by the availability of federal lands adjacent to affected tribes, and which are not under pressure from additional stakeholders. As a result, the potential for land swaps as a standard mitigation strategy is likely to be limited to small and geographically remote tribes, as land swaps must contend with the principle that land exchanges must involve equivalent sized tracts of land. Thus I argue that larger coastal tribes that are closer to more urban areas are thus more vulnerable, both politically and environmentally, than the groups that have thus far been able to negotiate mitigation programs involving land swaps. The federal response to issues involving water scarcity and other issues, on the other hand, are relatively less well-developed. For instance, while renegotiated water rights accords have strengthened the position of various tribes vis-à-vis other water rights stakeholders, the continued drought throughout much of the American West continues to diminish the total stock of water all users rely upon. As such, the negotiation of more advantageous water rights does not in and of itself address the vulnerability of certain groups if there is no water to be had. Furthermore, the political conflicts in such situations are likely to be much more acute than in the other types of climate change issues faced by other Native American groups insofar that all stakeholders over a broader geographic region face the same underlying vulnerabilities. These type of situations represent zero-sum games and any concessions granted to Native American groups are likely to be perceived as unfair by other stakeholders. The paper concludes with a series of policy recommendations which suggest that a broad and flexible approach to climate change mitigation should be pursued, one which takes into account the specific type of climate change vulnerability, the physical and demographic characteristics of the tribe in question, the costs involved, and the nature of political opposition towards specific policy proposals.

P-2236-05

Global and regionalized land uses in 2050: scenarios taking into account climate change

M. De Lattre-Gasquet (1) ; T. Brunelle (2) ; P. Dumas (3)
(1) CIRAD, DGD-RS, Paris, France; (2) CIRED, Nogent-sur-Marne, France; (3) CIRAD, Cired, Paris, France

How will future changes in land uses - within regions and on a global level - will affect food security, taking into account possible climate changes, as well as changes in cropping and livestock systems, changes in farm structures, rural and urban relations, food regimes as well as changes in the general context.

The Agrimonde-Terra foresight project on "Land use and food (in)security" considers this question. Launched by the French research institutes Cirad and INRA, the Agrimonde-Terra conceptual framework can be used to build land uses scenarios at national and global levels with narratives and quantitative illustrations. At national and regional levels, the foresight process involves a group of diverse stakeholders, and discussions on the direct and indirect causes of land use changes facilitate thinking about the possible futures (anticipation), getting new ideas and understanding different points of view (appropriation) as well as decision-making (action). A first workshop has taken place in Tunisia and land use scenarios have been built. On top of that, global and regional levels scenarios are built with the support of a Scenarios Advisory Committee and their are the basis for discussions on possible consequences of land use changes on food security. The scenarios have been build combining hypotheses on direct and indirect causes of land use changes, and looking at interactions and retroactions between the variables. The foresight exercice has a wholistic approach..

Climate change is one of the important indirect drivers of land use changes. It impacts the food production capacity of ecosystems in several ways. It changes the time maturity of crops, it alters annual yields as well as their inter-annual variability, and it changes the nutritious qualities of crops. As far as climate change is concerned, two contrasted scenarios have been taken into account, focusing on temperature change and biogeochemical cycles. The first scenario, entitled "Stabilization of Global Warming" corresponds to the RCP26 the AR5. The agricultural system does not experience any major change due to climate conditions compared to the current situation. The area of cropland suitable for agricultural production does not notably change compared to the current situation, but the stabilization of anthropogenic emissions requires massive efforts for sequestering carbon in the vegetation which may take the form of afforestation and/or production of bioenergy production with carbon capture and storage, or agro-forestry. Most of the land use changes, however, occur after 2050. The second scenario entitled "Runaway climate change" corresponds to the RCP 85 of the AR5. The agricultural system experiences strong impacts: there are increases in the area of cropland suitable for agricultural production but it is unevenly allocated as it mainly concerns the northern latitudes while arable cropland areas decrease in tropical regions. The average suitability of cropland areas also decrease significantly.

The combination of the climate change scenarios with scenarios concerning the direct and indirect causes of land use changes show that food regimes, crooping and livestock systems, and farm structures, will have to adapt to new situations.

P-2236-06

Geo-political maps of CO2(s) to facilitate scientific policy and public debate

K. De Pryck (1) ; T. Venturini (1) ; M. Deves (2) ; M. Robert (3) ; A. Reys (4)
(1) Sciences Po, Médialab, Paris, France; (2) Institute for Globe Physics, Paris, France; (3) University Paris Diderot, Paris, France; (4) Sciences Po Paris, Médialab, Paris, France

In the last decades, a humble chemical molecule has become one of the most important actors of modern collective life. Carbon dioxide, or CO2, is increasingly used as a key marker for politics and economics both at the national and international level. As such, establishing thresholds for C02 emissions is one of the main objectives of the UNFCCC (United-Nations Framework Convention on Climate Change).

This does not means, of course, that the CO2 has passed from the natural to the political sciences. It means that the molecule has assumed a variety of different meanings according to who use it. Chemists, biologists, geologists, soil scientists, physicists, climatologists, all have different CO2 definitions. And their definitions differ from those of the economists, geo-politicians and NGOs and probably

even more from perceptions by the public opinion. If we had to design one single CO2 cycle, we would have to erase all these differences to obtain some 'mean version' that would be unrealistic.

Instead of trying to average these definitions, it would be much more interesting to find ways to compare their different meanings. Each of them designs and represents a specific vision of the world and orientates future policies and actions. For instance, measurements of C02 emissions entail different responsibilities when represented in terms of CO2 per GDP, CO2 per capita or consumption/production-based CO2.

We started by exploring the scientific literature and used advanced scientometric techniques to disaggregate and map the references associated with the keywords "CO2" or "carbon dioxide". Our method consisted in:

- harvesting thousands bibliographical notices (299.629) mentioning "carbon dioxide" or "CO2" from ISI Web of Science,
- extracting all the references cited in the bibliographies of such notices,
- constructing series of co-citation networks (on various time-periods) in which disciplines emerge as tight clusters of references often co-appearing together,
- projecting the period on maps, together with other chosen metadata such as authors, keywords, subjects, countries and institutions.

A dozen of CO2 landscape maps were obtained showing the evolution of the research landscape concerned with CO2 through space and time. A first result to be discussed is the quick evolution of the key words around which research publications aggregate. Some interesting trends are observed (e.g. rise and fall of CO2 lasers in physics, movement from plant sciences to environmental sciences and the emergence of the climate change issue in the 1980s, development of geoengineering-related disciplines in the 2010s). The maps also highlight the role played by different countries, institutions or individuals in different research fields (e.g US dominance in environmental (and climate) sciences and China's proximity with issues of carbon capture and storage). In order to complement and strengthen our analysis, we invited specialists to comment the maps.

At this stage, the quali-quantitative method we developed – empowered by digital computation and guided by expert knowledge – can explicit some of the multiple representations of CO2 from a research perspective. Future works will explore whether the IPCC expertise is really representative of the rapidly evolving research landscape. We believe this exercise to be particularly useful as we approach the negotiating table.

Probabilistic analysis to improve baseline GHG emission determination in a developing context: The case of Chile

M. Díaz (1) ; R. O´ryan, (2) ; C. Benavides (3) ; J. Mallea (4)
(1) Universidad de Chile, Centro de Energía – Energy Center, Santiago, Chile; (2) Universidad Adolfo Ibáñez, Centro de innovación en energía, Santiago, Chile; (3) Energy Center, University of Chile, Santiago, Chile; (4) Universidad de Chile, Departamento de ingeniería industrial, Santiago, Chile

In developing contexts, uncertainty in most key variables makes it difficult to establish reliable baseline GHG emissions for the near and medium term future. Scarce information, lack of models and high variability in the main variables are typical in this context. However, these baselines are being increasingly required in the context of international negotiations of the Kyoto protocol and particularly the country must define and declare a baseline and a contribution to mitigation by 2015.

It is common to work with the best information available and obtain a "most probable" scenario, usually based on "reasonable" assumptions of values and trends in key parameters and also to consider extreme cases and assume that these are equally probable, generating scenarios with a wide range of variation in results. Another possibility is using mean values, however in this case, proposals can turn out to be very difficult to reach or affect productive sectors significantly since they may not adequately reflect the existing variability. Depending on the assumptions, a wide range of variation in results can be obtained, making it difficult for policymakers to identify the risks associated to a specific policy.

Probabilistic analysis may be very useful for determining these baseline emissions, incorporating uncertainty in the variables and propagation of uncertainty through the different processes in which they are involved. In particular GDP growth, one of the main drivers of increases in emissions, fuel prices, technology penetration levels are variables frequently used in this estimations. Expert opinion can also be incorporated systematically to improve these information gaps.

For this reason, in this paper we compare the results of a deterministic and probabilistic analysis for baseline GHG emissions in Chile up to 2030, based on the results of the Mitigation Actions Plans and Scenarios (MAPS) project (www.mapschile.cl). Considering the significant uncertainty attached to the main variables involved we establish the relevance for policy-making associated to incorporating uncertainty. Phase 1 and 2 results of this project show, using deterministic analysis, that emissions will increase in the period between two to five times compared to current emissions. Probabilistic analysis allows fine tuning these results and richer conclusions for future policy-making by establishing GHG emissions that are possible to achieve with a given level of certainty. This provides the regulator with more freedom in defining a baseline which he/she will not later regret. Additionally, the results of the importance analysis of uncertainty allow establishing the variables where more information is required for better decision-making.

P-2236-08

Transition to sustainability: are normative participatory scenarios a useful tool? Two case studies in the Brazilian Amazon

AP. Aguiar, (1) ; R. Folhes (2) ; A. Roberto (1) ; DC. Otávio (3) ; S. Emilie (4) ; P. Patricia (5) ; V. Ima (6) ; T. Peter (1) ; B. Mateus (7) ; K. Elza (7) ; ED. Nora, (1) ; T. Assis, (1) ; K. Kasper (8) ; C. Von Randow (9) ; B. Kruijt (10) ; A. Coelho (11)
(1) National Institute for Space Research (INPE), Earth system science centre, Sao Jose dos Campos, Brazil; (2) UFPA/Université Paris 3 Sorbonne Nouvelle, Belém/Paris, France; (3) UFPA, Numa, Belém, Brazil; (4) University of Aberdeen , Aberdeen, United Kingdom; (5) USP, São Paulo, Brazil; (6) Museu Paraense Emilio Goeldi, Belém, Brazil; (7) EMBRAPA Meio Ambiente, Campinas, Brazil; (8) Wageningen University, Wageningen, Netherlands; (9) Instituto Nacional de Pesquisas Espaciais, Ccst, Sao Jose dos Campos, SP, Brazil; (10) Alterra, wageningen UR, Wageningen, Netherlands; (11) FAPESPA, Belém, Brazil

Environmental scenarios were largely exploratory in the past decades, mainly at global and regional scales. Normative/backcasting approaches gradually become more popular and more widely applied over the last decade, due to the strongly normative concept of sustainability. Backcasting can be defined as enviosioning a desirable future, and then looking backwards in order to strategize and to plan how that vision of the future could be achieved. Here we present a normative participatory scenario approach conceived to explore what a «transition to sustainability» would mean (and require) in a heterogeneous and conflicting region such as the Brazilian Amazon. Scenario discussion for the Brazilian Amazon has mostly focused on future deforestation trends at broad-scale. In this work, we explicitly included the social dimension in the scenario construction process, enforcing that all the sustainability dimensions (social, environmental and economic) are taken into consideration. Here we present a synthesis of the scenario process and a synthesis of the results of two case studies at different scales.

The first case study was developed on a settlement project in Pará State, with the specific goal to explore how participatory scenario methods could contribute to the strengthening of territorial units, such as indigenous lands, settlement projects, conservation units. At PAE Lago Grande, a multi-scale approach was adopted, involving stakeholders at three communities and representatives of organizations at the settlement level. Thorugh a series of structured workshops, the actions to reach the sustainable/desired future at the several scales were

discussed, including the divergence/convergence between the scales. Then, we successfully reproduced a similar approach to the whole Brazilian Amazonia, involving representatives of civil society organizations, productive sector and the Federal Government.

Two contrasting futures for the region (Sustainability and Chaotic/Fragmentation) were built using the same workshop structure as in PAE Lago Grande. In this second case study, besides the qualitative scenarios, selected elements of the resulting storylines were quantified to generate explicit spatially representations of land use in the region in coming decades. The land use scenarios were in turn used by multiple climate, vegetation and hydrological models in the scope of the AMAZALERT project at different research institutions to explore the impacts on the provision of ecosystem services and regional climate in Amazonia. The resulting quantitative scenarios and impacts were then feed backed to the stakeholders, illustrating the outcomes of the stories they envisioned.

The normative scenario approach we adopted here was conceived as a tool to subside a broader discussion about "the future we want and how to get there", under the hypothesis that it may favor understanding of diverging points of view, facilitating the collective decision-making process and empowerment. In spite of the well know limitations of participatory methods, we consider the main indication of the potential of the approach the fact that, at the final debate of both case studies, some key stakeholder (from Government, environmental ONG and research institutions) showed interest in replicating the process in other contexts.

P-2236-09

Social and economic tipping points in adaptation processes: Reason for concern?

M. Garschagen, (1) ; J. Birkmann (2) ; T. Welle, (2)
(1) United Nations University,, Institute for Environment and Human Security, Bonn, Germany; (2) Institute for Spatial and Regional Planning, University of Stuttgart, Stuttgart, Germany

Tipping points have become popular epistemic elements within the assessment of climate change. The study of tipping points helps decipher the complexity in climate change dynamics. Yet, despite the increasing engagement with tipping points in hazards and expected impacts there has been little work to empirically assess tipping points in adaptive capacity and adaptation processes. Along the same line, tipping points have been linked predominantly to large-scale bio-physical systems (e.g. the instability of large ice sheets and the breakdown of ocean circulation systems). Little attention has, thus far, been paid to potential adaptation tipping points in social and economic systems and at lower scales. Resulting knowledge gaps are particularly relevant for coastal areas and cities where socio-economic change is often rapid, coupled with heightened levels of exposure and vulnerability to climate change hazards.

Through its conceptual and empirical engagement with tipping points in adaptation processes, the paper aims at contributing to a better understanding of potential future adaptation trajectories. The analysis links two scales: First, a global index-based assessment of risk patterns and trends is presented with a national resolution, focusing in particular on the possibility and effect of large-scale adaptation tipping points. Second, an in depth analysis of selected coastal urban areas in Asia, Africa and Europe is presented, drawing on ongoing research projects. The findings suggest that many types of tipping points in adaptation processes and capacities can be observed, spanning across hard and soft aspects (e.g. related to the financial costs vs. political feasibility of certain adaptation measures). A taxonomy of such adaptation tipping points is thus developed and implications for model-based appraisals of adaptive capacity are explored. The paper concludes by discussing epistemological challenges for a future adaptation science as well as practical lessons for risk and adaptation governance (e.g. how to incorporate tipping points into adaptation 'planning' or into a global architecture of adaptation financing).

P-2236-10

Climate change geo-indicators for policy-makers: downscaling for land-use planning in Caribbean Islands

JR. Gros-Desormeaux (1) ; F. Léone (2) ; P. Palany (3) ; M. Morell (4) ; P. Cantet (5) ; T. Lesales (6)
(1) Centre National de la Recherche Scientifique (InEE), Umr 8053 (crplc), Schoelcher, Martinique; (2) Institut de Recherche pour le Développement, Umr 0007 (gred), Montpellier, France; (3) Météo-France, Service Antilles-Guyane, Fort-de-France, Martinique; (4) BALWOIS, Montpellier, France; (5) Institut National de Recherche en Sciences et Technologies pour l'Environnement et l'Agriculture, Ur rhax, Aix-en-Provence, France; (6) CIHENCE, Paris, France

The Lesser Antilles are exposed to major and various hazards (earthquake, volcanism, hurricanes, floods, tsunamis, landslides, etc.). In a significant context of climate change, a set of institutional responses for the sustainable management of territories is being drafted. Recent works on the importance of using high-resolution model to study the climate change on small islands by Cantet and al. (2014), underlines the importance of the dynamical downscaling to study the impacts of climate change on the Lesser Antilles. The projections provided by the regional climate model suggest an increase in extreme rainfall events: longer dry periods, a bigger annual total precipitation, more frequent very heavy daily precipitation and a stronger 1 d maximum precipitation, whereas for the driving Global Climate Model, these trends are less intense. Within the framework of the EU Interreg CARIBSAT program, a Multi-natural hazards CARIBSAT GIS was produced by the GRED research laboratory (University of Montpellier, France) and the IRD agency (Institute of Research for Development, Martinique). The aim was to harmonize multiple sources of historical, scientific and geographical information. CARIBSAT GIS is useful to develop several sets of geo-risk and natural disasters indicators: natural hazards activity, human and socio-economic impacts, exposure levels. These geo-indicators are therefore helpful to elaborate territorial diagnosis and comparative risk analysis, at international or regional levels. In the poster, one main question will steer future research: How and by which mechanisms do the actors, who have produced and manage regional knowledge, can participate in drawing up and adapting or changing the frameworks of decision makers final action, mitigation intervention as regards to climate change information?

P-2236-11

Exploring the social-ecological dynamics of a coral reef resource system using bayesian belief networks

P. Leenhardt (1) ; J. Claudet (2) ; V. Stelzenmuller (3)
(1) UPMC, Paris, France; (2) CNRS, Usr 3278 criobe, Perpignan, France; (3) Thunen Institute, Hamburg, Germany

Social-ecological system approaches are now considered as the most relevant conceptual lens to establish biodiversity management strategies accounting for human-nature interactions. It reflects the dramatic paradigm-shift that environmental sciences have undergone in recent years, with increased recognition of the role of people in the dynamics of all natural ecosystems and of the feedbacks of ecological change on human uses and well-being. Social-ecological systems are complex adaptive systems characterized by complex feedback interactions, emergent processes, non-linear dynamics and uncertainty. While the science for modelling social-ecological systems is improving, transdisciplinary empirical studies aimed at investigating their dynamic under different scenarios of stressors or management actions are scant. Here, we developed a transdisciplinary approach to investigating the social-ecological system of Moorea island, French Polynesia. Conceptual models were built through participatory modelling workshops. Then, a Bayesian Belief Networks was developed using a 11-year long database and expert opinion to provide scenarios testing the effects of different stressors and management actions on the system defined by stakeholder groups. Preliminary results suggest that (1) the management of the social-ecological system of Moorea should be more targeted towards specific user groups, (2), more coordination is needed between marine and terrestrial agencies for a more

integrated coastal zone management and (3) the lagoon and the outer slope could be considered as two social-ecological subsystems.

P-2236-12

Climate impacts on adequate human livelihood conditions for well-being and development: framing uncertainties in projections of water availability

T. Lissner (1) ; CF. Schleussner (1) ; D. Reusser (2)
(1) Climate Analytics, Berlin, Germany; (2) Potsdam-Institute for Climate Impact Research, Potsdam, Germany

Climate change vulnerability and the consequent need for adaptation are unevenly distributed in the world and many developing countries are especially vulnerable to changes in climate. Climate change often adds on to existing development pressures that are responsible for low levels of social and economic welfare, increasing the vulnerability of such regions. Climate impacts may substantially reduce the adequacy of livelihood conditions, if adaptation and coping strategies are insufficient. Integrated approaches, including climatic as well as aspects of development are needed in order to identify adaptation requirements, opportunities and co-benefits. Ideally, development strategies as well as adaptation and mitigation should be complementary strategies, working towards improved livelihood conditions and sustainable pathways. The trans-disciplinary concept of «Adequate human livelihood conditions for well-being and development» (AHEAD) provides a conceptual framework for the identification of limitations to adequate livelihood conditions and the consequent need for adaptation and development. The approach allows addressing several topical challenges of climate impact assessments, such as the integration of concepts from different disciplines, data integration as well as the combination of processes at different scales. A particular challenge for the assessment of climate impacts and adaptation needs lies in the treatment of uncertainties, which normally multiply along the assessment chain as has been shown by the recent Inter-Sectoral Impact Model Intercomparison Project (ISI-MIP). The methodological implementation of the AHEAD framework provides a way of dealing with these uncertainties based on the representation of gradual adequacy of conditions using fuzzy logic.

To illustrate the utility of the AHEAD approach, we assess the adequacy of AHEAD conditions on a global scale at national resolution. We focus in particular on the availability of water resources in adequate quantity and quality, which plays an important role in meeting human livelihood needs. We use multi-model water resource estimates from ISI-MIP to illustrate, how the approach can provide a way forward in dealing with the substantial uncertainty in projections of water availability. Our results indicate that water availability limits the adequacy of livelihood conditions in some countries today, a situation that will aggravate over the course of the century; however for the majority of countries other aspects limit the adequacy of livelihood conditions. The presented approach shows how uncertainty ranges in modelling results may be framed in a way, which allows assessing their relevance with regard to specific questions. The uncertainty range of data on water availability is considerable for many countries, but for more than a third of the countries this range is outside of critical thresholds for water security and overall AHEAD conditions.

P-2236-13

From Static Socio-economic Sensitivity to Interactive Scenarios: New Tools in Support of Climate Change Adaptation Decision-Making

J. Lückenkötter, (1)
(1) TU Dortmund University, Faculty of Spatial Planning, Dortmund, Germany

For many years long-term scenarios of future socio-economic developments were mostly hidden in the background of climate change impact and vulnerability assessments. At the forefront of scientific studies on climate change were advances of the climate modelling community. Long-term socio-economic scenarios were nevertheless needed as drivers of the underlying emission projections. For this purpose four main 'storylines' of demographic, social, economic and technological developments were defined by the IPCC's Special Report on Emission Scenarios. But the socio-economic scenarios of the 'storylines' were coarse and remained largely in the background of impact and vulnerability assessments. In fact, the socio-economic sensitivity components of most assessments remained static, i.e. they used only the most recent data on population, economic output and other related indicators. Thus future climate conditions were often related to current (and not future) societal conditions.

Since the SRES scenarios new approaches and methods for demographic and socio-economic projections have emerged. And the IPCC eventually adopted a 'parallel modelling approach' allowing climate researchers and social science researchers to develop their models in parallel instead of in a sequential fashion. Social scientists developed a set of 'shared socio-economic pathways' that are only loosely linked to different policy assumptions and thus opened up even more flexibility for exploring different socio-economic constellations.

These methodological advances reflect the realization that socio-economic developments are much more open and dynamic and therefore perhaps even more difficult to project than long-term climatic changes. It is also an often neglected fact that socio-economic conditions in most parts of the world have in the past 50 years changed to a much greater degree than have climatic conditions – and this is likely to hold true for the future as well. Thus, the level of future climate change impacts will also be primarily determined by socio-economic changes. Moving from fixed (e.g. the most current) socio-economic sensitivities to a variety of flexible scenarios therefore holds the promise of greatly enhancing impact and vulnerability assessments and applied tools for policy advice.

This paper reviews examples of recent climate change impact and vulnerability assessments that treat socio-economic sensitivities in different ways – ranging from static status quo to flexible scenarios. A special focus is put on studies that have fully embraced the scenario approach. For example, some recent and ongoing European research projects like CLIMSAVE (Climate Change Integrated Assessment Methodology for Cross-Sectoral Adaptation and Vulnerability in Europe) or CLIP-C (Climate Information Platform for Copernicus) are offering users the ability to interactively explore different socio-economic development trajectories. The paper identifies methodological achievements as well as requirements and opportunities for decision-makers, but also highlights key challenges of these new approaches.

P-2236-14

Chaos in climate change impact estimates

E. Massetti (1)
(1) Georgia Institute of Technology, School of Public Policy, Atlanta, GA, United States of America

Global Circulation Models incorporate chaotic dynamics to reflect real-world weather patterns. This implies that extremely small perturbations of the climate system may generate very different weather patterns. Here I show that the SRES climate change scenarios generated by the Coupled Model Intercomparison Project phase 3 (CMIP3) --- ubiquitous in the impact literature --- display strong chaotic dynamics at regional and sub-regional level, at least until 2065. Chaos is triggered by changes to historic forcing in the year 2000 to reflect different emissions trajectories. This suggests that large uncertainty exists on how to link local climate change and global forcing. Furthermore, short- and mid-term differences in local climate change across different SRES emission scenarios reflect chaotic dynamics rather than different forcing patterns. I show that the «chaos» in the climate scenarios generates a «chaotic» relationship between exogenous forcing and local economic impacts on agriculture. «Perturbed exogenous forcing» model ensemble would resolve this uncertainty.

P-2236-15

Low-carbon transition scenarios for the French transportation sector: exploring the role of uncertainty on technology costs with robust optimization

C. Nicolas (1) ; S. Tchung-Ming (1)
(1) IFPEN, Economics, Rueil, France

Reaching very ambitious GHG reductions objectives will likely require abatement efforts from the transportation sector. On the supply-side, technological options for reducing transportation emissions consist in reducing the carbon intensity or increasing the energy efficiency. On the demand-side, reducing the amounts of travels and increasing modal shifts towards less carbon-intensive means are the major levers.

The identification of cost-effective mitigation strategies critically depends on the relative costs of transportation technological options which determine the competitiveness of substitution options. In long-term energy system models, cost assumptions need to be defined over distant horizons. The forecasted costs and prices take part in the uncertainty that carries weight on the model hypotheses and which is at the root of many criticisms (IPCC 2014).

Motivation The literature on energy modelling with uncertainty is very large: stochastic programming which mainly deals with large socio-economic or political uncertainties, scenario analysis (Babaee et al, 2014) or Monte-Carlo analysis can be used to obtain distributions of model outcomes (Rosakis and Sourie, 2005).

In this paper, we introduce an alternative way to tackle uncertainty in optimization energy system models. We rely on robust optimization (Ben-Tal et al, 2009) to make many model parameters simultaneously uncertain. So far, this technique has been scarcely used in energy modeling (Babonneau et al, 2012). The contributions of the paper are twofold. From a methodological perspective, we argue that robust optimization techniques are appropriate for introducing cost uncertainty from many sources in long-term optimization models. We use recent results from operations research to economically interpret model outcomes, and assess the robustness of the model to economic parameters through optimization. From a policy perspective, we aim to evaluate the hedging potential of alternative technologies, making a step towards the identification of robust technology portfolios and policy designs.

Methodology In order to assess how deeply our model solutions are affected by uncertainty and to help the decision maker to define policy, we used a recent methodology developed in the field of operations research: robust optimization (RO). The general principle of RO consists in immunizing a solution against adverse realizations of uncertain parameters within given uncertainty sets. The basic requirement for a robust solution is that constraints of the problem are not violated whatever the realization of the parameters in the set.

While stochastic or Monte-Carlo frameworks require the definition of probability density functions, the principle of RO consists in set-based descriptions of uncertainties. As such, only the extent to which parameters are likely to vary needs to be known. The robust counterpart of the initial problem thus includes variables that traduce the deviations of the worst-case parameters with respect to their nominal values. The number of potentially deviating coefficients can be controlled through an exogenous parameter – the uncertainty budget, which gives control on the degree of pessimism of the optimal solution. Our experimental setting consists in using a TIMES-based long-term planning model of the French energy-transport system. We derive a dynamic implementation of the RO method. We perform a set of parametric runs by setting increasingly stringent (i) abatement objectives on CO2 from transport by 2050 and (ii) uncertainty budgets. We make primary energy prices and transportation investment costs uncertain.

Results and discussion We identify robust technological mitigation portfolios (compliant with the modeled policy objectives for any random realization of the uncertain parameters), which vary with both the required level of abatement and the degree of pessimism on the certainty of the exogenous price/costs projections. Key messages are that (i) the diesel-gasoline balance is affected by uncertainty, partly in response to system effects (ii) there is a general tendency to incorporate more biofuels (iii) natural gas (including biogas) and electricity pathways are relevant hedging option for low carbon caps; for stringent objectives, they are pushed out of the market. We then discuss policy insights, showing that if the uncertainty budget is reasonably low (good confidence in prices/costs projections) it makes sense to incorporate a diversification logic in policy designs. However, if confidence is poor (high uncertainty budgets), then diversification may not be relevant.

P-2236-16

The application of scenario planning for decision-making in the face of climate change: issues of scale

S. Serrao-Neumann (1) ; D. Low Choy (2)
(1) Urban Research Program, Griffith University, Cooperative research centre for water sensitive cities, Brisbane, Australia; (2) Urban Research Program, Griffith university, Brisbane, Australia

There is widespread recognition that climate change will affect cities and regions worldwide. Projected impacts of climate change will be spatially non-uniform and the ability of communities to respond to those impacts will also vary significantly. Assisting multi-level decision-making involving climate change adaptation with scenario planning is well placed given the uncertainty related to climate science and projected impacts. This paper seeks to distill lessons on the use of scenario planning involving multi-stakeholders for decision-making related to climate change adaptation. Lessons are extracted based on the development and application of explorative scenarios (multiple plausible futures) by three distinct action-research projects involving different scales of stakeholder engagement in Australia: (i) regional, (ii) community of practice, and (iii) community scales.

The regional scale project focuses on the South East Queensland Climate Adaptation Research Initiative (SEQCARI) involving a multi-sectoral investigation of climate change adaptation in the South East Queensland (SEQ) region, comprising the sectors of urban and regional planning, coastal management, physical infrastructure, emergency management and human health. The SEQ region has been identified as one of six vulnerability hotspots to climate change in Australia. The community of practice scale project focuses on planning for climate change adaptation involving regional bodies responsible for natural resources management in the East Coast Cluster of Australia. The East Coast of Australia comprises a wide range of landscapes that will be impacted by climate change, including coastal areas, major catchments and agricultural areas that support two capital cities. The community scale focuses on the recovery phase of the Cardwell community in far north Queensland in the aftermath of category five tropical cyclone Yasi. Tropical cyclones affecting this area are likely to become less frequent but more intense in the face of climate change. At least two scenario planning workshops were conducted for each project to assist in the development and testing of proposed adaptation options. Adaptation options were developed through collaborative planning processes involving a range of stakeholders and aimed to reduce their vulnerability to future climate change impacts.

Findings indicate that at broader scales, such as regional level, exploratory scenarios enable the integration of multi-stakeholder and sector perspectives related to complex challenges such as climate change adaptation for human settlements. In particular, at that scale, scenarios provide opportunities for improved interaction between practitioners and understanding of sector-specific issues. In parallel, community of practice and community scales are better positioned for scoping more specific and tailored adaptation options. However, they lack broader interaction between different layers of actors involved in decision-making therefore hampering stakeholder's ability to ascertain feasibility and envision the implementation of adaptation pathways. Multi-stakeholder scenarios processes are known to be time consuming given stakeholder's unfamiliarity with the method. In the community scale project, it was also noted stakeholder's difficulty in grasping with both multi-dimension challenges related to and longer-term strategic thinking demanded for climate change adaptation.

Designing experiments for climate prediction

DA. Stainforth (1) ; J. Daron (2) ; S. Harrison, (3)
(1) London School of Economics, Grantham Research Institute, London, United Kingdom; (2) UK Met Office, Exeter, United Kingdom; (3) University of Exeter, College of life and environmental sciences, Penryn, United Kingdom

Complicated global circulation models are used to simulate and study the climate system. Increasingly they are also used to make projections of future climate. For instance, the results of the Coupled Model Intercomparison Projects (e.g. CMIP5) play a significant role in the IPCC assessment reports and are often used to guide adaptation planning and impacts assessments.

Here we will discuss what we mean by climate prediction and to what extent the modelling experiments which are run today, are sufficient to quantify changing climate in the 21st century. We will argue that the design of climate modelling experiments needs to be changed in the light of conceptual understanding in nonlinear dynamical systems theory, and better informed by concepts being explored in the philosophy of science and in approaches to robust decision making.

The concept of climate as a changing distribution will be illustrated using a low-dimensional climate-like mathematical system undergoing a forced change. The different roles that uncertainty in initial conditions can play will be discussed and used to illustrate the limitations on the probabilistic accuracy of predictions. It will be argued that today's ensembles of AOGCMs and ESMs are likely too small to be able to robustly quantify the changing climate within the model itself. This severely limits there value for both scientific understanding and for guiding societal decisions.

The implications of model error will be discussed and put in the context of the balance which must be achieved between the study of emergent properties and the use of reductionist models.

The consequences of initial condition uncertainty and model uncertainty will be drawn together to argue for a new approach to the design and interpretation of climate models and climate model ensembles; one which requires larger ensembles and greater computing resources but which encourages diversity in models and interpretational approaches mediated by physical understanding rather than statistical post processing. This stands in contrast to arguments which have been made for increasing resolution while reducing the diversity of different models.

Consequences of Climate Change Damages for Economic Growth

R. Dellink (1)
(1) OECD, Paris, France

This paper focuses on the effects of climate change impacts on economic growth. Simulations with the OECD's dynamic global general equilibrium model ENV-Linkages assess the consequences of a selected number of climate change impacts in the various world regions at the macroeconomic and sectoral level. The analysis finds that the effect of climate change impacts on annual global GDP is projected to increase over time, leading to a global GDP loss of around 1% to 3.3% by 2060 for the likely equilibrium climate sensitivity range. Underlying these annual global GDP losses are much larger sectoral and regional variations. Agricultural and health impacts dominate in most regions, while damages from sea level rise gradually become more important. Negative economic consequences are especially large in Sub-Saharan Africa and South and South-East Asia whereas other regions will be less affected and, in some cases, benefit thanks to adjustments from international trade. Emissions to 2060 will have important consequences in later decades and centuries. Simulations with the AD-RICE model suggest that if emissions continue to grow after 2060, annual damages of climate change could reach 4%-11% of GDP by the end of the century. Some impacts and risks from climate change have not been quantified in this study, including large-scale disruptions and the disutility from premature deaths. These will potentially have very large economic consequences, and therefore the costs of inaction presented here likely underestimate the full costs of climate change impacts when no policy action is taken. The stylised analysis clearly shows that with efficient adaptation policies, costs will be significantly lower. Mitigation not only brings the expected level of climate damages down, it also considerably reduces the likely uncertainty range. However, the role of adaptation is much more limited when ambitious mitigation policies are adopted. The opposite is not true: even with ambitious adaptation policies, there is a large role for mitigation to play in keeping the total costs of climate change as low as possible.More research is needed to assess the costs of inaction and the benefits of policy action, as well as the various uncertainties and risks involved. However, this should not delay policy action, but rather induce policy frameworks that are able to deal with new information and with the fact that by their nature some uncertainties and risks will never be resolved.

Climate change impacts and market driven adaptation: The costs of inaction including market rigidities

F. Bosello (1) ; R. Parrado (2)
(1) University of Milan, FEEM, and CMCC, Dep. of economics, Milan, Italy; (2) FEEM, Venice, Italy

To manage the complexity of economic assessments of climate change impacts, climate change research saw an increasing development and application of integrated assessment models (IAMs). Their distinctive feature is to describe in a controlled environment the "climate-change issue" in its entirety, i.e. connecting the climatic, the environmental and the social components. Two broad approaches can be identified in the economic quantification of climate change damages with IAMs. One makes ample use of reduced-form climate change damage functions. Basically, a more or less sophisticated functional form translates temperature increases into GDP losses. Parameterization of these functions derives from extrapolation of the impact literature or expert opinions. A different approach, often coupled with the use of Computable General Equilibrium (CGE) models, consists in translating climate change pressures into changes in quantity/quality of factors of production and/or in agents' preferences driving demand and supply behaviour in the models. GDP losses are thus the direct outcome of the simulation and do not stem from an explicit function and its ad hoc parameterization.

More than twenty years of IA research produced a vast literature on the cost of climate change. Due to their obvious policy relevance, these estimates are surrounded by a heated debate, and many authors suggest that they are likely to underestimate climate change costs. Many features of climate change, environmental and social

responses are still uncertain and/or not well captured by IAMs. For instance, relatively small changes in climate sensitivity can greatly change the cost estimates from these models (Ackermann and Stanton, 2012; Anthoff and Tol, 2013). Quantitative modelling frameworks are also ill suited to measure important social phenomena like conflicts, mass migrations, disruption of knowledge, learning and social capital potentially triggered by climate change (Anthoff and Tol, 2013; Stern, 2013). IAMs emphasize impacts on GDP, which even disregarding its deficiency as a welfare measure, captures flow and tend to overlook stock losses (Stern 2013). Risk and irreversibility associated to high damage low probability events is usually left out of the analysis which can seriously bias downward damage estimates (Weitzman, 2007, 2008, 2009, 2010; Ackerman and Stanton 2012). IAMs tend to be overly optimistic in describing timing and scale of adaptation processes, disregarding the fact that, agents may not use perfect information and for technological, economic, psychological and cultural characteristics may resist to some changes (Patt et al., 2010). All these critiques are particularly relevant when climate change impact assessments are conducted with CGE models. They provide a peculiar richness in the analysis of climate change costs, highlighting sectoral effects and, above all, tracking endogenous market adjustments and rebounds triggered by climate change shocks. But, at the same time, they are grounded on GDP, account just for marketable relations, typically model instantaneous and frictionless adjustments. Against this background, the assessments performed with CGE models tend to fall somewhat in the lower end of cost estimates.

This paper presents a simple exercise to address the following questions. Do climate change impact assessments performed with CGE models estimate lower GDP losses than reduced-form climate change damage based assessments? What is the role of market driven adaptation in determining these estimates?

We run a standard climate change impact assessment exercise with a recursive-dynamic CGE model using updated estimates of an extended set of impacts for different temperature increase scenarios. Then we extrapolate a reduced-form climate change damage function. We show that, at the global level, this is not significantly different from that produced by some established hard-linked integrated assessment models when the same impact categories are included. Furthermore, we perform the same exercise reducing what can be defined "market driven adaptation". In practice, we restrict the elasticity of input substitution in the production function, the substitutability of domestic and imported inputs, and finally sectoral workforce mobility. We demonstrate that, notwithstanding these frictions increase the cost of climate change impacts, they do not change substantively neither the qualitative nor the quantitative picture.

Accounting for Climate Impact and Cost Uncertainty in Integrated Assessment Models

A. Markandya (1) ; F. Bosello (2) ; E. De Cian (2) ; J. Polanco (3) ; L. Drouet (4)

(1) BC3 Basque Center for Climate Change, Scientific director, Bilbao, Spain; (2) FEEM, Venice, Italy; (3) BC3, Bilbao, Spain; (4) FEEM, Milan, Italy

We develop a methodology that uses the concept of a risk premium to account for risk aversion to climate change damages in the affected population. The premium is derived from the notion of risk aversion in the framework of expected utility theory, namely the amount that society would be willing to pay in order to reduce the riskiness of future damages. We estimate the risk premium for plausible average damage functions that are currently being used in Integrated Assessment Models to calculate the optimal levels of mitigation and adaptation. The new functions are referred to as risk-adjusted damage functions and they have higher damages than the expected values used previously. We have calibrated three sets of risk-adjusted regional damage functions for three different level of risk aversion, low, medium and high. With low and medium coefficients of relative risk aversion equal to 1 and 1.5 the additional damage component is quite small. The damage addition due to risk aversion is highly nonlinear and it increases significantly when the coefficient rises to 2. It is also interesting to note that the risk premium varies from region to region, implying that the degree of the adaptation response will be region-specific.

The new functions are used to estimate what they imply for optimal adaptation and mitigation with different versions of the AD-Witch model. The results show that the percentage increase in allocation to adaptation is around 10-20 percent for values of the coefficient of risk aversion of 1 and 1.5, but rises to as much as 80-200 percent for a value of the coefficient of 2. The impacts of including risk in damage estimation on mitigation are interesting and somewhat different. In the cooperative solution mitigation is increased 5-10 percent with the higher damages for low values of risk aversion and by 10-20 percent for higher values. Finally as far as the growth scenarios are concerned there appears to be little difference in terms of the impact that taking account of risk has on the calculations.

Further work is continuing to see the effects of the new damage functions at the regional level.

Global climate impacts: a preliminary economic analysis

JC. Ciscar (1) ; M. Perry (1) ; J. Pycroft (1) ; J. Abrell (2) ; M. Rozsai (1) ; W. Szewczyk, (1)

(1) European Commission (IPTS, EU JRC), Seville, Spain; (2) ETH, Zurich, Switzerland

Understanding the global implications of climate change at the appropriate country resolution is important for the policy process. The purpose of this presentation is to gain some first insights on the sectoral and regional pattern of the biophysical and economic consequences of climate change at the global scale, benefiting from the current bottom-up sectoral impact evidence. The study will consider a set of climate model runs and a limited set of impact categories within an integrated climate-biophysical-economic framework.

The main questions to be addressed are the following. Firstly, how important are the impacts of climate change for the big players in the international climate negotiations? Secondly, what are the distributional implications of climate impacts vis-à-vis Europe? Thirdly, what are the main uncertainties in the modelling and how they influence the results?

The project scope has several dimensions. Regarding the time horizon, it covers the climate impacts over the 2071-2100, compared to 1961-1990. The study considers few impact areas, for which there exist empirical bottom-up evidence: agriculture, coastal areas, and if possible, energy.

The study methodology is based on results from process or bottom-up biophysical impact models (from the ClimateCost EU project and, possibly, the ISI-MIP project). The economic valuation of climate impact categories will be carried out in a coherent and harmonized way with an economic multi-country, multi-sector computable general equilibrium (CGE) model in order to enhance the comparability of the different damaging patterns.

The authors have already conducted preliminary analysis of impacts in agriculture and coastal areas. The results indicate that there is a wide dispersion of impacts across the world, with strong geographical asymmetries.

Effort sharing taking into account adaptation costs and climate change damage

A. Hof (1) ; E. De Cian (2) ; G. Marangoni, (2) ; M. Tavoni (3) ; D. Van Vuuren (1)

(1) PBL Netherlands Environmental Assessment Agency, Department of climate, air and energy, Bilthoven, Netherlands; (2) FEEM, Venice, Italy; (3) Fondazione Eni Enrico Mattei , Climate change and sustainable development programme, Milan, Italy

The ongoing discussion about the feasibility of maintaining global temperatures below 2 °C encompasses not only the costs and benefits of achieving the target, but also the difficulty of reconciling regional efforts with the inequity of climate change impacts. If mitigation and adaptation actions, as well as residual damage from climate change,

will be distributed diversely across the world, can we devise a policy which aligns different country and regional views and incentives? In most of the scientific literature, equity issues related to mitigation, adaptation, and impacts have been disconnected. Most studies on effort sharing have focused on fair distributions of mitigation costs without considering adaptation costs and residual damage. Our study aims to fill this gap by investigating which mitigation targets in 2030 and 2050 lead to equalizing the sum of mitigation costs, adaptation costs, and residual damage as share of GDP across regions.

We employ two alternative modelling frameworks combined with two sets of regional climate change impact functions. These models provide a mapping of the residual climate change damages of 2 °C and of the resulting adaptation costs, and allow exploring how emission rights should be allocated to equalize the sum of mitigation costs, residual damage, and adaptation costs as share of GDP across regions. We show that a 2 °C world leaves considerable residual impacts and adaptation costs. Sharing the burden of the total costs of climate change, including residual damage and adaptation costs, reshuffles the emission allocation compared to an effort-sharing regime based on mitigation costs only. The financial implications can be significant, with a total of additional resources in the order of 100-200 USD billions in 2030 would need to flow to the high impact countries in India, Africa, and Rest of Asia, by means of trading emission rights. Countries with lower-than-average impacts, such as OECD countries and China, would buy such rights thereby financing those transfers.

The above numbers assume a global carbon market being in place from 2020 onwards. Even though such a global carbon market with the implied sharing rules is not easy to implement, our paper suggests that accounting for the total costs of climate change and including adaptation and damage considerations could achieve an effort distribution being perceived fair by a wider group of countries.

A predictive model of production loss under unanticipated shocks by extreme weather events

S. Willner (1) ; C. Otto (2) ; L. Wenz (1) ; R. Bierkandt (1) ; A. Levermann (1)
(1) Potsdam Institute for Climate Impact Research, Research domain sustainable solutions, Potsdam, Germany; (2) Potsdam Institute for Climate Impact Research, Research domain climate impacts and vulnerabilities, Potsdam, Germany

Risks of extreme weather events like floods, heat-waves and storms are likely to increase due to global warming. Since world markets are highly interlinked and local economies extensively rely on global supply and value added chains, extreme weather in one place may have repercussions elsewhere. Accordingly, a comprehensive climate risk management and cost estimation should take these interactions and dynamics into account.

Here, we present the dynamic damage propagation model called «acclimate». On the same time scale as the local events the model explores immediate response dynamics as well as the subsequent recovery phase of the supply network. While the pure damage propagation dynamics [1] as well as possibilities for demand changes and extension of production [2] have already been described, we concentrate here on a major extension that includes price dynamics and local economic optimization.

The model focuses on analyzing the indirect effects of local perturbations without taking into account economic growth. Its agents, i.e. production or consumption sites, are organized in a production network based on multi-regional input-output data (Eora MRIO database). This constitutes the baseline and is assumed to be an optimal state with respect to the economic rational of the model. Direct damage as perturbation due to climatic extreme events causes cascading deviations from the baseline along the network and thus leads to indirect production and consumption losses.

Each producing agent optimizes its purchase, demand distribution, as well as production and supply distribution to maximize their revenue. Due to the unanticipated nature of the events we assume limited foresight for the agents, who perform their optimization locally in a spatial as well as temporal sense. Since the time scale is too short to allow for immediate market clearance local price deviations are hereby taken into account. The agents for final consumption optimize analogously with respect to their consumption. This short-term behavior is complemented by middle-term adaptation in the form of rewiring within the production network. We furthermore allow for dissipation effects using storage capacities and temporary production extension.

With this model we estimate the economic costs of climate change induced production failures, including indirect costs with potential low-probability but high-damage events. We furthermore aim to systemically assess the limits of adaptation of the supply network. Concerning risk management, we stress the importance of global structural adaptation measures in addition to local adaptation.

'Planetary Economics': The Three Domains and their implications

M. Grubb (1) ; JC. Hourcade (2) ; K. Neuhoff (3)
(1) University College London, Institute of Sustainable Resources, London, United Kingdom; (2) International Research Center on Environment and Development (CIRED), Paris, France; (3) German Institute for Economic Research (DIW Berlin), Berlin, Germany

This paper summarises and outlined evidence for the economic framework developed in the book Planetary Economics. It maps out three domains of decision-making, each of which involves different actors, processes and for which our understanding rests on different theoretical foundations. Each operates at different scales of time and social entities: they are complementary, not competing, explanations of diverse economic phenomena. For this session, the paper will also tentatively map different economic theories on to this framework.

The paper will then explain the unique characteristics of energy and climate change issues which make all three domains simultaneously important, and indeed argue that the issues raised span all three domains in approximately equal measure. The paper will also suggest that understanding the different domains help to explain the extremes of cycles in international energy markets and the poor history of energy forecasting.

The paper will then outline lessons on the three corresponding pillars of policy and why any individual policy pillar has been in practice prone to failure. It will outline correspondingly the need for policy packages spanning all three are credible, economically efficient and environmentally effective – and hence, politically stable. The concluding part of this overview talk will touch on the international dimensions, in which each pillar would raise different aspects of international cooperation.

Evaluating Common Futures: Rethinking Prescriptivism and Descriptivism

K. Mintz-Woo (1)
(1) Doktoratskolleg – Climate Change, Philosophy, Graz, Austria

Stern's (2007) report has engendered an interesting methodological debate among climate economists. In evaluations of climate policy, assigning values to some key moral parameters (e.g. in the Ramsey formula, the pure rate of time preference δ and the elasticity of marginal utility of consumption η) weights the interests of future generations more or less strongly. This influences conclusions about the evaluation of damages and how imperative it is to respond to these damages.

In IPCC SAR WG3, Arrow et al. (1996) called the participants of this debate descriptivists and prescriptivists. Descriptivists like Hutt (1940); Manne (1995); Nordhaus (1994, 2008) think that, by appealing to (empirical) market data, they can avoid making their own value judgments. This view contrasts with prescriptivists (e.g. Arrow et al. 1996; Broome 1994, 2012; Dasgupta 2008; Stern 2007), who have argued that explicitly weighing the moral import of parameter assignments is an unavoidable part of addressing these types of long-term policy evaluations.

In this presentation, I have two contributions. First, I intend to help classify these methodologies among ethical theories, to help incorporate moral philosophical contributions. Second, in the case of the Ramsey framework, I introduce new worries for both the descriptive and prescriptive positions. These worries come from application of recent behavioral psychological theories: prospect theory and heuristic theory.

First, to understand the positions in a philosophical context, it is necessary to recognize that there is an important presupposition underlying the debate. I argue that economists have a particular metaethical orientation with respect to assigning values to such parameters: they are subjectivist.

I argue further that the two economic groups (descriptivist/prescriptivist) represent a disagreement between two subjectivist views: social constructivism and expert judgment. However, there are well-known economic problems with the descriptive methodology of assigning values to these moral parameters based on market data alone (Arrow et al. 1996; Broome 1994). First, we do not operate in a perfectly competitive market, and market distortions prevent price signals from reflecting the full social costs. Second, it is not clear that individuals make market decisions with consideration of future generations; it is much more plausible that individuals are acting on personal time preference. Third, we do not see safe assets with maturities on climate impact timescales.

To avoid these issues, one might suggest that the moral parameters in the Ramsey formula be investigated directly from market participants. There is a shortcut with η, for example, since under utilitarian assumptions, η characterizes both inequity aversion and risk aversion. Since the experimental paradigms for testing risk aversion for individuals are well-understood, one might try to reveal risk aversion from behaviour under risk.

My objection is that a psychological theory called prospect theory (Kahneman 2011; Kahneman and Tversky 1979) indicates that revealed risk aversion will not be appropriate for normative judgments about η. This is primarily because η considers the absolute value of changes in consumption (and in utility) whereas prospect theory suggests that individuals will view outcomes as changes from a neutral reference point. This means that prospect theory tells us that risk aversion elicitation will fail to provide normative guidance.

These worries might lead one to take the expert judgment methodology. However, such judgments are precisely the kind of judgments that Kahneman (2011) warns might be subject to heuristic evaluation. We might substitute more easily accessible quantities in for η. Instead of asking "What is the elasticity of marginal utility with respect to consumption [i.e. η]?" one could answer a question that is more easily answered, such as "What is the psychological value of imagining having different levels of consumption?" Affective responses to having a various restricted consumption patterns are easily accessible to guide the decision making process, but can distort it (Finucane 2000). It is also easier to comprehend one's own response to consumption over time than to explicitly consider intergenerational distributions. This second worry should also be accounted for in expert judgment.

O-2237b-02

Methodological foundations of policy-making in sustainability transitions

JF. Mercure (1) ; H. Pollitt, (2) ; N. Edwards (3) ; J. Viñuales (4)
(1) University of Cambridge, Land Economy, Cambridge, United Kingdom; (2) Cambridge Econometrics Ltd, Cambridge, United Kingdom; (3) The Open University, Environment, Earth and Ecosystems, Milton Keynes, United Kingdom; (4) University of Cambridge, Cambridge, United Kingdom

Policy-makers currently face unprecedented challenges and uncertainty when taking decisions that simultaneously affect economic development, technology and the environment. A lack of consensus on the impacts of climate policy in this complex interacting system has paralysed the policy-making processes, and policy indecisiveness has generated stagnation in investment decision-making, at the core of economic development. It is not clear to policy-makers how to reconcile economic policy supporting growth with climate change mitigation, and it is not clear how effective policies are likely to be.

This paper argues that policy-making based on conventional equilibrium science and economics is not fine-grained enough to capture the complexities of real-world human behaviour and its diversity, leaving a wide uncertainty gap for policy-making. We suggest that the use of dynamical methodologies involving complexity science coupled to behavioural science with sophisticated uncertainty analysis can provide appropriate tools to understand policy issues that involve a high degree of cross-sectoral interaction and correlations between agents, even at the aggregate level. This is to be used in a feedback loop with researchers in policy and law, in order to test potential policy packages while assessing their feasibility in the policy process.

We describe how policy-related interactions between each of three critical interrelated areas: technological change, the macroeconomy, and the natural environment, could be dynamically represented in much greater detail, allowing better representation of feedback processes related to policy choice. We describe what impact these developments would have on our predictive power and ability to constructively inform coupled technology-economy-environmental policy-making aimed at addressing climate change. We identify three areas of environmental policy where the high degree of behavioural correlation (positive re-inforcing feedbacks) and/or behavioural diversity makes their analysis impractical using conventional methods, and where the application of this methodology could be determinant for gaining appropriate insight for policy making: (1) the analysis of green growth, (2) cross-sectoral impacts of sector specific policies (e.g. biofuels), and (3) the effectiveness of policy for emissions reductions in consumer based sectors (e.g. private transport). By providing a concrete example, we suggest how a wider adoption of this approach could provide a step change in our ability to address the complex policy problems raised by sustainability transitions.

O-2237b-03

A framework to manage national decarbonization regimes

D. Kammen (1) ; JP. Carvallo, (1) ; P. Hidalgo-Gonzalez (1)
(1) University of California Berkeley, Energy and resources group, Berkeley, United States of America

There is widespread agreement that mitigating global warming to prevent disruptive climate change requires nations or regions to internalize the global externality of anthropogenic carbon dioxide emissions. The most straightforward approach is to establish a price on carbon emissions, either directly through a carbon tax or indirectly through a cap-and-trade market mechanism. Several studies attempt to find an "optimal" price of carbon that depends largely on intertemporal consumption preferences (notably discount rates) and the estimated "damage function" that changes in weather, crop yields, and productivity, among others,impose to the global economy. These models, however, provide little theoretical insight into the dynamics of the decarbonization transition and they cannot inform the consequences of different carbon prices in the evolution of a socio-technical system. Many jurisdictions are considering incremental carbon prices without acknowledging the existence of technological "tipping points" triggered by specific carbon prices that suggest stable but more aggressive earlier action. We use high temporal and spatial resolution model SWITCH(see, e.g. Mileva, et al., 2013; Carvallo, Hidalgo-Gonzalez, and Kammen, 2014) to study the effect of the trajectories of prices for carbon emissions on the evolution of power systems. We have developed this linear programming optimization tool and utilized it to examine energy and climate objectives for distinct models of four different regions: the Western U.S., China, Chile, and Nicaragua. For each of these regions we find a common pattern of non-additive effects of increasing carbon prices and non-linear/non-decreasing marginal abatement costs. Despite the significant differences in the current energy mix and local resources in these regions, we find that tipping points at ~$30/ton and ~$60/ton lead to significant 'transformative phases' in each system. Specifically, as these carbon prices are reached we observe significant changes in the energy investment portfolio that would not likely have taken place with simply small, incremental, changes in carbon prices. Our analyses for each particular region suggest significantly different socio-technical evolution pathways for each area depending on an initial choice of carbon prices and its interaction with other policies. For example, in Chile carbon prices below $30 favor entrance of natural gas, while higher prices make renewable energy sources economical but impose different operational restrictions in the grid that require a different set of investment decisions. In the case of China, a high-adoption of renewable energy stage and a carbon capture and sequestration stage are defined before and after a $10/ton price respectively, with major transmission infrastructure implications. We propose a framework of decarbonization regimes with four critical stages: an earlier stage of natural gas/nuclear replacement; a second stage with higher renewable energy penetration; a third stage defined by earlier retirement of coal plants; and a four stage with minimal marginal gains from higher prices. We use this framework to recommend appropriate supplementary environmental and technology policies to achieve mitigation goals.

2238 - Indigenous and Non-Indigenous Science in Collaboration for Our Common Future

ORAL PRESENTATIONS

K-2238-01

Collaboration of Indigenous Science and Western Science to Protect Landscapes and Our Common Futures

A. Poelina (1)
(1) MADJULLA, PO BOX 2747, Broome WA , Australia

Indigenous people of the world have unique knowledge systems that can contribute to all fields of scientific endeavors, particularly of generational experiences of being living witness to changing biodiversity and cultural landscapes as documented in our report titled Indigenous Engagement with Science towards deeper understanding (see http://www.innovation.gov.au).

The major challenge of generating and maintaining Indigenous knowledge systems and intergenerational practice is not simply an issue of science engagement; it is an issue of international importance for the earth's co-existence with humanity. The solutions presented by Indigenous researchers/scientists, and knowledge holders are founded in a trans-disciplinary approach of collective wisdom, an approach that recognizes and celebrates unity in diversity. The opportunity needs to be realized to invest in future partnerships which value and include Indigenous and western scientist/researchers and practioners working together.

These partnerships must recognize and respect the earth has rights and we as world citizens must guarantee custodianship of the commons, reliable prosperity and sustainable world development. The United Nation Declaration of Human Rights (1948) promotes the wellbeing and sacredness of all life not just human life (see http://www.un.org/en/documents/udhr/). In the words of twenty two Indigenous Philosophers in the Redstone Statement (2010) ,we are at a tipping point, and it is therefore essential for non-Indigenous and Indigenous, native and non-native people to act now, to hold and care for Mother Earth in order to protect the sacredness of all life (see http:// ww.Indigenousenvirosummit10.unt.edu). This world belongs to all of us and we must again learn to live, love and work together to protect the sacredness of all life.

As traditional custodians in Australia we recognise and value the protection of all inhabitants who are connected to ancient geological and living water systems; rivers, arteries giving life to our dry sun burnt country. We have a responsibility as scientist, researchers and practioners to generate multiple bodies of information and practice to inform our role not as activist but rather as actionist. I am passionate about working in a dialogic action way to bring about transformational change in the recognition and promotion of the multiple values of this uniquely rich Australian cultural landscape. Late last year with fellow Australians we showcased and shared the places we love, see https://www.youtube.com/watch?v=VBh0gnwzuwI

The Kimberley region of Western Australia is considered one of the last great wildernesses of the world. Vast areas of the region were National Heritage Listed in 2011 for multiple world values containing ; vast ramsar wetlands a rich feeding ground for extensive species of migratory birds, the world's largest dinosaur footprints and extensive trackways, ancient rock art, pristine coast lines, rich ecosystems, and unique living Indigenous cultures co-existing with Asian and European heritage. We need transparent participatory planning, which values existing natural assets as capital and includes people in planning. My vision is the planning, development and delivery of a Maroodwarra (Fitzroy River) and the Broome Coast Global Geo Park. Investment needs to be mobilised to conduct a Feasibiity Study to build on the recognition of national cultural and envrionmental heritage landscapes. The time is right to build a body of evidence, for valuing these multiple assetts as a geo world parks. We need to map alternative strategies for innovation and diverse economies on country if we want reliable prosperity and a sustainable common future against climate chaos.

K-2238-02

Indigenous and Non-Indigenous Collaboration: Essential for Addressing Climate Change in the 21st Century

J. Hook (1)
(1) Citizen of the Cherokee Nation, El Indio, Texas, United States of America

Indigenous peoples worldwide possess extensive knowledge that is essential for environmental and human preservation in the coming century. Many scientists, both Indigenous and non-Indigenous, believe that we are at a "tipping point" in maintaining the health of the environment, and consequently, of humanity, and that action must be taken immediately. In order to best utilize Indigenous cultural and cognitive resources in addressing Climate Change issues, respectful, trusting, mutually beneficial relationships and partnerships must be built. This requires that "Western" scientists and policy-makers develop skills for working effectively in Indigenous communities and understand their shared interests. While Traditional peoples and national or state governments are frequently in conflict with each other, examples of collaboration can be found.

The 2004 Indian Ocean tsunami provided one of the most powerful illustrations of the value of Indigenous knowledge. Indigenous communities fared far better than others, and commanded the attention of "Western" scientists, especially in the United States.

In meetings with Indigenous communities in Sarawak (Malaysia) subsequent to the tsunami, with the Tatar-Baskiri villagers of Ufa-Shigiri (Siberia, Russia), and with many American Indian Nations in the central United States, I kept hearing the same shared concerns: the need for cultural preservation, protection of Indigenous land, and a desire to engage with other Indigenous peoples and with Non-Indigenous leaders. Exploration of these shared issues led to requests for mutual dialogue, and from 2007-2010 four annual Indigenous Student Videoconferences were held. Participants from Comanche and Kiowa American Indian Nations, Siberian Baskiris and Tatars, and Sarawakian communities discussed Climate Change issues and related impacts on their communities. They shared various culturally-specific responses. Simultaneously, Traditional leaders expressed the belief that environmental threats needed to be addressed immediately. These concerns were clearly articulated in 2010 through the "Redstone Statement," a product of the International Summit on Indigenous Environmental Philosophy held in a Kiowa American Indian community of central Oklahoma, United States. Individuals from Indigenous communities met initially to compile case studies of climate change impacts. In the first meeting, however, a representative from the American Indian Ponca Nation challenged us to draft a statement articulating perspectives on environmental concerns and necessary responses. The subsequent process produced a consensus document describing a critical "tipping point," the product of environmental and cultural imbalance. The document was translated into Spanish and Russian, and is being used as a basis for education and action in Indigenous communities from Russia to Australia to Mexico.

Effective partnerships are only possible when «Western» scientists come to understand and respect the concerns expressed by Indigenous voices. Non-Indigenous scientists, policy-makers and politicians must recognize the importance of Indigenous participation in planning and implementing mitigation and adaptation efforts. This can only be accomplished if the non-Indigenous put effort into learning how to work effectively in Indigenous settings. An understanding of cultural perspectives such as holistic world-views, the importance of maintaining balance, intimate relationships with the environment and sacred places, and long-term sustainability is essential to building authentic relationships. Additionally, non-Indigenous partners must spend time on-site in Indigenous communities, meeting with elders and other knowledge-keepers. Finally, mechanisms and venues must be created through which Indigenous and non-Indigenous representatives can meet as equals to plan, explore options, draft strategies, and begin implementation projects.

There are examples of successful collaboration. The U.S. Environmental Protection Agency's Tribal Science Council began bringing Indigenous scientists and knowledge-keepers together with non-Indigenous scientists for collaborative efforts in 1999. Effective partnering is not only possible, it is essential!

O-2238-01

Indigenous knowledge from Land to lab to land: A framework to improve the flow for climate change adaptation

V. Gupta (1)
(1) National Institute of Industrial Engineering, Economics, Mumbai, Maharashtra, India

Rich traditional ecological knowledge (TEK) is not only vital for sustainability of livelihoods of indigenous people, it is also vital for the sustainability of natural resource. The efficiency and efficacy of this traditional knowledge on agricultural farms, forests, water, households, community resources etc are to be well recognised in the interest of the humanity and sustainability at large. Redstone Statement recognises that indigenous people across the globe have been confronting climate change and variability on regular basis due to heavy dependence on natural resources for their livelihoods. These hardships beside others have made them develop deep understanding of the natural resources and the climate they live in. Their TEK includes prediction of disasters, mitigation and adaptation to climate change besides conserving and preserving of natural resources. Indigenous communities have been transmitting knowledge for generations regarding judicious use of resource and restricting resource depletion.

The indigenous knowledge prevailing in customs, beliefs, practices and wisdom is rediscovered in modern science. Indigenous knowledge is documented and transmitted through ethos, epics and ancient texts. The modern science is experimented, analysed and documented in the labs under ideal resource conditions whereas indigenous knowledge is practiced on forests, fields, and farms under actual climatic and resource conditions. Therefore new knowledge of modern science is to be built up on indigenous knowledge without discrediting it. For sustainable planet, we need all stocks of indigenous and innovative knowledge which gets enhanced through continuous flow of it and supported by institution which is ethical in its framework. The ethno-ecological knowledge combined with ethno economics provides better understanding and choices to resolve these issues.

In India these aboriginal people are known as atavika and adivasi (indigenous), vanvasi (forest dwellers), girijan (hill people). These tribal communities as Bishnoi, Bhil, Gond, Santals, Bhotiya and Khasis are living majorly in states of Rajasthan,Uttar Pradesh, West Bengal, Bihar, Tamil Nadu, Meghalya and Himalya region in harmony with nature. The farmers in arid and semi-arid regions rotate crops and change the dates for sowing seeds as per climate conditions across India, Koli community of Mumbai change their fish catch pattern to enhance availability of fish in future, Navdanya programme promotes biodiversity conservation with the help of local tribal people. Religious and tribal traditions such as temple forests and sacred groves, rainwater harvesting, maintaining landscape heterogeneity and biodiversity through varietal flora and fauna and growing medicinal plants are just few examples of their efforts.

The aboriginal communities in developing countries like India face many issues alongside their hardship of livelihood like inequality in the access of resources, unequal distribution of growth, increasing urge of growth and consumerism all have impacted the livelihood dependent on natural resources as well as the sustainability of available resources. In many cases natural resources are reaching to the stage of economic depletion. The valuation and integration of their knowledge systems is not only desirable but essential for equity, empowerment, and security of underprivileged community besides natural resource management. Endeavours of integrating traditional ecological knowledge with western science requires due recognition for local long lasting cultural and institutional framework. Within this framework, their security of land, food, energy and livelihood and knowledge is to be ensured through policy framework. In this discussion I propose to provide a framework for traditional ecological knowledge security through innovative market and non-market incentives and disincentives to protect and promote wealth of indigenous knowledge for our sustainable common future.

O-2238-02

Integration of Indigenous Knowledge with ICTs in coping and adapting to effects of climate change and variability on Agriculture in Kajiado County, Kenya

C. Manei (1)

(1) University of Nairobi, Agricultural economis, Nairobi, Kenya

Climate change threatens production's stability and productivity. In many areas of the world where agricultural productivity is already low and the means of coping with adverse events are limited, climate change is expected to reduce productivity to even lower levels and make uncertainities in agriculture higher. To help in coping with the negative effects of climate change, local people employ traditional indigenous-knowledge based practices. This local based knowledge, which has evolved over several hundreds of thousands of years in tandem with the domestication of plants and animals, is critical for responding to climate change and variability effects at the local level. ICTs have the potential improve access to this knowledge among other relevant information and social networking opportunities. The research was carried out to assess relevant Indigenous knowledge used by Indigenous people to cope and adapt to climate change and variability effects therefore managing risks and uncertainities in agriculture as well as evaluate opportunities for utilizing ICTs to communicate this information. Results indicates that farmers have shifted to farming historically known drought tolerant crops, rain water harvesting, irrigation, use of organic manure, traditional methods of treating crops pests and diseases, change in planting time, preservation of pastures, indigenous food preservation methods, vaccination ,farmers are also increasingly relying on their own indigenous knowledge in predicting weather patterns compared to scientific knowledge. Various communication mechanisms taking advantage of ICTs such as radios and mobile phones are emerging as viable tools for dissemination of relevant information to the farmers because they are affordable and use of local language which is easily understood by farmers.

"Blue-ice": Framing climate change and reframing climate change adaptation from the Indigenous peoples' perspective in the northern boreal forest of Ontario, Canada

D. Golden (1) ; P. Smith, (1) ; CA. Audet, (2)

(1) Lakehead University, Faculty of Natural Resources Management, Thunder Bay, ON, Canada; (2) 90 Anemki Place, Office of the regional chief, Fort William First Nation, ON P7J 1L3, Canada

The northern boreal forest in Ontario, Canada, in the sub-Arctic above the 51st parallel, is the territorial homeland of the Cree, Ojibwe, and Ojicree Nations. These Nations are represented by the political organization Nishnawbe Aski Nation (NAN). January 6-March 31, 2011 the researchers and NAN collaborated in a study to record observations of changes in the forest environment attributed to climate change and share and exchange information and perspectives about climate change. Data were collected from ten First Nation communities across a geographic area of ~110,800 km2 (43,000 mi2). We explore climate change impacts through the lens of "blue-ice", a term embedded in their languages across the fieldwork area and reframe adaptation in the First Nations' perspective and worldview. Changes in blue-ice on the landscape is affecting transportation in traditional activities such as hunting and fishing, as well as the delivery of essential community supplies. The word 'adaptation' linked to climate change does not exist in their languages and the term is associated with European colonization. We propose the term 'continuity' to reflect the First Nation worldview. Our recommendation is giving First Nations' perspectives and knowledge of their territorial landscape a foundational role in the development of climate change policy for Ontario's northern boreal forest.

O-2238-04

Forest Carbon in Amazonia: The Unrecognized Contribution of Indigenous Territories and Protected Natural Areas

W. Walker (1) ; A. Baccini (1) ; S. Schwartzman (2) ; S. Rios (3) ; MA. Oliveira-Miranda (4) ; C. Augusto (5) ; M. Romero Ruiz (6) ; C. Soria Arrasco (3) ; B. Ricardo (5) ; R. Smith (3) ; C. Meyer (2) ; JC. Jintiach (7) ; E. Vasquez Campos (7)

(1) The Woods Hole Research Center, Falmouth, United States of America; (2) Environmental Defense Fund, Washington D.C., United States of America; (3) Instituto del Bien Común/IBC, Lima, Peru; (4) Provita, Caracas, Venezuela; (5) Instituto Socioambiental/ISA, São Paulo, Brazil; (6) Fundación GAIA Amazonas, Bogotá, Colombia; (7) Coordinadora de las Organizaciones Indígenas de la Cuenca Amazónica/COICA, Quito, Ecuador

More than half (52%; 4.1 million km2) of Amazonia's tropical ecosystems are contained within an extensive network of 2,344 Indigenous Territories (ITs) and 610 Protected Natural Areas (PNAs) spanning nine South American nations. These cornerstones of Amazon conservation are widely recognized for their exceptional biological, cultural, and linguistic diversity, and serve as both social and natural barriers to frontier expansion and fire. Carbon sequestration is a widely-acknowledged and increasingly-valued function of tropical forest ecosystems; however, until recently the information needed to assess the carbon storage capacity of Amazonian Indigenous Territories (ITs) and Protected Natural Areas (PNAs) in a global context remained either lacking or out of reach. Here, as part of a novel north-south collaboration among Amazonian indigenous and NGO networks, scientists, and policy experts, we link newly compiled spatial data sets on pantropical aboveground forest carbon density, Amazonian ITs and PNAs, and risks to their integrity from current pressures and/or near-term threats. We show that the nine-nation network of nearly 3,000 ITs and PNAs stores more carbon above ground (47,363 Mt) than all of the Democratic Republic of the Congo and Indonesia combined (40,797 Mt), and despite the ostensibly secure status of these conservation cornerstones, a conservative risk assessment considering only ongoing and planned development projects puts nearly 20% of this carbon at risk, encompassing an area of tropical forest larger than Colombia, Peru, and Ecuador combined. Our analysis suggests that the carbon stored across these landscapes is of a magnitude not previously appreciated in global terms, and is sufficient to either destabilize or contribute to the stabilization of the planet's atmosphere depending on the collective impact of ongoing and planned development projects. International recognition of and renewed investment in this globally vital network are therefore critical to ensuring their continued contribution to maintaining cultural identity, ecosystem integrity, and climate stability.

O-2238-05

Traditional knowledge and benefit-sharing in the 2015 agreement

A. Savaresi (1)

(1) University of Edinburgh, School of Law, Edinburgh, United Kingdom

Scientists have increasingly recognized the role of traditional knowledge as a means to adapt to climate change. Yet, the international climate regime presently says nothing on how traditional knowledge may be deployed and protected to tackle climate change. This state of affairs may, however, be about to change. States are considering including references to the use of the traditional knowledge of indigenous peoples and local communities in the new international agreement on climate change to be adopted in December 2015.

While it is too early to say whether references to traditional knowledge will be included in the new climate agreement, it is important to reflect on the implications of this possible development in the light of extant international instruments, especially those concerning biodiversity and human rights, which establish obligations to protect, maintain and promote traditional knowledge. This paper will therefore reflect on the scope for elaborating a common approach to the use of traditional knowledge under the climate regime, building on extant international law.

One area of crucial legal development on traditional knowledge is that concerning the interplay between the consent of indigenous peoples and fair and equitable benefit-sharing, as means to recognise, support and reward indigenous peoples and local communities for the contribution of their traditional knowledge to addressing global challenges. The Convention on Biological Diversity (CBD), for example, requires its Parties to promote the application of traditional knowledge with the approval and involvement of its holders, and to encourage the sharing of benefits from its use with indigenous peoples and local communities. The Nagoya Protocol on Access and Benefit-sharing to the CBD requires its Parties to ensure that the use of traditional knowledge associated with genetic resources for research and development purposes (including for the development of climate-related technologies) is subject to the prior informed consent (or approval and involvement) of indigenous peoples and local communities, as well as to benefit-sharing. Equally, the International Treaty on Plant Genetic Resources for Food and Agriculture (ITPGR) recognizes farmers' right to participate equitably in the benefits arising from the utilization of plant genetic resources for food and agriculture. The need to maintain traditional, often underutilized, crop varieties in the face of climate change has been explicitly recognized in the ITPGR framework. The ITPGR Benefit-sharing Fund has supported a number of projects focusing on management and use of plant genetic resources by indigenous peoples and traditional communities for adaptation to climate change. Finally, even though it does not make explicit reference to benefit-sharing, the United Nations Declaration on the Rights of Indigenous Peoples asserts indigenous peoples' right to maintain, control, protect and develop their traditional knowledge.

Presently, the negotiating text for the 2015 agreement mentions traditional knowledge in connection with adaptation to climate change, capacity building, and technology development and transfer. It does not say that indigenous peoples and local communities should receive a share of the benefits accrued from the utilization of traditional knowledge, or that they should consent before others can make use of such knowledge. The proposed paper will investigate how the law and practice emerged under the CBD, the Nagoya Protocol, the ITPGR and international human rights law could or should influence the development of the climate regime with regard to the use of traditional knowledge for climate adaptation purposes. It will argue that biodiversity and human rights law and practice embody internationally agreed understanding on matters upon which states have already reached painstakingly negotiated consensus. As Parties to the climate regime consider including traditional knowledge in the 2015 agreement, it is important to consider lessons that can be learnt from extant approaches to account for crucial equity considerations associated with the use of traditional knowledge.

P-2238-01

Quantitative analysis of Greenhouse Gas (GHG) as a Milestone Towards Negative Emissions in Egypt

A. Batisha (1)
(1) Environment and Climate Change Research Institute, Cairo, Egypt

Greenhouse Gas (GHG) analysis has been developed with the objective of providing an integrated perspective on Environmental sustainability. Emission baseline has been analyzed on a macro sector basis with a focus on key sectors; Energy, Industrial Processes and Product Use, Agriculture, Forestry and Other Land Use and Waste. Data has been collected from available public sources (local and international). A web based IPCC Inventory Software supporting users of the IPCC Guidelines has been used. Additional support to the greenhouse gas emission inventory community by giving inventory compilers a platform for exchange of all the current information and data they need, including a wide range of emission factors has been provided by means of the IPCC Emission Factor Database (EFDB). All Greenhouse Gas emissions divided into IPCC Guidelines Categories may be calculated from sectoral tables. National Key Category Analysis is implemented by performing a quantitative analysis of the relationships between the level and the trend of each category's emissions and removals and total national emissions and removals. The paper concludes that Sharing of research information may enable the African countries to use or develop emission factors that are more applicable than the IPCC default emission factors and may help to improve the quality of GHG inventories in a cost-effective way.

Toward a transdisciplinary framework for inter-relating indigenous knowledge systems and disaster risk reduction

MA. Baudoin (1) ; S. Athayde (2) ; S. Lambert (3) ; V. Okorie (4)
(1) Climate and Development initiative, geology, cape Town, South Africa; (2) University of Florida, Center for latin american studies, Gainesville, United States of America; (3) Lincoln University, Christchurch, New Zealand; (4) Obafemi Awolowo University, Ife, Nigeria, Federal Republic of

Perceptions of natural hazards and climate change vary across regions, societies and culture. While "western" expert-based knowledge focus on measuring, defining and forecasting hazards' occurrence, frequency and localization, local perceptions at the community level – often referred to as "indigenous knowledge" (IK) – adopts a context-specific and holistic view of natural, climate-related and human-made hazards and disasters. Indigenous knowledge systems intertwine cultural, symbolic, technological knowledge, natural resource management practices, beliefs and worldviews in perceiving, preparing and managing disasters.

This talk presents the preliminary results of a follow-up project from the Risk Interpretation and Action (RIA) Fellows of the International Social Science Council, involving indigenous and non-indigenous researchers and practitioners. Acknowledging the diversity of perceptions and understandings of risks, this collaborative work aims to develop an exploratory transdisciplinary framework drawing from literature review as well as from experiences and challenges faced by indigenous peoples in developed (USA, New Zealand) and developing regions (Nigeria, Brazil). The framework can be applied to foster dialogue and guide research and policy-making involving indigenous peoples in disaster risk reduction (DRR) and climate change adaptation (CCA), recognizing limitations and power issues in coordinating different knowledge systems, and respecting indigenous peoples' self-determination, worldviews and concerns.

With an objective to enhance cross-disciplinary learning, the proposed framework offers a broader understanding of disaster risks among indigenous people, scientists, practitioners and managers. Its structure encompasses (and adapts) the usual three phases of the DRR process, represented by indigenous symbols: preparedness (pre-disaster); response (during disaster); and recovery (post-disaster), adding a fourth transversal component, critical during the three phases, and related to framing, understanding and fostering dialogue across knowledge systems. Thus, the framework distinguishes common and contrasting features of DRR and CCA across diverse regions, cultures and types of disasters; it presents nuances of 'risk perception' and 'risk interpretation' among indigenous communities in different countries and contexts, as well as their creative responses or 'risk action'.

The outcomes of this study will be used to connect, foster exchange of ideas and experience, and facilitate training and learning among representatives of indigenous communities who face natural, industrial and climate change-related hazards. Moreover, this research contributes to foster transdisciplinary dialogue and research on indigenous, academic and practical knowledge systems towards DRR and CCA in a global scale.

P-2238-03

The Coastal Community as Context for Culture-Based Science Literacy

H. Buenvenida (1)
(1) Department of Education, Science Education, Roxas City, Philippines

People in a community who are closely connected to the local surroundings were often the first to notice their surroundings. This is because their knowledge is derived from long-term observational data maintained through an oral tradition. It is for this reason that the knowledge held by the community needs to be reflected in local classrooms. When we think of something or discover a new fact, we also think of all the interconnections between that fact and everything else. And so it is with their science: it is going to be connected to everything within their culture. The local funds of knowledge in the community included the culture, attitudes, beliefs, concepts, ideas experiences and stories of the people in the coastal community. The local funds of knowledge are stored in the people's lives, in their environment and their history. The local knowledge, wisdom and experience were valuable, appropriate and still relevant for people and can be capitalized to teach relevant science in schools. These knowledge bases are a rich resource for teaching biology, environmental science and ecology.

There were identified barriers in the teaching and learning situation in coastal communities; academic, situational, and dispositional. The set of learning materials represents my attempt to delineate a preparation content covering how regular classrooms and schools should be designed to ensure all students have appropriate opportunities to learn effectively. This, of course, includes the many that manifest commonplace behavior, learning, and emotional problem. However these materials develop are targeted to address the academic barrier .Nonetheless, parallel to the development of the materials, an approach (culture-based; contextualization: and community-based learning) was also espoused to enrich the material in its delivery to the mainstream classroom. The materials represent my attempt to deliver learning to the local students to answer some usual problems in their place; pollution, health, environmental protection, climate change mitigation, disaster risk reduction and preparedness and biodiversity. Relative to this, training, seminars, workshops are also recommended to address the said barriers.

This research suggests means and ways on how to respond to the question of how to support science teaching in rural and coastal settings and frames challenges to student learning as disconnects between community-based and school-based forms of science. This disconnect occurs when students do not see how the science in schools has value in or relates to their lived experiences and when schools do not see how the lived experiences of learners have value in learning and doing science. I have presented here a case of what I call «connected science,» which uses real-world problems and school—community partnerships as contextual scaffolds to bridge these diverse funds of knowledge.

The study developed two important theoretical contributions. First a model on how to create culturally relevant community-based learning through: (a) mining local funds of knowledge from the community, (b) constructing cultural memory bank, (c) developing a contextual-learning strategy for coastal communities, (d) developing a tailor-fitted instructional material for coastal communities and (d) teaching culture-based, and context-based science in schools. The second contribution is the Theory of Community Learning Exchange Valorization . This theory attempts to conglomerate conceptions and notions about the "mining" of the community funds of knowledge and the way this knowledge can be "valorized" and be "given back" to the community.

On a final note drawing on the assets of the communitycan help schools build citizens while infusing academic course work with meaning and relevance. Rather than diluting the school curriculum, community-based learning strategies increase the intensity of learning and the likelihood that young people will transfer knowledge and skills to new situations. By fostering student interest in their respective communities, these strategies sow the seeds of lifelong learning. When students see themselves as citizens, they take responsibility for what happens to their neighborhoods, communities, and country at large.

P-2238-04

Wunan Law and Human Identity through Connections with Country

J. Doring (1)
(1) Parthway, Broome WA, Australia

In the Kimberley region of North west Australia, much local knowledge is not only relevant to current scientific observations, but continues the oldest recorded human history of living WITH country. Once the first rock art appears documenting the evolution of the Wunan social order, we have ancient evidence of people sharing a complex legal association with landscapes that weave together identity and country binding people to environments inherited in perpetuity. Wunan law remains documented by Gwion rock art, preserved beneath skins of silica crystals leached by weathering from sandstone through a long history that spans millennia of changing climates from estimates of 25,000 years past up to the present day; the film GWION documents Paddy Nyawarra repainting a sentinel Gwion figure standing guard at the junction of three Wunan districts in 1999. Wunan laws defining human identity through land contradicts the assumptive stereotype of the 'nomadic aboriginal' with nothing new to offer modern science, in fact, and as published in Rock Art Research March 2014, Wunan is living evidence of the longest continuous stable social system documented by the human hand.

Wunan law proscribes social identity as living connections to country so over time Gwion artists were motivated to portray human figures with unique extensions to their body, making specific social connections to local flora and fauna. Many ancient Wunan law songs about birds and knowledge of Wanjina and Gwion rock art survive in Ngarinyin culture as part of customary law, as declared by native title belatedly recognised by the Federal Court of Australia in 2005. The ancestral evidence documented with cameras by four Ngarinyin munnumburra – experts in Wunan law, has been generously exhibited by three major museums in France. Now we can tell our children about a society that begins not with a warrior or king, but an artist called Wibalma. They can learn how the oldest society to record themselves through art began when the visionary artist Wibalma created the first sacred object, not of an animal but an ethic at the core of social order. Wibalma's sacred object of Justice was the catalyst bringing together many nomadic tribes, to find a consensus around the stone table at Dududu.ngari and fuse their identity with their country forever in Wunan law. Lines of stones mark positions where they stood in line to announce by oath, their homeland and name, in sequence from the central desert to the tropical north coast across to the western coastline. Aboriginal councillors who represent their country in public meetings today still follow the Wunan order of representing various districts.

As documented through the graphic evidence of Gwion artists, the Wunan law system has ordered sustainable land tenure connecting human to country for millennia. Aboriginal people across the Kimberley region continue to carry, but must struggle to preserve their ancestral legacy and protect fresh water resources in opposition to invasive mining projects. Observations of climate change must incorporate local knowledge, and across the north-west of Australia from desert to saltwater coastline, planners must include the pre-colonial Wunan map of water and country that gave each human being their individual identity. For example the name Nyawarra, refers to outcrops of black basalt appearing in his Wunan district of Galeru.ngarri dambun. Wunan law preserves many insights into the natural history of this extensive region and provides a historically meaningful nomenclature of flora and fauna and local landscapes as the fundamental framework of knowledge for future research and education.

High on the rock wall of Alyaguma covered with ancient paintings of the first matriarchs of visual metaphors signifying various stages of education throughout life. Starting from the roots of family blood and the single root of Wunan law, education proceeds into maturity once understanding the complex binary system of marriage and environmental relationships to country marked by two separated feet looking down. Then adults educate the new generation symbolised by the ripening plum fruit when monsoonal rains fall from above. The elements and meanings of the painting are illustrated and described with verbatim cultural evidence recorded on site by Ngarinyin munnumburra – experts in Wunan law and the living bush .

P-2238-05

Toponymy of an occupation early hunter gatherers in marine Quintero

C. Fuentevilla (1)
(1) Universidad Arcis, Santiago, Santiago, Chile

This is a presentation of the state of the art of research conducted in a series of explorations in the line of rocks from San Fuentes Lace up Pirate's Cove area, in the town of Quintero, Chile, between 2011 and 2013. It describes the finding of lithic evidence in five archaeological sites observed from perforations in the rocks as water toponymy signaling; based on the experience of discontinuous occupation of marine hunter-gatherers. As a result of continental settlement in the late Pleistocene and early Holocene epochs. This paleoenvironmental context generated conditions of survival, which according to weather representations, allowed the survival of anthropogenic Paleoindian presence. However the latitudinal gradient was also exposed to periods of cooling or neoglaciation. Therefore, while climate change was constant, it created new demands for adaptation in order to ensure the survival of hunter-gatherers. Therefore, their lithic technology fitted the necessary mobility of the group. A synchrony between their social structure and technology in understanding their decisions, represented in a toponymy of lithic signs to identify water as a source of survival. Keywords: Hunter-gatherers, paleoenvironment, lithic toponymy, Paleoindian, climate change.

P-2238-06

Indigenous Knowledge as Local Response to Globalization and Climate Change in Nigeria/Africa

G. Nwaka (1)
(1) Abia State University, Uturu, Humanities and Social Sciences, Uturu, Abia State, Nigeria, Federal Republic of

As we consider the Post-2015 Development Agenda for Africa, indigenous knowledge may prove to be "the single largest knowledge resource not yet mobilized in the development enterprise". Critics of African development liken the current pattern of development in the continent to building a house from the roof down as "all the institutions of modernization appear to be suspended over societies that have no firm connection to them, and whose indigenous institutions, even when oriented in the right direction, lack the necessary scaffolding to connect them to their modern surrogates". Africa contributes least to, but suffers the most from the disastrous consequences of climate change. While the industrialized and more affluent countries are rightly being called upon to take greater responsibility for the current global environmental and economic crises, Marshall Sahlins has rightly emphasized the need for all peoples "to indigenize the forces of global modernity, and turn them to their own ends", as the real impact of globalization depends largely on the responses developed at the local level. How can Africa engage with globalization, and cope more effectively with the worsening threats of flooding, droughts and other emergencies that result from extreme weather conditions?

For a long time African customs and traditions were misconceived as irrational and incompatible with the conventional strategies of development. But the current global economic and ecological crises have exposed flaws in the Western neo-liberal model of development which is largely to blame for these problems, and for widening inequalities within and between nations. With the obvious underperformance of the Millennium Development Goals in Africa, there is now renewed interest in an alternative approach which emphasizes the cultural dimension of development, and the overlooked potential of indigenous knowledge. This paper considers how indigenous knowledge and practice can be put to good use in support of good governance, agriculture and natural resource management, poverty alleviation, and the mitigation and adaptation to climate change. Although poverty may sometimes force people in the developing world to use resources unsustainably, most traditional African societies have deeply entrenched ideas about environmental protection and sustainability since their livelihood depends largely on the land and on the stability of the ecosystem. They believe that land and other forms of nature are sacred, and are held in trust by the present day users on behalf of dead ancestors and future generations. Chief Nana Ofori Atta of colonial Ghana emphasized to a British official that "land belongs to a large family of which many are dead, a few a living, and countless hosts are yet unborn".

The paper argues that the indigenous knowledge movement is not only a useful and creative way to respond to globalization, it also has great potential for the mitigation and adaptation to climate change. While Africa cannot now contemplate an insular and entirely home grown approach to its development, indigenous knowledge offers a model for rethinking and redirecting the development process, and for enlisting positive traditional values and institutions in a way that enables and empowers local actors to take part in their own development. Development agents, researchers and donors, who often assume a knowledge or capacity vacuum in Africa, should instead try to tap into indigenous knowledge for locally appropriate ways of forecasting weather systems, traditional techniques of soil management, pest and disease control, adopting suitable crop and animal varieties, and so on. By building on the indigenous we can make development more participatory and sustainable, and also promote intercultural dialogue in African development.

P-2238-07

Local Management of Andean Wetlands in Sajama National Park, Bolivia

PL. Pacheco Mollinedo (1) ; E. Villarroel (1) ; A. Domic (2) ; J. Capriles (3) ; C. Espinoza (1)
(1) Agua Sustentable, Climate Change Adaptation, la Paz, Bolivia; (2) Universidad Mayor de San Andrés, Campus Universitario de Cota Cota, Herbario nacional de bolivia,, La Paz, Bolivia; (3) Instituto de Alta Investigación, Universidad de tarapacá, antofagasta 1520, casilla 6-d, Arica, Chile

Andean wetlands or bofedales are commonly used by indigenous communities for livestock production. Decisions regarding management of bofedales involve the active participation of local people and their social institutions. Consequently, any action addressing emerging challenges must be implemented in coordination and agreement with local actors. This decision process requires an understanding of the local socio-economic and cultural dynamics, especially those related to land and natural resource management. In many Andean communities, the ayllu is the institution that governs decisions on regional land use. However, in the face of increasing challenges such as climate change and population growth, use of the ayllu has declined in favor of individual decision-making. Here we discuss how the Andean camelid herders of Sajama National Park in highland Bolivia rely on both the ayllu and family-level decision-making to manage their pastoralist landscapes, including their bofedales. Using a rights mapping methodology, we describe how water and wetlands are managed, and determine which decisions are taken at the community level and which are made at the family level. We conclude that indigenous collective organization networks are still significant for managing the system at a regional scale and possibly determinant for mitigating risks associated with climate change on sensitive ecosystems such as bofedales.

Since the Spanish conquest in the 16th century, the world view of native Andean indigenous communities had to interact with the dominant sociopolitical systems of the colonial and later republican period (Schiffers 1992, Regalsky 1994, Platt et al 2006). One important element of confrontation between these two visions was the form of land and natural resource management: collective vs individual. Indigenous communities adapted and developed a number of cultural and productive organizational strategies to cope with the new forms of domination, trying to maintain the logic and vision of the Andean territorial management strategies (Orlove 1977; Platt 1982; Spalding 1984).

One of the main strategies in the Andean world was access to the greatest possible number of ecological zones, which was a strategy to achieving food self-sufficiency and also an important risk management tool, mainly for climatic risks (Murra 1972; Browman 1983; Regalsky 1994).

Because of the social and economic importance of wetlands, especially for camelid (llama and alpaca) herders, communities in these areas periodically revise and adapt institutional arrangements for sustainable management. High Andean wetlands, known locally as bofedales, represent one of the most productive native vegetation types of the puna. However, they are seriously threatened by climate change as they depend on constant water flow, which is mostly assured by annual glacier melt and precipitation (Squeo et al 2006; Yager et al 2008; Ruthsatz 2012). In view of these threats, it is particularly important to document how local wetland management strategies are being adapted to cope with emerging challenges (Pinto-Romero 2011; Verzijl and Guerrero Quispe 2013).

Conclusions
The study shows the ability of Andean communities to face up to social and environmental challenges in Sajama National Park. The 5 ayllus that are part of the Park have managed their natural resources, which include Andean wetlands, since precolonial times. In doing so, they have maintained a balance between permanence (the principles and world vision of the Andean culture) and flexibility (changing strategies for adapting to constant environmental, sociopolitical, and economic change).

Finally, we raise the question of how the process of collective vs family-based decision-making will develop in future. Adapting to change appears to have accelerated in the last decades, and market influence is becoming more intrusive in the ayllus' daily operations. It is worth asking if this process will lead to a gradual dismantling of the ayllu and the loss of one of the main strengths of Andean communities: collective organization networks.

Indigenous knowledge for seasonal weather and climate forecasting across East Africa

M. Radeny (1) ; M. Nyasimi (1) ; J. Kinyangi (1) ; J. Recha (1) ; D. Mubiru (2) ; H. Hahoo (3) ; DY. Ayal (4)
(1) ILRI, CCAFS East Africa, Nairobi, Kenya; (2) NARO, Kawanda, Kampala, Uganda; (3) Sokoine University, Agricultural engineering and land planning, Morogoro, Tanzania, United Republic of; (4) UNISA, Addis Ababa, Ethiopia

Advance knowledge of climate information is important in helping farmers make decisions about allocation of land, labor, and agricultural enterprises in a season. It enhances their capacity to adapt to climate variably and climate change. Climate information coupled with agro-advisory services offers greater potential to manage climate related risks in the face of increasing uncertainty. While progress has been made in provision of climate services for farmers, significant gaps still exist with regard to downscaling location-specific forecasts, reliability, timeliness, and user-friendly climate information that effectively addresses the needs of farmers. Consequently, most farmers rely on indigenous knowledge (IK) for their seasonal forecasts, where locally observed variables and experiences are used to assess and predict the local weather conditions and particularly the onset of rains as it determines the sequence of many of the farm operations. However, IK experiences for climate forecasting are not widely documented and often passed on from one generation to the other through oral history and local expertise, creating a wide inter-generational gap between its custodians and the young generation.

This paper presents a synthesis of existing IK in weather forecasting across four sites in three East Africa countries — Borana (Ethiopia), Lushoto (Tanzania) and Hoima and Rakai (Uganda). Across the sites, farmers and livestock herders use various local indicators to predict weather patterns, especially the onset, magnitude and cessation of the rainy seasons. The indicators can be grouped into three main categories: meteorological traditional indicators, astronomical indicators and biological indicators. Meteorological indicators commonly used to predict onset of rains included appearance of dark clouds, direction and strength of the wind, maximum and minimum temperature, plant responses to changing conditions, monitoring of the physical state of water and off-season advance indicators of cloud behavior at night. For instance, excessive heat and warming towards the end of the dry season indicates a likelihood of above normal rainfall. Similarly, high temperatures during the night indicates a likelihood of rainfall the next day. Astrological weather indicators include the position and appearance of the moon and sun. In Lushoto, the occurrence of a halo moon indicates the likelihood of the onset of rains for both major and minor seasons. In Ethiopia, the Borana herders employ astrological indicators and interpret the alignment of celestial bodies including the size and appearance of the star, the brightness of the sun, and appearance and form of cloud cover. Biological indicators are further disaggregated into animal and plant indicators. A change in animal behavior at the onset of rains is believed to be triggered by aroma from volatile compounds that increase in intensity when changes occur in humidity. In Uganda, the sound from amphibians during day time and those of specific birds are used widely to estimate the likelihood of the onset of rain. In Tanzania, appearance of certain physiological stages of insect populations, such as thrips in the wetland indicates the likelihood of an above normal rainfall season. Plant indicators most frequently used in Uganda included the sprouting of young shoots of the Mvule tree and blossoming of coffee bushes. In Tanzania, common plant indicators included flowering of venonia, pears, Albizia spp. and plums. Shedding of leaves of black nightshade also indicate the onset of rain.

We observe that farmers and herders were using these local indicators to make important agricultural production decisions including the timing of land preparation, dry planting, and purchase of seeds, type of crops to grow, agronomic practices to use, and labor allocation. In Borana, IK forecasts are used to plan livestock mobility and sharing of livestock amongst relatives to minimize losses during drought conditions. In Ethiopia and Tanzania, farmers considered IK climate forecasting a reliable source of climate information. They extend IK for forecasting of extreme events e.g. droughts and timing of the onset of rains. The paper demonstrates that farmers' trust and willingness to apply scientific forecasts would likely increase when IK forecasting are integrated with modern scientific methods. Therefore, a systematic documentation of IK and a framework for integrating IK and scientific forecasting from the national meteorological agencies can improve the accuracy of climate forecasts for farmers in East Africa.

P-2238-09

Linguistic Identity and Indigenous Knowledge

L. Zamorshchikova (1)
(1) North-Eastern Federal University, Institut of modern languages and regional studies, Yakutsk, France

The North as a cultural-historical form of civilization is composed of socio-cultural communities of individuals with well-known and persistent traits and characteristics, such as language, culture, environment, economics and spirituality. Geographical and cultural conditions of the North influence the formation of similar elements of the mental and linguistic identity of the peoples of the North. The common feature defining all northern communities is the deeply ecological aspects of their culture and recognition of a special relation with nature.

The research is aimed at study of northern world view through free association experiment's database realized in indigenous communities. The associative verbal nets reveal the peculiarities of spiritual and material culture, ethnic stereotypes of behavior, traditional beliefs and specificity of ethnic world view. The strings of verbal associations translate into assemblages of ideas, identities and behaviours which found their owner experientially located in self-contained worlds of people, events, values, norms and constraints (Rapport, Overing.).

The world view is a major component of culture and contains all the essential elements of traditional and cultural knowledge which an individual, belonging to a particular culture, needs in order to adapt to both natural and social components of his/her surrounding environment. This is the lens, so to say, through which people see the world in which to act. The structure of the world view is shaped in the early stages of ethnogenesis, and remains largely immutable throughout the life of an ethnic group (S. Lurie). It defines ethnic identity and uniqueness of a particular culture and, hence, its carriers – the members of an ethnic group comprising a social community characterized by a specific cultural model which mediates the nature of their activity in the world.

The data of free association experiment (associative-verbal nets) in so far as they reflect unconscious layers of the mind, especially within the context of inter-cultural contact in a multicultural and multilingual environment, present interest not only for the investigation of a variety of scientific problems, but also of many issues of everyday life of indigenous peoples. Language, culture, and the relationship to the land are key elements in a seemingly fragile and yet tenacious Arctic indigenous identity. There is high correlation between language retention and traditional lifestyle of indigenous peoples of the North. They live in close contact with the land, the sea, and the animals. Many indigenous Arctic peoples continue to live partial or total subsistence lifestyles, which is reflected in their languages, most obviously in their vocabularies, but

also in the contents of their everyday stories, which often involve hunting, fishing, and encounters with animals (especially bears).While the links between language, culture and environment may not be obvious to outsiders, they are deeply embedded in the daily life of Northern indigenous peoples (L.Grenoble).

Government policies in the sphere of national relations in the Republic of Sakha (Yakutia) place particular importance upon questions of vitality of small indigenous peoples' languages and cultures. The indigenous peoples of Yakutia, living in the inhospitable climate of the North, created unique modes of life and have interesting and instructive histories, traditions, and original cultures. Globalization and the pressure of mass culture endanger not only their languages but their traditional ways of life.

The researches of North-East Federal University of Yakutsk has been conducting psycholinguistic research on linguistic identities and indigenous world views of the peoples of the North, living on the territory of Yakutia. In this context linguistic research plays a vital role in the efforts to preserve the ethnic languages and by extension cultures of the people living in the North of Russia (Yakuts, Evens, Evenki, Yukagirs) since language not only communicates, but also encodes essential aspects of cultures and fixe their uniqueness for preserve and translate to the next generations.

2239 - Co-production of knowledge : How to interact to produce climate adaptation research, between scientific communities and stakeholders, at local or international, also between North and South countries ?

ORAL PRESENTATIONS

K-2239-01

Unpacking the co-production of knowledge in adaptation to climate change

S. Dessai (1) ; S. Beck (2) ; J. Porter (1) ; J. Van Der Sluijs (3)
(1) University of Leeds, Leeds, United Kingdom; (2) Helmholtz Centre for Environmental Research – UFZ , Leipzig, Germany; (3) University of Bergen, Centre for the study of the sciences and the humanities (svt), Bergen, Norway

The Intergovernmental Panel on Climate Change (IPCC) has been instrumental in raising political awareness of climate change at the global level, whilst the knowledge produced by the IPCC and other high level scientific programmes is seen as relevant it's not always "usable" for decision-making at the local and regional level where adaptation to climate change is crucial. Despite advances in climate science and adaptation policy, critical understandings of which approaches can most effectively harness science and technology for long-term sustainable adaptation is still lacking. "Usability" of science cannot be taken for granted. In order to fill the gap between the supply of scientific findings and its demand at different levels of decision-making, co-production has become a key concept guiding major international research initiatives. "Co-production" has a myriad of meanings, some practical-organizational orientated others social-philosophical. This talk aims to unpack how, why, and to what extent, the concept of co-production can inform scholarly debates and practical exercises on adaptation to an uncertain future climate. The talk is informed by a recent international workshop on the topic and empirical work conducted in the United Kingdom on the construction and use of climate change projections in long-term adaptation decision-making.

Climate change adaptation: towards a new geography of knowledge?

C. Buffet (1) ; S. Huq (2)
(1) Centre Alexandre Koyré (EHESS/CNRS), Paris, France; (2) International Center for Climate Change and Development (ICCCAD), Dhaka, Bangladesh

Facing critics and distrusts towards a "Northern Science" accused to mainly follow Northern interests (Lahsen, 2004), IPCC strove to better include Southern Scientists in report production (Dahan, 2008). However, as noted in its fifth report (WGII), there remains a North-South inequality in research production and access, in spite of a raising involvement of Southern Scientists. This discrepancy is both rooted in research funding and limits of capacity (Burkett, et al., 2014).

The issue is thus particularly sharp for Least Developed Countries (LDCs), who are both the less responsible, the most affected and the less in capacity to forecast and respond to the impacts of climate change.

In parallel, this perspective led to a progressive construction of Southern capacities, both within UNFCCC (LDC expert group), Ministries (focal points to implement NAPAs) and among civil society (academics, think tanks, NGOs). Beyond North-South cooperation for technological transfers and impact model regionalisation, the emergence of "bottom-up" approaches since 15 years, in particular «Community-based adaptation», deeply changed adaptation framing: this approach involves humanities and social sciences, jointly with the population and authorities actually living the models and striving to adapt.

Through examples from Bangladesh, one of the "hot spots" of adaptation, this talk aims at underlining the current development of Southern capacities that contribute to a "new geography of knowledge".

O-2239-01

Developing robust adaptation strategies: the importance of embodied knowledge, local knowledge and place attachment

R. Lidskog (1) ; P. Castro (2)
(1) Örebro University, Environmental sociology section, Orebro, Sweden; (2) ISCTE-IUL, social psychology, Lisbon, Portugal

This presentation focuses on the importance of including local knowledge in developing strategies for climate change adaptation. The background for this focus is that the current intertwining of, and reliance on, legal-institutional and scientific expertise in environmental policy-making often leaves little room for inputs from actors on local levels, although these many times possess detailed and relevant knowledge. Regarding climate change adaptation, research in both rural and coastal areas has recently shown how meaning and identity bonds to places (expressed in place memories, norms, narratives, identities and motives) indeed matter for adaptation. Whereas a number of studies have been conducted around place (mainly in terms of place identity, sense of place and place attachment) one thread seems however to be conspicuously missing: that of place knowledge proper. A reason for this maybe the epistemic division of labor in our societies where local knowledge is re-defined as a subjective and cultural construct, contrasting it with the "real", objective and universal knowledge provided by scientific expertise. At the same time there is an increased recognition both in science and society that environmental problems require elements of local knowledge for their solution; contextually generated knowledge about local circumstances and local practices are relevant because global risks always have local and place-specific implications. Local knowledge is bond to place through its relation to living; people live in specific places and gain embodied knowledge (not least in the form of routines and habits) about how things are and work in their local surroundings.

This kind of relations to place developed and supported through knowledge and their implications for addressing climate change adaptation are discussed by using findings

from two different studies in rural areas; i) a focus group study of farmers (N=50) conducted in Natura 2000 areas of importance for climate change adaptation; ii) a study of professional expertise (N=20) that try to persuade forest owners to consider climate change in their forest practices and a study of forest owners (N=15) in forest areas that are prognosticated to be heavily affected by climate change. Through these empirical studies, it is possible to gain knowledge both on how professional expertise try to approach lay actors on local level and on how farmers and forest owners acknowledge their situation as well as evaluate and handle knowledge claims for changed action provided by expertise. The analysis finds a number of strategies through which farmers and forest owners evaluate and negotiate expert claims, resulting in partial appropriation and partial rejection of them. By reclaiming their local knowledge, accentuating how this knowledge binds them to particular places and expressing their embodied and (em)placed knowledge, they re-signify and re-contextualise the original expert advice.

A central finding of this study is that it is not knowledge as a product or property, but as practice that matters when addressing issues of local adaptation to a changed climate. The reason for this is that knowledge is not distributed and transferred in a mechanical way, but is instead actively appropriated and thereby also transformed. In this dynamic process, different kinds of epistemic bonds are central. Thus, by focussing on knowledge practices – how knowledge is developed and appropriated in different institutional and spatial settings – the knowers and his/her knowing are put at the centre, and these practices constitute an important condition for developing adaptive strategies and measures to be implemented locally.

O-2239-02

Blending local and scientific knowledge to support innovative action by community-based institutions to adapt to global change

R. Reid (1)
(1) Colorado State University, Dept. of Ecosystem Science and Sustainability, Fort Collins, United States of America

Today, scientists, government officials, community members and non-profits work together to blend different knowledges and apply this joint understanding to real world problems concerning global change in local social-ecological systems around the world. This transdisciplinary work often starts with explorations of different ways of knowing and what constitutes 'truth' in the cultures of research, practice and those of other stakeholders. Teams of 'boundary spanners' often lead this work and attempt to not only reach across disciplinary boundaries in academia, but the many institutional, jurisdictional, political and other boundaries that occur in practice when working in social-ecological systems.

At the community level, innovative institutions are arising to improve the sustainability of local systems, sometimes strengthened by the decentralization and devolution of power in different settings globally. These institutions are often led by local community members collaborating with diverse stakeholders at different scales. This is creating a revolution in the ability of local actors to respond to global and climate change in local land-, lake- and sea-scapes.

Here, I describe some principles and examples of the models that different transdisciplinary teams are using around the world to bring together diverse knowledges and create innovative solutions to global change problems. These include different practical methods like workshops to brainstorm research questions and methods, practitioner or landowner-led research projects, integrated practitioner-researcher field teams, 'what does it mean' workshops to interpret data, and co-production of knowledge products. I then review several models for integrating different knowledge sources and co-producing knowledge, based on case studies. I will conclude with a description of future directions for co-production and the potential for co-produced knowledge to be a catalyst for social change when working on global change issues.

O-2239-03

Building Institutional Capacity for Climate Change Policy: The Chilean Experience in Co-producing knowledge for acting

P. Calfucoy (1)
(1) MAPS Programme, MAPS Chile, Santiago, Chile

Chile, as part of its climate change policy, assumed in 2010 the challenge of generating evidence nationwide to project long-term scenarios and options for mitigation of greenhouse gases (GHGs), in order to support its position in the international negotiations on issues of climate change and simultaneously, evaluate alternatives that contribute to a low carbon development for the country.

This effort, was materialized in MAPS – Chile, a project of South-South cooperation with South Africa, Brazil, Colombia and Peru, in which a process of scientific research was integrated with multi stakeholder participation to estimate the baseline emissions of the country and to evaluate mitigation actions and scenarios that might contribute to a low carbon development path.

MAPS Chile integrated a logic of co-production of knowledge with the participation of national scientist, policy makers and experts from the academia, the public sector and NGO`s under the coordination and policy guidance of the State of Chile. The project was successful, giving its results were used to define the Contribution proposal to be presented at COP 21.

From the perspective of sociology of science and technology, the analysis of this experience seeks to deepen in the understanding of mechanisms and methodologies for the formulation of policies on climate change in developing countries. Centered on the concept of Co-production (Jasenof, 2010), the analysis focuses on the governance structure of the project, the strategic decisions, and the methodology that articulated the interaction between institutions and individuals who participated, to finally identify the main strengths and weaknesses to inform climate change policy in developing countries.

The methodological approach for the study was qualitative. I apply content analysis using secondary data together with discourse analysis from semi-structured interviews that allowed knowing the perceptions and opinions of the participants in the project.

Among the main results of the study, I highlight:

i) The valuation of the participants of the process of opening the black box of modeling. The co-production of knowledge was understood as the exercise of defining between the scientist and the stakeholders the main assumptions, evaluating in conjunction the quality and availability information and making explicit the scope and limitations of the methodologies used. This, according to interviewees, allowed a better understanding for non-experts of the constraints and opportunities for sectorial and macroeconomic modeling. Additionally, this process provided credibility and validity to the results, while recognizing the levels of uncertainty intrinsic to this type of research. The methodology generated procedural legitimacy to the results. The agreements thorough the participation process about the key parameters that will be used in the modeling process, facilitate the recognition of the results. The project successfully validate their interim decisions and to rest the legitimacy and validity of their results in their agreements.

ii) The valuation of the participants regarding integrating local knowledge: The process of building the results with the participation of local researchers and experts contributed to a better understanding of the micro dynamics of the sectors, a better understanding of the country's productive structure for estimating emissions and the technological and feasibility constraints. In particular, the discussion about the penetration rates of potential mitigation actions are valued as an exercise done by the incumbent people and not imposed by external actors, outside the country's reality.

iii) The valuation of strengthening decision-making in the public sphere by enriching the understanding of the causes of the problems, their dynamics and implications. The exercise of co-production facilitated the socialization

of complex results because of the opportunity of learning gradually in the process. It includes the «opportunity to learn from the dynamics of other sectors», «the opportunity to visualize areas of complementarity with other colleagues and topics» «The opportunity to learn from methodological tools».

O-2239-04

Strengthening the science-policy interface for climate change adaptation at the regional level

H. Dannevig (1)
(1) Western Norway Research Institute, Sogndal, Norway

Despite a vast amount of scientific knowledge, society is unable to properly address the pressing issues of adapting to climate change. Planned adaptation, or adaptation planning, is a policy issue which owns its existence to climate science and it is comprehensible only through abstract scientific models. Adaptation planning therefore involves translations of these, as well as assessments of risk and uncertainty, and in order to support these processes, various institutional arrangements for the strengthening of the science-policy interface have been developed (Hoppe & Wesselink 2014). The Intergovernmental Panel of Climate Change (IPCC) is itself an example of this. While there has been widely recognized that planned adaptation to climate change is a multi-level governance issue (Keskitalo 2010), research on adaptation governance has tended to focus either on the local or the national governance levels; while regional adaptation governance have seen limited attention (Hanssen et al. 2013). The local level of government on the other hand has been deemed a key actor in the governance of adaptation. In the case of Norway, as in most western industrialized countries, there is a strong belief that the local level of governance has the key role in this respect. But despite large efforts from national government agencies and the research community in supplying local government with tailor-made and downscaled climate change projections and comprehensive guidelines, climate change adaptation is still lacking. As a response to the mixed success with municipal adaptation integration, there has been called for stronger involvement of the national level (Amundsen et al. 2010), stronger coordination between levels and across sectors (Hanssen et al. 2013) and a strengthening of the knowledge provision through various boundary arrangements that links experts and knowledge users for the purpose of production of knowledge for policy-making (Corfee-Morlot et al. 2011). This paper contributes to existing research on climate change governance by examining how regional government in Norway has interpreted its role in coordinating climate change adaptation in spatial planning policy networks. Drawing on concepts from research on boundary work, it critically assesses how regional government in Western Norway configured boundary arrangements between scientific and policy communities. This is addressed through an analytical focus on the nature and extent of boundary work, i.e. the translation, mediation and communication (Cash et al. 2003), that regional government actors engage in through their application of policy coordination instruments. Empirically, the research involves a review of on-going spatial planning processes in six municipalities from four counties in Western Norway. The study concludes that even though adaptation is not treated as a salient issue in most municipalities, the regional adaptation governance coordination is creating a hybrid management space that aid mediation between the local users knowledge and expert adaptation knowledge, and thus hold the potential for better local level adaptation planning.

P-2239-01

Current adaptation practices: case studies in France, Portugal and Greece

A. Bailly (1) ; A. Lillebø (2) ; T. Paramana (3) ; C. Parrod (4) ; S. Luís (5) ; A. Stépanian (6) ; G. Le Cozannet (7)
(1) BRGM, ORLEANS, France; (2) University of Aveiro, Department of biology & cesam, Aveiro, Portugal; (3) National and Kapodistrian University of Athens, Faculty of Geology and Geoenvironment, Laboratory of physical geography, Athens, Greece; (4) Acteon, Colmar, France; (5) ISCTE-Instituto Universitário de Lisboa, Libon, Portugal; (6) BRGM, Marseille, France; (7) BRGM / CNRS, BRGM-DRP-R3C / CNRS-LGP (UMR-8591), Orleans, France

The warming of the climate system is now unequivocal and a strong warming of air temperature as well as an acceleration of sea-level rise is projected in the Mediterranean regions of Europe (IPCC, 2013). At the same time, adaptation measures are being set up to cope with the impacts of those changes on both the environment and the society. To which extent do these adaptation policies actually meet the challenge posed by future climate change? To answer this question, a detailed understanding of the current practices of adaptation is needed, as well as a comprehensive view of how this adaptation is perceived by its main actors. However, such information is lacking at present. Therefore, a literature review has been combined with 47 semi-structured interviews conducted on three coastal sites in France, Portugal and Greece, where different approaches toward risk prevention and adaptation to climate change are in place. In order to identify gaps between the theoretical framework and the practical situation at local scale; the interviewees have been asked with their general knowledge of climate change (present and future changes) and on the existing and desirable adaptation policies / measures.

The interviews and the literature review underline similarities and differences in the countries approaches, organization and awareness. France, Portugal and Greece have different level of national policies development regarding climate adaptation and climate change awareness can be influenced by local in situ situations. But even when climate change and climate adaptation are subjects of concern, a lack of concrete "local" implementation is pointed out by stakeholders, as very few adaptation measures have been implemented yet. Indeed, climate adaptation is recognized as a traversal issue by the interviewees. Hence, related policies have to fit within already developed and complex sectorial legal frameworks related to water management, risk prevention, health, environment and so forth.

Literature review and stakeholders interviews both highlight the time scale issues related to difference between climate change and political mandate's time horizons. They also stress a gap between science and non-scientific local stakeholders for expected knowledge and actions, and this gap tends to be reinforced by the complexity of the legal framework for climate adaptation. This complexity is particularly pointed out by interviewees acting at regional and local scales in France, which is the country where adaptation to climate change has been the most considered in various regional sectorial policies.

To overcome these specific barriers to adaptation, the interviewees suggested that one first step could be the creation of interest groups at regional level, gathering all concerned actors and a complementary lead could be to adopt laws at the national level to incite local authorities to act together with regional actors. The next step would then be to design adaptation measures and to assess their

efficiency.

This work has received funds from the ADAPT-MED project (CIRCLE2-MED).

Vulnerability as Transformation: Photo-voice Adaptation in the Philippines

Y. Cai (1)
(1) University of the Philippines, Diliman, Women and Development Studies, Quezon City, Philippines

In this participatory action research (PAR), the author rethinks the role of vulnerability in the framework of transformative adaptation through the application of Photovoice in three disadvantaged urban communities in the Philippines. Few planning scholars and practitioners have developed systematic adaptation models and tools to address climate-related risks and vulnerability from the local perspective. This research explores disaster risks and capacities for adaptation through the lens of a marginalized population and emphasizes vulnerability as the transformational factor for innovative adaptation. The Philippines has faced frequent and devastating typhoons and raging floods, especially in the past few years, which have killed thousands and destroyed millions of homes and businesses. Climate risks as well as adaptive capacities of vulnerable populations, such as women, have been overlooked or even distorted. During a one-year period, this research project provides disadvantaged community members with digital cameras (through smart phones) and fundamental training, facilitates them to cultivate narratives and social media networks, and encourages communities to develop action mechanisms for disaster preparedness, mitigation, and recovery. Through an empowering Photovoice approach, it reveals climate risks and capacity building of a disadvantaged population in metropolitan Manila and Cebu City. Disadvantaged participants facing frequent climate hazards embody resilience via flexible and entrepreneurial strategies. It demonstrates the missing perspective of the current climate adaptation framework: vulnerability can transform creative and collaborative adaptability.

P-2239-03

Evaluating the Resilience of Traditional and Non-Traditional Family Farming Systems in Mountain Areas of Peru

E. Chavez (1) ; G. Quartieri (2) ; O. Madalengoitia, (3) ; E. Michaud (1)
(1) National University of San Marcos, Faculty of Veterinary Medicine, OIKOS Asociation., Lima, Peru; (2) IUSR http://www.unisrita.it, PHYSICS, SAN PIETRO INFINE (Caserta), Italy; (3) OIKOS, LIMA, Peru

The mountain agricultural systems of Peru could help to improve the resilience facing the climate change. These systems, mostly of them kept in familiar farming milieu provides ecosystem services (like water basin conservation) and with a low carbon impact, have potential to improve mountain resilience, conserve the biodiversity, and improve the food security. The presentation is focused on comparing the hydro-management, food security and energy consumption of two types of production systems. One based in the use of petrol derivate and «modern» techniques and another based in the recycle of products and with the use of traditional knowledge.

The central Andean region (covering Peru, Ecuador and Bolivia), is one of the world's centers of origin and domestication of animals and plants. In this region the domestication processes innovated the use of traditional and particular agricultural system by means of techniques, experiences and improvement processes.

These systems are part of our bio-cultural history that has been created by people in thousands of years as a result of the interaction of Andean people and its diverse environments. These systems, mostly of them kept in familiar farming milieu, have an enormous potential to improve mountain resilience, conserve the biodiversity, and improve the food security in these key loci. However there are many drivers (included the climate change and wrong federal management) that jeopardize the continuity of this farming systems.

Given that 79.3% of agricultural units in Peru are family farms, this presentation will analyze water management practices amongst traditional family farmers and compare these with the practices of modern settles to analyze whether and how they improve resilience to water scarcity. Likewise, the research will compare strategies for achieving food security and identify potential drivers of food security risk resulting from climate change. Energy consumption between these two groups will also be compared, based on the assumption that traditional farming systems do not employ petroleum derivate products as an agricultural input, instead using traditional knowledge and its techniques, practices and production processes.

Lessons from local adaptation governance experiments in Quebec (Canada)

G. Cloutier (1) ; J. Glowacki (2)
(1) Université Laval, École supérieure d'aménagement du territoire et de développement régional, Québec, Québec, Canada; (2) Université Laval, Québec, QC, France

Adapting local areas to climate change is a wicked problem for local policy makers, as it involves a continuous struggle between the collaborative efforts of multiple stakeholders, the changing of mindsets, the lack of resources and the difficulty in deciding between alternative planning scenarios. Even if the percentage of local governments involved in one way or another in adaptation planning is high, most initiatives never leave the drawing board. This can be attributed to the recent emergence of this concern. As well, the research conducted and the tools developed so far by researchers have little application that could help practitioners with their analysis of interactions between the various climatic impacts and their practices.

Also, decision makers involve, more than ever before, a variety of stakeholders in the decision-making process, following, in that sense, the collaborative planning prescriptions: citizen panels, public hearings, audits, charrettes, etc. contribute to reinforce public participation in local governance. These participation possibilities support, in return, the legitimacy, validity and sustainability of decisions taken. Despite this, development targets and public policies are not always consistent with local contexts and local initiatives. Gaps between theoretical objectives and daily life contribute to the shifting of climate governance outside of the institutional frame of action. This is true not only for climate change: the whole urban political space is moving outside of the traditional frame of action.

The discussion and reflection on how to act and adapt the local space to climate change take place on different grounds and through new modes of collaboration, which will be examined through the analysis of the presented case studies. In developing countries and in cities of the developed world, non-governmental organizations, regional governments or other development-based associations draw from and modify existing modes of governance in order to carry out climate governance experiments. Such experiments take form independently from national and international programs, they cross scales and jurisdictional boundaries and their goal is to contribute to the local community response to climate change. These efforts take inspiration from existing governance patterns and improve them. They offer local actors a possibility to coordinate and harmonize between different types of interventions, preoccupations and available resources without depending on public policies and intervention.

Local adaptation experiments are a way to explore original and innovative practices. Although experimentation has been shown to be a significant contributor to the augmentation of adaptive capacity at various scales, little research has been carried out on the analysis of current practices and what they can teach us about the mainstreaming of this process. This presentation will analyze two local adaptation experiments in Québec, Canada, which seek to adapt to increasing flood risk and the urban heat island effect.

How do such experiments take place? What data, expertise and financial resources are mobilized? What kind of institutional, organizational and economical contexts give way to these experiments? Based on preliminary results, this communication analyses the context and implementation of the two local adaptation experiments:

1) a local flood zone Committee; 2) an urban greening initiative. Content analysis, participant observation, a press review and site analysis, are used to highlight the experiment characteristics and to understand how experimenting contributes to enduring adaptation of local systems.

P-2239-05

Towards an International Sustainability Center Bretagne-Loire An international knowledge arena for global partnership and potential links to "Future Earth"

B. Grambow (1) ; E. Lorant (2) ; Y. Lagadeuc (2)
(1) Mines Nantes, Université Nantes, CNRS-IN2P3, SUBATECH, Nantes, France; (2) Université Rennes I, Rennes, France

Orienting research and educational programs to tackle society's major challenges, the new French federal university Bretagne Loire (UBL) is proposing to create the first International Sustainability Center, ISC in France as a highly visible cornerstone of its transdisciplinary IDEX initiative UBL+, focused on ocean/land/food/health/society. It is our belief that the proposed approach could very well be related to the "Future Earth" program in co-design & co-production of scientific knowledge on global sustainability.

UBL represents a very large territory of the size of Ireland with 27380 people working in research, 225000 students in higher education, and five laboratories of excellence in transdisciplinary focus areas (Ocean, Immunology, Nuclear Medicine, ICT and Mathematics), hosting 3 OSU and 4 Zones atelier, smart specialization fields in the area of sustainable agriculture, ocean and renewable energy. Acknowledging the limitations of current disciplinary oriented research and education systems to address global environmental change or global sustainability, UBL aims with the Idex proposition to forge a new type of university, establishing a solution oriented knowledge arena, of which ISC is a central part, increasing impact of leading edge research, cross scale system observation, learning, demonstration and exchange, accounting for the interrelationship between world oceans, global environmental change and climate, and environmental (soil, water, air), agricultural, urban, health and societal changes in our costal regions. The goal is to foster participative and international exchange between scientists, students and civil society, providing for scientific excellence in transdisciplinary studies of very complex global long-term systems, developping new pedagogical methods for transdisciplinary and international culture. Groundbreaking transdisciplinary science includes the need of opening up scientific disciplines to other ones (including numeric and social sciences), to other systems of thinking, and for dialog with stakeholders for joint problem framing, research definition and a plurality of interests on issues in sustainable development.

Inspired by and in collaboration with the Julie Ann Wrigley Global Institute of Sustainability (GIOS) of Arizona State University, the ICS shall become a Center for international meetings, exchange, research and education, focused on the link between transdisciplinary focus areas (oceans, land-sea interfaces and societies in transition; sustainably constructing food of future…) and the notion of sustainability. At the image of the global challenges to address, and with strong symbolic dimension, the place of the center «without walls» will be the entire regional interconnected territory, to offer an exceptional demonstrator in, for example, the major challenges linked to the land-sea continuum, the transitions to a sustainable urban planet, the question of food sustainability and health, digital transition and culture etc., assuring effective linkage between social challenges, transdisciplinary focus areas and territorial development.

The buildup of the ISC will start from partnerships already in existence and propose new international partnerships (ASU, the University of Colorado, Anglia Ruskin University, and French Guyana, University of California, U Laval etc.)). The "Future Earth" program provides an appropriate frame for fully integrating the global mission in the ISC orientations, with contributions by civil society, including NGO, ("co-production of knowledge") to the research process (participative investigations) concerning issues that have a major impact on society (e.g. integrated management of a coastal zone or water).

A typical example for the importance of "Future Earth" program is already in discussion between UBL and ASU/GIOS: the question is how to transition to a future that will be driven by the dynamics of urbanization. The InCAS and other mechanisms will be critical for building the international network and developing the critical questions to develop the world's best program in urban sustainability within Future Earth. Another "demonstration project" could be an observatory (without walls) able to assess long term trends in local and large scale ocean/land distribution pattern of toxic, radiotoxic and nutrition elements and its spatial and temporal variation at local and regional scales including water, soil, plants, trees, animal and human contamination indicators in urban, agricultural, littoral and mining environments, considering biodiversity and food chain sustainability

P-2239-06

From Household Coping to Community Based Adaptation: individual, communal and institutional responses to climate change by low-income households in Khulna, Bangladesh

AN. Haque (1)
(1) University of Cambridge, Geography, Cambridge , United Kingdom

The relationship between "coping" and "resilience" increasingly features in academic, policy and practical discussions on adaptation to climate change in urban areas. This study examines this relationship in the context of households in "extreme poverty" in the city of Khulna, Bangladesh. It draws on a quantitative data set based on 550 household interviews in low-income and informal settlements that identified the extent of the underlying drivers of vulnerability in this setting, including very low income, inadequate shelter, poor nutritional status and limited physical assets. A series of focus groups were used to explore the ways in which physical hazards have interacted with this underlying vulnerability, as a means to understand the potential impacts of climate change on this particular group of urban residents. These outcomes include frequent water-logging, the destruction of houses and disruption to the provision of basic services. The main focus of the paper is on describing the practices of low-income urban residents in responding to climate-related shocks and stresses, placing these in a particular political context, and drawing lessons for urban policies in Bangladesh and elsewhere. A wide range of specific adaptation-related activities can be identified, which can be grouped into three main categories – individual, communal and institutional. The study examines the extent to which institutional actions are merely "coping" – or whether they create the conditions in which individuals and households can strengthen their own long-term resilience. Similarly, it examines the extent to which individual and communal responses are merely "coping" – or whether they have the potential to generate broader political change that strengthens the position of marginalized groups in the city.

The vulnerability of individuals, communities and cities to climate variability and change is an outcome of the interaction between an external threat or hazard and the internal characteristics of a system. For residents of low-income and informal settlements in urban areas in the global South, these internal characteristics – which may include limited income, few assets and poor provision of basic services – are particularly important in shaping the consequences of climate-related hazards. Similarly, effectively responding to climate change requires not only addressing the direct outcomes of particular events but also more generally building the resilience of marginalized and vulnerable groups. This study examines these underlying drivers of vulnerability as they affect extremely low-income residents of the city of Khulna, Bangladesh – and the individual, communal and institutional responses to these. The analysis contributes to an understanding of the dynamics of climate change impacts and responses in rapidly growing urban centres in Bangladesh, and to the relationship between urbanization, poverty and climate risk throughout Africa, Asia and Latin America. More specifically, however, it examines the potential for actions taken at the household and community level in urban areas to go beyond offering short-term "coping" solutions in response to specific events, resulting instead in more transformational changes that address the underlying

drivers of vulnerability.

P-2239-07

Exploring the preconditions for transformative change in the context of climate impacts and adaptation

G. Hovelsrud (1)
(1) University of Nordland, Faculty of social sciences, Bodø, Norway

While climate change is projected to substantially influence primary industries in the northern regions climate change is not perceived to be an immediate concern when compared to outmigration, jobs, and the social and economic viability of municipalities (Hovelsrud et al. 2010). This relates to the apparent disconnect between the abundance of scientific knowledge about climate change, the overwhelming evidence that such changes are caused by human action and the general societal response and political commitment to deal with the challenges (Hulme 2009, Jasanoff 2010; Szerszynski and Urry 2010). And mainstream political science and governance theories fail to explain why people and institutions do not act on climate change (O'Riordan & Jordan 1999).

In this presentation we draw on a broad range of adaptation studies; a useful starting point for studying preconditions for transformative processes. One of our findings inspiring this study is that the perceptions of high resilience towards climate risks are expressed in the narrative «vi står han av» – "we always handle hardship", reflecting deep seated perceptions of resilience, linked to high variability in resources, climate and socio-economic conditions. This phenomenon has by others been attributed to different understandings and interpretations of reality between groups of people or individuals. If climate change is not perceived sufficiently salient to warrant action, resilience may decrease and societal transformation may not be possible. It is a major challenge that the climate change message and the need for societal change do not resonate well with many parts of society, combined with the findings that adaptation is not likely to take place without stronger policy measures (Dannevig et al. 2013, Tøsse 2012). On the other hand adaptation is taking place and has been associated with extreme events, observations of change, engaged officials and contact with researchers, which is reflected in the finding that society needs to better understand how climate change will affect them directly (Dannevig et al. 2013). How climate change knowledge is co-produced by science and policy we argue will be filtered through current perceptions and values, influencing their potential for transformative responses.

Perceptions of risks and the need to act on the basis of scientific knowledge hinge on whether scientific knowledge is viewed as salient, credible and legitimate (Cash et al. 2003) and on the individuals' risk perception, norms, values, culture and livelihood (O'Brien & Wolf, 2010, O'Riordan & Jordan 1999). The presentation will investigate the interplay between the local and national levels in providing salience to the climate change issue. We surmise that perceptions of risk have a bearing on the observed inertia in society to respond to the overwhelming evidence of climate risks. We analyze this inertia by applying the cultural theory of risks (CTR) to our empirical findings.

Processes for self-determined transformative adaptation: The learning journeys of small scale farmers in the arid west of South Africa

B. Koelle (1) ; N. Oettle (2)
(1) Indigo development and change, Nieuwoudtville, South Africa; (2) Environmental Monitoring Group, Rural Programme, Nieuwoudtville, South Africa

A group of small-scale rooibos tea farmers embarked on a transformative adaptation journey more than 15 years ago by defining their community vision. This community is situated in the Northern Cape Province in South Africa and is severly affected by climate variability and change.

Today significant changes can be seen on an individual and communal level. This paper explores the aspects of the learning journey, using the results of qualitative interviews that have been conducted in the course of the past 15 years with various community members. Three key areas are examined: drivers of transformative processes on the personal and communal level, the role of experiential learning in transformative adaptation processes and ways of facilitating transformative adaptation processes.

At the start of the learning journey the Suid Bokkeveld community was socially and politically disenfranchised and economically margnialised. A participatory process facilitated by two local NGOs supported locally driven action research processes, the establishment and organisational development of a local trading co-operative owned by the farmers themselves. Embedded in these processes were opportunities for personal transformative learning specifically focusing on women within the Suid Bokkeveld community.

The paper explores enabling factors for communal and transformative adaptation in local communities, including sharing knowledge and insights with other communities, stimulating personal development and learning, supporting action research processes to develop adaptation strategies drawing on different types of knowledge (scientific and local knowledge alike). Participatory and experiential learning processes have been a key component and included participatory monitoring of livestock exposure to extreme heat stress, monitoring of water resources on farm level and local level weather monitoring. These processes carefully examined the impact and possible responses to climate extremes in order to plan ahead and be prepared for these possible shocks.

Using the transformative journey of the Suid Bokkeveld as an example, approaches and tools for facilitating transformative learning are discussed. These approaches include facilitation of the articulation of a collective vision for effective adaptation, the communication of climate information on the local level, ownership of learning processes by vulnerable communities and ways of facilitating reflective learning processes for transformative adaptation.

Model Forests and Open Collaborative Science: empowering stakeholders to adopt transformative adaptation practices

J. Lorenzo (1)
(1) CATIE – Tropical Agricultural Research and Higher Education CEntre, Turrialba, Cartago, France

This presentation is related to an ongoing project which is being implemented in two Model Forests of Latin America (in Costa Rica and Colombia). Model Forests are social initiatives which aim at improving governance and the sustainable management of natural resources within forest-rich territories (www.bosquesmodelo.net). Through an Open Collaborative Science (OCS) approach, the project pursues several objectives, including fostering participation and "citizen science" as well as improving

adaptive capacity of local communities within the Model Forest territories by opening up the research process related to climate change.

The contribution presented will describe the context of the study and approach being taken within the specific project and how it can potentially help to tie knowledge to local problem-solving by increasing stakeholders participation in different aspects of the research lifecycle, through establishing a more interactive relationship between citizens and the academia. It is based on the belief that research and education need to be adapted to new realities, and has a strong capacity-building and knowledge-sharing component. It is also based on the premise that adaptation should be holistic, taking into account all aspects of life.

This work is part of the recenlty launched Open & Collaborative Science in Development Network (OCSDNet) research project, supported by Canada's International Development Research Centre and the UK Government's Department for International Development (www.ocsdnet.org).

Addressing the research evidence needs for evidence-informed city resilience planning: Insights from Shimla city, India

J. Patra (1)
(1) Shimla Municipal Corporation, Climate Change Resilience, Shimla, Himachal Pradesh, India

Cities, the engines of economic growth and centres of innovation, are at greater risk of climate-induced changes. In a rapidly urbanizing India, key urban functionalities and infrastructure facilities are highly exposed to climate-related hazards and extremes. Two recent natural hazards in India, the Kashmir Floods (September 2014) and the Cyclone Hudhud (October, 2014) have highlighted how urban centers are witnessing a new regime of disaster and climate risk. Urban development is one of the key priorities of India's government and the new initiative of 100 Smart Cities is a step in that direction. Climate resilient urban development strategies are the core of this initiative. But one of the key challenges that policy makers, city authorities, planners and investors face is with regard to availability to robust, reliable and relevant climate risk information at the city level. Although city level climate risk assessments are being undertaken by many scientific and research organizations, most of these information hasn't been able to address the needs of city authorities and planners. How do we address these gaps in evidence-informed city resilience planning in a developing country context? Based on a systematic analysis of research evidence needs of city-level stakeholders in the capital city of Shimla in the climate-sensitive Indian Himalayans, including city authorities, this paper highlights a series of barriers, individual and institutional, that result in such gaps. It also underscores some of the emerging opportunities through which the science and research communities could better understand and address the information needs of the policy makers and urban practitioners. More importantly, it demonstrates how such a city-level institutional system could open up new windows of opportunity to mobilise partnerships and resources for city resilience planning and implementation.

P-2239-11

Our common future, our common Global. Assessing Sustainability of local production systems: A proposal based on socio-ecological resilience and collaboration

RA. Seiler (1) ; MB. Wehbe (2) ; A. Vianco, (3) ; A. Mendoza (3) ; A. Baronio (3) ; A. Tonolli (4)
(1) Agrometereology, Agriculture, Rio Cuarto, Argentina; (2) Economic Science, Economy, Rio Cuarto, Cordoba, Argentina; (3) Econometrics, Economy, Rio Cuarto, Cordoba, Argentina; (4) Agricultural engineering, Engineering, Mendoza, Argentina

Sustainability and resilience are key conditions for reaching a balanced functioning of socio-ecological systems, facing internal conditions and external shocks like those expected from climate change. However, there is no agreement on how to get a good measure for both concepts to allow for managing local production systems. As result of a two-year research a methodology for assessing sustainability was developed based on a collaborative process between science, policy and civil society to improve resilience, and therefore sustainability of local production systems according to the internal conditionings to the system and the impacts of climate change and other global environmental changes as well.

The presented work is a joint contribution from an interdisciplinary research group from seven universities in the Centre-West of Argentina, and summarizes the analytical and methodological procedure to assess sustainability, based on the concept of resilience of socio-ecological systems. The four dimensions of the sustainability (ecological, economic, social and institutional) and their relationships are organized in a Sustainability Matrix which shows, on the one side, the Aggregated Demands from each dimension to the other dimensions, and on the other, it shows the actual contributions to Human Wellbeing. Within the matrix, a number of components (e.g. water, soil, air, and biodiversity, for the ecological dimension) need to be defined according to pre-established criteria for each of the dimensions. These components, expressed through one or more indicators (e.g. for "water", indicators of quality, quantity and source would be needed) are to be related to the rest of components in the Matrix aiming at identifying synergies and trade-offs.

The components in the Matrix are not fixed but they depend on the characteristics of the production system or of the region under analysis. The Principal Diagonal of the Matrix tells on the state of the system or the baseline for each dimension through the set of components under the same stated criteria. The rest of the Matrix establishes relationships among dimensions and their components. As a way of exemplification, it is possible to think about the demand of a production system in terms of the availability of particular natural resources to develop the production process. The existence and specificities of natural resources spatially distributed determine not only the characteristics of an ecosystem but also the potential of the production system to develop, as well as the limits to such a development. The same methodology applies for all the relationships among dimensions.

The value of the methodology and its sensitivity rests in an exhaustive knowledge of the productive systems under analysis and of its functioning. As a matter of fact, scientific interdisciplinary groups, citizens, firms, NGOs, and the government, are required to participate in collaboration through bridging organizations to establish proper relationships between dimensions, the components of the systems and the variables/indicators for accurately assessing each of the components.

Finally, the sustainability indicator to be constructed is a relative measure to its potential value and indicates the current position of the system in terms of its desired state. The inter-temporal and regular application of the methodology will determine an accurate evaluation of a system's dynamic towards sustainability.

P-2239-12

Climate Change Research and Communication: Exploring potential connections

DL. Taina (1)
(1) State University of Campinas, Campinas, Brazil

In face of the delicate moment in which we live through the effects of climatic alterations and the intensification of extreme phenomena, the circulation of information about climatic changes is becoming increasingly important. How can we think about the communication of climatic changes as a potent and effective movement to provoke broader reflections on the subject? In our research group at the State University of Campinas, in Brazil, we participate in the scientific research of climate change, as well as study communication proper, combining to create an important field for reflection and the assembly of knowledge in connection with different areas, such as natural sciences, political science, sociology, philosophy, arts and multimedia. Confronting the complexity that is involved in the subject of climate change, we look to construct interdisciplinary researches and creations, in which we focusing important questions and concepts that cross climate change approaches.

Every day we are drowned by the excess of information and news of climatic catastrophes, scenes that show places devastated by natural disasters, such as dried up rivers, water shortages in cities and the melting of polar ice caps. These images and information create narratives and stories about the potential end of the world. And often, these stories possess sterilizing effects by creating the sensation that nothing can be done because the scale of the problem has already become so big to the point that we don't know what actions to take and therefore become paralyzed. In this context we look to think critically about the quality of the information that is being produced about climate change, seeking to think of communications that create other possible narratives and stories to stimulate other types of thinking related to the environment, to the climate and life. We believe as the author Donna Haraway suggested, with her challenge to live "with the problem" of climate change and create "other possibilities" in the face of these sterilizing stories. We shouldn't think that there's no way out, but rather we should create multiple ways out, developing other trains of thought and new collective actions to deal with the climate changes already in motion.

It's with this intuition that in our research we seek to create other means, together with communication, telling new stories and establishing connections with different ways of knowledge. We believe in the interaction between art, communication and science as a powerful possibility to disseminate new scientific findings in a different approached. In this sense, we developed productions that seek to provoke distinct experiences with climate change communication creations like videos, reports, art installations, and workshops. We are developing a video collective creation workshop named TransClimatic VideoNarratives that we will work aesthetic and videos concepts to create new stories with the public. How do people understand and interact with the climate and nature? How can we establish relationships with water and heat, and how can we establish connections with the climatic elements and feelings that they can generate? Therefore, we aim to study possibilities of generating knowledge from sensory experiences in order to enfold climate change subjects through different approaches, seeking to contribute for the dissemination of knowledge and promote public participations. Our studies integrate the activities of the sub-group Scientific Communication and Climate Change from the Brazilian Network on Global Climate Change Research (Rede CLIMA).

2240 - Perceptions of climate change

International Perceptions of Climate Change Over the Past 25 Years: A Review

W. Poortinga (1) ; S. Capstick, (2) ; L. Whitmarsh (3) ; N. Pidgeon (2) ; P. Upham, (4)
(1) Cardiff University, Welsh School of Architecture, Cardiff, United Kingdom; (2) Cardiff University, School of psychology, Cardiff, United Kingdom; (3) Cardiff University, School of Psychology, Cardiff , United Kingdom; (4) University of Leeds, School of earth & environment, Leeds, United Kingdom

The ways in which individuals, societies, and polities respond to climate change are in many cases contingent on public perceptions of its causes, consequences, and wider implications. Understanding popular opinion on climate change is therefore critically important to enable a social transformation to a low-carbon economy. Public perceptions of climate change are known to differ between nations and have fluctuated over time. Several explanations have been put forward for these variations. With over two decades of research on public perceptions of climate change, we are now in a position to take stock of the key trends over this time period and the factors behind the changes. In this contribution we will present the findings from a systematic literature review of studies that have used longitudinal methods to examine changes in and drivers of public opinion on climate change. In this review we consider early, seminal work on public perceptions of climate change from the 1980s onwards, and national and international surveys with a longitudinal component. Studies point to growing scepticism in the latter 2000s in a limited number of developed countries. However, most parts of the world have seen growing concern about climate change in same time periods. We conclude that the imbalance in the literature toward polling data, and toward studies of public perceptions in Western nations (particularly the United States), leaves much unknown about the progression of public understanding of climate change worldwide. Furthermore, more research is required that uses inferential statistical procedures to understand the reasons behind trends in public perceptions. (Session 2240 - Perception of climate change).

Public perceptions of weather and climate change in the United Kingdom

W. Bruine De Bruin (1) ; AL. Taylor (1) ; S. Dessai (2) ; C. Lefevre (3)
(1) Leeds University Business School, Centre for Decision Research, Leeds, United Kingdom; (2) University of Leeds, Leeds, United Kingdom; (3) Northumbria University , School of psychology, NewCastle, United Kingdom

BACKGROUND.
Public perception surveys in the US have suggested that Americans' concerns about climate change are related to their experiences of very hot weather. Such findings raise questions about the climate change beliefs of people in regions with moderate climates, including the United Kingdom (UK). Indeed, our work has suggested that UK residents may actually feel good about the prospect of warmer summers (e.g. Lefevre et al., 2015; see also Palutikof et al. 2004). Such findings raise the question of whether other types of locally experienced weather may be associated with concerns about climate change, among residents of those countries. Indeed, relatively little is known about whether public concerns about climate change may also be associated with perceived changes in other weather-related events, such as heavy rainfall. We therefore examined (1) the extent to which UK residents perceive different types of weather and related events to have changed in frequency over the lifetimes; and (2) the relationship between perceived changes in the frequency of these events and climate change belief.

METHOD.
We report on an initial UK-wide survey that was conducted January/February of 2013, with longitudinal follow-up surveys occurring in October 2013, April 2014, and July 2014. These surveys contained items asking participants about the extent to which they perceived nine types of weather-related event to have increased or decreased in frequency over their lifetime (including heatwaves and heavy rainfall, among others). Participants also rated their concerns about climate change, using a reliable 3-item assessment.

RESULTS.
Our analyses showed that participants tended to perceive wet-weather and water related events (heavy rainfall, flooding, coastal erosion) to have increased in frequency over their lifetime, while hot summers and heatwaves were perceived to have decreased over their lifetime. Moreover, controlling for the effects of demographic variables and environmental values, we found that perceived increases in wet-weather were significantly associated with greater climate change concerns, with perceived change in the frequency of of hot-weather making a comparatively small contribution. These findings held in the initial survey as well as the longitudinal follow-up surveys that were held as the weather changed across seasons.

CONCLUSIONS.
We found that amongst UK residents, perceptions of wet weather and related events are more strongly associated with beliefs about climate change than perceptions of hot weather. These findings suggest that those seeking to communicate about climate change with audiences in regions with temperate climates should not limit their focus to heat-related impacts, but also emphasize other types of locally salient weather.

Analysis of factors shaping small-scale farmers' perceptions about climate change in South Africa: A behavioral approach

P. Hitayezu (1) ; E. Wale, (1) ; G. Ortmann, (1)
(1) University of KwaZulu-Natal, School of Agricultural, Earth, and Environmental Sciences, Pietermaritzburg, South Africa

Raising public awareness of the real threat posed by CC has been a common pledge in many countries' CC response policies. In many cases, however, tendencies by policymakers to overlook the differences in public opinions have resulted in policy inertia, passive resistance, and even active opposition. Therefore, effective CC communication requires a good understanding of public opinions and a recognition of individual variation in learning processes. In South Africa, for example, recent empirical studies have shown that small-scale farmers hardly recognize the patterns of local climatic changes. The studies, however, have simplistically argued that the misperceptions could be due to the complexity of biophysical processes that can be hardly discerned by farmers. They have often overlooked the importance of socio-psychological, institutional and cultural processes underlying individual perceptual formation.

Based on key insights of the behavioural decision research, this study investigated the affective, experiential, cognitive and cultural factors shaping the perceptions about climate change among small-scale farmers in the midlands region of KwaZulu-Natal, a major hotspot of climate change in South Africa. A principal component analysis of perceptions about climate change revealed two contrasting perceptual shapes. Whilst meteorological records indicated that the area has experienced drying trends in summer coupled with warming and wetting trends in winter over the last four decades, CCP1 score revealed inaccurately perceived trends of cooling and drying winters and warming and drying summers. CCP2 score exhibited stark similarity with meteorological observations.

Using a Double-Hurdle estimation strategy, the results of the Probit model suggested that climate change perception is triggered by emotive factors (holistic affect) and value judgement, as well as socio-demographic factors such age, gender, education, and agro-ecological conditions. In line with the conceptual expectations from the behavioural approach, the results of the Truncated regression model showed that the CCP1 score increases with holistic affect and inherently experiential socio-demographic factors such as, age, and distance to the rivers, whilst the CCP2 score is determined by cognitive and socio-cultural factors, including knowledge, education, extension, and trust.

Based on these findings, the study concludes with some recommendations for effective regional CC communication strategies that recognize individual variation in learning processes.

Mental models of climate change: Basis for risk evaluation, policy support, and message reception

G. Böhm (1) ; A. Bostrom (2)
(1) Psychology, Bergen, Norway; (2) Policy, Seattle, United States of America

Human behavior plays a central role in climate change risks. In addition to precipitating rapid global warming by burning fossil fuels, humans can also act to prevent, ameliorate or adapt to climate change and its consequences. It is therefore important to understand how people perceive climate change, its impacts, and the opportunities for and effects of human actions. Mental models are an essential part of risk perception; they shape subjective risk evaluations, policy preferences, and the reception of risk communications.

We present 3 studies in which we pursued three aims: (a) describe lay causal mental models of climate change risks, (b) relate mental models to risk judgments and policy preferences, (c) draw conclusions concerning the communication of climate change risks.

Study 1 (N=133) employs a cognitive mapping technique to elicit people's mental models. Participants also evaluated a set of climate change risks on several psychometric risk scales. Results show that mental models are structured according to a causal chain that ranges from attitudes via behaviors, pollution, and environmental impacts to impacts on humans. These components differ systematically in perceived risk and perceived controllability. Network analysis reveals that lay models tend to be simple and unconnected.

Study 2, an experiment with USA MTurk participants (N=892) suggests that even when controlling for causal beliefs, mindsets can have a significant effect on support for mitigative policies, but perceptions of the costs of action have a much larger deterrent effect on support. Study participants were assigned randomly to experimental conditions, two of which were designed to promote concrete, specific thinking, two to promote abstract, goal-oriented thinking. Participants in an abstract mindset were significantly more likely to support increasing taxes on fossil fuels. But the effect is much smaller than the association with perceived social and personal costs. Causal beliefs—such as that increasing taxes on fossil fuels will effectively slow or stop climate change—remain positively associated with support for such taxes, whereas political ideology drops out as a predictor of policy support, once mindset and other factors are taken into account.

Study 3, a cross-national survey, demonstrates the important role of risk perceptions and causal beliefs in the formation of policy preferences of economics and business undergraduates from six countries: Austria, Bangladesh, Finland, Germany, Norway, and USA (total N = 664). Five constructs were measured: risk perception, perceived causes, perceived consequences, perceived effectiveness of a set of policy actions, and support for the same set of policy actions. Regression analyses with policy support as criterion and the other factors as predictors show that policy support can be predicted by risk perceptions and causal mental models. In all analyses, adding perceived causes and perceived effectiveness as predictors adds significant explained variance. Perceived effectiveness is generally a stronger predictor than ascribed causes.

Taken together, the studies show that mental models shape both people's evaluation of climate change risk and their support for specific policy options. Causal beliefs seem more important that political ideology, but perceived costs may have deterrent effects. One implication of the results is that all communications must relate to people's mental models and that promoting an abstract, goal-oriented mindset strengthens policy support. Furthermore, communicating the effectiveness of policy actions may influence support for these actions more than providing other causal knowledge. Future research should address the exact mediating roles of mindset, perceived risk, causal beliefs, and perceived policy effectiveness in shaping policy support and the processing of communications.

Believing, Belonging and Behaving: Exploring Mismatch between Climate Change Perceptions and Individual Mitigation Behaviours across 27 European Countries

R. Muttarak (1)
(1) International Institute for Applied Systems Analysis, World Population Program, Laxenburg, Austria

Individual behaviour is key to CO2 emission reduction. Despite increased awareness of climate change, climate-related beliefs however do not always translate into actions. This study aims to explain the mismatch between beliefs and behaviours by investigating the role of individual socio-demographic, meso and macro level factors across countries and over time. The study employs a novel 3Bs framework -believing, belonging, behaving- originally developed to analyse religiosity in sociology to identify underlying drivers of climate-related actions at micro, meso and macro levels. According to the 3Bs framework, individual socio-demographic characteristics influence internal attributes e.g., values, knowledge and climate risk perceptions (Believing), which can trigger behavioural responses (Behaving). Similarly, external factors e.g., the institutional and cultural conditions of a social group, community and country where people belong (Belonging) mediate attitudes and behaviours. The empirical analysis

is based on the Eurobarometer surveys for the years 2008, 2009, 2011, and 2013 (Modules 69.2, 72.1, 75.4 and 80.2, respectively) covering over 100,000 respondents in 27 member countries of the European Union. Preliminary results show that women and the highly educated express greater concern about climate change and are more likely to undertake personal actions to mitigate climate change. The public concern about climate change however has decline, especially in the period after the 2008 financial crisis. There is substantial geographic variation for both perceptions towards climate change and climate-related actions, and, importantly, for the extent of the mismatch between attitudes and actions. For instance, residents in countries like Austria, Spain, and Slovenia have both a relatively high concern about climate change and a high proportion of individuals undertaking mitigation actions. On the other hand, a group of many new EU member countries such as Estonia, Latvia, Lithuania and Poland display both relatively low level of concern about climate change and low level of mitigation actions. Likewise, the same proportion of individuals from Luxembourg and Bulgaria (73.0%) perceived climate change as a very serious problem but only 30.8% of residents in the latter perform mitigation actions as compared to as many as 79.1% of the former. Understanding what barriers prevent individuals from some countries to take actions despite their climate change concern is therefore crucial for policy interventions.

Climate Change Perception and Adaptation Strategies In Osun State

R. Adeyemo (1)

(1) obafemi Awolowo University, Agricultural Economics, Ile-Ife, Osun State, Nigeria, Federal Republic of

The impact of a changing climate are already being felt in Sub Saharan Africa with more droughts, more floods on the coastlines of West Africa, more strong storms and more heat waves taxing individuals firms and governments, drawing resources away from developments. Continuing climate change at current rates will pose increasingly severe challenges for developments. Since over 90% of agriculture in Sub Saharan Africa is rain fed and water supplied are expected to decrease and to become more erratic in most regions, local water management such as micro-catchments, dams and tanks and small irrigation from underground water will be key opportunities for adaptation. Malaria is spreading to higher previously safe altitudes and becoming resistant to drugs.

The objectives of this research are to; determine farmers perception to climate change, based on farmers field experiences, explore innovative adaptation approaches needed in this kind of African environment and examine tested traditional knowledge useful for adaptation at the local setting

The study is based on four local government areas in Osun State. The areas comprise the food basket areas of the state. Structured questionnaires was developed to generate primary data which are complimented with secondary data. The data collected are subjected to descriptive and statistical analysis.

It is on record that agricultural productivity has declined in all the zones in Nigeria including the areas of study. The region economies are highly dependent on natural resources. This research will be able to indicate strategies for climate change adaptation in agriculture, what lessons have been identified and new innovative approaches that can be applied to similar areas in Sub Saharan Africa.

P-2240-02

Heterogeneity of climate change perceptions in two Caboclos' communities of the Amazon Estuary, Brazil

V. Zeidemann (1) ; O. Almeida (2) ; S. Rivero, (1) ; CM. Alvez-Valle, (3) ; N. Moreira, (4)

(1) Federal University of Pará, Economic Graduation Program, Belém, Pará, Brazil; (2) Federal University of Pará, NAEA, Belem PA, Brazil; (3) Federal University of Juiz de Fora, Ecology, Juiz de Fora, Brazil; (4) Federal Institute of Pará, Fishing resources, Belém, Brazil

There is a general consensus that peoples and societies perceptions are a necessary prerequisite for adaptation and responses to climate change (Maddison 2006, Brain et al. 2009, Capstick et al. 2015). However, climate change impacts, and consequently perceptions, are unevenly distributed with regional, and even local, disparities (Tambo and Abdoulaye 2013). For example, scholars suggest that farmers that have more experience are more likely to perceive climate changes (Maddison 2007, Silvestri et al. 2012). In addition, household characteristics, such as household head's gender, age, level of education, and access on information about climate change, have also been identified has important factors affecting perceptions of climate change (Deressa et al. 2009). Since adaptation to climate change comprises a two-step process: the ability to perceive changes, and subsequently, to respond to those changes, the understanding of the heterogeneity related to perceptions of climate change among individuals and societies is very important when fostering adaptation to climate change.

Our study aims to explore (1) how caboclos communities' residents in two islands of the Amazon Estuary, Brazil, perceived climate changes (2) how those perceptions varied among respondents and communities, and (3) what factors influenced perception heterogeneity to climate change. The caboclos communities studied have their livelihoods based mainly on açaí berries collection, fishing activities, and shrimp harvest. Therefore, we explore how those communities perceived climate change impacts, specifically temperature, rainfall and tide level changes, on those three economic activities, and what factors determine perceptions variation regarding the climate change impacts on those activities.

To collect data on how caboclos communities perceived climate changes on temperature, rainfall and tide level, and their impacts on açaí berries collection, fishing, and shrimp harvest, we applied structured interviews to 239 residents of Arumanduba and São João Batista communities, in the municipality of Abaetetuba, Pará state. Besides climate change perception questions, we also gathered information on gender, age, level of education, time of residence at the community, property size, and filiation to fishers association and workers unions. We also applied focus group discussions to further understand residents' perceptions.

Preliminary results showed that perception to climate chance varied according climate change type (temperature, rainfall, and tide level changes) and also on the type of economic activity being impacted by those changes. Gender and affiliation to fishers association and worker unions seems to influence perceptions regarding rainfall and tide level changes, but not on temperature changes. Further analyses will be performed to refine those preliminaries results, and also to determine if residents' age, level of education, time of residence, and property size affect their perception regarding climate changes occurring in the last 20 years, and on the impact of those changes on fishing, acai berries harvest and shrimp harvest activities.

Knowledge on how caboclos communities perceive climate changes and their impacts, but also the factors that affect the way those communities perceive those changes and impacts, are extremely important to assist policy aiming to foster adaptation and also decrease vulnerability of those communities to future climate changes.

P-2240-03

Has self-interest of climate scientist influenced their perceptions of global environmental change? A Rebuttal to climate change contrarians' allegation against climate scientists

HJ. Bak (1)

(1) Kyung Hee University, Center for Science, Technology & Society, Seoul, Republic of Korea

GEC is still controversial in the public in many countries, although scientists almost reached a consensus over the causes and results of it. One of the reasons is the attack against climate science and IPCC by climate change contrarians. They have claimed that mainstream

climate scientists, influenced by their interest of research fund and liberal political ideology, have exaggerated the seriousness of GEC for political purposes and made uncertain claim of anthropogenic global warming. Social scientists, historians, and environmental NGOs have counter-attacked these contrarians indirectly by debunking the influence of their own conservative ideological orientation, conservative think tanks, and the fossil fuel industry on their activity. However, little effort has been made to examine the validity of the contrarians' claim with empirical evidence: whether or not climate scientists' warning on GEC has been influenced by their own professional ideology and interests. Among many reasons, there is a serious methodological challenge to answer this question: it is difficult to know whether the high level of concern about GEC among climate scientists has resulted from their expertise (as most scientists claim) or their interests (as contrarians claim).

This study attempts to test the validity of the contrarians' allegation by taking an innovative way to separate potential influence of expertise from interests on climate scientists' concern about GEC. To use Collins and Evans (2002, 2007)' terms, this study classified a sample of Korean scientists (n=365) into three groups, 1) contributory experts who conduct climate research, 2) interactional experts who do not conduct climate research but have much knowledge on it, and 3) scientists-in-general who do not have much knowledge on climate change, and compared their perceptions/presentations of global climate change. In this way, this study attempts to distinguish the influence of expertise (contributory and interactional experts vs. scientists in general) and the influence of interests controlling for expertise (contributory experts vs. interactional experts). Using this classification of expertise, this study hypothesizes that, if scientists' interests of research fund have effect on their perceptions/presentations of GEC, contributory experts having such interests may perceive/present GEC as a more serious problem than may other scientists who do not have such interests. In particular, if the contrarians' allegation is valid, there should be a significant difference in the perceptions/presentions of GEC between contributory experts and interactional experts who have a high level of expertise in GEC but do not have professional interests in climate research such as research funding.

The results of this study demonstrates that there has been little difference in the perceptions/presentations of GEC among contributory experts, interactional experts, and scientists in general. The same was the case even when covariates such as gender, age, income, and political ideology were controlled for. These results therefore strongly suggest that the allegation against mainstream climate scientists made by contrarians was hard to find ground and that we should take climate scientists' warning agaist GEC more seriously. Perhaps, climate science has been politicized too much.

P-2240-04

The green of your eyes: Social judgments of different types of pro-environmental behaviours

R. Bertoldo, (1) ; P. Castro (2)
(1) ISCTE-IUL, Cis, Lisbon University Institute, Lisbon, Portugal; (2) ISCTE-IUL, social psychology, Lisbon, Portugal

There is today an international consensus on the fact that our societies have to alter the way they interact with the environment (IPCC, 2013). Today, environmental claims are part of our daily lives to the point that they integrate different types of environmentally significant behaviours (Stern, 1999): activist, non-activist and private sphere behaviours. A previous study has shown that pro-environmental behaviours can be associated with the perception of both competence and warmth - i.e., people that present them are seen as more competent and warm that people that do not. However, it is not tested whether if these pro-environmental behaviours were activist ones, clearly questioning the current state of affairs, they would still be regarded as competent and warm. Therefore, this study had the objective of comparing different types of environmentally significant behaviours in terms of their attribution of competence and warmth. To do so, we presented participants with a target that presented either an activist behaviours (demonstration), a non-activist behaviour from the public sphere (signing a petition), or a private sphere behaviour (purchase of organic products, recycling and saving water and energy). Then participants were asked to form an impression of the target and attribute to it adjectives from the competence and warmth dimensions. Results show that targets presenting any type of environmentally significant behaviour equally are seen as competent. Where targets are differentiated is in their perceived warmth: activist behaviours are seen as less warm than the others. These results confirm the distinction between perceived agency and communion. Given that all targets behave and demonstrate agency towards the environment, they are all seen as equally competent. But the activist target, which demonstrates intentions to change the current state of affairs, is seen as less cooperative and communal than the targets presenting pro-environmental behaviours form the private sphere. Implications of these results for the environmental social change are discussed.

Exploring The Concerns Of Emerging Climate Sceptic Groups Within Civil Society

M. Bliss (1)
(1) The REAL Institute, EDON, France

Exploring the concerns of emerging climate sceptic groups within civil society - a growing proportion of society are using the information age to research the past, observe the present and are subsequently becoming organised to protect the future, reflecting a perception of man's influence on climate change - whether intentional or unintentional.

P-2240-06

How do perceptions of climate change affect performance of risk management instruments & farmer welfare in Malawi?

R. Cavatassi (1) ; A. Cattaneo (2) ; J. Graff-Zivin, (3) ; N. Mccarthy, (4) ; L. Lipper, (5)
(1) Food and Agriculture Organization, Agricultural development Economics, Rome, Italy; (2) Food and Agriculture Organization of the United Nations (FAO), Agricultural Development Economics Division, Rome, Italy; (3) UC San Diego, Economics, San Diego, United States of America; (4) LEAD Analytics, Washington, DC, United States of America; (5) FAO of the UN, Agricultural development economics division, Rome, Italy

This paper provides new insights on how climate change affects Malawian farm households' risk management options. The options considered in our farm-level stochastic simulation model are (i) the adoption of risk-smoothing farm practices, (ii) diversification among crops, (iii) safety nets, and (iv) other public interventions such as improving extension and providing better climate information. A traditional risk management approach typically assumes that probabilities are known by all actors. However, climate change can affect the probability and severity of yield losses in ways that are difficult for individual farmers to incorporate in their decision-making.

Simulations are run solving a stochastic farm model where a farmer chooses a staple crop and technique (conservation or traditional) plus up to one diversification crop to maximize utility within a given Malawian Agro-ecological zone (AEZ). The staple crops to choose from are local maize or hybrid maize, whereas the diversification crops are Groundnut Chalimbana, Groundnut CG7, Beans, & Pigeon Peas. Conservation techniques that the farmer can choose are soil & water conservation, intercropping, or combining the two.

In the results presented here we focus on how improving climate information available to farmers changes the expected outcomes. We refer to a misalignment in expectations when farmers have insufficient information to evaluate the change in systemic risk brought about by climate change and behave as if this distribution had not changed. From the results in Table 1, we observe that (i) mean profits can be greatly affected by lack of information under increased variability of rainfall in sub-humid areas, and (ii) an increased variability of temperature in semi-arid areas can have a considerable negative effect if not anticipated.

Table 1. Impact on mean profits of increasing by 30% the standard deviation of rainfall (Rain SD) or of temperature (Temp SD), depending on whether the change in variability is correctly anticipated by the farmer or not (unanticipated).

		Mean Profits (Malawian Kwachas)	
Malawi AEZs	Scenarios	Anticipated climate change	Unanticipated climate change
Tropic warm/ semi-arid	Baseline	5,578	5,578
	Rain SD + 30%	2,430	2,102
	Temp SD + 30%	6,056	4,901
Tropic warm/ sub-humid	Baseline	5,859	5,859
	Rain SD + 30%	7,950	2,244
	Temp SD + 30%	3,627	3,627
Tropic cool /semiarid & subhumid	Baseline	10,719	10,719
	Rain SD + 30%	4,980	4,729
	Temp SD + 30%	7,944	9,877

In our analysis, improving information available to farmers addresses this misalignment by providing the correct probability distribution to farmers managing risk. The paper then provides insight on the robustness of different instruments, such as diversification or safety nets in the face of limited knowledge of the probabilities of weather events, and the value of providing information in the efficiency of such instruments. Budgetary implications are also explored for different instruments such as weather index insurance and safety nets. Results indicate that misalignment of farmer expectations may cause large budgetary outlays by government due to a lack of appropriate adaptation decisions when only limited information is available to farmers.

"Visions of the future" from selected scenarios: Science warnings, the changing of scarcity concept and prospects for a new society

R. Corazza (1) ; PS. Fracalanza, (2) ; E. Ortega, (3) ; MJ. Bacic, (2)

(1) Geosciences Institute / State University of Campinas – IG/ UNICAMP, Science and Technological Policies, Campinas, SP, Brazil; (2) Institute of Economics, Campinas, SP, Brazil; (3) Food Engeneering Faculty, Ecological engeneering and applied informatics laboratory, Campinas, Brazil

Most of conventional, non-scientific or specialized media nowadays focus on the problems of financial-economic international crisis and on worldwide terrorism actions. Challenges to curb Climate Change and the other major planetary environmental problems appear in the main information vehicles as specific topics, frequently disconnected to these other urgent and fair issues of economic possibilities of the world and the global safety under the menaces of the growing forces of fundamentalism and intolerance.

Yet, these planetary challenges are deeply imbedded in our social, economic and geopolitical world. Facing the first ones will require profound and extensive reorientation of the latter. There will be no possible escape from a dystopic future for the great majority unless this fundamental interdependence are recognized and proper, creative faced by world leaders, jointly with citizens, businesspersons, and society as a whole.

The scientific literature on the future prospects of the world in this sense spreads from late 1960s to the present and brings together a set of issues that can be enlightening when it comes to devise possible paths to alternative socio-economic and political arrangements to face current predicaments of humankind.

This paper draws on the results of a critic literature review on the topic of the visions of future, highlighting the contributions of the reviewed works on three selected and interrelated issues: Science warnings, the underlying scarcity concept (being it openly stated or not) and the prospects of the future of the society (whether it be utopian or dystopian).

The Table 1, below, summarize the contributions reviewed, its authors and the disciplinary scientific field, and institutional and historical contexts within which they have been proposed. The main, even if not the unique, criteria for selecting these works were the adherence to the theme and the prominence of them in the literature reviewed. The sources employed as bases for the survey were SciELO, Periódicos CAPES and Scholar Google for the systematic review and selected books and papers for backward and forward chaining review.

Table 1. Visions of the Future: contributions and reviewed authors

Contribution	Date	Authors
Environment, Power and Society	1971	Howard Odum
The Limits to Growth	1972	Donella and Dennis Meadows and colleagues
Beyond the Limits	1992	Idem
Catastrophe or New Society: a Latinamerican World Model	1976	O. Herrera and colleagues
Great Transition: the promise and lure of the times ahead	2002	Raskin, P., T. Banuri, T.; Gallopın, G.; Gutman, P.; Hammond, A.; Kates, R. and Swart, R.
IPCC (Intergovernamental Panel on Climate Change) 4th Assessment Report	2007	R. K. Pachauri; A. Reisinger
Ecosystems And Human Well-Being	2005	Millenium Ecosystems Assessment

The main purpose of this paper is to draw from the reviewing of these selected contributions a set of answers for the following questions: i) which are the scientific warnings made in terms of environmental change?; ii) which is the underlying concept of scarcity?; iii) which are the ideas or the prospects for the reorganization of social and economic life?; iv) which roles are social and economic actors supposed to play in order to implement this reorganization?

P-2240-08

Does poor understanding of causes for climate change lead to bad protective choices?

G. Guedes (1) ; A. Simao (2) ; R. Raad (3) ; G. Assunção (4)

(1) Federal University of Minas Gerais, Department of Demography, Belo Horizonte, Minas Gerais, Brazil; (2) Federal University of Minas Gerais, Center for development and regional planning, Belo Horizonte, Brazil; (3) Federal University of Minas Gerais, Department of economics, Belo Horizonte, Brazil; (4) Federal University of Minas Gerais, Department of statistics, Belo Horizonte, Brazil

In this paper we analyze how people's perception of causes for climate change, and their understanding of global warming, may be associated with their behavior regarding flood preparedness. We also analyze if their social representation of floods is affected by how they

perceive causes for temperature and precipitation locally. Microeconomic models of optimal choice under uncertainty (as in Savage, 1972) are our theoretical basis to link perceived uncertainty regarding local climate parameters with behavioral intention regarding preparedness against flood hazards. Models of choice under uncertainty state that individuals choose a subjective prior to make sense of the expected benefit of their choice. Among risk-averse individuals, increase in uncertainty may lead to overprotective behavior, which results in an aggregate loss of social well-being. Poor understanding or lack of knowledge about causes of increasing uncertainty, such as the one brought about with climate change, may lead to the choice of incorrect subjective priors, adding an extra loss in expected benefits. Combining mathematical simulations with Thematic Net Analysis applied to a representative sample of 1,200 urban households in Governador Valadares, Brazil, 2014, we show that individuals seem to overuse protective measures against flood hazards, resulting in an aggregate social loss. This loss is even higher among risk-averse individuals. Our qualitative results suggest that, as expected, knowledge on local temperature and precipitation change is more common than the understanding of global warming. Among those who acknowledge local climate change, understanding of causes is superficial and often wrong, adding a layer of difficulty for risk-averse individuals to correctly choose a subjective prior that maps risk of floods onto their portfolio of electable actions. Governador Valadares was chosen because river flood is recurrent in the area, reaching thousands of families along the river every other year. The river water is also one of the most polluted among the Brazilian rivers', producing involuntary risk exposure to waterborne diseases when it floods. The results found in this study highlight the importance of proper scientific communication of causes and consequences of climate change to the general public, in order to increase population support for adaptation policies, as well adherence to protective and preventive behavior.

P-2240-09

Perceptions of climate change in the mainstream media as portrayed through the coverage of the water crisis in São Paulo

R. Henriques Melo-Santos (1) ; C. Nolasco (2) ; M. Lahsen, (3)
(1) INPE – National Institute For Space Research, Earth System Science, São José dos Campos – SP, Brazil; (2) INPE – Brazilian National Institute for Space Research, CCST – Earth System Science Centre, São José dos Campos, SP, Brazil; (3) National Institute for Space Research (INPE), Earth system science centre (ccst), São José dos Campos, SP, Brazil

For many decades, drought has been a very cruel and close reality to millions living in the Northeast region of Brazil. By contrast, for those in the Southern regions of the country, water scarcity has rarely been a matter of concern and it was associated only with remote, socio-economically deprived regions. That reality changed in 2014 when the megacity of São Paulo, home to 12 million people, suffered a serious water crisis. The magnitude of the water crisis and the speed in which it occurred took many by surprise and it is referred to as the most severe in decades. Its consequences unfolded throughout the region like an epidemic and turned into front page news. Among the causes of the water crisis listed by the media, was irresponsible management of water resources, excessive water use by the population and an extreme environmental situation. Scientists have been warning that intense drought and lack of rainfall throughout Brazil are a result of climate change (Gutiérrez et al., 2014), and that further warming and reduction in precipitation is projected for the southeast of Brazil for the coming decades (Chou et al., 2014). The present study examines the representations of climate change in the mainstream media, as portrayed through the coverage of the water crisis in São Paulo. It also examines the importance given to scientific data on its reports. It seeks to understand how the most influential outlet press, the newspaper Folha de São Paulo, explains the causes of the water crisis, in particular the extent to which it covered governance and climate change. Attention is given to whether the management and mitigation of the water crisis addressed in the news, took into consideration knowledge and data produced by the scientific community. A sample of reports, published during the period of August 2014 to March 2015 in the newspaper Folha de São Paulo, were classified by section and type, and thus, identifying whether the newspaper relates the crisis to climate change or to governance issues or both, and whether the newspaper content is based on scientific or non-scientific information. Understanding how issues are framed in this and other national news media is important because they shape public knowledge, customs and perceptions of the Brazilian society.

P-2240-10

Navigating the line between participation and tyranny - Lessons learned in using participatory methods to engage community members in pro-environmental behaviours in rural China: The Case of Farm in a Box

E. Kennedy (1) ; S. Evans, (2)
(1) Lund University, Social Work, Lund, Sweden; (2) Good to China, Shanghai, China

Discussions and responses to climate change have predominantly remained at the global and national levels with limited inclusion of people who live in regions that are heavily impacted by and vulnerable to climate change. The implications of climate change at the local level and the possible positive impact of locally driven climate change actions are consistently overlooked within the international community of climate change experts. It is necessary to not only include, but to also work closely with local communities in the discussion of climate change, sustainable development and resilience building as local communities provide a source of local knowledge rooted in cultural traditions as well as a source of community level action. However, navigating between participatory methods and tyranny is an issue that has received attention within participatory research and community engagement literature. Focusing on the case study of Farm in a Box, a sustainable food source that promotes pro-environmental behaviours and education opportunities, we will examine the lessons learned in the process of using participatory methods to engage community members in pro-environmental behaviours in rural China.

P-2240-11

Learning about climate-related risks: decisions of fish farmers in a role-playing simulation game

P. Lebel (1) ; L. Lebel (1)
(1) Chiang Mai University, Unit for Social and Environmental Research, Chiang Mai, Thailand

Background: Successful river-based cage aquaculture in Northern Thailand depends on managing a number of climate-related risks. Previous surveys and observation of recent high flow or flood events as well as an extreme seasonal drought with low flows have shown that the risks are season-, river- and place-specific implying that the experience and risk profiles of individual farms vary substantially. Earlier work also showed that farmers use a combination of adjustments to rearing practices, cropping calendars, as well as financial and social measures to manage those risks which they perceive as being manageable. Moreover, individual risks are often addressed through multiple practices and strategies; conversely, a particular management practice can have a bearing on several different risks. Farmers also recognize that risks must be managed at both farm and higher spatial and administrative scales. Social relations and information, and not just culture techniques, play critical roles in managing these complex combinations of risks.

Purpose: The purpose of this study was to improve understanding of how farmers make investment decisions in their fish farms when faced with risks from floods that are imperfectly known and which may be changing.

Methods: A role-playing simulation game was created to capture some of the key features of the decision-making context and explored with farmers in the field on hand-held tablets. In the game farmers were given a choice between low, mid or high stocking densities, representing a wide range of levels of investment in each round or crop. Under normal conditions profits are higher the higher the stocking density, but if it floods losses are correspondingly higher. Selecting a low stocking density thus was a relatively

certain bet compared to choosing a high stocking density. Games consisted of 20 rounds. Each game was randomly assigned to one of 18 different treatments or conditions that included different likelihoods and impacts of floods, investments in adaptation measures, or provision of information. In-depth interviews were conducted post-game to reflect on strategies used in the game and in practice.

Results: As hypothesized more frequent or larger impact floods reduced cumulative profits. Farmers reduced their stocking densities when playing in games with high likelihood of floods but did not do so as expected when impacts were larger. Farmers found it's harder to learn - choose the most optimal density or improve score within a game - when floods were common or had large impacts. Farmers learnt most when risks were decreasing and least when they were increasing. Providing information about likelihoods prior to a game had no significant impact on performance or decisions, eventhough interviews implied a reasonable understanding of likelihood information. Within individual games farmers responded to a flood with a reduction in density in the next crop if they had just chosen high, but with a shift to high if they had previously chosen low. Post-game interviews suggest most farmers found the simulation game represented key features of their decision context, the main discrepancy being inability to take short-term measures to reduce losses when a flood was imminent.

Significance: The methods and findings of this study underline the importance of understanding decision-making behavior around risks for climate risk management. The novel combination of experimental, role-playing and qualitative methods revealed limitations in common assumptions about the ease of learning about likelihoods and consequences from experience. In the context of climate-related risks and a role-playing game situation, the findings suggest there may also be an emotional rather than purely analytical response to losses. The findings also suggest that decision-support systems for aquaculture need to take into account how recent experiences and other factors influence risk perceptions and decisions.

P-2240-12

The media coverage of climate change and air pollution in French press

M. Madelin (1) ; S. Duché, (1)
(1) University Paris Diderot, Sorbonne Paris Cité, Umr prodig, Paris, France

Climate change and air pollution has become two major concerns of the French, objects of issues, debates and, therefore, recurring topics in the media. The study of a theme through its media treatment is rich and can illustrate the interface between scientific knowledge and its return to the public. Or it can reveal a potential difference between the two, and more widely be used to understand representations of phenomena through the words and their associations.

This paper presents a media coverage analysis on climate change and air pollution in French national newspapers, from a corpus of 2.961 press articles. The temporal study shows mainly a relative recent and strong media influence of climate change, and to a less extent a response to air pollution episode and policy measures. The semantic analysis identifies four lexical fields: economy, transport, legislative framework - policy and environment. Finally, the articles with the terms of climate and weather show a diversity of approach taken by reporters and are found in various topics (from a HAC). Between these two items, the media treatment of air pollution has been very little covered in contrast to controversial issues around climate change, but the two are often related, sometimes not in a relevant manner.

P-2240-13

Dangerous climate here and now: Do our indicators let us perceive the signals? The 2003 heat wave in France

C. Mays (1) ; M. Poumadere (1)
(1) SYMLOG France, Research and consulting, Paris, France

Fifteen thousand persons died in the French episode of heat wave in August 2003, during the hottest summer in Europe since 1500. Yet it took months or years for this count to be recognized. The heat wave dangers resulted from the intricate association of natural and social factors. Unusually high temperatures were combined here with socioeconomic vulnerability and in particular, social attenuation of hazards - a multi-form inability of individuals and institutions to recognize that people were dying of the heat. The French experience confirmed research establishing that heat waves are a major mortal risk, number one among so-called natural hazards in postindustrial societies. Yet France in 2003 had no policy in place, as if dangerous climate were restricted to a distant or uncertain future of climate change, or to preindustrial countries. We analyze the heat wave's profile as a strongly attenuated risk in the French context, as well as the causes and the effects of its sudden shift into amplification. Entrenched indicators can mask or reveal the dangers of climate change. Improving indicators might be a significant lever in bringing about more sustainable behaviors.

P-2240-14

Perception, Collapse and Climate Change: an Anthropological Theory Approach

F. Miguel (1) ; I. Ibiapina (2) ; M. Curi (1)
(1) Universidade de Brasilia, Centro de Desenvolvimento Sustentavel, Brasilia, Distrito Federal, Brazil; (2) Universidade de Brasilia, Antropologia social, Brasilia, Distrito Federal, Brazil

In this paper, we intend to discuss from the point of view of current anthropological theories, the possibility of misperception of climate changes in human societies that historically have collapsed, as well as those that are in process. We analyze critically the ethnographic cases presented in Jared Diamond's book Collapse, from the ecological theories and Tim Ingold's ecology of life. Our intent is to understand if the new ontologies proclaimed in those anthropological theories, which deny categories such «misperception», since perception is not supposed to be a vision of nature out there, but a process among different person-organisms in continuous changeable environment, can deal with the historical experiences of collective collapse.

P-2240-15

Cultural biases on climate change discourse - Findings on multinational survey in ICA-RUS Project

S. Munakata (1) ; Y. Fujigaki (2) ; E. Yagi (3) ; Y. Yamanouchi (3)
(1) Mitsubishi UFJ Research & Consulting Co,. Ltd., Environment and Energy Dept., Tokyo, Japan; (2) The University of Tokyo, Tokyo, Japan; (3) Osaka University, Osaka, Japan

Climate change discourse tends to be framed by a particular set of values. There are different fundamental worldviews and perspectives jostling for position, and disagreement among the prescriptions for climate change can partly be explained by the underlying antinomy.

Nation-wide Web surveys were administered in 3 countries (Japan, USA and Germany). Respondents were questioned social value preferences relating to Mary Douglas' grid and group scores, preference on global mitigation target, and risk perceptions on climate change impacts. Then they were shown mitigation options with its GHGs reduction amount, cost, uncertainties and side effects. Finally, they can choose cost allocation options between citizens and industries, and between developed and developing countries. Respondents could immediately confirm the result of their selections on the Web in terms of estimated temperature increase in 2100 and burden of mitigation costs so as to respondents can examine the balance and consistencies among target, costs and GHG reductions.

The cultural characteristics of each country are shown in grid and group score distributions. The respondents in USA put emphasis on interests of individuals ("low-group"). Germany shows tendency of sharing common target ("high-group"). Japan can be characterized by the narrowest distribution biased toward hierarchical tendency ("high-grid and high-group"). These cultural

biases are reflected in the survey results. The public of USA doesn't like legal binding of global common target, in contrast to the other high-group countries. The public of Japan accepted harder GHG reduction efforts in developed countries than in developing countries, in contrast to the other low-grid countries insist on the same level efforts.

In group interviews, public of Japan often shows the tendency to leave decisions on climate change to his institutions. This observation is another evidence of institutional nature of Japanese society.

The Ministry of the Environment, Japan established an interdisciplinary research project, Integrated Climate Assessment – Risks, Uncertainties and Society (ICA-RUS) conducted by Dr. Seita Emori, National Institute for Environmental Studies. This research is a part of the ICA-RUS project.

P-2240-16

Misperceptions of Climate Change among Family Farmers – The Case of Mato Grosso State

S. Nasuti (1) ; G. Litre, (1) ; M. Bursztyn, (1) ; C. Saito, (1) ; SC. Da (2) ; C. Henke, (3)

(1) University of Brasília, Center for Sustainable Development, Brasília / DF, Brazil; (2) Universidade do Estado de Mato Grosso, Caceres, Brazil; (3) University of Brasília, Ecoa, Brasília / DF, Brazil

In Brazil, climatological data has shown a steady increase of temperature levels in all Brazilian regions over the last 50 years. On the other side, rainfall levels records have remained stable in many areas of this country. This is the case of several areas of the Mato Grosso (MT) state, Brazil's second largest producer of agricultural products such as soybean, and sugarcane, and one of the most threatened by climate change. Approximately 70% of the surveyed areas of MT, including the Chapada dos Guimarães in the Cerrado biome, have revealed stable rainfall levels between 1980 and 2010. However, when interviewed about climate change, the vast majority of family farmers pointed out to a perceived decrease of rainfall levels and suggested that this was the main reason for their economic losses at the farm level and a threat to the sustainability of their livelihoods.

In this regard, this project aims at understanding why so many family farmers wrongly attribute their loss of agricultural productivity to a decline in rainfall levels that has not been registered by meteorological stations, thus mal-adapting to the challenges that climatic change poses to their livelihoods and to the overall sustainability of family farming in the state.

P-2240-17

How anthropogenic greenhouse gas emissions are changing the odds of individual extreme weather events – a communication opportunity

F. Otto (1) ; K. Haustein, (1) ; P. Uhe, (1) ; M. Allen () ; H. Cullen (2)

(1) University of Oxford, Oxford, United Kingdom; (2) Climate Central, Princeton, NJ, United States of America

Warming of the global climate system is unequivocal, predominantly due to rising greenhouse gases with direct implications from rising mean global temperatures for some slow-onset events such as sea level rise, which can therefore be linked directly to past emissions. In many regions, however, extreme weather events, like heatwaves, floods, and droughts, are associated with greater loss and damage. An increase in average temperatures will lead to an increase in the frequency or magnitude of some extreme weather events including heat waves and droughts. For example, the deaths of at least thirty-five thousand people in Europe are attributable to the record-breaking heat wave of 2003. Extreme heat events and subsequent droughts can be directly linked to the loss of human life as well as damage to, or the significant diminishment of economic productivity.

The emerging science of probabilistic event attribution (PEA) has demonstrated over the last decade that it is now possible to attribute the fraction of risk caused by anthropogenic climate change to particular weather events and their associated losses. In other words, PEA enables us to give a quantitative estimate of how much anthropogenic climate change is costing us today.

This ability could potentially have a huge impact on climate change communication. Extreme events, in particular those that are not just rare from a meteorological perspective but also lead to societal and monetary damages and interrupt everyday life usually receive a very high level of public attention. If attribution studies show that a particular event was indeed made more likely due to anthropogenic climate change, i.e. anthropogenic climate change has increased the chance of the event occurring at this point in time, human induced climate change is transformed from something that is happening at some point in the future to a real threat in the here and now. Previously these studies took months to accomplish, delivering results long after public attention has peaked. Through a new partnership between Climate Central, a non-profit organisation providing TV weather forecasters with climate information, the University of Oxford Environmental Change Institute and other academic partners this huge communication opportunity will be taken to the next level by building a modelling and communication framework that provides decision-makers, and in particular the public, with the means to make clear the quantitative connections between greenhouse gas emissions and extreme weather events in real-time.

This fast turnaround ensures that any communication opportunity will have maximum impact as an extreme event only remains topical while it is unfolding. By hearing the science as the public experience the event, they will really begin to fully understand climate change.

P-2240-18

The Role of Climate Change Concern in the Acceptability of Energy Supply Technologies and Energy Demand Reduction

W. Poortinga (1)

(1) Cardiff University, Welsh School of Architecture, Cardiff, United Kingdom

As a large proportion of carbon dioxide emissions are generated by the domestic sector, individuals need to make drastic changes to their current lifestyle in order to play their part in climate change mitigation. Not only do they need to change their personal behaviour, they also have to accept new low-carbon technologies in order to decarbonise the energy they are using. This paper presents the results of large-scale nationally-representative survey (n=1,822) on public perceptions of climate change and energy futures in Britain. It examines the role of climate change perceptions in the willingness to accept low-carbon energy-supply technologies, such as solar and wind energy, and their willingness to change their behaviour to reduce energy demand. The study found that concern about climate change was strongly associated with the acceptability of both demand-side measures and supply-side technologies. In addition, the study found that personal values and environmental identity are important factors in the willingness to accept low-carbon technologies and energy demand reduction. It appeared that people with traditional conservative values were less likely to engage in low-carbon behaviours due to higher levels of concern about energy security. Individuals with self-transcendence values were more willing to engage in low-carbon behaviours and to accept low-carbon energy-supply technologies as a result of higher levels of environmental identity, concern about climate change, and personal norms. The results of this study will be put into a wider programme of research on public perceptions of climate change and energy choices to discuss the role of human choices and behaviour in the transition to a low-carbon economy. Furthermore, international comparisons will be made to explore different views on what are acceptable transition pathways. The paper will be part of the session «Towards solutions that transcend technology and markets: the role of choices and behaviour change» (3316 – Behaviour Change).

P-2240-19

Addressing the Adversities of Climate Change through Mindfulness and Resilience : A Conceptual Framework

P. Rishi (1)
(1) Indian Institute of Forest Management, Bhopal,MP, India

In India, climate change could represent additional pressure on ecological and socio-economic systems that are already under stress due to rapid urbanization, industrialization and economic development. With its huge and growing population, long densely populated and low lying coast lines, and an economy that is closely tied to natural resource base, India is considerably vulnerable to the adverse impacts of climate change, which requires exorbitant efforts on the part of respective communities to cope and adapt. There is a need to build a resilient community full of eco consciousness and mindfulness ,capable to face climate change and associated disaster risk with psychological hardiness and strong will power. For that, governments need to be aware of current and future potential risk and take more initiative in order to enhance the eco consciousness and resilience of the urban systems and communities. Co-adaptation is one such form of collective action whereby stakeholders of a community work together with a government agency to undertake some aspects of environmental issues which can be potentially threat full to the changing climate (Tompkins and Adger, 2004).

Socio psychological and spiritual factors play an important role in this regard to make serious efforts to modify and alter the life styles and behaviours of people in order to prove themselves as environmentally sensitive citizens across the planet, better suited to today's environmental needs. Life style change also helped in developing human resilience to climatic variability in a more positive way to promote subjective as well as global well being .Implications for psychological and Spiritual health were also discussed.

P-2240-20

Challenges to climate change adaptation: A case study on flood risk perceptions in the Hawkesbury-Nepean catchment, Australia

M. Shafaq (1)
(1) University of New South Wales, Institute of Environmental Studies, NSW, Australia

The Australian climate is characterised by extreme weather conditions. Future unpredictability has placed pressure on government agencies to increase their effectiveness of managing adaptation to extreme weather events, increase coordination and improve risk communication and community participation. Efforts to increase adaptation to climate change at different levels of government and among a wide-range of stakeholders require identifying and understanding the barriers that hinder adaptive actions. This abstract is part of a PhD research that looks in to barriers to flood management under a changing climate and intends to identify bottlenecks that create maladaptation. The research takes the Hawkesbury-Nepean catchment as case example. The catchment is characterised by ambitious development goals with 180,000 new developments in the floodplain of the two major rivers (Hawkesbury and Nepean Rivers) of this catchment, unique topography that increases the risk of floods in this regions, and challenge to maintain conservation of the Blue Mountains as a World Heritage Site.

This research paper explores the perceptions of residents to flood risks to their property and the likelihood of other factors that can influence this perception and hence their low response to take action in government-led measures to mitigate impacts of climate change. The data was collected through on-line, face-to-face and postal surveys. A total of 540 postal surveys were distributed and 81 face-to face surveys were conducted from residents residing in the Hawkesbury-Nepean catchment across five suburbs. Findings of this research show that generally communities have a low perception of flood risks in the region and that factors such as proximity to the Rivers, gender, age and duration of living in the area can influence perceptions of flood risks to property. These factors influence an individual's attitude to either be proactively engaged in adaptive action or continue to remain in denial. Another important aspect that was identified to influence perception was the false expectation of communities of government authorities. Government authorities were seen as responsible for 'keeping communities' safe' and so if development is approved on floodplains it translates as a flood-safe region. The outcome of this research is to provide a better understanding of communities residing in inland floodplains to contribute towards developing effective risk communication strategies thus enabling better management of floods and achieving increased level of support from the communities.

P-2240-21

Small Scale Peri - Urban Farmers' Adaptation to Climate Change in Domboshawa, Zimbabwe

VI. Tanyanyiwa (1)
(1) Zimbabwe Open University, Geography & Environmental Studies Department, Harare, Zimbabwe

Zimbabwe is a semi-arid country heavily reliant on regular rains (generally November to April). Rainfall exhibits considerable spatial and temporal variability characterized by shifts in the onset of rains, increases in the frequency and intensity of heavy rainfall events, increases in the proportion of low rainfall years, decreases in low intensity rainfall events, and increases in the frequency and intensity of mid-season dry-spells. Extreme weather events, namely tropical cyclones and drought have also increased in frequency and intensity in the country. Agriculture is the main source of income for most smallholder farmers who depend on rain fed cropping and livestock rearing in Zimbabwe. Adaptation of agriculture to climate variability and change impacts is vital for sustenance and food security. In order to develop appropriate strategies and institutional responses, it is important to have a clear understanding of the farmers' perceptions on climate change adaptation at farm-level. Thus, this study identified, evaluated and suggested farm-level adaptation strategies to climate variability and change in Domboshawa; a peri-urban communal area located 26km north east of Harare, the capital of Zimbabwe. Domboshawa is located in Ward 4 of Goromonzi District in Mashonaland East Province. Domboshawa is comprised of about 40 000 households with an average household size of 5 people and with more than 75% of these people relying on farming. The research design used in this study was both qualitative and quantitative (mixed) in nature. A combination of both methods yielded more validity and reliability than using either method on its own. The study of climate change adaptation is focused on inquiry based on the description of experience and such studies adhere to a philosophical of understanding social phenomena which traditionally advocates for the use of qualitative and quantitative data. Simple random sampling was used to select 45 respondents for the questionnaire. The population registers from the Headmen of each of the five wards; Munyawiri, Mawanga, Shumba, Murape and Pote were obtained which constituted the sampling frame. Each entity or individual was selected one at a time and independently therefore ensuring that each entity had an equal chance of being selected from the three selected villages. Purposive sampling was used to select people or organisations that are working in the area. Specific method used in the Quantitative approach is the survey. Qualitative methods used include Participatory Rural Appraisal (PRA), specifically, resource mapping, historical trend lines, and seasonal and daily activity calendars. Focus group discussions and in-depth case studies were also used. Climate vulnerability and capacity which combines local and scientific knowledge will be used to elicit for knowledge that is locally generated by the farmers to adapt to climate change. Findings revealed that local people perceived changes in rainfall and temperature based on their daily experiences. The majority of the smallholder farmers have adopted measures to address climate change and variability which include crop diversification, soil and water conservation practices, off-farm income activities and integrated crop and livestock diversification. The smallholder farmers are constrained in their daily farming activities by poor infrastructure, inadequate credit facilities as the farmers lack collateral and multifunctional input and output markets. Empirical analysis of rainfall suggests decreasing rainfall trends between 1920 and 2008.The study concluded that there is need to educate farmers on climate change so that they are able to design adaptation strategies that take into cognizance existing local level knowledge and practices on land and water management so as to boost agricultural production. While there are multiple stressors that confront farmers, climate variability and change remain the most critical and exacerbate livelihood insecurity for those farmers with higher levels of vulnerability to these stressors. Climate

variability and change might also have a positive impact and localised benefits in the context of structural changes in community's social organisation and economic activities under certain circumstances. There is need for agricultural research to support appropriate agricultural innovations and development of new livelihood activities emerging as farmers respond to climate variability and change.

P-2240-22

Public perception of climatic change and the risk control action of the government in metropolitan area of Belém, Brazil

S. Thomas (1) ; O. Almeida (2) ; CCC. Gena (3) ; S. Rivero, (4) ; VDA. Atila (5)

(1) Federal University of Pará - UFPA, Centre for Higer Studies on Amazon -NAEA, Belem, Pará, Brazil; (2) UFPA, NAEA, Belem PA, Brazil; (3) Federal University of Pará - UFPA, Economy, Belem, Pará, Brazil; (4) Federal University of Pará - UFPA, Institute os social science icsa, Belem, Pará, Brazil; (5) The Fluminense Federal University, UFF, Rio de Janeiro, Brazil

The extreme hydroclimatic changes such as floods, drought, soil erosion and collapse of river margins expose several negative impacts on the daily life of the population who live in the metropolitan city of Belém, in the Amazon region of Brazil. The characteristics of spatial occupation of the city favour the risk associated with these changes and the whole population is vulnerable to it.

The objective of this study was to analyse the perceptions of students of Federal University of Pará, Brazil (UFPA) about climate change risk caused by extreme hydroclimatic events in the metropolitan city of Belem and their vision about the Government action to reduce the risk caused by these extreme events. In addition, the research analyses public opinion in relation to citizens' participation in decision-making and confidence in the ability of the State in risk governance.

The main hypothesis of this study is that the public opinion on the perception of problems related to extreme hydroclimatic changes is important for making public policies related to risk governance by the State.

This research employed the same structure of questions of Tien (2013)[i] used to evaluate the perception of risk in relation to climate change in Taiwan. The questionnaires were applied to all undergraduate students of economics from Federal University of Para, from the morning and night course during the months of May to June 2014.

In the perception of respondents about climate change, 78% think the importance of climate change is not exaggerated. Despite the accelerated industrialization and commercial farming are important factors for economic growth, 71% of respondents agree that combating climate change would be favourable to the Brazilian economy. More than half of total respondents (51 percent) agrees that a possible implementation of environmental protection would facilitate the Brazilian economic development and 75% of the respondents disagrees with the permanence of oil subsidies.

About 62% of respondents are not willing to pay more taxes on clean energy and environment. It is noticed that the population support Government initiative to mitigate the effect of climate change, but they are not ready to pay for it. In the opinion of 54% of students, the information available on the origin of climate change is insufficient and do not contribute to understand the actual situation of the problem. A significant 72% percentage of students considers insufficient the actions of private companies to deal with climate change. They believe that the Government should establish policies to mitigate climate changes.

The study pointed out that the lack of communication and transparency of Government hinders actions that could be undertaken on climate change mitigation and adaptation. Most respondents disagree that the Government grants subsidies to fossil fuel companies. At the same time, they are not willing to pay more tax to fund climate change mitigation. The study shows that there is a perception of climate change risk by the population and there is demand for more transparent communication available to them of public policies adopted by the government on risk governance.

A Sense of Place: Social Recovery in the Post-Disaster Reconstruction in Sichuan, China

H. Wu (1) ; C. Hou, (2)

(1) Sichuan Agricultural University, School of Architecture and Urban-Rural Planning, Dujiangyan, Sichuan , China; (2) Sichuan Agricultural University, School of architecture and urban-rural planning, Dujiangyan, Sichuan, China

Climate change has been triggering frequent global environmental crisis. Those environmental crisis bring plenty unwanted relocations, which deeply affect survivors' physical and social environments. While, most post-disaster reconstruction and recovery give predominant priority to the physical reconstruction, by timely producing enough housing and sound infrastructures for survivors, there is a lack of attention on the social recovery of the survivors, such as assisting them settling in the new environments. Taking the post-disaster reconstruction conducted after the Wenchuan earthquake, Sichuan, China, May 12, 2008 as an example, this paper addresses the problem that the lack of synchronization and imbalance between physical and social reconstruction resulted in the most earthquake survivors to experience unstable attachments to their new environments. Based on this phenomenon, this paper presents a reflection on how post-disaster physical reconstruction (particularly in China) could be improved by utilizing the survivors' social and individual memories. Focusing on the memory workshops and walk-along interviews with the local earthquake survivors, this paper uses the method of storytelling to examine memory's function in the earthquake survivors' relocation process. This paper argues that the local earthquake survivors' memories of their daily lives and their use of spaces in their original homes provided means to support their social recovery process, assisting them to grow attachments to their new dwellings, to reestablish their social networks, and to redevelop a sense of place. This paper suggests that the local residents' place-related social and individual memories should be considered as a new method for policy makers, urban designers and social workers to understand the changing of natural environment and how this is impacting humanity.

2241 - New representations and new frames for the climate change debate

ORAL PRESENTATIONS

K-2241-01

Climate and the Future of Inequality

S. Jasanoff (1)

(1) Harvard Kennedy School, Pforzheimer professor of science and technology studies, Cambridge, United States of America

Climate change has been presented as the great equalizer, one of those productions of the modern risk society that places all of humanity at the same disadvantage with respect to a calamitous future. Social studies of risk, however, paint a very different picture, showing that the adverse consequences of risk fall disproportionately on the most vulnerable segments of global society. How might the future of climate policy look if climate change were reframed in terms of the inequality of its shorter-term impacts rather than the potentially longer-term equalization of a world at risk? The talk focuses on the

disciplinary and institutional means through which imaginaries of climate equality and inequality are created and propagated, including law, economics, and climate science itself.

O-2241-01

A new framing and a new governmentality order for the climate problem

A. Dahan (1)
(1) EHESS / CNRS, Centre alexandre koyré, Paris, France

For the last 25 years, anthropogenic climate change has been framed as a global environmental pollution problem, which must be solved by reducing human greenhouse gases emissions through a global agreement negotiated under the auspices of the UN. The role played by sciences in the construction of the problem is essential, and is well summarized by the claim «science speaks truth to power,» with science and politics assumed to be hermetically separated. Although in reality this «linear model» is largely inadequate to account for the much more complex links between climate science and politics, notably within the IPCC, it has long been hegemonic, leading to debates focused on science rather than political responses.

This dominant framing has been undermined by the failure of major assumptions underlying international negotiations: it is now clear 1) that climate change is a geopolitical, economic, and development problem as much as an environmental one, 2) that we cannot solve it in isolation from all the regimes (energy, development, trade..) which perform the economic and financial globalization, and 3) that the needed industrial and social transformations have to be named and largely debated.

As the Paris CoP approaches, this paper critically examines the mistakes and the illusions of this framing, suggesting a new order of governmentality.

O-2241-02

Climate Change, Adaptation, and Community Discourse: Framing for Vulnerability and Transformation

D. Schlosberg (1)
(1) University of Sydney, Sydney Environment Institute, Sydney, NSW, Australia

The impacts of climate change are already having an affect on communities. From increased storm frequency and flooding, to heat waves and fire danger, to food insecurity and migration, climate change is no longer a future concern, but a present experience. The politics of climate change, therefore, have moved beyond a sole focus on global or state action on the mitigation of emissions, to local and regional adaptation policy.

One of the central frames for adaptation is risk and disaster management; in Australia, nearly every local government council has a Climate Change Adaptation Plan clearly framed by risk. This paper examines the very different framing for adaptation policy articulated by community groups that are primarily concerned with the vulnerability of basic capabilities and broader social and economic transformation. I assess two sources of this community discourse and framing. First, a content analysis of the websites, Facebook and Twitter feeds of environmental and community advocacy groups in Australia is examined to assess the main topical concerns expressed. Second, a deliberative democratic community adaptation policy consultation processes was run in Sydney. Using Q methodology and discourse mapping, the preferences of individual participants are mapped with regard to adaptation policy priorities both before and after the deliberative events. The consensus statement and policy recommendations put together by citizens as part of the deliberative process are also explored for indications of a framing quite different from a simple risk management approach

There are two key findings to report. First, community groups express a particular concern for vulnerability of basic capabilities in climate-challenged communities; these concerns are also clearly reflected in the community consultations. This contrasts with the language and policy framing of local governments on risk management and emergency response. Second, the deliberative process helps to increase the collective attention to both vulnerable capabilities and communities and the importance of transformation of local policy and process, and brings consensus around such framings. Ultimately, it may be that the disconnect between government and citizen framing is due, in part, to a lack of community engagement and participation in the development of adaptation plans, which has led to the exclusion of the diversity and widely varying concerns of community groups in the development of local adaptation policies.

Carbon sink geopolitics: Using Science and Technology Studies to explore the futures of collective climate action

V. Ehrenstein (1)
(1) Goldsmiths- University of London, Department of sociology, London, United Kingdom

In the mid 2000s, as part of the international effort to decrease greenhouse gas emissions, the negotiation process on climate change started to look at how to reduce carbon releases caused by tropical deforestation - an item and forthcoming regulation referred to as REDD+. By drawing on Science and Technology Studies and a multi-sited fieldwork, which investigated the archives of climate negotiations and followed between 2009 and 2012 the problem of CO_2 emissions assignable to tropical forest loss (from DRC's Ministry of environment, to the 17th session of the Conference of the Parties in Durban and Europe-based offices of carbon experts), this presentation suggests using the case of REDD+ to explore the notion of carbon sink geopolitics as a potential learning opportunity for future climate actions.

The transformation of tropical forests into a carbon sink that should be taken care of occurred through diverse public aid interventions deployed in low-income regions (e.g. the Congo Basin), relentless scrutiny exercised by non governmental organisations on behalf of intact forests or the rights of indigenous people, research and commercial activities dedicated to measurement and quantification aspects, and lively debates within intergovernmental negotiations about the rules of a possible market-inspired mechanism. Such effort dedicated to preserve carbon sinks - or at least to make sure that the consequences of their exploitation (e.g. through logging or agriculture) do not go unnoticed - is still inscribed in the interstate and quasi-legal United Nations Framework Convention on Climate Change. Yet, the geopolitics that the REDD+ process might be a precursor of and that this presentation proposes to sketch is an assemblage of, among other things, monitoring instruments like earth observation satellites, financial redistribution vehicles like multilateral funds, and institutionally mobile actors like expatriate consultants and environmental activists. I argue that, while this geopolitics relies on the geographical and political order established by the United Nations, it develops in the interstices of such division, in inter-national spaces, where it creates a collective concern, the carbon stored by tropical forests, and its socio-technical community.

O-2241-04

Politics of the Earth: Three Scientific Challenges in the Anthropocene

F. Gemenne (1) ; B. Latour (2)
(1) Sciences Po, Politics of the earth, Paris, France; (2) Sciences Po, Medialab, Paris, France

It has been argued that the Earth had entered the Anthropocene since the industrial revolution. The Anthropocene is best described as a geological epoch where humans have become the driving forces of changes on the planet. The epoch is characterized by a radical transformation of the relationship between humans and the Earth, of which climate change is one of the most evident transformations. It signals a new phase in the relations between a planet regulated by he laws of physics and biology, and human societies regulated by the laws of economics and politics. This transformation needs us to reconceive the scales and dynamics of collective action, to think together the World and the Earth.

"Politics of the Earth" is a new interdisciplinary programme

that seeks to achieve this objective. Its scientific perimeter is organised around two central dimensions, which depend on each other: a dimension of representation, and a dimension of government.

These two dimensions encompass thematic and methodological stakes, which can only be addressed through a common work between natural and social sciences. In order to think these multiple scales and dynamics, the Anthropocene imposes new representations, which are being made possible through the production of new data. Many of these data and databases, however, remain impossible to combine together, which prevents researchers from thinking the transformations of the Earth-Workd nexus in its multiple dimensions, and which also prevents an effective government of these new stakes.

The programme "Politics of the Earth" gathers research labs from different disciplines in different universities, around three challenges that crystallise the Anthropocene:

- Geopolitics of carbon dioxides;
- Expertise of risks and mediatisation of disasters;
- Dynamics of critical zones and urbanisation conflicts.

This session aims to present the preliminary results of the programme, which was launched in January 2015, and to show how these interdisciplinary perspectives can help represent climate change in the framework of the Anthropocene.

This paper reviews the methodological and practical issues that have bearing on the ways in which geoscientists, historians and archaeologists collaborate in the study of the societal impacts of climatic changes in the Mediterranean basin. We begin with discussing the methodologies of the three disciplines in the context of the consilience debate, i.e. the attempts at unifying different academic disciplines, in particular from among the sciences and the humanities, that work on finding answers to similar questions. We demonstrate that there exists a number of significant similarities in the fundamental methodology between history, archaeology, and environmental sciences, due to their common interest in studying the past societal and environmental phenomena; this has to do, for instance, with the use of narrative structures as the means of communicating research results, which is common to the three of them. Consequently, we also present and compare the different narratives of the societal impact of climatic change that are characteristic for each discipline, which it is necessary to comprehend in order to engage in fruitful interdisciplinary exchange. Finally, in the second part of the paper, we focus our discussion on the four major practical issues that hinder communication between the three disciplines. These include terminological misunderstandings, problems relevant to project design, divergences between the publication cultures, and differing views on research impact. Among other recommendations we make, we suggest that scholars from the three disciplines should aim at creating a shared, hybrid publication culture, which should also appeal to a wider public, both within and outside of academia. Finally, we present possible actions on the part of both scientists and humanities scholars (archaeologists and historians) that – if taken – will solve several of the challenges discussed in paper.

2242 - Migration dynamics under current and future climate change

Climate migration and the politics of causal attribution: a case study in Mongolia

M. Benoit (1)

(1) Wuhan University School of Law, Wuhan, China

Migration is always multi-causal. Ascribing a specific cause to migration, such as through the concept of "climate migration," participates consequently to a political exercise – a play of shade and light where attention is focused on the responsibilities of certain actors rather than others. This is the case, this article argues, regarding internal migration in Mongolia, whereby, during the last two decades, nomadic or semi-nomadic herders as well as inhabitants from small urban centres come to settle in insalubrious suburbs of the capital, Ulaanbaatar. The Mongolian authorities are keen to highlight changing environmental conditions that can be traced to climate change: a change in precipitation patterns and an increase of average temperatures contribute to cause large loss of livestock during harsh winters (dzud). Yet, a multitude of other factors concurrently influence the migratory behaviour of Mongolia's nomads: unregulated and unsustainable pastoral practices, the insufficient provision of basic and support services in the countryside, or, more generally, the lack of public support to the agricultural sector. Identifying concurring causes of migration suggests alternative response measures, and this article argues that Mongolia should urgently rectify its development policies to provide a room for each of its citizens.

How can migration support adaptation? Testing the climate change adaptation-migration nexus

J. Blocher (1) ; F. Gemenne (2) ; N. Perrin (3)

(1) University of Liège, Sciences Po Paris, Liege, Belgium; (2) Francois.Gemenne@uvsq.fr, Observatory of versailles-saint-quentin-en-yvelines, Guyancourt, France; (3) University of Liège, Cedem, Liège, Belgium

Empirical evidence shows that in the face of environmental and climate stress, migration is a common household strategy aimed at supporting basic needs and livelihood strategies (c.f. Foresight 2011). Policy makers commonly view adaptation measures as means to reduce migration pressures. But migration may also be seen as an adaptation strategy itself; as a way to reduce population pressures in climate-prone places while migrants already living outside

of vulnerable areas provide important resources to help communities adapt and respond to climate change.

However, the application of the environment and climate change adaptation-migration nexus has not been empirically tested, nor has the policy apparatus needed to deliver this potential been developed and assessed. More research is needed if policy interventions are to enhance the positive effects of migration on adaptive capacities and distinguish potentially maladaptive effects. The objective of this conceptual and methodological paper is therefore to flag different possible choices that can be made to study and represent the relationship between migration and adaptation, employing insights from a recently developed and tested survey instrument for the 'Migration, Environment and Climate Change: Evidence for Policy' (MECLEP) project.

The first section defines adaptation as it relates to mobility in the broad sense, taking care to anchor the potential of migration to build resilience and increase adaptive capacities within complex and potentially maladaptive processes. Then insight is given into the current body of knowledge contributing to this important area of inquiry. The next section addresses the climate change adaptation- migration nexus as it relates to the three main vantage points: the individual migrants themselves, the community of origin, and the community of destination. Conceptual and methodological difficulties met to-date are explored, with a reflection on how different approaches are best utilized in empirical studies. Insights from the MECLEP representative household survey implementation and research strategy, recently tested in at least three countries (Haiti, Papua New Guinea, Viet Nam) are brought to the fore. A final section weighs the challenges and advantages of the MECLEP approach and suggests what solutions may exist to advance the project and the field of research overall.

Abrupt climate change superimposed to RCP 8.5 IPCC scenario : potential consequences for population migration

G. Ramstein (1) ; D. Defrance (1) ; C. Dumas (1) ; S. Charbit (1) ; J. Alvarez-Solas (2) ; F. Gemenne (3) ; JP. Vanderlinden (3)

(1) LSCE, Gif-sur-Yvette, France; (2) Universidad Complutense, Madrid, Spain; (3) University of Versailles-Saint-Quentin-en-Yvelines, Observatory of versailles-saint-quentin-en-yvelines/cearc, Guyancourt, France

From Paleoclimate studies we know much more about abrupt changes as Heinrich events which are huge amount of icebergs periodically spreading over North Atlantic.

These events occured when the Laurentide ice sheet was unstable during glacial times. Recently, new mecanisms envolving ocean and cryosphere were developped to explain these instabilities [1, 2]. In contrast, Greenland and Antarctica were more stable during last glacial/interglacial cycles. Ongoing global warming has also for consequence to make Greenland and West Antarctica out of equilibrium. Therefore, in future climate, new abrupt climate changes linked with surges from the cryosphere may happen again. To investigate this issue we built 3 scenarios corresponding to about 3 meter sea level rise : one melting part of Greenland, another one without West Antarctica ice sheet and last one is a mix of both. These scenarios are superimposed to RCP 8.5 which is the most pessimistic one used by IPCC. They allowed us to diagnose major climate changes, especially in regions with high population density (Monsoon areas).

We will first explain the methodology and the scenarios we used. These experiments have indeed, many common features with Heinrich events simulations in the past and housing experiments in the future [3]. Especially, the ITCZ shifts and its impacts on monsoon areas but also long term change in thermohaline circulation will be described. The consequences of such atmospheric and ocean perturbations will be also considered from a population migration point of view.

Most of the study focused on population migration only due to sea level rise, but here we developed an original approach using consistent climatic scenarios accounting for both sea level rise and induced climate changes.

Unsettling Futures - Climate change, migration, and the immobility of climate politics

G. Bettini (1)

(1) Lancaster University, Lancaster, United Kingdom

The message that climate science and current emission trajectories are sending is clear: limiting global warming to 2°C is more and more an unlikely prospect. This predicament is hard to apprehend also because a 3 or 4 °C warmer planet is a largely unknown place, where socio-ecological spaces and relations look differently. Visualizing the impacts of such severe climate change - and of our responses to it - requires a radical imaginative effort.

If we take the possibility of 3 or 4°C warmer planet seriously, we can expect changes in the very ways in which humans understand, plan and experience their (im)mobility. And in effect, the question of how climate change will influence human migration has alimented a florid debate in the last decade. Academics have written reams about climate-induced migration, and policy negotiations have gathered pace. To be sure, various steps forwards have been taken. The securitizing drives once 'justified' by the fear of mounting waves of climate refugees have given way to the milder imaginaries of resilience, adaptation and development. While previously signified solely in terms of forced migration, the nexus climate change-migration is looked upon from a more comprehensive vista. Displacement, reduced mobility (with the issue of 'trapped populations'), voluntary migration (preached as a legitimate adaptation strategy), planned relocation and resettlement are co-protagonists of today's policy debates. The environmental determinism previously dominant is thereby gone, and more nuanced understandings of (climate) migration have prevailed.

Nonetheless, there is a striking dissonance between the paucity of those debates and the re-imagination necessary for formulating a politicized understanding of so called climate migration. While we should feel no nostalgia for the alarmist narratives of the past, the current mundane discourses anaesthetise the radical challenges posed by the climate-migration nexus. The prospect of unprecedented changes is dealt with through an attempt to reproduce "business as usual". The emerging discourses contemplate displacement, trapped populations, migration as adaptation and planned relocation in ways that conciliate the agendas of dominant international agencies. The current approaches to climate migration are a re-proposition of the measures predominant in the fields of development, aid, migration, risk management and climate adaptation, which have proved functional to the re-production of neoliberal relations.

In other words, the emerging discourses foreclose the political by sterilizing the radical questions that might emerge. To the radical transformations associated to a 3 or 4 °C warmer planet, the "new" discourses on climate migration respond with 'more of the same', making sure that nothing can change even in the front of epochal changes.

Potential Migration Impacts in Extreme Climate Change Scenarios: A Systemic Perspective

C. Zickgraf (1) ; P. Ozer (2) ; F. De Longueville (3)

(1) University of Liège / University of Reims Champagne-Ardenne, Center for ethnic and migration studies (cedem), Liège, Belgium; (2) UNIVERSITY OF LIEGE, Departement of

environmental sciences and management, Liege, Belgium; (3) University of Liège, Cedem, Liège, Belgium

With the target of limiting global warming to 2°C becoming increasingly difficult to achieve, policymakers and other decision-makers need to begin to plan ahead for adaptation to changes in climate associated with higher levels of global warming. The HELIX project (High-End cLimate Impacts and eXtremes), an EU FP7 project funded by the European Commission, seeks to provide a clear, coherent, internally consistent view of a manageable number of "future worlds" under higher levels of global warming reached under a range of physical and socio-economic circumstances. In this presentation, we specifically address how migration will fit into this picture. Assessing future migration under extreme climate change is not a facile task. Often predictions of massive future displacements are based on the numbers of people living in a risk zone, without taking into account differentiated vulnerabilities and capacities for resilience. Moreover, predictions of massive human displacement in the future tell us little about the character, scale, or destinations of these projected movements. Therefore, in one of the tasks of HELIX, a multi-disciplinary team seeks to appraise future migration based on empirical investigation into how people have historically and are currently responding to environmental changes.

One of the critical insights revealed through HELIX thus far is the importance of people's perceptions of climate change in determining their migratory responses and intentions. Based on survey data from several West African countries, we compared populations' perceptions of climate change with objective climatic data. This comparison showed that most West African people are affected by what is externally considered to be 'non-significant' change. These results highlight that people are increasingly vulnerable as the 'system' (social, demographic, economic, environmental) in which they live becomes less and less able to resist different stressors, even those of limited magnitude. This finding has significant implications for migration: some of the surveyed people directly migrated in response to these changes and others plan to migrate if rainfall conditions worsen in the future. As people's migratory decisions and intentions are based on their own perceptions of climatic changes and their ability to withstand them rather external risk/resilience assessments, an increase in migration could occur faster than previously expected in West Africa in the coming decades, calling for new policy responses that have to include the resilience capacity of the entire 'system'.

Much like policy must address the decreasing systemic resilience of vulnerable populations, future climate change-related migration policies and approaches would do well to consider human (im)mobility responses from a systemic perspective. A second HELIX case study details the interconnections between various stressors (demographic, economic, environmental, etc.) and differentiated mobility patterns in a fishing community in Saint-Louis, Senegal. As climate change exacerbates populations' pre-existing vulnerability, it cannot be isolated from other pressures. Likewise, displacement and voluntary migration cannot be separated from each other. Findings show that 'voluntary' labor migration is intimately intertwined with other forms of mobility, including relocation and displacement. Those fishermen who engaged in international migration were often able to preemptively relocate their households to locations safer from the imminent effects of climate change, decreasing their likelihood of future displacement. These interrelated movements call for policy approaches that treat vulnerability and mobility – internal and international, voluntary and forced – holistically. As livelihoods dependent upon natural resources (fishing, agriculture, etc.) will become increasingly difficult to maintain with extreme climate change, people in the future may, in fact, be less able to move voluntarily without some degree of capital (human, social, financial). If migration as an adaptation strategy is not facilitated, therefore, it may decrease populations' capacities to deal with the effects of climate change and put them at risk of becoming 'trapped' or displaced in precarious conditions in the future.

O-2242-06

Predicting the social impacts of climate change: Migration, environment and climate change in a world of global uncertainties

D. Ionesco (1)
(1) International Organization for Migration, DMM/MECC, Geneva, Switzerland

The links between global environmental change and migration have been explored at length, and existing academic and institutional evidence suggests that environmental migration is a reality; what is harder to foresee is what forms it will take in the future. Will more people be forcibly displaced due to climate change and natural disasters? Will more people resort to migration as a positive adaptation strategy in the context of climate change? Will people be able to migrate at all, or will they find themselves trapped in vulnerability?

This presentation will explore the difficulties around predicting future migration flows in the context of climate change, by presenting the complexity of the phenomenon and the multiple factors at play, and by examining the phenomenon in a more general context of uncertainties around local climate change impacts, around future demographic, social and economic change, adaptation measures to come, future policies that may or may not be taken, and, very importantly, individual perceptions, reactions, needs, and ability to leave or stay. The presentation will build on IOM's long term research, operational and policy experience in the area of environmental migration, and provide some concrete examples and recommendations for future research and action.

O-2242-07

Migration associated with large-scale land acquisitions, land tenure and land degradation

D. Gharbaoui (1) ; S. Vigil (2) ; N. Pearson (1)
(1) University of Liège, Cedem, Liège, Belgium; (2) Center for Ethnic and Migration Studies, University of Liège, Liège, Belgium

The proposed presentation intends to extend current debates on migration and climate change to emphasize the importance of land planning for environmentally-induced migration with a particular focus on current research on large-scale land acquisitions, land tenure and land degradation. The panel will use a bottom-up approach to explore examples of local and regional case studies on migration dynamics associated to land management. The first case study will focus on the issue of land tenure in the Pacific regional context, the second will analyze the issue of large-scale land acquisitions in Senegal and Cambodia and the last case study will illustrate how land degradation could be a major challenge in the context of environmentally-induced migration in Burkina Faso.

The need to focus on land in the particular context of climate-induced migration is crucial as the Intergovernmental Panel on Climate Change (IPCC) emphasized in its fifth assessment report released in March 2014; past examples shows that environmental change can affect land rights and land use, and at the same time, change of land use has also become in turn drivers of migration. This is particularly relevant for the Pacific region where retreating from affected coastal areas through migration as an adaptive strategy to changes in environmental patterns has always been part of the Pacific Islands' communities culture and practices. In the coming decades, the adverse effects of climate change in the region are likely to exacerbate both slow and sudden-onset environmental events threatening sustainable livelihoods and increasingly leading Pacific Islanders to use migration as coping method. However, there is a lack of study on land rights and land tenure systems that have been given little importance in the literary and policy debate on adaptation strategies in the context of Climate Change. It is crucial to address this dimension, particularly in the context of Pacific Islands, where in the majority of the countries, 80% of land is under customary tenure. Dalila Gharbaoui will study the role of land tenure in planned relocation exploring a sub-regional case study involving past examples of planned relocations in Fiji, Papua New Guinea and Vanuatu. A major difficulty with this type of human mobility is the disarticulation of communities and social structures following the relocation process, particularly crucial in the context of the Pacific region where the link between individuals and their land, has been an extension of their identity for millenaries.

Another crucial study of land in the context of climate-induced migration focusses on the case of policies aiming at biofuel production incentivising the acquisition of large tracts of land in the Global South, often overlooking the rights of local populations and leading to the forced displacement of whole communities. Through the example of climate change mitigation policies leading to "green grabbing", we can see how the multi-causal links between climate change, migration and displacement are further complexified. The links with the category of environmentally-induced migration occur most visibly when such agro-fuel projects destroy the local land and the water resources, forcing people off their land in what could be seen as a form of tertiary displacement. Whilst those analysing the social consequences of land investments need to pay more attention to the migration outcomes, there is also a need for environmental migration scholars and practitioners to broaden the spectrum of their analyses. In order to better understand how the climatic agenda, through legitimising many recent land acquisitions has impacted local population movements in different ways, depending on particular historical and political circumstances, Sara Vigil will give field insights from both Senegal and Cambodia addressing more deeply those questions.

Another important aspect that will be discussed in the context of climate migration addresses the issue of land degradation. Based on her findings from field research conducted in Burkina Faso in 2012, Nakia Pearson will give insights on the migratory practices and adaptive strategies of farmers who have moved in response to the land degradation since the 1970s Sahel droughts in order to better define the tipping points of loss and damage, as well as how mitigation strategies may play into migration.

O-2242-08

Protecting the rights of people displaced and at risk of displacement

NM. Birkeland (1)
(1) Norwegian Refugee Council, Partnerships and Poliy Department, Oslo, Norway

Every year around the world, tens of millions of people migrate and are forcibly displaced by floods, wind-storms, earthquakes, droughts and other disasters. Many find refuge within their own country but some have to go abroad. In the context of climate change, such movements are likely to increase. National and international responses to this challenge are insufficient and protection for affected people remains inadequate. States and other duty bearers need to protect and assist people displaced or at risk of displacement by disasters and the effects of climate change. Assisting such people is not only a humanitarian imperative; it is an essential component of disaster risk management, climate change adaptation and development planning.

The impact of climate change is most acutely felt by individuals and communities with pre-existing vulnerabilities which often are characterized by the limited enjoyment of rights. Many of the most important protection challenges in disaster situations related to climate change are long-standing protection and human rights concerns which are brought to light and further exacerbated by the emergency. While people displaced within their own countries are covered by national laws, international human rights law, the Guiding Principles on Internal Displacement and a few regional instruments, a serious legal gap exists with regard to cross-border movements in the context of climate change. These people are in most cases not refugees under international refugee law, and human rights law does not address critical issues such as their admission, stay and basic rights. Criteria to distinguish between forced and voluntary movements in the context of disasters have not yet been elaborated.

According to the Inter-Agency Standing Committee (IASC) protection is defined as: "... all activities aimed at obtaining full respect for the rights of the individual in accordance with the letter and the spirit of the relevant bodies of law (i.e. HR law, IHL, refugee law)." Such activities can be responsive, i.e. aiming to prevent imminent or stop on-going violations, remedial, i.e. aiming to provide redress (e.g. access to justice, reparation or rehabilitation) for past violations, or environment-building, i.e. aiming at creating the necessary legal and institutional framework, capacity and awareness that is necessary to promote respect for human rights and prevent future violations. Those affected by the disaster and climate change thus become individual rights holders who can claim rights from particular duty bearers rather than simply being passive beneficiaries and recipients of charity.

Displacement in the context of disasters and climate change cause and worsen protection risks such as sexual and gender-based violence; family separation; child trafficking; unequal access to assistance; discrimination in aid provision; enforced relocation; loss of personal documentation; land disputes and issues related to land and property rights. In view of this protection gap, there is a need for an inter-governmental process to address the challenges of cross-border displacement in the context of disasters and the effects of climate change.

2242-POSTER PRESENTATIONS

P-2242-01

Environment and human migration in context of Climate Change: empirical insights from urban migrants in Ulaanbaatar, Mongolia

S. Bilegsaikhan (1)
(1) Seoul National University, Department of Environmental Planning, Seoul, Republic of Korea

Global climate change and regional environmental changes resulting from the process are known to influence ecosystem-dependent populations relatively directly. Human mobility, particularly rural-urban migration under the changing climate, is one of such complex issues that is highly context specific. This nexus of climate change-environment-migration is gaining growing attention not only from climate change researchers but also rural and urban development policy makers in the recent decades. Thus to contribute to the betterment of understanding of this social phenomenon and to provide with empirical evidence that could aid planning of adaptation strategies to future environmental changes in Mongolia, this paper presents a retrospective in-depth investigation of environmental factors of migration among urban migrants in Ulaanbaatar, who, before immigrating to the city, were traditional rural pastoralists in some of the most weather extreme prone regions in the country. Theorizing migration as one of possible adapting strategies taken by a household as a response to environmental changes, this study explores similarities and differences in forms of migration among households (vulnerable migration versus resilient migration), elements that have enabled successful migration (different forms of capital) and urban integration issues after settlement in the city. The study emphasizes on two major occurrences of drought and drought-related winter disasters since a major socio-political shift in the country - democratization in the 1990s.

P-2242-02

Small Island Developing States, Sea Level Rise and Migration: Exploring Sovereignty and Resource Rights in Abandoned Nations

D. Carey (1) ; A. Fuentes, (2)
(1) University of Waterloo, Geography and Environmental Management, Waterloo, Ontario, Canada; (2) University of Waterloo, Geography and environmental management, Waterloo, Canada

Small island developing states constitute the world's most vulnerable nations to the impacts of climate change. Countries such as Tuvalu face the very real risk of permanent abandonment within the next century as a result of sea level rise. The social, political and legal implications of migrants from vanishing countries is currently an area of intense research. Aspects such as retained sovereignty and self-governance in foreign lands are being explored at length. What is largely being overlooked, however, are implications of resource ownership within the borders of what could be described as an abandoned country. If the sovereign governing capacity of a nation collapses with the abandonment of said nation, do they retain formerly established resource rights, or do they become subject to

laws of the high seas? To date, there is no legal answer to this question. To address these matters, as well as those of sovereign governing within a foreign nation, we propose that nations willing to host migrants work to establish a legal framework which mirrors the self-government agreements employed between Canada and First Nations populations. To make this relationship agreeable and beneficial to the host nation, we recommend that the government of the island set to be abandoned agree to cede or share resource rights within the territory waters of the abandoned nation.

P-2242-03

Changements climatiques et la Migration dans les régions de Mopti et de Sikasso

NP. Cisse (1) ; OK. Famagan (2)

(1) Institut Supérieur de Formation et de Recherche Appliquée (ISFRA), Sciences Humaines et Sociales, Bamako, Mali; (2) Faculté d'Histoire et de Géographie, USSG, Bamako, Fhg, Bamako, Mali

Cette étude a porté sur les communes de Dourou, dans le cercle de Bandiagara (Région de Mopti) située en zone soudano sahélienne, avec une pluviométrie moyenne annuelle de 477mm et de Kouoro, dans le cercle de Sikasso (Région de Sikasso) en zone soudano guinéenne où les précipitations moyennes annuelles sont supérieures à 1 300 millimètres. L'approche méthodologique s'est appuyée sur une recherche documentaire, la réalisation d'enquêtes quantitative et qualitative.

Les résultats ont révélé que les populations des zones enquêtées ont une perception négative de l'évolution des facteurs climatiques, au cours des 20 dernières années: diminution de la pluviométrie, hausse des températures et augmentation de la force des vents.

Les conséquences de cette péjoration climatique sont multiples et diverses : diminution de la fertilité des sols avec pour corollaire la baisse de la production agricole ; diminution des ressources en eau (tarissement précoce des points et cours d'eau et leur ensablement), diminution du l'effectif du cheptel et des pâturages, etc.

Face à ces effets néfastes des changements climatiques, les populations ont développé plusieurs stratégies d'adaptation dont l'organisation des départs des membres de la famille, à l'intérieur (exode rural) comme à l'extérieur (migration internationale).

Les résultats ont montré que la commune de Dourou, à l'instar du plateau Dogon, est une zone traditionnelle d'émigration orientée surtout vers le Ghana et la Côte d'Ivoire. Les migrations, observées au niveau interne dans la commune de Dourou, sont le fait d'une volonté manifeste d'accéder aux ressources encore disponibles dans les zones d'accueil. Par contre, dans la commune de Kouoro, cercle de Sikasso (zone de forte immigration interne), une rétroaction négative lie cette immigration aux effets néfastes des changements climatiques sur les ressources naturelles. D'où de nouveaux départs des populations de cette commune vers les zones aurifères et les grandes villes à l'intérieur du pays.

Les changements climatiques qui se sont amplifiés de 1970 à 1990, ont renforcé ces migrations internes. Comprendre le lien entre changement climatique et migration consiste à appréhender les facteurs d'accroissement de la migration et d'en évaluer les conséquences, les opportunités d'anticipation pour atténuer les mouvements de populations.

En vue de minimiser les effets néfastes des changements climatiques et des flux migratoires, les populations ont développé certaines stratégies qui son entre autres :

- Le développement des activités génératrices de revenus (AGR) ;
- La création de cantines scolaires dans les écoles pour diminuer la déperdition scolaire par la migration ;
- L'utilisation des semences améliorées plus adaptées ;
- la règlementation de la coupe du bois et le développement de bonnes pratiques de gestion des ressources naturelles pour fixer les populations sur leurs terres d'origine.

Mots clés : changements climatiques, migrations, vulnérabilité, stratégies endogènes d'adaptation..

P-2242-04

Climate change, human mobility and disaster risk reduction: The contributions of international law and pathways for implementation post-2015

A. Kron (1) ; S. Atapattu (1) ; K. Lofts (1)

(1) Centre for International Sustainable Development Law, Montreal, Quebec, Canada

Tens of millions of people are displaced each year due to natural disasters.[1] As the frequency and intensity of natural disasters and slow onset events such as drought increase due to climate change, rates of migration are set to rise further.

The inter-relatedness of climate change and migration has been emphasised in academic scholarship and public policy for a number of years. At the 2011 Nansen Conference, the Special Representative to the Secretary-General (SRSG) on disaster risk reduction, Margareta Wahlström, noted in her capacity as Chairperson that "[c]limate change acts as an impact multiplier and accelerator to other drivers of human mobility".[2] Indeed, the draft negotiation text for a new instrument on climate change contains a call for a climate change displacement coordination facility as part of the loss and damage section.

Disaster risk reduction (DRR) can also provide means to prevent displacement (e.g. through early warning systems), and to mitigate the effects of such displacement.[3] As there is no UN organ dealing exclusively with migration, it is important that entities such as the United Nations Office for Disaster Risk Reduction (UNISDR) contribute to furthering displacement issues, particularly in regards to disasters, which account for the majority of those forcibly displaced around the globe.

The Hyogo Framework for Action 2005-2015 strives to promote a culture of proactive measures in regards to DRR.[4] As the present Hyogo Framework will expire in 2015, UNISDR has been tasked with facilitating the development of a post-2015 framework for disaster risk reduction. Thus, a new Hyogo Framework will be adopted at the World Disaster Conference in 2015 and then put forward to the General Assembly.[5] The Hyogo Framework is referred to in the proposed text for the Sustainable Development Goals,[6] and SRSG Wahlström has also emphasized the importance of such cross-fertilization.[7]

Scholars such as Elizabeth Ferris have proposed suggestions on climate change, resettlement and planned relocation, drawing upon e.g. the rules relating to development-forced displacement and resettlement. These considerations are partly reflected in the zero draft for a new Hyogo Framework, which calls for "regular disaster preparedness exercises, including evacuation drills",[8] and in the negotiating text at the UNFCCC.

This presentation aims to examine the establishment and implementation of the new frameworks on DRR and climate change from an international legal perspective, looking specifically at the rights of displaced persons. A particular focus will be placed on internal displacement caused by climate change. First, this submission will analyse the existing obligations relating to migration and climate change, including voluntary mechanisms for human mobility and planned relocations. Second, it will cover methods of implementation, including good practices, monitoring, and the importance of reliable data. Lastly, it will feature some concluding remarks and potential areas for future research.

Migration and climate change in rural Africa

E. Massetti (1) ; C. Cattaneo (2)
(1) Georgia Institute of Technology, School of Public Policy, Atlanta, GA, United States of America; (2) FEEM, Milan, Italy

We study how climate affects migration decisions of households in Ghana and Nigeria. If migration is part of the present adaptation portfolio of households to different climatic conditions, it is reasonable to expect that it will also be an adaptation to climate change. Thus, we also provide estimates of the expected impact of future climate change on migration in Ghana and Nigeria.

It is important to stress that we are interested in climate --- the average of weather conditions over a long period of time --- rather than in short-term weather fluctuations, which represent single realizations of climate. Our approach accounts for the long-run adaptation response to climate. The existing literature has instead mainly focused on the relationship between weather variability as well as weather extreme shocks, such as flood or drought, and migration. Overall this literature suggests that out-migration is a common response to agricultural productivity losses due to harmful weather events. The analysis of migration response to weather variation and shocks is a very interesting area of research but estimated elasticities should not be used to provide estimates of the response to slowly changing climate patterns.

In this paper we instead regress long-run migration patterns of households on climatic conditions and on other control variables. The advantage of this method is that it fully accounts for adaptation to the present climate. Migration is one of the many possible adaptations to local climatic conditions. The method thus identifies the relationship between climate and migration by exploiting the cross-section variation of climate and of long run migration decisions.

What is the expected shape of the relationship between climate and migration? It is reasonable to assume that with less favorable climatic conditions the incentive to migrate increases. However, migration is an expensive investment and it may be too costly for some households. High temperatures and extreme precipitation patterns reduce agricultural productivity in presence of agricultural adaptation for many reasons. However, migration is a costly investment. Climate change may increase the incentive to migrate but with incomplete and imperfect markets households may not be able to migrate because they may see a reduction in the very capital required to enable a move. Thus, given these different channels, working in opposite direction, the relationship between climate and migration decisions deserves an empirical analysis.

In this paper we narrow our focus on Ghana and Nigeria. The data are drawn from two different household surveys that gather individual as well as household information. We heavily draw on the predictions of the New Economics of Labor Migration, introduced by Stark and Bloom (1985), which emphasizes the role played by the family in migration decisions. Migration of some individuals respond to an overall family strategy, designed to adapt to current climatic conditions.

Our results reveal that the relationship between the probability that at least one member of the household is a migrant and temperature in the dry season is hill-shaped. A hill-shaped relationship results as well between precipitation in the wet season and migration. The highest propensity to migrate is at 23°C during the dry season and at 125 mm/month of precipitation during the wet season. This relationship holds only for households that are engaged in farming activities. The empirical findings reveal that migration decisions of non-farming households are not affected by climate. Our findings are robust to a series of alternative model specifications. Households located in districts with mild temperatures/precipitations have a positive chance to become migrant families if temperatures/precipitations increase. On the contrary, in districts with already high temperature/precipitations, the reverse occurs. Mild temperatures/precipitations benefit agricultural productivity and makes migration more likely. On the contrary, for higher levels of temperatures/precipitations, households may be caught in a poverty trap from which they cannot escape, as a consequence of productivity losses. We also calculate non-marginal changes of migration using geographically and seasonally differentiated climate change scenarios.

P-2242-06

The Role of Climate Change for Migration in the Past, Present and Future

I. Schumacher (1) ; JF. Maystadt, (2) ; E. Strobl (3)
(1) IPAG Business School, Paris, France; (2) University of Lancaster, Lancaster, United Kingdom; (3) Ecole Polytechnique , Economics, Paris, France

In this article we investigate the changing role of climate change as a driver of migration. We take a temporal perspective, where we analyze why and how climate change affected incentives to migrate in the past, how it affects incentives to migrate in the present, and what this may tell us about how climate change may impact incentives to migrate in the future. Our focus is on economic determinants of incentives to migrate, and how climate change alters these economic determinants.

To this we add a meta-analysis of the literature on climate change and migration, where we study the determinants of migration and climate change in the literature. We single out roughly 60 articles that look at climate change as a driver of human migration. In particular, we focus on the common issues of publication bias, and as to what kind of datasets and variables tend to be the most informative.

P-2242-07

International migration and climate change impact: a macro-economic assessment for SLR

G. Standardi (1)
(1) FEEM - Fondazione ENI Enrico Mattei, Venice, Italy

The relationship between climate change and migration has been poorly understood in the literature (Stern, 2013; Licker and Oppenheimer, 2013). Different methodologies have been used producing different outcomes (Beine and Parsons, 2012; Marchiori and Schumacher, 2011; Morteux and Barnet, 2009; Sheen and Gemenne, 2011). The aim of this work is to show under which economic conditions climate change can cause international migration and to what extent international migration can be beneficial or detrimental to reduce the economic losses of climate impacts.

To achieve this goal we use a Computable General Equilibrium (CGE) model, which is calibrated to the Global Trade Analysis Project (GTAP) database (Narayanan et al., 2012) for the year 2007. Differently from the GTAP macro-economic model (Hertel, 1997) we make possible for labor to move outside the borders of ten large macro-regions: Europe (EU), North America (NA), Latin America (LA), Former Soviet Union (FSU), China (Chi), India (Ind), Rest of Asia (RoA), Sub Saharan Africa (SSA), Middle East and North Africa (MENA), Oceania and Japan (OJ). The physical impacts stem from the DIVA software (Hinkel and Klein, 2009). DIVA is a widespread tool which computes the land loss caused by Sea Level Rise (SLR) at a very high geographical resolution. The cumulative land loss in Km2 (submergence plus erosion) from 2007 to 2100 for each one of the ten regions is divided by the total amount of land in these regions in 2007. We use these ratios as

negative productivity shocks affecting the use of both capital and labor in the CGE model.

In order to build a reliable economic and demographic scenario at the end of the century, we rely on the projections of GDP and population provided by the International Institute for Applied Systems Analysis (IIASA) for the Special Report on Emissions Scenarios (SRES) A2 (Nakicenovic and Swart, 2000). We have two cases. In the first one the labor is completely immobile at the macro-regional level while in the second one we model an integrated global labor market. The migration process is entirely determined by the movements of workers who react to the relative wage signals induced by climate change.

The results show a world SLR economic loss around 2.64% of global 2007 GDP under the assumption of immobile labor and a SLR economic loss around 2.59% under the assumption of mobile labor. Table 1 reports results. Rest of Asia is the most affected region by SLR but interestingly some regions as China, FSU, SSA and MENA gain from SLR. Except Rest of Asia, Latin America and India all the regions are able to decrease their economic losses or to increase their gains when the labor is more mobile at the international level. We observe a migration process mainly from Rest of Asia to the other macro-regions. It is worth noting that we do not consider within-region migration.

All this suggests that the international migration driven by a more flexible and integrated global labor market could represent a useful adaptation strategy option to slightly reduce the economic impact of SLR even if it cannot substitute in any way the adoption of strong mitigation policy to trim down damages, especially in the Rest of Asia.

Table 1	% Productivity loss on labor and capital	% GDP change (labor mobility)	% GDP change (labor immobility)	Net migration flow (Milions)

Ecological and social aspects of the Arctic zone of Yakutia, Russia

N. Stepanova (1) ; G. Tuyara (1) ; N. Bochkarev (2)
(1) North-Eastern Federal University, Yakutsk, Russia; (2) Yakut Scientific Center, Yakutsk, Russia

Migration loss of population is characteristic for Siberia and Far East of Russia and is especially influenced Arctic zone. Number of population in Yakutia had shortened for 15% during 1990-2013, while in the Arctic districts of Yakutia - twice (for 53%). In 90-ies migration generally touched non-ingenious population who had migrated to other regions of Russia. Nowadays the internal migration prevails; people from the Arctic districts move to the ones with more comfortable climate and economic conditions and better jobs opportunities.

The fall of industrial production and quantity of population in Arctic had shortened the volume of pollution emissions caused by stationary sources in this area. In 1990-2009 it was reduced twice. In 1990 Arctic zone expel 21% of pollution emissions of the Republic Sakha (Yakutia), today it is only 12% of total mission in Yakutia. But because of the extremely low temperatures and massive permafrost occurrence the potential of Arctic nature to self-healing is low.

Today the main source of pollution is the living-support system, including heating system, transport, especially big vehicles which supplies Arctic zone with goods and fuels using winter roads. Housing and communal system in Arctic is characterized by high costs and low effectiveness, the huge disperse inhabited territory, isolated from the united energy supply system. Distances between populated localities in Arctic are about 600-700 km., heating period lasts from 223 to 365 days. Heating is organized by the low power disjointed boilers (with powers less than 2 Gkal/hour). These low efficiency boilers increase antropogenius environment pollution. Arctic districts heating system runs-out up to 80% and heat losses in the system are about 32%.

Arctic area deficits productive forces for neutralizing stationary sources pollutions. In Yakutia in general the level of neutralized pollution with regard to the level of its emission lowered from 75,9% in 1990 to 64,8% in 2009. While in the Arctic zone this figure started in 1990 lower, only with 15,7% and reached 6,6% in 2009. The same situation is observed in draining water downthrow: in Yakutia volume of draining downthrows is about 60%, while in Arctic zone there are now water cleaning facilities.

The decentralized energy systems modernization strategy of the North and Arctic zone focuses on the projects in alternative energy sources, automation of heating system. But nowadays it can hardly be implemented due to the limited access to the imported equipments and technologies, as well as to the local budget deficits. This situation can stay fixed for the several years.

Before soviet period Arctic was poorly inhabited territory with the extreme climate and poor food resources. This land cannot feed many people, and there were now huge settlements, people were spread over the territory for they can feed theirselves by hunting and fishing. Thaw the antropogenius pressure was low. Beside innovation and new technologies usage for the Arctic development it is necessary to determine the quantity of population limits in this area. It will allow making decisions in economic and social policy in this area. It is probably necessary to move people from the depressive districts of Arctic zone to more comfortable once.

2243 - Multi scale adaptation and responses in vulnerable coastal sectors under climate change risks

ORAL PRESENTATIONS

K-2243-01

Coastal adaptation under high-end climate change

A. Sánchez-Arcilla (1) ; R. Nicholls (2) ; J. Hinkel ()
(1) Universitat Politècnica de Catalunya (UPC), Maritime Engineering Lab. (LIM/UPC), Barcelona, Spain; (2) University of Southampton, School of civil engineering and the environment and tyndall centre for climate change research, Southampton, United Kingdom

The reduction of greenhouse gas emissions and the resulting level of global warming remain uncertain. The thermal inertia of sea water commits us to a continued increase of mean sea level at decadal to centennial scales. The increase of human pressure and economic development in coastal zones will aggravate the problem. Conventional hard coastal defences are costly and increase the risk of catastrophic consequences in case of failure and may exacerbate the loss of territory (e.g. wetlands) through coastal squeeze. Adaptation needs to be a long-term process covering a wide range of management strategies.

To face this challenge, advanced scientific information on the processes and impacts will be a key element in order to develop robust adaptation pathways. Such pathways must take into account plausible high-end sea level rise scenarios and changes in storminess as well as quantitative impact projections. This information will allow an objective definition of tipping points for adaptation, the effect of feedbacks between the various components of the coastal system and the efficiency of novel coastal interventions. The adaptation pathways will allow defining a sequential set of interventions that facilitate the maintenance of coastal zones under all climate scenarios. The role of novel solutions promoting natural accretion mechanisms and using eco-morphodynamics to reduce coastal mobility needs to be explored as this has the potential to increase our chances to maintain healthy coastal systems under a variety of climates. From here we shall derive advance information on when, where and how to act, especially if change is at the high end, and this will facilitate the sustainability of these areas.

Within the EU research project RISES-AM- we are projecting impacts at global, regional and local scales. The global modelling is based on the DIVA code, addressing the flooding and erosion impacts worldwide. The regional modelling is based on a variety of hydro-morphodynamic models which reflect the site specific expertise and available model calibration/validation. As illustration for the Mediterranean we are analysing the Catalan and Croatian coast, the former with a sequence of models specially adjusted for this coastal sector and the second one with a regional adaptation of DIVA. The level of resolution and processes at this regional scale is much higher than for the global analyses, including surges, wave action and long shore and cross shore sediment transport components together with the human pressures and infrastructures existing along the coast.

The local dimension can be illustrated by the Ebro Delta and other small-scale Mediterranean deltas where both the vertical dynamics of the coastal plain and horizontal dynamics of the coastal fringe are being studied. For this particular case the suitability of “green” interventions based on promoting natural accretion is also being examined so as to assess its performance under present and future climate conditions. The resulting analysis will allow identifying and partially quantifying adaptation tipping points that will be presented in the paper. This will go associated to determining critical thresholds as a function of scale and related by way of illustration to the availability of space or sediment. The combination of climatic pressures, coastal responses and the expected socio economic evolution will be the building blocks for defining an adaptation pathway suited to the studied coastal areas, illustrated in the paper by the three scales mentioned above.

Responding to Changes in Coastal Zones

N. Bednarsek (1) ; T. Klinger, (2)
(1) University of Washington, School of Marine Affairs, Seattle, United States of America; (2) Universtiy of Washington, School of marine and environmental affairs, Seattle, WA, 98105, United States of America

Changes in climate and associated stressors will impose critical changes in coastal ocean systems. We propose a session to address changes in the coastal ocean, using the California Current Large marine Ecosystem as a model system. The CCLME is a productive upwelling zone along the west coast of North America. It supports economically and culturally important fisheries and provides other essential ecosystem services. A large and growing population lives in the adjacent coastal zone. Climate and associated stressors are projected to influence circulation, productivity, and biogeochemical processes, including acidification and hypoxia, in the CCLME, with consequent effects on social and economic systems. In this session we will include perspectives that range from changes in physical and biogeochemical processes to those of ecosystem services and socio-economic responses. We will close the session with a forward-looking perspective on collective action.

The Coastal Cities at Risk (CCaR) Project: Research advancing climate change adaptation planning and implementation in Metro Vancouver, Canada

L. Mortsch (1) ; G. Oulahen (2) ; K. Tang (2) ; Y. Klein (3) ; K. Damude (1) ; E. Joakim (1) ; D. Harford (4)
(1) University of Waterloo, Geography, Waterloo, Ontario, Canada; (2) Western University, London, Ontario, Canada; (3) ACT, Simon Fraser University, Vancouver, British Columbia, Canada; (4) Simon Fraser University, Adaptation to Climate Change Team, Public Policy School, Vancouver, BC, Canada

Many low-lying coastal cities, already coping with population growth, urbanization and economic, social, environmental and health challenges, are becoming increasingly exposed to climate change impacts related to rising sea levels and changing flooding risks. In order to respond to these challenges, proactive adaptation is becoming a fundamental and necessary response in a future that is likely to have increasingly frequent and more severe climate-related hazards. By understanding vulnerability and resilience, and their influence on adaptation planning and implementation, the capacity of these cities to address future climate change hazards and stressors can be improved. A Canadian-funded international research project - Coastal Cities at Risk: Building Adaptive Capacity for Managing Climate Change in Coastal Megacities (CCaR) - seeks to explore these issues in Bangkok, Vancouver, Lagos, and Manila. This presentation highlights results from Metropolitan Vancouver, British Columbia, Canada. It explores the unique challenges and opportunities in a complex urban environment that influence the effectiveness of adaptation planning and policy development. A variety of thematic areas related to this issue were addressed, including physical, economic, social, institutional, and health while employing a broad range of scientific approaches from natural, social science and applied engineering. This presentation highlights the social science component and the advances made in the social and institutional themes. Examples presented explore: the production of vulnerability to flood hazards, identifying indicators of resilience, and mainstreaming climate information. Multiple methods such as literature synthesis, focus groups, interviews, surveys and content analysis were used in combination with social vulnerability and resilience indicator development and mapping. The component on production of vulnerability to flood hazards applied a conceptual framework - across scales

and across actors – to identify and situate factors that influence vulnerability, mapped vulnerability indicators and "ground truthed" results with key stakeholders. Out of this research emerged an interest in developing resilience metrics, particularly examining how social resilience been defined in the climate change and hazards fields and what indicators have been developed for the neighborhood scale. From this literature review, an extensive list of metrics has been developed. The "mainstreaming" exercise used a policy scan to assess how municipal, sub-national and federal government policies facilitate or constrain the incorporation of climate change information into decision-making for adapting to flood hazards. In the project, there was a strong commitment to engage with the community to access local information and expertise in order to ground the research but more importantly to initiate a two-way dialogue as a means of enhancing awareness and knowledge transfer. This process has contributed to building local adaptation capacity as CCaR research results have been incorporated into municipal adaptation planning and implementation.

A Psychological Perspective on Behavioural Adaptation Challenges to Climate Change in Coastal Cities of India

R. Mudaliar (1) ; P. Rishi (2)
(1) Aix-Marseille Université-CNRS, UMR ESPACE 7300, Aix-en-Provence, France; (2) Indian Institute of Forest Management,Bhopal, INDIA, Human Resource Management, Bhopal,MP, India

Coastal India faces a perceived potential threat owing to the vast sea-side development and huge populations in the vicinity of the coast. Climate change in coastal areas is associated much with flooding, SLR, land inundation, storms, cyclones etc. India has been identified as one amongst 27 countries which are most vulnerable to the impacts of global warming related accelerated SLR (UNEP,1989).Therefore, there is a pressing need to address issues related to climate stress, adaptation, vulnerability and coping in coastal cities of India, especially from the psychological perspective. The established fact that anthropogenic factors account for one of the major contributors to climate change makes it necessary to probe into behavioral facets as in spite of the best possible efforts around the globe to combat climate change, it is felt that people are still not as seriously aware/ alarmed of the expected future risk as they should be. If environmental stressors persist chronically, they may lead to inner conflicts that can be psychologically disturbing for individuals and may even give rise to physiological, emotional, cognitive and behavioral changes.

In light of the above, the present behavioral study assessed the cognitive understanding of climate change, climate stress and actions and reactions of coastal people with a special focus on behavioral adaptation and subjective well being. The study was conducted on a sample of 454 adults, both males and females (Age 18 years and above) in two coastal megacities of India namely Mumbai and Chennai keeping in mind the coastal hazards and vulnerability issues associated with these cities (TERI,1996). Especially designed Climate change perception Inventory (CCPI) based on a four-point Likert type rating scale format was used to assess the respondents' Climate Change Awareness (CCA), Climate Stress and Emotional Concern (CSEC), Coping/Adaptation, Institutional Accountability (IA), and Coastal Subjective Well Being (CSWB). Results indicated a good level of CCA and subjective well being among coastal people. Respondents were found to be experiencing a moderate amount of climate stress and were unable to fully cope with it. They expected more efforts on the part of government and environmental institutions for adapting with climate change in coastal cities and suggested various adaptive strategies in this regard. Results were interpreted in line with article 6 of New Delhi Work Program of UNFCCC (2007) in which special effort to foster psychological/behavioral change has been stressed through public awareness.

O-2243-02

First results from the world biggest coral planting program (Baa atoll, Maldives)

F. Ducarme (1)
(1) Muséum National d'Histoire Naturelle, Ecologie et Gestion de la Biodiversité, Paris, France

This work presents the first results of the world's biggest coral planting program, located in Baa atoll UNESCO Bioscphere reserve (Maldives), and led by SeaMarc / Marine Savers association, with scientific support from the MNHN.

Maldives is known as a very low island country, constituted of more than 1200 sandy islands not exceeding 2m high. This country shelters an extremely rich marine biodiversity along with a population of 400 000 inhabitants, but faces concerning threats from weather condition change, water acidification and sea level uprising. All these islands being constituted of coralline sand and protected from wave action thanks to coral reefs, the health of corals directly impacts the very existence of the islands, and severe erosion can already be observed in some urban islands with damaged reefs such as Malé.

The Marine Savers program has started planting coral frames in 2007 and standardized the methods and gears in 2010, on the basis of a crowd founding system financed by resort tourists. More than 3000 coral frames have been planted to date at different sites and depths, totalizing more than 200 000 coral grafts, from more than 20 different species of scleractinian corals. The frame growth have been surveyed, photographed and managed on a biannual basis, and >150 representative frames of different ages have been weighted in order to give a proxy for total biomass.

This study aims at providing a synthesis of these growth results and rate, along with observations on natural colonization by sessile, benthic and pelagic species. Results proved that this method can produce a substantial amount of coral biomass in a rather short time span, and recreate habitat conditions suitable for most reef species. Most coral species proved to be extremely site-sensitive, and show important growth discrepancies depending on slight condition differences.

Such experiment could help understanding growth and survival of different species of corals coral under different conditions, and provide an important technical basis for further restauration or ecological compensation projects. As the frames developed by Seamarc are moveable, this system also aims at developing a way to help conserving young coral sprouts in deeper waters during bleaching events in order to achieve quicker and better ecological resilience, and in a longer run selecting the more resistant genes for climate change adaptation.

O-2243-03

Surviving from "rob" (tidal flood) – how local knowledge helps coastal villagers in Demak, Central Java

AD. Ekaputri (1)
(1) Indonesian Institute of Sciences (LIPI), Research Center for Population, Jakarta, Indonesia

Indonesia is an archipelago country with coastline spans more than 90,000 km, the fourth longest in the world. The coastal areas house around 60% of the total Indonesia population. However, in the past few decades these areas has been threatened by increasing sea level rise, including Demak, a city located in the northern coast of Central Java. In 2010, Bedono, one village in Demak, suffered the most impact from "rob" or tidal flood with half of the village area sunked into sea, including villagers' residences. This has caused a significant number of local people lost their homes and livelihoods. With no sufficient guidelines on how to survive from "rob", villagers forced themselves to adapt based on their own knowledge. A five-year research conducted by LIPI in Demak showed that villagers' behavior to adapt depends on the level of sea rise. The extreme case where houses are permanently drowned, villagers relocate to neighbouring villages. For other cases, villagers elevate their houses' floors, reschedule time to cook, prepare

house cleaning utensils, and protect their children's health. In the context of livelihood, villagers arrange the time to seed the fishpond so it can be harvested before tide comes and destruct the production process. One local knowledge that proves to be useful is silvofishery, integrating fishpond with planting mangroves. It has successfully decreased level of destruction in coastal areas as well as improving villager's wellbeing. These adaptations based on local knowledge should be taken into account by the government to improve the climate adaptation strategies and programs.

O-2243-04

Infrastructure and societal challenges in addressing climate impacts in the North Coast of São Paulo, Brazil

D. De Freitas (1) ; CDSJ. Wilson (2) ; FMDG. Luiz (3)
(1) Technological Institute of Aeronautics, Department of water and environmental sanitation, Sao Jose dos Campos, Brazil; (2) Technological Institute of Aeronautics, Engineering division of infrastructure, department of water and environmental sanitation., Sao Jose dos Campos, Brazil; (3) Federal University of São Paulo, Campus Baixada Santista, Oceans institute, Santos, Brazil

Worldwide, coastal communities are challenged by the increase in frequency and magnitude of natural events associated with climate variability and change. During the last decade, several significant events such as storm surges, cyclones and sea level rise have caused substantial damage to coastal infrastructure and communities. For example, continuous erosion and frequent storm tide inundation threaten coastal settlements and infrastructure by making then more vulnerable to landslides and flooding, respectively. These issues demand special attention in developing countries, where populous irregular settlements (such as slums) are common in coastal areas, experiencing greater vulnerability to natural disasters and other environmental risks. Nevertheless, climate change and its related impacts are neither well understood nor taken into consideration at local and regional planning scales in developing countries. Brazil is an example of such problem. At the local scale, there are pressures related to settlement for construction and operational assets associated with port expansion and the development of oil and gas industry mega-infrastructure. At the state and national scales, there are political and economic pressures imposed by development associated with the Pre-Salt oil exploration offshore which does not consider local management needs and priorities on land use planning. In this study, we present the major findings of the RedeLitoral, a multidisciplinary project with the objective of evaluating the knowledge climate change impacts effects on society, built infrastructure and land use planning in a region experiencing fast development in the south-east of Brazil. Our results indicate that human settlement, mainly driven by tourism and mega-infrastructure developments, has induced urban sprawl towards the most vulnerable areas, making these populations and associated infrastructure more susceptible to the impacts of climate change. Fragmented and sectored licensing processes does not consider the cumulative and synergistic environmental effects resulting in inadequate public policies. Local coastal management initiatives show intense rearrangement, but changes are mostly focused in the ecological-economic zoning and creation of marine protected areas, and climate change mitigation and adaptation strategies are not a priority in the planning agenda.

P-2243-01

Climate Change, Biodiversity and Human Well-Being in the Coastal Communities around the Eko Atlantic City in Nigeria

AA. Akinwale (1)
(1) University of Lagos, Industrial Relations and Personnel Management, Akoka, Lagos State, Nigeria, Federal Republic of

With astronomical increase in the rate of urbanisation and deficits in environmental protection in Nigeria, coastal communities are at risk of the consequences of climate change, especially flooding, biodiversity loss, and food scarcity. This situation constitutes dangers to human well-being in the coastal communities in Nigeria. Therefore, this study examines human well-being in the context of climate change and biodiversity in coastal communities around the Eko Atlantic City in Nigeria, focusing on how the dangers of climate change can be mitigated with minimal discomfort to people and organisms in the coastal environment. The study is based on analysis of primary and secondary data in conjunction with the theoretical framework of political economy and underdevelopment. While extant literature and documents on climate change, biodiversity and urbanism in Lagos state of Nigeria constitute the secondary data, primary data were obtained via 20 Key Informant Interviews (KIIs) and 8 Focus Group Discussions (FGDs) conducted in four Local Government Areas (LGAs): Apapa, Eti-Osa, Ibeju-Lekki, and Lagos Island, respectively. The KIIs and FGDs involved youth and community leaders in several coastal communities in the selected LGAs. The discussions essentially dwell on the following issues: (1) the manifestation of climate change in coastal environment in Lagos state of Nigeria; (2) official efforts to mitigate the dangers of climate change in Lagos state; (3) consequences of land reclamation on biodiversity in the coastal environment; (4) public reactions to government's efforts in the reclamation of lands and construction of Eko Atlantic City; and (5) how human well-being can be improved for achieving the goal of sustainable development in the coastal environment. The findings reveal that climate change constitutes a threat to biodiversity and general socioeconomic development through extreme temperature, coastal erosion, frequent flooding, loss of land, drought, and increased salinity of water, which have become a recurrent environmental problem in Nigeria. To prevent further encroachment by the sea, the Lagos state government has embarked on reclamation of lands and construction of a city project known as Eko Atlantic City through public-private partnership. The project is a 4-square mile extension of Lagos towards the edge of the Atlantic Ocean with a view to mitigate the problem of flooding through a 35-foot tall seawall protective barriers on the one hand, and the problem of growth by using the extension as a site for new apartments, on the other hand. Three out of every five participants describe the Eko Atlantic City project positively in terms of its strategic location and attractions. However, all the participants in the KII and FGDs expressed concerns over the perceived failure by the government to take the well-being of the poor into consideration before and after the reclamation of lands for the construction of the Eko Atlantic City. There is consensus among the participants that only the wealthy persons and big industries have bought the lands reclaimed from the Atlantic Ocean. Two-third of the participants observes that land reclamation has created ecological imbalance and displacement of some people and organisms in the affected areas in Lagos state. The findings suggest that the Eko Atlantic City project is a form of internal colonialism which may be largely detrimental to human well-being in the coastal environment in Lagos state. It is noted that with adequate support from national and international environmental protection agencies the current situation in the coastal environment in Lagos state can be corrected through appropriate policies and enforcement of standard practice. Also, there is need for more attention on urban resilience systems to protect coastal communities in Lagos state from natural and manmade disasters.

P-2243-02

Determinants of Farm-Level Adaptation Practices to Climate Extremes: A Case Study from Odisha, India

CS. Bahinipati (1) ; L. Venkatachalam, (2)
(1) Gujarat Institute of Development Research, Economica, Ahmedabad, India; (2) Madras Institute of Development Studies, Economics, Chennai, India

A large number of rural households in the state of Odisha, India are dependent on agriculture for their basic livelihoods, which is affected by the frequent occurrence of climate externalities like cyclones and floods. In response, the farm households do also undertake adaptation measures to minimise the economic impact of these externalities. It is, imperative to analyse the current adaptation strategies of the farm households so that future adaptation policies aimed at scaling up adaptation strategies can be designed effectively. Using a survey

data of 285 farm households in the cyclone and/or flood prone districts of Odisha, the present study identifies the farm-level adaptation measures as well the determinants of these measures: agricultural extension, access to Mahatma Gandhi National Rural Employment Guarantee scheme, received crop loss compensation and informal credit. It is concluded that the government adaptation policies and investment options should take into account these determinants in order to enhance the adaptive capacity of the rural farmers in the cyclone and flood prone regions of the state.

P-2243-03

Integrating science into legal frameworks for sea-level rise planning – an Australian case study

J. Bell (1)
(1) University of Queensland, TC Beirne School of Law, Brisbane, Australia

One of the anticipated impacts of climate change is sea-level rise, with Australian communities likely to be particularly affected. It is estimated that 85% of Australians live within 50 kilometres of the coast (Department of Climate Change, 2009), making sea-level rise planning a major concern for Australian governments.

Despite this high level of risk, the inherent uncertainty surrounding the timing and extent of sea-level rise impacts makes it extremely difficult to garner political and public support for sea-level rise planning. Sea-level rise has been a politically divisive issue in Australia, with policies introduced by governments, and then removed following an election and shift in power to a more conservative administration. Sea-level rise has also caused considerable conflicts between state and local governments.

However, despite this challenging political environment, there are some good examples of sea-level rise science being integrated into law in Australia. These examples include large-scale mapping of hazard areas linked to a planning code, planned retreat policies teamed with conditional development approvals, and innovative approaches to seawall planning.

This presentation will explore some of the novel approaches to integrating science into legal frameworks for sea-level rise planning, and demonstrate how legal barriers have been overcome.

Planning for coastal relocation: analysis of relocation drivers in Hurricane Sandy affected communities

A. Bukvic (1) ; A. Smith (2) ; A. Zhang (3)
(1) Virginia Tech, Urban Affairs and Planning, Blacksburg, United States of America; (2) Virginia Tech, Psychology, Blacksburg, United States of America; (3) Virginia Tech, Statistics, Blacksburg, United States of America

The future viability of some coastal communities has been severely challenged by the recent major disasters, as well as other episodic and chronic coastal hazards. These events also instigated a dialogue on their long-term resilience, adaptation options, and the possibility of permanent relocation from high risk areas. Little is known how exposure to disaster, in combination with other contemporary coastal challenges, affects willingness to consider relocation on a household level in highly-developed urban settlements. The main objective of this paper is to provide a bottom-up perspective on this dilemma via identification of demographic determinants and other disaster-related concerns that may influence support for relocation among coastal residents. More specifically, this study takes an interdisciplinary approach to examine the effects of pre-disaster socio-economic household characteristics, level of preparedness, disaster exposure, experience with recovery, concerns with other coastal stressors, relocation assistance support needs, community embeddedness, and resource loss on relocation decision-making. The findings hereby reveal that the willingness to consider relocation is primarily influenced by the age of respondents, disaster exposure, level of experienced stress related to recovery, personal financial recovery concerns, future cost of living in high-risk area, concerns with increase in crime and future flooding, and disaster-induced resource loss. Lastly, the findings reveal that age by itself has a buffering/protective effect on stress and relocation consideration, such that older age predicts less stress and reduced interest in relocation, however, conditional on the level of experienced resource loss. Specifically, as resource loss increased, being older no longer protected respondents from disaster-related stress or consideration of relocation. Considering that relocation process is likely to occur in incremental and successive stages rather than all at once, these observations can provide a vital guidance as of which constituents may and under what circumstances decide to relocate sooner or later. This bottom-up perspective on contemporary coastal concerns and stressors that could drive decision to relocate can help inform the development of relocation policy that will more accurately reflect local circumstances and preferences and therefore receive more support for implementation.

P-2243-05

Paleoenvironmental changes of Heuksan Mud Belt (HMB) in the southeastern Yellow Sea, Korea

HG. Cho (1) ; KY. Kwak (1) ; C. Hunsoo (2) ; SJ. Lee (3)
(1) Gyeongsang National University, Geology, Jinju, Republic of Korea; (2) Korea Institute of Geoscience and Mineral Resources, Petroleum and marine research division, Daejeon, Republic of Korea; (3) Korea Environment Institute, Environmental policy reseach group, Seoul, Republic of Korea

Quaternary paleoenvironmental changes of the Heuksan Mud Belt (HMB), a development stretching south to north along the southwest coast of the Korean Peninsula, are interpreted as having been mostly controlled by rises in sea level after the Last Glacial Maximum (LGM). The present study investigates paleoenvironmental changes in the HMB through clay mineral changes in samples obtained from the Korean Institute of Geoscience and Mineral Resources (KIGAM) borehole, HMB-103(core depth: 38.55 m), of 2012. Preferred-oriented specimens of 174 samples in 20 cm intervals were prepared and semi-quantitative analyses for 4 important clay minerals were then conducted using X-ray diffraction according to the Biscaye's method (1965). Clay mineral contents within the clay portion of core deposits were, in descending order: 58.5-70.6% (avg. 64.5%) illite; 8.7-21.7% (avg. 16.0%) chlorite; 10.1-17.3% (avg. 13.2%) kaolinite; and 1.9-16.4% (avg. 6.4%) smectite. The deposits were classified into the following three units, according to the 4 clay mineral content: top-13.5 m (Unit I); 13.5-21.0 m (Unit □); 21.0-38.5 m (Unit □). Chlorite and smectite contents were lower in Unit I than in Unit □, while chlorite content decreased and smectite content increased from bottom to top in Unit □. The kaolinite content was similar in Unit □ and Unit □, and showed a decreasing pattern with decreasing depth in Unit □. The content of illite was higher in Unit □ than in Unit □, but had the lowest content in Unit □, where it showed a pattern of increase with decreasing depth. In general, illite and smectite had a negative correlation, and illite content was higher in the upper part of the drill core than in the bottom part, the smectite content showed the opposite tendency. The classification of units according to the clay mineral content is similar to that of sedimentary stratigraphic unit classification in geophysics exploration data. As a result of carbon age dating, the top part was found to be 2,700 cal yr BP, and the bottom part 50,000 cal yr BP, showing a range of periods dating from before LGM to the current interglacial period. Before LGM, the sea level was low, and sediments with a high smectite and a low illite content flowed in from the south of the research region where the depth of water was relatively deep. After LGM, as the sea level rose and the coastline moved to inland, sediments with lower smectite and higher illite were then supplied from Korean rivers. It is also supported by the form of uppermost Unit I progressing from the east to west. The deposit rate of the core deposits before LGM, which occurred 18 kyr ago was 2.07 m/kyr, for the period 18-11kyr it was 4.9 m/kyr, and following the last glacial 11 kyr ago it was 3.35m/kyr. Such changes represent deposit rate changes according to the rise in sea level. The

clay mineral composition change in borehole HMB-103 is considered to be caused by the movement of fine-grained sediments and the associated changes in the circulation pattern of surface currents with the deepening of the water depth due to climate change and a rise in sea level following LGM.

P-2243-06

Failure of Resilience & Adaptation in Agricultural Practice and Alteration of Socio-Ecological Structure Due to Ocean Acidification in 3 States of India

B. Ghosh (1)
(1) Asian Marine Conservation Association, Coastal Agriculture, Kolkata, West Bengal, India

'Climate change' is the major point of discussion of any political & decision- making agenda of any nation in general, and intergovernmental meetings and summits in particular. World community now understand that because of world's development sustainability depends upon its all the 'key-factors' that significantly play into various thrust areas like growth in agriculture, education and industry, and their respective drivers.

The problem of changing climate that reflected into adversities primarily into agriculture, education and industry has already been satisfactorily be identified by many researchers from academia, but not having the direct solution available, as of now, the policy makers have therefore to depend on some approach-- more of theoretical, than 'straightforward practical'. In this premises, the concepts like 'resilience', 'vulnerability' and 'adaptation' have come into play.

This paper shows that how resilience and adaptation fails in agricultural practices in and nearby coastal areas of 3 States (West Bengal, Andhra Pradesh and DIU-U.T.) of India, due to lowering of pH (Ocean Acidification) in nearby estuarine and coastal water increasing the 'vulnerability' in the socio-ecological structure that also have altered the pattern of local economic activities like 'tourism' and 'fish drying industries'.

Local government responses to sea level rise in Metro Vancouver

D. Harford (1)
(1) Simon Fraser University, Adaptation to Climate Change Team, Public Policy School, Vancouver, BC, Canada

Attention to climate change and sea level rise has intensified in recent years in Metro Vancouver. The region has been identified as one of the top cities in the world with assets at risk from rising seas, and vulnerabilities in the region include municipal property and infrastructure, and agricultural lands, as well as transportation infrastructure that supports the region's position as a gateway for global trade including railways, roads, port facilities and the international airport. Despite dense settlement and more than a century of industrialization, the region continues to sustain rich aquatic and terrestrial biodiversity, but climate change and approaches to adaptation also threaten environmental values. Experts have identified the need for regional collaborative governance to address climate change impacts, across the xx municipalities in the region, and four levels of government (local, provincial, federal and First Nations). There is a clear need for alignment of objectives among neighbouring coastal areas - without this, efforts undertaken in municipal silos could increase the risks.

In November 2012, nine local governments and organizations from Metro Vancouver, BC's Lower Mainland already leading in climate change adaptation work took part in a workshop on regional approaches organized by West Coast Environmental Law and ACT. Sea level rise was identified by participants as the most critical issue requiring collaboration, and WCEL/ACT moved to facilitate the formation of the Sea Level Rise Collaborative (SLRC), designed to add capacity to these entities given a common lack of resources and the challenges of data gaps. Seven local governments are now working together to share scientific resources, risk assessment methodologies and implementation approaches. Additional priorities include understanding legal risks and seeding broader regional collaboration, across other levels of government and sectors. A provincial representative has recently joined the collaborative, and the SLRC has a pilot project underway demonstrating green approaches to coastal resilience.

Actions to date include a design charrette to develop approaches to the new regional flood construction levels - 4.5 metres - based on the provincial estimate of 1 metre of SLR by 2100—exploring strategies that accommodate sea level rise and increase adaptive capacity over time. These approaches will be more cost-effective than shoreline armouring, will enhance community livability and protect coastal habitat. This and ongoing activities will help catalyze policy changes, new codes and standards, development of understanding of regional collaborative approaches as a key response to climate change impacts, and engagement of the local citizenry and professionals practicing in industry sectors related to this area.

P-2243-08

Eco-technological management of atoll island against sea level rise

H. Kayanne (1)
(1) University of Tokyo, Department of Earth and Planetary Science, Tokyo, Japan

Atoll island countries comprise low, flat islands consisting of calcareous sand and gravel formed from coral and foraminifera. The islands are maintained both by the physical processes of sand transportation and sedimentation and by the ecological processes of biological production. In the past, the inhabitants maintained their islands wisely in accordance with geo-ecological processes, such as the conservation of coral reef ecosystems, sandy beaches, and coastal vegetation, and cultivated taro using fresh water lenses formed in the island sediments. At present, however, the population concentration on the capital islands has led to inappropriate land use, degradation of coral reef ecosystems, destruction of geo-ecological processes through the construction of landfill sites and sea walls, and reduction in and deterioration of water resources due to the effects of over use and sewage. All these «local» problems have disrupted sand production-transportation-sedimentation process.

The submergence and inundation of atoll islands are regarded as a result of sea levels rise. However, the present problems are not as simple as submergence caused by rising sea levels; indeed, they are induced mainly by local problems. These problems have reduced the resilience of the atoll islands as historically maintained by their inhabitants.

«Global» issues also degrade coral reefs. Bleaching induced by global warming and ocean acidification resulting from increased CO2 also degrades coral reef ecosystems and reduces sand production. The modulation of El Niño, drought, and intensified typhoons induced by global warming threaten water resources in these islands. The problems in atoll countries involve inter-related local and global problems. Plans to adapt to global changes based on a simple scheme may instead reduce the resilience of these islands. To maintain the sustainability of islands against future global change, it is essential to regenerate geo-ecological processes by removing local problems so as to construct highly resilient islands.

To regenerate coral and foraminifera production, ecosystem rehabilitation is necessary. This should be achieved by improvement of coastal environment by sewage treatment and waste management. Rehabilitation would be supported by foraminifera and coral culture and transplantation and their habitat generation, however improvement of coastal environment is a prerequisite. Sand transportation and sedimentation processes should be reopened. An open-cut the causeway will enhance sand delivery from the ocean to the lagoon, nourishing the lagoon coast. Removal of the jetties or their reconstruction with piles and backfilling the dredges would re-open the transportation passage along the coast. Vertical seawall will enhance erosion rather than sedimentation at its foot. Therefore, beach nourishment is proposed as a shorter-term coastal protection and rehabilitation plan that enhances but dose not conflict with the long-term sandy beach rehabilitation.

Yet, the local problems themselves originate from the globalization of the economy and society. In traditional

island societies, the inhabitants kept their islands robust, albeit poor economically, by means of local governance indigenous to each island. However, the globalized economy and society, together with the introduced Western political system, have led to the centralization of the population on the main islands and to inappropriate land use.

Without considering the background factors, island management programs will never be acceptable for atoll societies in terms of sustainability unless they consider the appropriate geo-ecological processes. Moreover, geo-ecological processes differ with geological, climatological, and biogeographical variation; island governance differs according to historical and cultural background; and the expression of local problems depends on the local economic and societal background. Therefore, resilience and governance must be constructed in accordance with this geographical variation.

P-2243-09

Unpacking the Co-production of Knowledge in Adaptation to Climate Change: The Role of Local Knowledge in a Coastal City – Tainan, Taiwan

HC. Lee (1) ; R. Chen (2)
(1) National Central University, Chung Li, Taiwan; (2) Chinese Culture University, Taipei, Taiwan

As most of climate change research initiatives are more focused on natural sciences, it is almost impossible to understand the earth system without addressing humans as influencing the planet and as an essential driving force in shaping the future of Planet Earth. Thus, a major new step has taken to the development of science – from disciplinary to interdisciplinary, from one sector to cross-sectoral, and from natural sciences to social sciences and the humanities.

Based on the research results from a 3-year (2013-15) core research program – Taiwan Climate Change Adaptation Technology (TaiCCAT), this paper takes an interdisciplinary approach by examining the role of local knowledge to plan, manage and communicate local adaptation strategies in Tainan, Taiwan. Selected by Lonely Planet and Michelin as a must-see three-star tourist destination, Tainan, at the same time, has been at risks of rain storms and mud slides at mountain regions, urban flooding and coastal sea-level rise. Policy responses like building dikes or not, opening or closing water gates, water distribution among industrial, agricultural and residential sectors are frequently made by relevant government authorities with inputs from community groups.

To ensure government, business, society and academia have the foresight, knowledge and tools to adaption to climate change, this paper further conducts in-depth interviews with stakeholders from mountain, rural, urban and coastal regions for cross-checking its research findings. Tainan experience so far points to the importance of early engagement, trust-building, involvement of all stakeholders and assessment of knowledge needs and knowledge exchange. Hopefully in the future, it may become a robust example for co-design, co-production and co-delivery of knowledge also consistent with and called for by Future Earth research initiative.

P-2243-10

Why urban poor exposed to climate change in coastal Bangladesh are more concerned about ecosystem disservices than services?

MM. Saroar (1) ; N. Fatema, (2)
(1) Khulna University, Urban and rural planning discipline, Khulna, Bangladesh; (2) Khulna University, Development studies discipline, Khulna, Bangladesh

Urban poor get numerous benefits from ecosystem services. Roles of urban ecosystem services in the wellbeing of urban poor are extensively discussed, yet little is known about the vulnerability of urban poor to ecosystem disservices. Particularly in the context of climate change some of the ecosystem disservices might seriously affect the urban poor's wellbeing by impacting their livelihood, security and comfort. Therefore, this research is aimed to answer the question- why some urban poor are more concerned about getting protection from ecosystem disservices than getting benefits of ecosystem services? Accordingly three objectives are framed. First, to identify range of urban ecosystem services and disservices which the urban poor take into account to ensure their wellbeing. Second, to examine whether urban poor really care more about protecting them from ecosystem disservices than taking advantage of services. Finally, to identify the factors that determine urban poor's differential preference for ecosystem services/disservices.

This study was conducted taking coastal Khulna- a metropolis exposed to climatic disasters, as a case. Empirical part of this study was done in a large low-income settlement, named Rupsha slum. Family heads of a total 235 households selected randomly were interviewed through administering a semi structured questionnaire. From a list of 25 ecosystem services and disservices, respondents were first asked to rate in a 5-point Likert scale (very low =1 to very high = 5) if they get benefit from/affected by a particular ecosystem service/disservice. Second, they were asked to rate by using the same scale (a) the importance of those services and (b) their concern against those disservices. By employing Principal Component Analysis (PCA) on their responses to first question, the 25 categories were bought down to four practical utilities/negative utilities. These four categories are related to (a) livelihood, (b) comfort, (c) security and (d) recreation. For the second question, each person's responses (denoting both importance & concern) were first summed up and later dichotomized taking median as the cut-off point. With this, the respondents were reclassified into two distinct groups: (a) low benefit seekers vs high benefit seekers from ecosystem services, (b) low concerned vs high concerned about ecosystem disservices. Taking each of these two groups as dependent variable, two Ordered Probit models were developed to identify the factors that influence the respondent's positive preference (expressed earlier as "importance") and negative preference (expressed earlier as "concern") towards ecosystem services and disservices respectively. As independent variables, in addition to variables that are identified in Personal Motivation Theory (PMT) (such as intrinsic benefits, extrinsic benefits, perceived severity, perceived vulnerability), various socio-economic, ecological, demographic, behavioural, spatial and governance related aspects were employed in the Probit models.

Initial result shows that the urban poor take into account both green and blue ecosystem services for their wellbeing with a varying combination though. Variability is rather less as regards gaining advantage from various green ecosystem services such as green parks, streetscapes, urban forests, playgrounds. However, high variability is observed in regards to their concern over ecosystem disservices, particularly derived from blue ecosystem services such as rivers, canals, urban swamps, natural drainage. Ecosystem disservices which they care most are waterlogging, storm water overflows, surface run off and smell from decomposed waste. Probit models' results show that importance of ecosystem services to respondent's wellbeing are significantly determined by age, occupation, education, distance from house, access fees etc. On the contrary respondent's concern over ecosystem disservices are significantly determined by age, gender, occupation, season of a year, tenure of housing, length of stay, etc. However, other factors have limited influence. The findings would help designing appropriate interventions for (a) enhancing urban poor's access to ecosystem services, and (b) protecting urban poor from the vulnerability of ecosystem disservices. Therefore, this finding would give synergies to ongoing efforts of building resilient urban community in the context of changing climate.

P-2243-11

Social Memory and Social Change in a Portuguese Natura 2000 Coastal Area: Understanding Communities' Adaptation to climate change

E. Seixas (1) ; P. Castro (2) ; M. Carla (1)
(1) CIS-IUL, Lisbon, Portugal; (2) ISCTE-IUL, social psychology, Lisbon, Portugal

This presentation analyzes how social memory is linked to social change and climate change (CC) adaptation

in a Portuguese Natura 2000 coastal area of fishing importance, by looking at residents' narratives, paying particular attention to those of fishermen. Narratives are fundamental for linking the past, the present and the future, as well as for constructing meanings and identities. The stories that communities in Natura areas relevant for CC adaptation tell about the past are thus important for legitimizing specific social representations of the changes required for CC adaptation (e.g., representations of the new bio-conservation laws and regulations) while de-legitimising other, alternative, representations, and it is important to understand them and their role.

The study draws on (n=24) in depth qualitative interviews and walking interviews with residents of a Portuguese Natura 2000 Southern coastal area (n=16 interviews with fishermen). The guiding research questions are: How do residents' narratives about the past make sense of current social change and contribute to coastal CC adaptation or make it difficult? How do resident's narratives about the past legitimize specific social representations of bio-conservation laws and of coastal trades and practices, in particular those linked to fishing? What can the particular ways in which residents' narratives link the past the present and the future tell us about identity and representational processes, and about how these are affected by power differentials?

The preliminary analysis of the interviews suggests that (1) perceptions of a decrease in the main resources (fish and shellfish), (2) technological innovation and (3) the introduction of new legislation restricting fishing activities in the Natural Park have created a series of tensions in identity and representational processes, with consequences for power relations and social cohesion. These tensions evidence several representations of discontinuity with the past, differentiated according to the type of social change evoked: (1) change induced by a decrease in the 'resource' (2) change induced by technological innovation and (3) change induced by the introduction of new legislation and other social/economic policies.

In the interviews with the fishermen, the claims that the resource has decreased are linked to claims that in the past theirs was a much simpler trade, since they could always count that there would be more fish available to catch the next day. Conversely, in the present, fishermen claim to have to rely much more on their knowledge and experience, and there is an intensification of individual competition within the trade. They link the decrease in the resource to several factors like pollution, technological advances and, although not often, also excessive fishing. Technological innovation is described in a conflicting way: on the one hand, as advantageous since it contributes to facilitating the practices of fishing. As such, it is linked to a claim that in the past the trades and practices of fishing were more dangerous. On the other hand, it is associated with a decrease in the resource. When talking about the introduction of new Natura 2000 legislation restricting fishing in the site, as well other social and economic policies setting the conditions of the fishermen trade, interviewees often claim that before the laws were introduced it was much simpler to be a fisherman. On the whole, this narrative proposes then that (techno)science reduced the risks of the profession, but now laws are too restrictive of the trade. Also present in the narratives are claims that the use of technological solutions by other social actors with competing practices (such as specific kinds of fishing nets used by large fishing companies or diving equipment used for capture in breeding niches) are contributing to the depletion of certain species and that laws in these cases are necessary for balancing the ecosystem. On the other hand, one finds also a representation of continuity with the past, linked to the idea of an ancient attraction/'addiction' to the sea and stressing the agency of the fishermen in their 'career' and pursuing a highly demanding occupation. This research shows the importance of analyzing the conservation of biodiversity and coastal adaptation by considering the narratives of the affected communities and the way that social memory is linked to social change adaptation. It highlights the multifaceted, dynamic and flexible nature of social memory and the way it is regulated by social psychological processes.

P-2243-12

Coping with climate change impacts: The case of coastal fishing communities in Patuakhali region, Bangladesh

AR. Sunny (1) ; MM. Islam (2)

(1) Sylhet Agricultural University, Department of Coastal and Marine Science, Sylhet, Bangladesh; (2) Sylhet Agricultural University, Department of Coastal and Marine Fisheries, Sylhet, Bangladesh

Globally, Bangladesh is considered as one of the most vulnerable countries to the anticipated impacts of climate change. Following that situation, scientific community often uses Bangladesh as a test case of studying climate change impacts and respective adaptation strategies in different professional groups. However, very few studies focused on the coastal fishing people, though they are one of the most vulnerable professional groups to climate change impacts. Based on a fieldwork in four fishing communities in Patuakhali region of Bangladesh, this study identifies livelihoods strategies that fishers adopt to cope with the impacts of climate changes that impinge on them and possible ways to enhance their capacity to make climate resilient fishing communities in Bangladesh. To collect empirical data, household survey was conducted and a number of qualitative tools such as interviews, focus group discussions, and oral history were employed. Coastal fishers in the study areas suffer from a number of climate changes related events such as cyclones, tidal surges, and saline water intrusion. Combination with high frequency of natural disasters, weak economy and acute poverty make fishing people very vulnerable to any shocks. In response to multi-faceted vulnerabilities, fishers adopt a number of strategies in considering long-term sustainability of their livelihoods. Immediate aftermath of the any disaster, fishers are found to survive depending on personal savings, relief from government and NGOs, taking loan from NGO and mohajon (money lender) or by doing extra labor to increase income and savings. Improvement of physical capital such as brick-built housing structure is a common strategy found among better off fishers. Fishers are also found to plant trees around their house to get protection. In response to increased salinization of ground water, fishers harvest rainwater. In case of long-term adaptation, fishers put utmost importance to secured future of next generation and want to educate their children so that they can be able to leave risky professions and vulnerable place. The government support is not enough to increase the adaptive capacity of the people due to insufficient structural protection, poor management, rise of corruption. A number of suggestions elicited from fishers' perception for effective tackling of climate change related vulnerabilities that includes construction of more cyclone centre having effective infrastructure and communication system, construction and repairing of embankment, mangrove afforestation to protect embankment, public private partnership for climate protection such for coastal afforestation, starting of rationing of food support, mobile banking system for cash support, training to improve skills for alternative employment opportunities to reduce pressure from fishing, disaster management training, checking corruption by introducing risk allowance for law enforcing personnel and other governmental officials during disasters rehabilitation, recruitment of trained graduates having deep knowledge on coastal resource and disaster management, providing sufficient buoys in boat, helicopter rescue system from fishing place, wireless network or specialized software response system for early warning of disasters.

P-2243-13

Harvesting energy: People's place-based perspective on mitigating climate change with renewable energy technologies on the German North Sea Coast

D. Süsser (1) ; M. Döring, (2)

(1) Institute of Coastal Research, Helmholtz zentrum Geesthacht, Human Dimesnions of Coastal Areas, Hamburg, Germany; (2) Institute of Geography, University of Hamburg, Hamburg, Germany

Discussions on mitigating climate change revolve around the question of how to enable low-carbon energy transition based on renewable energy technologies (RETs) such as wind or solar energy. Communities and individuals have increasingly been recognised in public and policy for making an important contribution to sustainable energy transition. This includes the implementation of RETs in places to which people feel attached to (Devine-Wright, 2011). A discrepancy is still remaining between the general openness to ecological ways of generating energy and the local resistance against the implementation or extension

of RETs in the form of NIMBYism (Devine-Wright, 2013a). Considerable research has been undertaken to better understand resistance against RETs while – so far – it has not sufficiently been investigated of how place attachment positively or negatively contributes to individual and collective innovation processes (Rogers, 2003). The paper takes this gap in research as a starting point and presents a socially embedded perspective by drawing on recent research carried-out in the area of place attachment (Manzo and Devine-Wright, 2013) and locally embedded entrepreneurship (Audretsch, 2011; Feldmann, 2010). Our study is based on qualitative interviews undertaken with inhabitants of and a standardised household survey in the coastal municipality Reußenköge (North Frisia; Germany) in 2014 and 2015. It represents a rural area in which grain production and harvesting fields were the main agricultural practices due to historically reclaimed fertile marshland. This situation, however, changed with advent of onshore wind energy at the end of the last century and solar energy and biogas at the beginning of this century. In due course, the coastal municipality of Reußenköge developed from an average agricultural into a so-called model-region for the generation of renewable energy by harvesting wind with wind turbines and sun with solar installations. In brief, Reußenköge represents a recent show-case example for examining the social processes underlying the implementation of RETs in coastal areas. In the course of our qualitative study, analytical emphasis was put on people's place attachment, their understanding of climate change and how the latter two relate to the adoption of renewable energy technologies on an individual and community level. Questions addressed are the following: How does individual and collective attachment to the place of Reußenköge interact with the adoption and implementation of RETs? How do people understand and relate to the phenomenon of climate change? Has local entrepreneurship in Reußenköge shaped the municipality and in what ways? What are the important characteristics of this local entrepreneurship? In sum, the paper firstly aims at unravelling people's place-attachment in times of a climate-oriented energy transition in Reußenköge (Devine-Wright, 2013) by analysing the social meanings associated with RETs and, secondly studies socially embedded drivers of change and perceived social adjustments connected to the transition from harvesting fields to harvesting the energy.

Climate variability and change in fisher communities of Benin coastal zone: Vulnerability and adaptation strategies

F. Thoto (1) ; D. Houessou (1) ; A. Aoudji (2) ; S. Weissenberger (3)

(1) Centre d'Actions pour l'Environnement et le Développement Durable (ACED), Cotonou, Benin; (2) Université d'Abomey-Calavi (UAC), Faculté des sciences agronomiques (fsa), Abomey-Calavi, Benin; (3) Université du Québec à Montréal (UQAM), Institut des sciences de l'environnement (ise), Montréal, Canada

Climate variability and change are major challenges for communities in coastal regions. The coastal area of Benin in sub-Saharan Africa is also experiencing the negative effects of climate in terms of sea-level rise, rapid coastal erosion and significant variations in rainfall and temperature. Fishing remains the main livelihoods mean in these coastal areas, and is directly affected by the negative effects of climate variability and change. Fishing communities of Grand Popo and Ouidah in South-western Benin are the most affected by these effects and are more vulnerable. This study used an integrated approach that combines both biophysical and socio-economic factors determining vulnerability within a community or household. Indicators were used to develop an index of vulnerability to climate variability and change in order to compare and explain the levels of vulnerability of fishing communities. This research is part of a regional project funded by the Canadian International Development Research Center which is implemented in Benin, Senegal and Canada. The findings of the study showed, for fishing, that the municipality of Grand-Popo is more vulnerable to climate variability and change than Ouidah in terms of the level of exposure, sensitivity, and adaptive capacity. A community with low adaptive capacity does not directly reflect a high vulnerability. It is the combination of exposure, sensitivity and adaptive capacity that determines vulnerability. However, fishing households experiencing high exposure, therefore experience more climate shocks, have a high probability of being the most vulnerable, this is the case for the municipality of Grand-Popo. Similarly, households with high exposure, high sensitivity and low adaptive capacity have a greater vulnerability. On a practical view, the findings of this research showed the importance of supporting fishing communities in diversifying their livelihoods in order to reduce their vulnerability to climate variability and change.

Coastal Mitigation and Adaptation in a Small Island Developing State: Vanuatu a Case Study

SM. Von Schwerin (1)

(1) Experienced consultant, Specialising South Pacific SIDS; EbA and Eco-DRR, Dee Why, NSW, Australia

Considered one of the poorest and least developed of the Small Island Developing States (SIDS) in the South Pacific, Vanuatu is limited in its ability to reponds to risk associated with climate change. An archipeligo comprising 83 islands located in the western region of the South Pacific between New Caledonia and Fiji, the Climate Risk and Adaptation Country Profile (CRACP Vanuatu 2011) descibes Vanuatu as being «hampered by its highly vulnerable socio-economic and ecological standing». The key challenges that limits Vanuatu's ability to respond to climate variabiability and change include: political instability and weak institutions; unequal distribution of economic benefits gained from existing policies; disparity in income distribution and access to basic services; and, increased urban migration to urban centers with limited employment opportunities(CRACP).

As a natural resource/environmental planning expert with over 30 years experinece, living and working in Vanuatu, I present pragmatic solutions based upon my indepth knowledge and understanding of mitigation and adaptation climate change related issues facing the Ni Vanuatu islanders. The case study addresses adaptation and mitigation measures, including a review of the before and after of the recent Category 5 cyclone that hit the island chain in March, 2015.

Appropriately for a number of the South Pacific Small Island Developing States this presentation focuses on a grassroots perspective oriented towards natural and science based solutions: ecosystem-based adaptation (EbA) + ecosystem-based disaster risk reduction (Eco-DRR).

The innovative component of the oral presentation is not limited to purely scientific analysis of mitigation and adaptation options associated with climate change. It will also bring to the Conference the voices and concerns of local Ni Vanuatu and IKiribati from Vanuatu regarding their current socio-economic vunerabilities and concerns, economic drivers in conjunction with current, cutural

and historic understanding of climate change risk. A key component of the presentation will be to address local and regional responses, discussing pathways for integration across sectors and stakeholders.

The scientific and techolonogical breakthroughs releveant to this paper include ,but are not limited to: computer modelling; development of renewable energy limiting CO_2 emissions and reducing dependency on coal power stations: drill systems for geothermal energy; solar and wind power generation and storage; biological treatment of waste water; protection of freshwater lens and water resource; sustainable agricultural production; early warning systems; and the role of natural ecosystems in increasing coastal community resilience and hazard reduction from projected climate change events.

The trade-offs, co-benefits, risks and feedbacks are discussed along with the primary barriers which include:

1. the dispersed nature of the archipeligo and mountainous terrain making administration, communication and operation costly and challenging
2. limited domestic market with little potential for economies of scale
3. increasingly competitive international markets for tourism and investment
4. a social and cultural system with limited understanding and experience with business concepts and practices

My presentation concludes with a local area case study that examines the integration of EbA and Eco-DRR as a tool for climate change adaptation promoting socio-economic and ecological resilience. The case study Lapita project, which has been running almost 15 years, provides innovativeadaptation and mitigation solutions for climate change from the botton up perspective. These solutions may be readily adopted at the regional basis throughout Vanuatu and the South Pacific.

P-2243-16

Adapting to impacts of coral reef bleaching on ecosystem services in Asia-Pacific

T. Yeemin (1) ; S. W. (1) ; K. W. (1) ; S. K. (1) ; S. W. (1) ; S. M. (1)
(1) Ramkhamhaeng University, Department of Biology, Faculty of Science, Huamark, Bangkok, Thailand

Ecosystem services are the benefits that humans gain from functioning ecosystems. Coral reef ecosystems provide a lot of economic benefits, especially reef tourism, recreational fisheries, fisheries production, shoreline protection and natural products. However, coral reef ecosystem services are threatened by various anthropogenic and natural disturbances. Determining how ecosystem services are associated with biodiversity is required for investigating the consequences of biodiversity loss and for setting objectives and priorities for coral conservation and management. Studies on functional redundancy within coral communities, the number of taxonomically distinct species that show similar ecological functions, are very important for understanding the consequences of biodiversity loss. A case study in the Gulf of Thailand revealed that the low Acropora coverage at the study sites before the 2010 coral bleaching event was still a result of the previous severe coral bleaching in 1998. Densities of juvenile Acropora colonies before the 2010 coral bleaching event were also very low at the study sites, with no recruitment for several years. Several Acropora species that were previously observed in these areas are presently at risk for local extinction or may have already disappeared.

Quantifying coral reef ecosystem services in the Gulf of Thailand and the Andaman Sea has been documented with emphasis on linking coral reef conditions with various types of ecosystem services. Given coral reef management and restoration plans in Thailand as an example, the coral reefs are categorized into four different groups depending on their threats and type of uses. The coral reef that is in a degraded status and is used for tourism is the priority area for coral reef restoration. The coral reef restoration plan concentrates on using passive restoration in 4 strategies and 15 measures, by reducing threats from tourism, water pollution, sedimentation and fisheries. The active coral restoration by numerous asexual and sexual reproduction methods and techniques will be carefully considered prior to applying at appropriate reef sites for tourism, research, education and raising public awareness. The major concerns are simple and cheap restoration methods, community involvement, high tolerant species to bleaching and multi-species transplantation.

The coral reef management and restoration project in tourist hot spots in the Gulf of Thailand is a good case study for adapting to impacts of coral reef bleaching in Asia-Pacific. The project was initiated and funded by the network of provinces in the eastern Thailand. It aims to survey and establish an ecological and socio-economic database for managing the coral reefs and enhance their resilience to climate change. In addition, artificial substrates for coral recruitment and ecotourism are provided at tourist hotspots with the participation of local communities in managing natural resources and environment, wherein public awareness and education are enhanced. The project shows effective collaboration between scientists, local communities and local government officials as decision-makers to integrate scientific data into policy and adaptation measures. The coral reef restoration sites can be used to support ecotourism and learning opportunities for students. Continuing efforts in capacity building, public awareness and education through disseminating printed materials and conducting training courses, workshops and seminars for stakeholders, youth, students and local government officials can enhance resilience in coastal communities. Strengthening the long-term monitoring, evaluation and reporting of the project can provide lessons for conservation of coral reefs in tourist hotspots influenced by climate change, especially coral bleaching events.

Perspectives of planners on adaptation to climate change in Indonesia

R. Yoseph-Paulus (1)
(1) Local government of Buton Regency, Regional Development Planning Agency (Bappeda), Baubau, Indonesia

This paper focuses on understanding what knowledge local planners at city, regional, and provincial levels have regarding climate change adaptation (CCA), and what informs their perceptions and understanding. Four main themes were investigated: their perception of climate change impacts on local communities; the level of CCA policy development; the extent of CCA mainstreaming in the development agendas of local governments; and the level of planning for CCA. The findings were derived from the perspectives and insights of 26 local planners, working for local governments from seven different Indonesian coastal cities. Several significant factors that need to be addressed in order to plan for and implement effective CCA and disaster management at local levels in Indonesia were identified. These included increased climate change awareness at local levels; the level of coordinated efforts of government and non-governmental organisations required to enable CCA; increased capacity development to enhance community resilience; access to financial incentives and programmes; and greater motivation to address climate change impacts to enable CCA development.

This paper presents some key findings from the EU-FP7 funded projects AMAZALERT and ROBIN (Role of Biodiversity in the Climate Change Mitigation), both focusing on the effects of future climate change and land use change on ecosystem services provided by tropical forests in Latin America. New research has demonstrated that a complete dieback of the Amazon rainforest within the 21st century caused by climate change alone is unlikely; however a risk of forest dieback or other forms of irreversible ecosystem degradation on a lower spatial scale still exists. Because of the potentially severe consequences of such ecosystem degradation for the many important services they provide, on various spatial and temporal scales, it is wise to be prepared for the unexpected. Joining the outcome of the two projects, we will present a map of risk of ecosystem degradation, the main factors involved and most useful monitoring and warning mechanisms. We will evaluate the role of biodiversity in degradation as well as its potential to provide critical indicators of ecosystem decline.

Our models show forecasted changes in the biophysical state and the ecosystem services that the environment provides, under future scenarios. These allow us to compare severity of climate change, the influence of socio-economic context, and the implementation of different levels of policy protection of biodiversity and ecosystem services in alternative futures. The models suggest that there may be difficult trade-offs to take into account among ecosystem services, carbon and biodiversity, under these contrasting scenarios.

In combination, climate change (warming, drying, extreme events) and land use change (deforestation, fragmentation) could have a profound effect on the ecosystem, changing carbon cycle, water cycle, nutrient cycle and biodiversity in an irreversible way: from a wet, high biomass high biodiversity system to a much drier low biomass low biodiversity system. As trees and precipitation are bound together in a positive feedback loop (trees cause precipitation, trees need precipitation - in a hydrological cycle with evapotranspiration) and trees and fire in a negative feedback loop (intact rainforest is fireproof, dry forest and savannah are prone to fire causing more tree mortality), the system has multiple steady states and a critical transition from one state to another would be hard to reverse. If and when such degradation would occur, an Early Warning System (EWS) that would detect the imminent change would help to minimise its impacts.

Although earlier work suggested that early warning signals might exist, such that the onset of large scale dieback could be detected and potentially halted before irreversible critical transitions could occur, current work suggests that there is uncertainty whether critical degradation would show any critical 'tipping point' behaviour, and whether such change would be associated with detectable early-warning signals, such as enhanced but slowing down variability in variables ahead of thresholds that are associated with the change. Because of this, monitoring for early detection and warning of change is essential, both on the ground and using satellite images, as monitoring is prerequisite for finding solutions and early adaptation. Due to time lags between the system reaching adverse conditions and the response of the system to these adverse conditions (ecosystem degradation) we might be able to reverse the process before it becomes irreversible.

Since much of any critical change would occur through changes in the hydrological cycle, river levels, rainfall amount, soil moisture and temperature range appear among the most important candidates for monitoring, along with biomass, carbon exchange and energy budgets, but monitoring needs may differ according to the specific risk in a subregion. Local communities will be the first to notice subtle change in processes in their home territories, e.g. changes in ecosystem services provision, so combining high tech knowledge like satellite imagery with low tech on the ground observations should be the most promising way forward.

Actions against ecosystem degradation include reforestation, agroforestry production systems without burning, and agricultural no-tillage system.

O-2244-02

Threat to Farmland Riparian Biodiversity in Tankwidi Agroecosystem in the Sudanian Savanna of Ghana – Implication to Managing Risks to Climate Change

EA. Boakye (1) ; NH. Dibi (1) ; VR. Barnes (2) ; S. Porembski (3) ; M. Thiel, (4) ; FN. Kouamé, (1) ; D. Kone, (1)

(1) WASCAL Graduate Research Program in Climate Change and Biodiversity, Université Felix Houphouët Boigny, Abidjan, Ivory Coast; (2) Faculty of Renewable Natural Resources, Kwame nkrumah university of science & technology, Kumasi, Ghana; (3) Institute of Biosciences, University of rostock, Rostock, Germany; (4) Department for Geography and Geology, University of wuerzburg, Wuerzburg, Germany

Riparian forests (RF) are integrative part of the agroecosystem as they improve water quality and serve as habitat for fauna such as birds, insects and other organisms that are essential for crop pollination, seed dispersal and nutrient cycling. Despite their importance, RF are under the threat of deforestation from agricultural intensification in catchment areas. In order to ascertain the impact of the deforestation on the riparian area, this study used remote sensing techniques and field inventorying to assess riparian forests diversity on communal farmland (FA) and protected forest reserve area (FR) along Tankwidi rivercourse in the Sudanian savanna of Ghana. The paper also discusses the findings of the research in the light of managing risks of climate change effects on farmland riparian biodiversity in the savanna zones of Ghana.

Post-classification analysis of Landsat images revealed a reduction in forest cover from 1985 (23%) to 2013 (7%) in the river catchment. This forest loss is likely to affect elements such as light and wind leading to changes in the microclimatic conditions of the forest remnants to exert a strong effect on biodiversity in the catchment.

Further, a ground survey of sixty randomly selected plots (500 square meters per plot) equally divided between

FA and FR along the river in a 50m buffer zone showed a reduction in the number of woody species (diameter ≥ 5cm) from FR (40) to FA (19). Anogeissus leiocarpus and Mitragyna inermis were the most abundant species in both FR and FA. Shannon-Wiener Index for woody species diversity reduced from FR (2.5±0.09) to FA (1.8±0.14). This diversity decline is an indication of the degrading quality of the farmland riparian habitat and could have negative effect on the ecosystem services expected from the entire riparian biodiversity for sustainable food production.

Within the FR in particular, there were more species (58%) in the lower diameter class (5-15cm) than the other higher diameter classes (15-50cm) suggesting successful regeneration. The reverse was observed in FA where the individuals in the lower diameter class were fewer (26%) than the higher diameter classes. This indicates that the RF on farmland is not being reproductive and therefore, may not be able to sustain the ecological succession of the riparian woody vegetation for the perpetuity of their functions.

The observed reduction in woody species density from FR (17.7±1.1) to FA (7.3±0.53) is likely to increase the surface exposure of the riparian area in farmland. This will increase grassy fuel loads, decrease relative humidity, increase temperature and wind speed to heighten risks to savanna fires. Managing this risk on farmlands will not be possible unless a conscious effort is made to educate farmers on the roles of riparian forests, replant to enhance the diversity and density or area excluded from farming for the full recovery of riparian woody vegetation as climate change adaptation strategy.

O-2244-03

Impact of climate change on vulnerability to bushfires in Côte d'Ivoire

V. Kpan Noel (1)
(1) Université Alassane OUATTARA de Bouaké, Géographie, Abidjan, Ivory Coast

In Côte d'Ivoire, climate variability related to changes in rainfall patterns since the droughts of the 70s contributed to the impoverishment of rural areas and environmental degradation (Dje, 2009). Faced with these climatic disturbances, it is imperative to study the causes of these changes and evaluate their impact on the socio-economic human activities. One consequence of these changes is the proliferation of bushfires with its attendant degradation of ecosystems in place. Bushfires are hazards that disproportionately affect the tropics. By their heterogeneity in biomass, these areas face triggers fire. Indeed, from December to mid-March each year, the Harmattan blows over northern Côte d'Ivoire. The grasses become dry and the bush easily converts fuel in the presence of a spark. Increasingly, the practice of fires for land spares no region of the country given the growing techniques characterized by extensive farming has resulted in the destruction of large forest areas. Most fires are voluntary, criminal or originate carelessness and not in dry countries (Kouakou, 2013).

In Côte d' Ivoire, the lights are mostly man-caused mostly for hunting «small game» and agricultural activities during periods of soil preparation. The wildfire is an uncontrolled fire caused by the fires to burn weeds and other vegetation covering the crop land, pasture renewal fires for fodder for cattle, the production of charcoal, imprudence like cigarettes lights, camping shepherds or deliberately caused fires by bandits and cattle rustlers (Decleire, 1999). The bushfires have for this purpose more disadvantages than advantages (SODEXAM, 2006). In Cote d'Ivoire, 120 deaths and more than 5,000 km2 of land and forests were destroyed by bush fires between 2004 and 2014, twice the size of Luxembourg (Orange CI, 2014). Before the armed conflict of 2002, bushfires destroyed 450,000 hectares of forest, 250,000 hectares of food and cash crops burned a loss of more than 89.5 million CFA francs (Euro 135 877) 350 property and loss of life (Bayo, 2014).

From the socio-economic data (the map of localities, population density and the general census of population and housing (RGPH) of the Cote d'Ivoire in 1998), climate (rainfall, temperature air and the average relative humidity) for 14 synoptic stations of the meteorological network of Côte d' Ivoire and vegetation data (NDVI and map of the dominant vegetation of the country), lights vulnerability indices have been calculated from bush. According to the results in synthetic form from the GIS map, periods favorable to bush fires and exposed areas are identified with determining the level of risk for each locality.

O-2244-04

Pluviometric deficit and impact on wood-energy in climate changes context in the south of Senegal

SD. Badiane (1) ; C. A. (2) ; N. P. (1) ; K. A. (1) ; A. Ndiaye (1) ; CBCD. M. (1)
(1) Cheikh Anta Diop University, Geography, Dakar, Senegal; (2) Gaston Berger University, Geography, Saint-Louis, Senegal

In Senegal, as in most sahelian countries, wood is still used as a primary energy source. The majority of rural households do not have access to new energies. Wood ensures for the case of Senegal, about 20% of national energy coverage. This figure shows the significant contribution of forest resources to meet the energy needs of the country. Much of the wood energy is provided by forest in southe of Senegal.

Best climate conditions in the past, contributed to maintain forest because of the presence of water. The development of the forest is dependent on the occurrence of water in the forest basin of Casamance.

The importance of forest explains the production of wood energy (firewood). The abuse of forest resources causes a degradation of these and whose lower rainfall has exacerbated the drought of 70 years. Indeed, climate change has disrupted production systems including agro-forestry systems. Consequently with water deficit, the production of wood energy remains uncertain in long term to meet future needs.

This contribution tries to demonstrate the relationship between water deficit resulting from climate change and the availability of fuel wood in Casamance. It attempts to answer the question, how the reduction of rainfall over a long period affects energy production systems?

O-2244-05

Rakhal (Yew) benefiting the knowledge of Biodiversity in Neeldhar (Pangi Valley) in the context of Climate Change for Sustainable Development

P. Sharma (1) ; PL. Uniyal, (1)
(1) UNIVERSITY OF DELHI, BOTANY, DELHI, India

This paper constitutes a first attempt representing the relationship between Climate Change, Biodiversity, and Ecosystem services, with a specific emphasis on Rakhal (Yew), Neeldhar forest, Pangi valley, Chamba district, Himachal Pradesh. Firstly, we took Rakhal (Yew, Endangered plant) as biodiversity indicator that integrates changes in biodiversity due to some of its interesting novel populations in Neeldhar. Secondly, this indicator's novel populations are integrated into two simultaneous situations to capture the marginal impacts of changes in Biodiversity (i.e. Yew population decline) in Pangi Valley and on the value of ecosystem goods and services (Taxol) due to Climate Change. Our results confirm these novel populations play a role of Biodiversity as a nature-based policy solution for Climate Change mitigation, involving local community in Neeldhar for human livelihoods and Sustainable Development. We conclude, nature-based mitigation policies are more cost-effective and better at coping with the ethic and inequality issues associated with distributional impacts of the policy actions.

O-2244-06

Fostering forest system resilience through managing biodiversity : the case of Mediterranean forests

F. Lefevre (1) ; R. Alia, (2) ; L. Coll, (3) ; H. Daly-Hassen, (4) ; D. Pettenella, (5)
(1) INRA, Ecology of the Mediterranean Forests, URFM, Avignon, France; (2) INIA, Cifor, Madrid, Spain; (3) CTFC, Solsona, Spain; (4) IRESA, Tunis, Tunisia; (5) UNIPD, Padova, Italy

Mediterranean climate regions are considered as a hotspot for biodiversity, with many endemic species adapted to their hot dry summers and mild winter conditions. There, human societies have for centuries adapted their socio-economic systems to constrained climatic conditions and related risks (drought, fire, etc.) that now, under most climate change scenarios, are expected to expand rapidly at a larger scale. Thus, Mediterranean climate regions are a reservoir of resources and experience of potential interest for adaptation to climate change in other areas.

Mediterranean forests provide multiple goods and services for multiple users, including water cycle regulation and carbon sequestration at national and global level, fuelwood, forage and other products that contribute significantly to the income of the local human population that. However, climate change is expected to be particularly severe at these latitudes and, furthermore, climatic fluctuations have a higher impact in those fragile areas : tipping points can be crossed with low fluctuation. Therefore, advancing on the understanding of the resilience mechanisms of Mediterranean forest social-ecological systems is a general concern but also a potential relevant source of information.

Mediterranean forests resilience results from the interplay between human decisions and actions and natural processes. Considering the context of change, facing increased hazards and uncertainties, a new paradigm emerges where adaptation and long term preservation of options are both needed, following a more flexible approach to managing forests. Biodiversity is not only a reservoir of living forms with different hierarchical levels (individuals, populations, communities) but also a set of processes that permanently puts the diversity in evolution. Thus, nature-based solutions should combine exploration, exploitation and dynamic conservation of diversity and processes.

Aiming to propose solutions to foster resilience of Mediterranean forest systems through managing biodiversity, the research project INFORMED (INtegrated research on FOrest Resilience and Management in the mEDiterranean), funded by the ERA-Net FORESTERRA, is conducted by a multidisciplinary consortium of 21 research groups from 10 countries, representing both the Northern and Southern Rim. Mediterranean forests are viewed as complex social-ecological systems where management, ecological and socio-economic processes operate at different spatial-temporal scales and interact, determining their response to disturbance and disturbance regime scenarios.

INFORMED relies on a process-based approach that integrates knowledge (i.e. data and models) issued from a broad range of case studies representing various forest types, socio-economic assets and global change scenarios found in the area, from Northern Africa to the Mediterranean margins of temperate forests. The project aims to (1) produce global change scenarios specifically dedicated to the Mediterranean forests, (2) develop quantitative assessment of biodiversity and functional response of Mediterranean forests to disturbance and management, (3) develop integrated assessment of ecosystem services and their dynamics based on ecosystem functions and their economic evaluation, and (4) evaluate adaptive management strategies, policy and governance options for their expected impact on resilience of Mediterranean forests.

To illustrate this original multidisciplinary research, we present the overall interdisciplinary conceptual framework where different mechanisms of flexibility are considered jointly, and the first evidence deriving from the past work on resilience in the selected case study areas.

2244-POSTER PRESENTATIONS

P-2244-01

Current status and potential impacts of climate change on the distribution of consumed plants species by the endangered western derby eland (Taurotragus derbianus derbianus) in its last wild refuge Niokolo Koba National Park, South-Eastern Senegal

M. Camara (1) ; S. Da Sié (2) ; FN. Kouame (1) ; S. Bienvenu (3)

(1) GRP Climate Change and Biodiversity, University félix houphouët-boigny, Abidjan, Ivory Coast; (2) Competence Center of the West African Science Service Center Climate Change and Adapted Land Use, Biodiversity modelling, Ouagadougou, Burkina Faso; (3) Institut des Sciences de l'Environnement, (ise/fst) university cheikh anta diop of dakar, Dakar, Senegal

Within the last decades, biodiversity became an important topic of social, political and scientific discussion because of its essential role in human well-being and survival. However, biodiversity is facing increasing threats, leading to its loss, caused by different factors among which climate change. It is urgent to take action to ensure its sustainable use and conservation. The Western Derby Eland (Taurotragus derbianus derbianus Gray, 1847), the biggest antelope worldwide is recorded as endangered species even close to extinction. Endemic to West Africa its wild habitat is shrunk nowadays to Niokolo Koba National Park (NKNP) Southeast Senegal with Soudano-Guinean climate, where an exponential decrease of its population is noticed. Conservationists in hope of preserving its genetic pools established the first breeding herd worldwide to an ex-situ conservation site, the Bandia reserve Centre West with a Sahelo-Soudanian climate. Researches have been carried out on derby eland in wild but they had a narrow-scope, mainly oriented on aerial and ground survey in the national park. Until today, very few is known on the wild eland in its last natural refuge. Previous studies have defined Boscia angustifolia, Grewia bicolor, Hymenocardia acida, Strychnos spinosa and Ziziphus mauritiana as consumed woody species by eland. A step to maintain and allow the population increase of Eland within the NKNP is to assure the presence of these woody species in the area. Therefore, knowledge on their current and future distribution within the NKNP is important for the perpetuity of the eland in its last wild refuge. The aims of this present work are to (i) identify the current potential distribution of eland's consumed plant species with climatic and land-cover variables as predictors and (ii) predict the future distribution of these species based on different climate models and scenarios for decision makers and rangeland managers. To achieve these aims two types of dataset are necessary: species occurrence and environmental data. Occurrence points of each woody species were obtained from field observations and additional records from herbaria of natural collection downloaded from GBIF website (Global Biodiversity Information Facility). Environmental variables were downloaded from Worldclim database for climate data and from the Global Landcover database for land cover variables. Possible impacts of climate change on the distribution of Eland consumed plant species in the Park were analyzed based on three climate models (CNRM-CM5, HadGEM2-ES, and MPI-ESM-LR) and two climate scenarios (RCPs 2.6 and 8.5), at two periods of time (2050 and 2070). Current and future potential distributions of suitable habitats for the woody species were determined at a spatial resolution of 30 arc-second using the Maximum Entropy (MaxEnt) approach.

Preliminary results of the ongoing analysis show a good potential distribution of consumed plant species by eland in the NKNP in general. Three out (Grewia bicolor, Hymenocardia acida, and Ziziphus mauritiana) of the five woody species are found almost everywhere within the park. In contrary, Strychnos spinosa has is range restricted to the central part while Boscia angustifolia is confined in the eastern part. Projections illustrate a negative impact of climate change on the consumed plants by the eland, with a severe loss of suitable habitats for most of the species, except from Hymenocardia acida and Ziziphus mauritiana which will likely remain within the NKNP.

The loss of suitable habitats for the consumed species by eland will have negative impacts on his maintenance in the park. We therefore recommend the development of strategies for a good conservation of these remaining plant species by reducing for example human actions.

P-2244-02

Climate change adaptation for the Amazon basin: how can ecosystem-based solutions be multiplied?

P. Ceotto (1) ; T. Kasecker, (2) ; R. Pinheiro, (1) ; JMC. Da Silva (3) ; FR. Scarano, (4)

(1) Conservation International, Americas Sustainability

Center, Rio de Janeiro, RJ, Brazil; (2) Conservation International, Brazil field program, Rio de Janeiro, Brazil; (3) Universidade Federal do Amapá, Pós-graduação em biodiversidade tropical, Macapá, Brazil; (4) Conservation International and Universidade Federal do Rio de Janeiro, Americas sustainability center and departamento de ecologia, Rio de Janeiro, Brazil

Land use change has meant to date a reduction of nearly 20% of the natural cover of the Panamazonian region, which comprises eight Amazonian countries and one overseas territory. There are projections suggesting that if the current pace of deforestation is not halted soon, climatic conditions will become drier and the system may turn into an opener and drier one, where fire risks are higher and precipitation and humidity lower. This ´savannization´ would potentially have large-scale impacts on climate, biodiversity and livelihoods locally, as well as globally.

The latest IPCC assessment report pointed out a set of sub-national and national initiatives of climate change adaptation in the Amazon that are based on ecosystems. Ecosystem-based adaptation (EbA) refers to practices that reduce human vulnerabilities by harnessing the capacity of nature to buffer human communities against the adverse impacts of climate change. The Amazon region simultaneously holds the largest continuous green tropical cover of the planet and a population of more than 30 million habitants, many of which live in poverty. The poorest are the most vulnerable people to climate change. Then, these characteristics turn the Amazon into a key geography to implement and learn from practices related to ecosystem-based adaptation and sustainable development. Protected area networks, indigenous territories, community management, conservation incentives and forest restoration are all practices that can be considered EbA as long as they reduce societies´ vulnerability to climate change by protecting natural resources and improving livelihoods.

In this paper we review some of the existing national and sub-national policies and practices taking place in the Amazon that can be classified as EbA. Mapped cases include from national-level policies (such as those related to low carbon development or conservation agreements) to local level initiatives (such as sustainability policies at municipal level or community management of areas under protection). We analyzed the selected cases on the basis of the following criteria: resilience potential, risk reduction, cost-effectiveness, emissions reduction, replicability, and scalability. We emphasize the need to showcase, measure and share success stories to favor dissemination of solutions across the region. Main conclusions are that 1) protected areas networks and indigenous lands that add up to more than 45% of the total cover the Amazon need further consolidation; 2) national and sub-national conservation incentive mechanisms need further assessment but have a high potential for replication across the region; 3) efforts aiming for sustainability at sub-national level must be measured and understood for potential replication or even to inspire the design of new policies; 4) adaptation to climate change in Amazonia will be predominantly ecosystem-based, but planning requires regional level integration and exchange of policies and practices between national and sub-national actors.

P-2244-03

Climate Change impact of loss Agro-biodiversity in Georgia

K. Nadiradze (1) ; M. Goginashvili (2)
(1) Association for Farmers Rights Defense, AFRD, President, Tbilisi , Georgia; (2) Tbilisi State University, Economic and business faculty, Tbilisi , Georgia

Climate change is occurring more rapidly than anticipated and the increase in extreme weather events threatens more disruptive effects to agriculture. Existing technologies and current institutional structures seem inadequate to achieve the mitigation needed to adequately slow climate change effects, while also meeting needed food security, food safety livelihood and sustainability goals in Developing Countries especially like Georgia. Identifying actions that are science-based, utilize knowledge systems and technology transfer in new ways, and provide resilience for food systems and ecosystem services in agricultural landscapes despite the future uncertainty of climate change and extreme events. Recognizing the urgency, Association for Farmers Rights Defense, AFRD organzing the Training Programs for its member farmers on this important topics: Climate Smart Agriculture, Mitigation and Adaptation, Conservation of Agrobiodiversity and creation of in-situ, ex-situ, in-farm and on-farm collection of seeds and species of must threatened Agro bio-diverse endemic plants in Georgia. We also know that the most diverse ecosystems will be the most resilient and adaptable in the face of changing climates. Every species has a role to play in a functioning ecosystem, and conserving ecosystems is therefore an important way of conserving species. However, in order to ensure effective conservation, climate change management strategy of our NGO will require reliable scientific data both on the nature of climate change and on its potential impact on plants and plant communities.

P-2244-04

Traditional Knowledge in the Use and Management of Forest Ecosystem for Livelihoods and Food Security in Nigerian Savanna

F. Olorunfemi (1) ; M. Fasona (2) ; G. Oloukoi (3) ; P. Elias (4) ; V. Adedayo (4)
(1) Nigerian Institute of Social and Economic Research, Social and Governance Policy Research Department, Ibadan, Oyo State, Nigeria, Federal Republic of; (2) University of Lagos, Lagos, Geography, Lagos, Nigeria, Federal Republic of; (3) Lead City University, Environmental management, Ibadan, Nigeria, Federal Republic of; (4) University of Lagos, Geography, Lagos, Nigeria, Federal Republic of

Indigenous traditional knowledge and biodiversity are complimentary phenomena essential to human development and sustainable resource management. The rural communities have a significant role to play in maintaining the integrity of ecosystems to ensure that it continues to support livelihood activities. This paper discussed traditional knowledge in the use and management of forest resources in the Nigerian savanna and how this knowledge has been used to improve the livelihhods of the people. It combines focal group discussions, key informants interviews and household survey in 11 communities across 10 local councils with vegetal surveys. The results of this study revealed that people in the area possess considerable knowledge of the natural resources they use and how to ensure the sustainability of some these resources to ensure that they continue to support their livelihoods. Strategies and programmes that are more likely to succeed will require integration of coordinated efforts aimed at poverty alleviation and food security with measures to combat land degradation, reduce loss of biodiversity and ecosystem services. Such integrated measures must be science-based but community driven to ensure its sustainability and synergy.

Bio-Diversity, ecosystem functioning, and human wellbeing in changing landscapes: Future challenges

A. Venkata Nagavarma (1)
(1) P.G.Courses & Research Center, D.N.R.(Autonomous) College(Andhra University - Estd. 1945), ECONOMICS, BHIMAVARAM, Andhra Pradesh, India

Climate change affects the living world, including people, through changes in ecosystems, biodiversity, and ecosystem services. Ecosystems entail all the living things in a particular area as well as the non-living things with which they interact, such as air, soil, water, and sunlight. Biodiversity refers to the variety of life, including the number of species, life forms, genetic types, and habitats and biomes (which are characteristic groupings of plant and animal species found in a particular climate). Biodiversity and ecosystems produce a rich array of benefits that people depend on, including fisheries, drinking water, fertile soils for growing crops, climate regulation, inspiration, and aesthetic and cultural values. These benefits are called "ecosystem services" - some of which, like food, are more easily quantified than others, such as climate regulation or cultural values. Changes in many such services are often not obvious to those who depend on them.

The future of humanity depends on whether or not we have

a vision to guide our transition toward sustainability, on scales ranging from local landscapes to the planet as a whole. Sustainability science is at the core of this vision, and landscapes and regions represent a pivotal scale domain. Themain objectives of this paper are: (1) to elucidate key definitions and concepts of sustainability, including the Brundtland definition, the triple bottom line, weak and strong sustainability, resilience, human well-being, and ecosystem services; (2) to examine key definitions and concepts of landscape sustainability, including those derived from general concepts and those developed for specific landscapes; and (3) to propose a framework for developing a science of landscape sustainability. Landscape sustainability is defined as the capacity of a landscape to consistently provide long-term, landscape-specific ecosystem services essential for maintaining and improving human well-being. Fundamentally, well-being is a journey, not a destination. Landscape sustainability science is a place-based, use-inspired science of understanding and improving the dynamic relationship between ecosystem services and human well-being in changing landscapes under uncertainties arising from internal feedbacks and external disturbances. While landscape sustainability science emphasizes place-based research on landscape and regional scales, significant between landscape interactions and hierarchical linkages to both finer and broader scales (and externalities) must not be ignored. To advance landscape sustainability science, spatially explicit methods are essential, especially experimental approaches that take advantage of designed landscapes and multi-scaled simulation models that couple the dynamics of landscape services (ecosystem services provided by multiple landscape elements in combination as emergent properties) and human well-being.

Building Resilience at Sub National level Using Climate Resilience Framework

SK. Yadav (1) ; A. Dixit, (1)
(1) Institute for Social and Environment Transition-Nepal (ISET-N), Research, Kathmandu, Nepal

Nepal's ecosystems generate various goods and services for its people. Climate change with its direct consequences on the hydrological cycle can impact ecosystems, lives and livelihoods seriously and adversely. These changes will lower the resilience of ecological and infrastructural systems as well as the functioning of water, food and livelihoods services. Ecosystem based adaptation as an element of an overall strategy can help educe the vulnerability of ecosystems and build people's resilience in the face of the adverse impacts of climate change. This paper will present the use of climate change vulnerability in wake of changing climate taking into account the role of ecosystem services using the climate Resilience Framework (CRF). The CRF conceives climate vulnerability to be highest when increased exposure intersects with fragile systems, social marginalization and constraining institutions. Drawing on findings of research conducted in Nepal's Western Development Region the paper will discuss the use of both top down and bottom up approach to assess risks and develop strategies for building resilience at sub national levels.

Mitigation delay sensitivity of temperature, sea level and ocean acidification

P. Pfister (1) ; T. Stocker (1)
(1) Physics Institute, University of Bern, Climate and environmental physics, Bern, Switzerland

With annually increasing anthropogenic carbon emissions, the commitment to climate change and its impacts continues to grow. A policy-relevant metric for this growth is the mitigation delay sensitivity (MDS), measuring the additional commitment per decade until emissions start to decrease. For the peak temperature increase ΔT, MDS can be estimated analytically using idealized emission scenarios (Allen and Stocker, 2014; Stocker, 2013). Here, we use an Earth System Model of Intermediate Complexity to evaluate the MDS of ΔT, steric sea level rise (SSLR), and two ocean acidification impacts following Steinacher et al. (2013). We examine the dependance of the MDS on the rate of increase (r) and subsequent decrease (s) in annual emissions, for three different equilibrium climate sensitivities (ECS) of 1.5, 3.0 and 4.5 K. The modeled MDS is in good agreement with analytical estimates for ΔT and SSLR, except for scenarios with very high cumulative emissions. For standard parameters (ECS = 3.0 K, r = 2% and s ranging from 5% down to 0.5%), MDS amounts to 0.3-0.7 K/decade for ΔT and 7-20 cm/decade for SSLR by 3000 AD. With regard to ocean acidification, we find that partial Aragonite undersaturation of the Southern Ocean surface (by 2100 AD) may be avoided with sufficiently early and stringent mitigation. MDS is 15-17% of the Southern Ocean area per decade for standard parameters, but for s>3% no undersaturation occurs if emissions start to decrease before 2030. Further loss of strongly supersaturated ocean surface areas (associated with coral reef habitats) is virtually unavoidable, but can be substantially reduced by mitigation. For standard parameters, we are already committed to a loss of roughly 30-90% of these areas by 2100 AD, even with immediate mitigation (with respect to preindustrial); MDS amounts to an additional loss of 22-66% of the remaining area per decade.

Do ENSO modeling discrepancies affect the climate-carbon feedback?

A. Bastos (1) ; C. Gouveia (1) ; R. Trigo (1)
(1) Instituto Dom Luiz - Universidade de Lisboa, Lisbon, Portugal

The El-Niño/Southern Oscillation controls most of global climate variability on inter-annual time-scales. In particular, ENSO affects temperature and precipitation patterns in South America and Southeast Asia, although its influence extends to remote regions and latitudes.

ENSO is also known to play an important role in the carbon-cycle, influencing a large fraction of variability in atmospheric CO2 growth rate, mainly due to its impact on terrestrial ecosystems in the Southern Hemisphere. During El-Niño events, lower than average precipitation and warmer temperatures are registered in most of northern and central South America, South Africa and most of Australia, leading to reduced CO2 uptake by vegetation, and to increased fire activity. During the cold phases (La-Niña), the patterns are approximately reversed and the land-sink is enhanced.

Although Earth-System Models (ESMs) in CMIP5 do include representation of the ocean-atmosphere coupling processes that produce ENSO, they still present difficulties in modeling some of the most relevant features of the phenomenon, such as the temporal evolution and recurrence periods of warm and cold phases .

It has been shown that the difference between model estimates of future CO2 concentration are related to their biases in representing present atmospheric CO2. Moreover, the larger disagreements of future CO2 uptake are due to

uncertainty about the future response of the land-sink to climate change. It has been further shown that part of the uncertainties in future estimates of CO2 storage on terrestrial ecosystems are related to the differences in the climate forcing from the global circulation models (GCMs).

Here we investigate whether the discrepancies between observations and modeled ENSO may explain biases in the modeled present land-sink in CMIP5 ESMs. We evaluate the performance of ESMs in reproducing, for the period 1959-2011, a set of temporal features, such as the intensity, spatial configuration, and spectral properties of ENSO. Subsequently, the ability of ESMs to reproduce the global land-sink strength and variability was evaluated and compared to the relationship between the modeled ENSO and variability in the modeled land-sink. We find that biases in the land-sink are related to the way ESMs simulate the response of terrestrial ecosystems to ENSO variability and that this, in turn, is mainly dependent on the spectral properties of the modeled ENSO. The ESMs that mis-represent the peak periodicity of ENSO in the 3-7 years band tend to present larger errors in the modeled land-sink characteristics. The nature of this relationship between ENSO discrepancies and land-sink biases was studied by evaluating the influence of discrepancies in ENSO frequency on temperature and precipitation patterns within each model.

The analysis was further extended to the future RCP4.5 and RCP8.5 scenarios, by evaluating the influence of the discrepancies of the present terrestrial CO2 uptake on the future land-sink and the role played by ENSO in these discrepancies.

O-2245-03

Spread of ocean heat uptake efficiency in CMIP models

E. Exarchou (1) ; J. Gregory (2) ; T. Kuhlbrodt (2)
(1) IC3, Barcelona, Spain; (2) NCAS, University of Reading and Met Office Hadley Centre, Reading, United Kingdom

During transient climate change, the ocean heat uptake efficiency, quantified by the ratio between the rate of ocean heat uptake N and surface global-mean temperature change DT, can quantitatively measure how effectively the heat is vertically transported in the deeper ocean, thus moderating surface transient change. Among models of the Coupled Model Intercomparison Project (CMIP) framework, the spread in the values of k varies by about a factor of 2. The spread in k affects the model spread in projections of ocean heat uptake and thermal expansion, therefore contributing to the uncertainty in model future projections of transient climate change. We investigate potential sources of model spread in kappa by using a set of 23 CMIP models with CO2 increasing at a rate of 1% per year. In the set of models we analyse, in line with previous studies, the models with the strongest AMOC have the strongest CO2-induced AMOC reduction. We find that the models with the strongest AMOC, and consequently the models with the strongest AMOC reduction, have the strongest ocean heat uptake efficiency. Despite the strong correlation with AMOC, the largest portion of the ocean heat uptake efficiency and of its spread comes from the Southern Ocean. By further analysing the detailed process-based heat budgets in three models, HadGEM2, GFDL-ESM2M and MPIESM-LR, which have k values from the low, middle and high part of the kappa spread, we find that the spread in these three models mainly arises from changes in advection. The dominant part of the advective ocean heat uptake takes place in the Southern Ocean. We explore potential physical mechanisms that link the Southern Ocean advective heat uptake, hence the Southern Ocean overturning, with the AMOC and the ocean heat uptake efficiency.

Forest Mortality, Economics, and Climate

L. Hawkins (1) ; B. Law (2) ; P. Mote (3) ; A. Plantinga (4) ; J. Hicke (5) ; M. Allen (6) ; R. Betts (7)
(1) Oregon State University, Earth, Ocean, and Atmospheric Science, Oregon, United States of America; (2) Oregon State University, Forest ecosystems & society, Oregon, United States of America; (3) Oregon State University, Earth, ocean, & atmospheric sciences, Oregon, United States of America; (4) University of California Santa Barbara, Natural resource economics and policy, California, United States of America; (5) University of Idaho, Geography, Idaho, United States of America; (6) University of Oxford, School of geography and the environment, Oxford, United Kingdom; (7) University of Exeter, Geography, Exeter, United Kingdom

Forests in western North America provide critical economic and environmental services including watershed protection, timber production, and carbon sequestration. Recently this region has experienced widespread forest mortality attributed to droughts, fires, and regional warming. Forest mortality rates doubled in the Pacific Northwest between 1990 and 2010 with bark beetles killing trees across 11 million hectares in B.C and the western U.S. The complex interactions among climate, ecosystem response, and economic factors govern the impacts these stressors will have on terrestrial ecosystems in the future. To examine how major forests will function under future climatic and land use regimes we couple an improved forest mortality model to NCAR's Community Land Model (CLM4.5) incorporating a predictive model of mountain pine beetle outbreaks and a forest product economic model. The economic model estimates the values of private forest investment, wood products, recreation, and water. Annual harvest levels, silvicultural investments, and forest management strategies feedback into CLM. This methodology will elucidate feedbacks among climate, land use, forest ecosystems, carbon sequestration and ecosystem services. To assess uncertainty in the simulated forest response to climate change a dynamic vegetation model (TRIFFID operating within the Hadley Centre Earth System Model) is used to generate a super-ensemble of simulations using crowd sourced computing (climateprediction.net). This novel form of evaluating intrinsic variability allows for thorough investigation of model sensitivity to parameterization. Outcomes of this work will provide policy makers and resource managers with tools for developing adaptive strategies for responding to projected warming, drought, insects, and economic factors.

Modeling and visualization of the marshes vegetation

A. Sadovski (1) ; P. Montagna, (2) ; S. King, (3)
(1) TexasA&M University-Corpus Christi, Corpus Christi, TX, United States of America; (2) Texas A&M University-Corpus Christi, Harte research institute for the gulf of mexico, Corpus Christi, United States of America; (3) Texas A&M University-Corpus Christi, School of engineering and computing sciences, Corpus Christi, United States of America

This paper deals with a mathematical models of the vegetation growth in the marshes of the Gulf of Mexico. It is a spatial-temporal model of multi-species competition presented in the form of the system of partial differential equations. Analysis of the behavior of such a system is studied through simulation and visualization tools. The objective of the study is to find the impact of fresh water releases and precipitations on the vegetation cover of marshes so it can be used for future preservation of the marsh ecological system.

Coastal marshes are important ecosystems that provide many benefits to human health and well-being including: protecting the inland areas from storm surge, storing water, removing nutrients that flow in from watersheds, and providing nursery habitat for key commercial and recreational fisheries. Yet, marshes are under extreme pressure from development and 50% of the marshes nationwide have disappeared since the founding of the United States.

The Texas coast is flat, hot, and windy; which makes coastal marshes very susceptible to effects of climate change and water resource development. Climate change can have three effects: sea-level rise, water cycle alterations, and temperature alterations. The main effects will be to drown marshes during rising water levels or dry them out as evapotranspiration rates increase during droughts. Water resource development has decreased water delivery to marshes in the Nueces Delta by 45% over the last 40 years, which has led to marsh degradation.

There is a need to understand the dynamics and the interactive roles of climate and water cycle changes in order to predict changes in salt marshes in the future. This information is critical for resource management. However, few tools exist to forecast effects of human activities on marsh function. Results and models of this

ongoing research could be extended to coastal estuaries in other regions of the world.

Optimal climate policy under socio-economic scenario uncertainty

L. Drouet (1) ; J. Emmerling (2)
(1) FEEM, Milan, Italy; (2) FEEM, Milano, Italy

The role of uncertainty in the field of climate change has been widely discussed in recent years. A focus has been on the role of uncertainty in the climate sciences part of climate change, in particular uncertainty about the magnitude of climate change due to greenhouse gas emissions, e.g., as measured by the famous climate sensitivity parameter. In applied policy analysis, integrated assessment models (IAMs) can be used to assess the costs and benefits of climate change policies. Besides the crucial climate parameters and impact estimates, these models require the specification of a baseline population and GDP growth scenario along which optimal climate policies are studied.

Here, we study the role of uncertainty about these baseline assumptions to contribute to the literature about how and how much uncertainty does affect the optimal policy. We make use of a new set of socio-economic development scenarios that the IAM community currently works on , called socio-economic shared pathways (SSPs). These scenarios will serve as a reference to explore the long-term consequences of climate change and the climate policy strategies. They can serve at least to assess the range and hence uncertainty of future baseline growth and population assumptions for the context of climate change, which is what we aim for in this work.

We focus on the role of socio-economic uncertainty to address three research questions that come up in this context. Firstly, we ask what is the optimal climate policy and how robust is it in the presence of socio-economic uncertainty. Notably, we estimate the cost of this uncertainty and how different decision rules for finding the optimal climate policy when the baseline is unknown can be derived including making use of recent developments in the context of robust decision making. Secondly, and related, we discuss how measures of the costs of climate change and climate policies can be measured and compared when different baselines are considered. Given that policy costs and other measures such as impacts are typically expressed relative to a baseline, comparing those values with different baseline projections is not trivial as we show. Thirdly, we more broadly discuss how scenario development exercises can inform decisions under uncertainty taking into account the different “worlds” described.

Evaluation the accuracy of post processing approaches on RegCM4 outputs in forecasting precipitation(Case study: North West of Iran)

N. Ghahreman (1) ; I. Babaeian (2) ; S. Lookzadeh (3)
(1) University of Tehran, Irrigation and Reclamation Engineering, Karaj, Islamic Republic of Iran; (2) Climatological Research Institute, Mashhad, Islamic Republic of Iran; (3) University of Tehran, Irrigation and reclamation engineering dep., Karaj, Islamic Republic of Iran

The seasonal forecast of precipitation which is generally presented qualitative and probabilistic can be used for decision makings in agriculture, water resource management and hydropower production to alleviate the adverse effects of extreme events like drought and flood. The Earth Systems Physics (ESP) group of the Abdus Salam International Centre for Theoretical Physics (ICTP) maintains and distributes a state-of-the-science regional climate model called the ICTP Regional Climate Model (RegCM), which has been successfully used in different regions of the world for diverse range of climate-related studies. This study was conducted with two aims: Evaluation the performance of RegCM4 dynamic model in forecasting monthly, seasonal and annual precipitation in four selected stations in North West of the Iran namely Tabriz, Ardabil, Khouy and Urumia and testing the accuracy of stepwise regression for post processing the outputs of model, in a 30-years period from 1982 to 2011. The required observed weather data of study stations for running regional climate model RegCM4 were collected from Iran Meteoroligcal Organization (IRIMO) archive and rest of the data were adopted from ICTP database, with NetCDF format including three sets of weather data NNRP1 with a 6-hour-time step and a horizontal resolution of 2.5 2.5 on the reanalysis data of National Center of Environmental Prediction of United States, sea surface temperature, (SST) with a horizontal resolution of in 1 from the type of (OISST) belonged to National Oceanic and Atmospheric Administration and surface data (SURFACE), which were consisted of three topographic data (GTOPO), the vegetation or land use of (GLCC), and the soil type data (GLZB), with a horizontal resolution of 30 30 seconds from United States Geological Survey, for the period 1982 to 2011. To determine suitable rainfall scheme, the normal year of 2009 was selected for running the model using different schemes Accordingly, Kuo scheme with the minimum bias, comparing to observed precipitation amounts in the entire 36 synoptic stations of the region, was chosen as the main scheme. The time interval was set as 24-hour, spatial resolution of 30 30 km2, and the number of grid points were 152 in longitude (iy) and 168 in latitude (ix) during the study period of 1982 to 2011. Geographical area center was placed at 30.5◦ (N) and 50 ◦ (E), respectively. The outputs of the model are three types; atmospheric (ATM), surface (SRF) and radiation data with the format of NetCDF, each containing a large number of meteorological variables. By excluding the precipitation (tpr) from the model outputs, the nine significant variables with the highest correlation with precipitation were determined as: q2m □ t2m □ps □v1000 □v500 □u1000 □u500□ omega1000, omega500.For post-processing the outputs of the model, the multiple linear regression (MLR) approach was used. Except for the warm month, the output of RegCM4 showed a wet bias and overestimation. Applying multivariate linear regression equation, (and in some cases two-variable) on the output of the model led to a better agreement between observed and simulated values of precipitation such that, in 75% of the cases, the bias and relative error decreased for the monthly, seasonal and annual forecasts. At all stations except for Urumia, performing the post processing improved the accuracy of RegCM4 output at all time scales. Further scrutiny is recommended for explaining the variations among the stations

P-2245-03

Regional Arabian Peninsula Modeling Findings and Integrated Climate Change Programme

G. Jane (1)
(1) Abu Dhabi Global Environmental Data Initiative (AGEDI), Abu Dhabi, United Arab Emirates

AGEDI launched a follow-up to this initial study of Climate Change in the UAE in 2011 with the aim of establishing a climate change work programme that could build upon, expand and deepen the understanding of vulnerability to the impacts of climate change as well as identify practical adaptive responses at the local, national and regional levels. A 5-stage stakeholder consultative process involving nearly 100 stakeholders helped define the overall scope of the programme, and establish the types of outputs considered to be the most useful for future policymaking at the multiple scales envisioned.

The first-of-its-kind effort in the Arabian Gulf, the project represents a timely and strategic initiative that can help regional leaders, innovators and decision-makers better understand critical stakes and the range of options available to them across the 5 key thematic areas. The 12 integrated sub-projects also represent an organizing framework to engage partners from across the region on issues that are widely considered to be high priority, while also involving several international organizations to facilitate replication in other regions of the world.

The first two subprojects on high resolution modeling for both atmosphere and the Arabian Gulf are now complete and being openly shared. The findings create the foundational information for the remaining projects of the programme. Interestingly, the results towards modeling

of sea level change and what are its current limitations as opposed to scenario building have create rich dialogue which has helped bridge the disconnect between the science- policy interface.

The modeling has occurred in a nested configuration to cover the Arabian Peninsula at a 12km grid and a 4km grid over the UAE as well as part of Oman and Saudi. 4km is extremely computationally heavy and substantially more robust than the previous studies undertaken by EAD etc. The Oceans Modeling is also run at 1 km resolution which is also incredibly precise in comparison to global modeling which we also used for past studies in the region.

Regional Ocean Models (ROMs) are essential for understanding how future climate change will affect specific locations within the world's oceans. Such models are a significant improvement over coarse resolution ESMs because they more realistically capture local oceanographic processes and characteristics, such as sea surface temperature profiles, circulation patterns, fresher simulations of the Earth's climate.

The ROM for the Arabian Gulf has been developed, based on ESM boundary conditions and local data, and used to make climate change projections out through the late 21st century. The outputs of the study provide a Gulf specific basis on which to conduct the subsequently planned vulnerability assessments of the programme regarding marine biodiversity and socioeconomic systems, as well as be an asset to researchers in the region regarding future climate change and the marine environment.

Regional atmospheric modeling is essential for understanding how climatic conditions will change at specific locations within the region. Such models are a significant improvement over global models because they more realistically represent local to regional meteorological dynamics, such as orographic precipitation, land-ocean wind breezes and circulations, surface heating and evaporation, on-shore and off-shore wind patterns, and other factors that influence current and future climate.

The primary goal of the regional atmospheric modeling using WRF was to develop projections of regional climate for the Arabian Peninsula at fine spatial and temporal scales. The modeling effort builds off and reflects the large-scale features and temporal trends from GCM simulations based on the IPCC's 5th Assessment Report (AR5). The modeling was conducted on the NCAR-Wyoming Supercomputer or "Yellowstone".

The outputs of the study provide a Gulf region-specific basis on which to conduct subsequent planned vulnerability assessments under the programme regarding terrestrial biodiversity, water resources, coastal zones and socioeconomic systems.

P-2245-04

Southern Ocean wind response to North Atlantic cooling and the rise in atmospheric CO2

SY. Lee (1)

(1) Academia Sinica, Research Center for Environmental Changes, Taipei, Taiwan

Southern Ocean, believes to be a CO2 sink (Takahashi, 2012), remains a mystery player in understanding the global carbon cycle and in predicting future climate change. Key evidence from marine proxy record indicates intensification of wind-driven upwelling in the Southern Ocean during the late Pleistocene glacial terminations and suggests that the anomalous southern hemisphere midlatitude westerlies were forced by North Atlantic cooling via atmospheric teleconnection (Anderson et al., 2009). In this study, we investigate the response of Southern Ocean climate to North Atlantic cooling using an AGCM coupled to a reduced gravity ocean to link the empirical observation with climate theory. In comparison between our cooling and basic state experiments, we observed a nearly 25% increase in the Southern Ocean midlatitude westerlies in particular in the Pacific sector during austral winter. We propose a two-step mechanism of the north-south climate connection: (1) the response of the tropical ITCZ to North Atlantic cooling; (2) the resulting effect of the altered Hadley circulation on the Southern Ocean winds. In light of the vital role of the Southern ocean ventilation to atmospheric CO2 concentration, we forced an earth system model with dynamical biogeochemical cycle by anomalous wind field observed in the AGCM and found a ~20 ppm atmospheric pCO2 rise in equilibrium state. The model results support the hypothesis that the Southern Ocean wind-driven upwelling was susceptible to intensive North Atlantic cooling under a glacial climate. We emphasize the intimate coupling between the northern and southern hemisphere climate via atmospheric teleconnection mediated by tropical climate system.

P-2245-05

Climatic sensitivity of the Brazilian Earth System Model integration submitted to abrupt CO2 change

JF. Pesquero (1) ; N. Paulo (1)

(1) National Institute for Space Research, Center for Weather Forecasting and Climate Studies, Cachoeira Paulista, Brazil

This work analyzes the climatic sensitivity response of the Brazilian Earth System Model (BESM-version 2.5) when exposed to abrupt CO2 changes. We will calculate differences between two, 30 years experiments of the BESM model, from 2007 to 2036 (30 years), both of runs start from a 150 years spinup, but one run has atmospheric CO2 constant concentration at preindustrial values (280 ppmv) and the other has constant and abrupt 1200 ppmv ("4xCO2"). The work analyzes the differences of abruptly changed integrations (1200 ppmv) and not abruptly integrations (280 ppmv), more precisely, calculating 12 Climate Extreme Indices using the fields of precipitation, maximum and minimum temperature over South America. The difference of 4xCO2 and 280 ppm integrations for Constant Drier Days (CDD-CLIMDEX index) are showing 60 days of increased CDD over northern South American continent. Note that both of the Northeast as the Southeast and southern Midwest regions of Brazil are showing similar characteristics in magnitude of CDD between 5 and 30 days.The BESM model Total Precipitation (PRCPTOT-CLIMDEX index) indicates an increase from 50 to 200 mm on the South, Southeast of the Midi West of Brazil. The Constant Wet Days (CWD-CLIMDEX index) are decreasing 20 days over the great part of North Region of Brazil. When comparing BESM Frost Days (FD-CLIMDEX index) with FD of the Community Climate System Model (CCSM4), there is a very similar pattern but the BESM showed elevated number of FD. When comparing Summer Days (SU Climdex index) between BESM and CCSM4 models, both of models showed very similar profile of Summer Days, but the CCSM showed smaller values than BESM. Finally, these results showed that the model BESM has a good climatic sensitivity response.

A theoretical Basis for Integrated Assessment Models

FA. Pinto Siabatto (1)

(1) PIK, Potsdam, Brandenburg, Germany

A mathematical model that couples structural change of countries and flows' dynamics has been developed. It proposes a comprehensive representation of the socio-economic structure. The model introduces an explicit description of three processes: GDP growth, the mitigation of damages from uncertain impacts in economic activities, and socioeconomic adjustments that bring about the adaptive capacity. It also holds a representation of resilience. The model makes explicit the endogenization problem that needs to be solved. Working out this problem will allow the numerical assessment of resilience. It also paves the path to the harmonization of metrics relating resources, economic flows and social welfare.

Photochemistry of ozone at the surface of cloud water droplets: insights from computer simulations

M. Ruiz-Lopez (1) ; J. Anglada (2) ; M. Martins-Costa (1) ; JS. Francisco (3)

(1) University of Lorraine, SRSMC, Vandoeuvre-lès-Nancy, France; (2) CSIC, Departament de química biològica i modelització molecular, Barcelona, Spain; (3) University of Nebraska-Lincoln, College of arts & sciences, Lincoln, NE,

United States of America

Atmospheric reactions in condensed media such as water droplets, organic aerosols, soot, sea salt particles, etc., are thought to play significant roles in the troposphere. Reactions at surfaces have attracted special attention, in particular those occurring at the air/water interface of water droplets since clouds represent about 7% in volume of the troposphere. Typically, water droplets exhibit a high surface area to volume ratio and this is certainly a determining factor for surface reactions to compete with bulk reactions. The molecular properties of compounds interacting with an aqueous interface have been often considered as being intermediate between the properties in the two bulk phases but there is now compelling evidence that chemistry at the air/water interface may be quite different from both the gas and the bulk.

However, the experimental study of chemical processes at aqueous interfaces is not straightforward. To get further insights in this domain, in the last few years, we have developed a computational strategy that combines quantum chemistry methods, classical molecular mechanics models, and computer simulations based on the molecular dynamics approach.

In this communication, we report recently obtained results for the photochemistry of ozone at the surface of cloud water droplets. Photolysis reactions are central to atmospheric chemistry. Ozone in particular, absorbs UV and visible light and photodissociates to produce molecular and atomic oxygen either in the ground or excited states. Atomic oxygen can then react with water or methane molecules to form the highly reactive hydroxyl radicals, often referred to as the "detergent" of the troposphere. These processes have been widely investigated in the gas phase but when ozone is adsorbed at the surface of cloud water droplets, the ozone-water interactions modify the spectral signatures, and the mechanism and the kinetics of the photolytic (and subsequent) processes are presumably different and deserve to be investigated in further detail.

Indeed, our computer simulations predict that the hydroxyl radical formation rate at the air/water interface is enhanced by four orders of magnitude, suggesting that clouds can influence the overall oxidizing capacity of the troposphere on a global scale.

3301 - Climate Intervention: Evaluating its Risks, Benefits, and Potential

Climate Intervention: A Summary of the U.S. National Research Council Report on Geoengineering

W. Abdalati (1)
(1) University of Colorado, CIRES, Boulder, CO, United States of America

Climatologically, humans are in unfamiliar territory. Failure over the last few decades to adopt substantive climate mitigation strategies has continued to stress the planet in ways that present some well-understood and some poorly understood risks that pose a threat to human livelihood across the globe. These risks, which continue to increase as greenhouse forcing proceeds unabated, have raised some important questions about the viability of climate intervention (often referred to as geoengineering) as a means to avoid or reduce some of the consequences of climate change. Strategies for such intervention fall into two categories, representing two very different approaches to addressing the climate challenge. The first is carbon dioxide reduction – the removal from the atmosphere and reliable storage of carbon, which has elements of a mitigation approach in that it seeks to reduce the amount of CO2 that enters or remains in the atmosphere. The second is albedo modification, which seeks to increase the amount of sunlight reflected from the Earth, thus reducing the surface incident radiation.

There is a pressing need for a careful and clear scientific foundation that can inform ethical, legal, and political discussions surrounding climate intervention. Toward that end, the National Research Council (NRC) of the U.S. National Academy of Sciences undertook a study to assess the current state of knowledge associated with climate intervention, which resulted in a set of recommendations to inform future decisions on possible climate intervention research and deployment. This talk will present the NRC committee's findings and recommendations, which speak to: the state of readiness of climate intervention methods and the associated challenges, their value in the context of mitigation and adaptation strategies, research needs for advancing our understanding of climate intervention approaches in order to make informed decisions on their deployment, and governance considerations for such research.

Climate intervention is fraught with a wide range of risks and uncertainty. The key question that underpins the need for and approach to research is whether climate change may push society to a state in which the risks associated with non-intervention may outweigh the risks of intervention. Making such an assessment requires a foundation of knowledge and understanding.

K-3301-02

Volcanic Eruptions as an Analog for Stratospheric Geoengineering

A. Robock (1)
(1) Rutgers University, Department of Environmental Sciences, New Brunswick, NJ, United States of America

In response to the global warming problem, there has been a recent renewed interest in geoengineering "solutions" involving "solar radiation management" by injecting particles into the stratosphere, brightening clouds or the surface, or blocking sunlight with satellites between the Sun and Earth. No systems to conduct geoengineering now exist, but a comparison of different proposed stratospheric injection schemes, using airplanes, balloons, and artillery, shows that using airplanes to put sulfur gases into the stratosphere would not be expensive. Nevertheless, it would be very difficult to create stratospheric sulfate particles with a desirable size distribution. While volcanic eruptions have been suggested as innocuous examples of stratospheric aerosols cooling the planet, the volcano analog also argues against geoengineering because of ozone depletion, regional hydrologic responses, and other negative consequences. Volcanic eruptions are an imperfect analog, since solar radiation management proposals involve the production of a permanent stratospheric aerosol layer, while volcanic layers are episodic. Nonetheless, we can learn much from the volcanic example about the microphysics of stratospheric sulfate aerosol particles; changes in atmospheric circulation, producing regional climate responses, such as changes to the summer monsoon; atmospheric chemistry; changes of the partitioning of direct and diffuse insolation; effects on satellite remote sensing and terrestrial-based astronomy; and impacts on the carbon cycle. There are 26 reasons why geoengineering may be a bad idea, and five reasons why it might be a good idea. Some of these can be evaluated with climate modeling, and some using the volcanic analog. Observations of the next large volcanic eruption will help to understand the evolution in stratospheric sulfate aerosol size distribution over the first few months after the eruption. Much more research is needed before we can quantify each of these, so that policymakers in the future can make informed decisions about whether to ever implement stratospheric geoengineering. Given what we know today, global efforts to reduce anthropogenic emissions and to adapt to climate change are a much better way to address anthropogenic global warming.

K-3301-03

The governance of solar geoengineering

S. Schäfer (1) ; N. Moore, (1)
(1) Institute for Advanced Sustainability Studies, Potsdam, Germany

This talk will give an overview of past developments in the governance of solar geoengineering research, contextualize these developments within broader debates on research governance, and conclude with an outlook on how the early governance of solar geoengineering research is relevant to potential future dynamics of international conflict and cooperation on solar geoengineering. Solar geoengineering research has proven fertile ground for calls for and adoption of understandings that reflect new characterizations of science (for example, as 'post-normal'), new ways of assessing scientific results (for example, through 'extended peer review' or 'technologies of humility'), and new processes for conducting research (for example, 'transdisciplinarity' or 'mode 2 science'), which aim to foster cooperation between broader sets of stakeholders and thereby to accommodate their values and beliefs into the research process. Whether these can be put into practice or not will set precedents and norms that are carried forward into negotiations over future activities, including those that may be deployment-related.

Studying the limitations of stratospheric aerosol injections by microphysical processes and interaction with radiation using the IPSL climate model

C. Kleinschmitt (1) ; O. Boucher (2) ; U. Platt (1)
(1) Heidelberg University, Institute of Environmental Physics, Heidelberg, Germany; (2) Laboratoire de Météorologie Dynamique, CNRS / IPSL, Paris, France

Current studies assessing climate engineering by stratospheric aerosols injections (SAI), like those performed in the framework of GeoMIP, reveal numerous risks and undesirable side effects of this method. But they largely rely on the assumption that increasing radiative forcing by greenhouse gases can be counterbalanced by sufficiently large aerosol injections, at least on a global scale. However, there are various processes that might have the potential to severely limit the efficacy of SAI, but which are not considered in most of the participating earth system models. Among them, there is coagulation of aerosol particles leading to an increase in particle size, which reduces scattering efficiency and stratospheric

lifetime through sedimentation. Interaction with infrared radiation, i.e. the aerosol's own greenhouse effect, can also limit the desired cooling effect.

In order to get a better estimate of the cooling potential of SAI from global climate simulations, all these processes were implemented in the IPSL climate model using an aerosol bin scheme. A new radiative transfer scheme is used to account not only for solar, but also for terrestrial infrared radiation. Results from climate model experiments showing the influence of each one of the relevant microphysical and radiative processes on the cooling potential if SAI will be presented.

Cirrus cloud thinning: Do the right conditions exist, and how can it be tested with observations?

D. Mitchell (1) ; A. Garnier (2) ; M. Avery (3)
(1) Desert Research Institute, Atmospheric Sciences, Reno, Nevada, United States of America; (2) UPMC-UVSQ-CNRS, Laboratoire atmosphères, milieux, observations spatiales, Paris, France; (3) NASA, Atmospheric composition, Hampton, United States of America

This presentation will describe recent scientific developments on a climate intervention (CI) method sometimes called cirrus cloud thinning, addressing (1) new evidence that supports its underlying physical assumptions; (2) a means of field testing the CI method without affecting the environment (i.e. without cloud seeding); and (3) how to reduce uncertainties concerning its radiative and climate impacts.

While GCM testing of cirrus cloud thinning suggests it has some advantages over stratospheric aerosol injection, cirrus CI will not work when ice is primarily formed through heterogeneous nucleation for T < -38°C. Field campaigns have shown that ice in cold cirrus is generally produced heterogeneously, but these campaigns have not addressed the cirrus at high latitudes that would determine the effectiveness of cirrus CI.

A new understanding of thermal absorption in two split-window channels has rendered a reinterpretation of a standard CALIPSO satellite retrieval (the effective absorption optical depth ratio, or βeff), and a tight correlation between βeff and the N/IWC ratio has been demonstrated, where N = the ice particle number concentration and IWC = ice water content. When applied to cold semi-transparent cirrus clouds having emissivities between 0.4 and 0.8, we find that (1) polar cold cirrus (T < -38 C) occur much more often during winter than during summer and (2) N/IWC is relatively high at high latitudes during winter, suggesting that homogeneous nucleation occurs frequently there. Homogeneous nucleation is further supported by the fact that high N/IWC values tend to coincide with regions of low mineral dust concentration as predicted by CAM5 (Storelvmo and Herger, 2014, JGR). This high N/IWC during winter (and probably from Dec. - April) is likely to have a strong greenhouse effect that may increase high latitude temperatures by 2-5°K relative to cirrus conditions where heterogeneous nucleation dominates (Storelvmo et al. 2014, Philos. Trans. A, Royal Soc.). Thus, implementing cirrus CI at high latitudes (in both hemispheres) only during the months when noontime solar zenith angles are very low or when the sun never rises (i.e. seeding only 15% of the planet) may have a comparable cooling effect at high latitudes where global warming is most severe, and may have a mean global cooling of 1.4°K as shown in Storelvmo et al. (2014, Philos. Trans. A, Royal Soc.). These satellite findings indicate that cirrus CI is a real possibility.

These N/IWC satellite retrievals also show that N/IWC at high latitudes during summer is relatively low and characteristic of heterogeneous ice nucleation. This may be the result of higher mineral dust concentrations, expected to be higher during summer at high latitudes. This apparent changing of ice nucleation mode from winter to summer may provide a natural means of field testing the cirrus CI method, without any need of cloud seeding from aircraft. The DOE ARM program is considering a field program for sampling wintertime Arctic cirrus (T < -40°C) in response to these satellite retrievals due to their importance to climate science. In situ measurements of wintertime cold Arctic cirrus would enable their microphysical properties to be parameterized (i.e. cloud temperature related to effective diameter De; De related to mass-weighted ice fall speed) and contrasted with microphysical properties/parameterizations associated with cirrus formed at similar temperatures through heterogeneous ice nucleation. GCM simulations using these parameterizations would then be able to evaluate the actual potential climate impact of cirrus cloud seeding (i.e. cirrus CI) at high latitudes, thus reducing various uncertainties associated with cirrus CI such as its cooling impact.

If a large scale CI field experiment were ever conducted on winter high latitude cirrus, this satellite method could be used to monitor these clouds and to determine whether the CI method was working (i.e. seeding with efficient ice nuclei was changing the nucleation mode).

Finally, it is noteworthy that cirrus CI appears to be the only radiation management CI approach that preferentially cools the Polar Regions where the effects of global warming are most severe.

O-3301-03

Low-cost low-risk space-based geoengineering - is it possible?

A. Ellery (1)
(1) Carleton University, Mechanical & Aerospace Engineering, Ottawa, ON, Canada

Space-based geoengineering is often discarded as an approach to geoengineering on the basis of cost and feasibility. The Angel approach is to launch modular component spacecraft into the Sun-Earth L1 point forming a solar shield to reduce the amount of solar energy incident on the Earth. The cost and feasibility constraints generally revolve around the issue of launch capacity from the Earth's surface. The proposed American lunar Resource Prospector Mission (PRM) slated for launch in 2018 offers another approach - the robotic use of lunar resources to bootstrap the feasibility of lower-cost space missions by reducing the amount of launched material. We present a preliminary feasibility and technological development assessment to manufacture the modular spacecraft required to realise a modular solar shield concept. The RPM mission will be investigating the extraction and processing of lunar soil - in particular, ilmenite (FeTiO3). It may be extracted magnetically and ilmenite grains are preferentially enriched in volatiles. Although dominated by hydrogen - itself a useful reductant as well as propellant with oxygen - these volatiles include carbon compounds that may potentially be manufactured into plastics (silicone plastics in particular to conserve the carbon inventory). These volatiles may be evolved by heating the ilmenite grains to ~600oC using a simple fractional distillation column. The ilmenite is further heated to >900oC with recycled hydrogen (from lunar water ice or recovered volatiles) to yield oxygen, wrought iron and titania ceramic/glass: $FeTiO3 + H2 \rightarrow TiO2 + Fe + O2$. Although the primary interest for RPM is in the recovered oxygen to support human lunar colonisation, our interest is in the iron to form the basis of a robotic industrial infrastructure. As well as iron, cast lunar basalt offers the possibility of compressive material as sacrificial structures to conserve iron for incorporation into manufactured spacecraft structures - wrought iron is a perfectly adequate structural material. The Moon exhibits a hostile thermal environment so thermal control materials will be essential in any infrastructure as well as the spacecraft modules. TiO2 is an excellent thermal (and electrical) insulator which may be formed into fibreglass. As well as thermal conduction, thermal conduction material is required - fernico, an alloy of iron, nickel and cobalt, is an excellent thermal and electrical conductor. Both Ni and Co may be sourced from mass concentration regions of the Moon, marking the locations of iron meteorite material. Semiconductor material - silicon - is available from lunar silicates minerals. From these materials, we have the basic elements we require to build a spacecraft mechanically, electrically and thermally. The only Earth-imported reagents required for isolation of these materials are Na and Cl which nevertheless are recycled. The materials must be formed into useful structures, components and parts. The advent of 3D printing offers a versatile means of manufacturing that can handle plastics, metals and ceramics. Selective laser sintering is an approach that uses lasers to thermal fuse particles into layers, thereby building 3D structures that cannot be manufactured in any other way. Electronics without solid state manufacturing techniques represents a particular challenge though progress has been made in printed plastic electronics. Another option is to use 3D

printing to manufacture vacuum tube-based electronics for simple control systems. This approach is favoured because it relies on ceramics and metals already extracted. Indeed, thermionic emission with vacuum tubes offers a viable form of electric energy generation from thermal sources. My group has been exploring how to 3D print electric motors using multiple lunar-derived materials – core of iron plates, insulating plates and bobbins, and conducting wire – to construct a 3D printable universal motor. If successful, this offers the prospect that 3D printing could manufacture further manufacturing tools – lathes, milling stations, etc to perform further manufacturing functions. Furthermore, electromagnetic launchers are derivatives of electric motors arrayed linearly rather than radially (different scale of course). This offers the prospect of launch with minimal fuel use. Indeed, 3D printers could potentially manufacture complete robotic devices – manipulators for assembly of parts, rovers for geological surveying and 3D printers themselves for self-replication. A corollary to this capability is that such 3D printing systems could manufacture the spacecraft modules required to implement a solar shield with a modest inventory launched from Earth.

Climate Engineering and Policy Interaction Networks: The Challenges of Regulating a Complex System

J. Lawhead (1)
(1) University of Southern California, Earth Science / Philosophy, LOS ANGELES, United States of America

The global climate is a complex system. Among other things, this means that a complete analysis of the climate as a whole involves attending to the ways in which various geophysical and biological subsystems influence and constrain one another's behavior. This fact is widely appreciated. Less widely appreciated is the fact that climate policy design and analysis involves very similar considerations. Global policy initiatives like climate engineering will not be implemented in a social vacuum, and the emerging consensus is that climate engineering would be best employed as part of a multi-faceted strategy that also involves mitigation and adaptation programs. In light of this, it is vitally important that we think about the ways in which different climate-related policies might influence and constrain one another before we begin to implement any significant global policy.

While feasibility analyses and impact studies exist for many proposed climate engineering programs, very little attention has been paid to the ways in which such programs might interact with and constrain other international and national climate policies. This paper explores this "interaction problem" from an interdisciplinary perspective, focusing on a detailed hypothetical case study in which a solar radiation management by stratospheric aerosol injection program is combined with a global system of economic carbon credits. The conjunction of these two programs raises practical, theoretical, and ethical concerns that don't appear when either policy is considered alone, and which might significantly alter the effectiveness and feasibility of both programs. This incomplete picture, arising from analyzing climate engineering proposals in isolation, is a potentially dangerous oversight as we move closer and closer toward possible implementation.

P-3301-01

Response of Indian Subcontinent to the Geoengineering of Climate: The effect of SRM on Cloud Area Fraction and Rainfall

P. Arora (1) ; SK. Mishra (2)
(1) IIT Delhi, Civil Engineering, New Delhi, India; (2) IIT Delhi, Centre for atmospheric sciences, New Delhi, India

The objective of this paper is to study the effects of Solar Radiation Management (SRM) on the climate over the Indian Subcontinent, particularly how it changes the cloud area fraction and total precipitation over the region. Cloud area fraction and precipitation are highly model sensitive parameters which depend greatly on other parameters like surface air temperature and evaporation. These parameters play a major role in governing small and large scale weather activities in any area and a small change in them can trigger repercussions on a much larger scale. As such it becomes extremely important to analyze closely the effects of SRM on our climate before implementing it in reality. The data for five important and interdependent variables: cloud area fraction, total precipitation, precipitable water, evaporation and surface air temperature was studied exhaustively for nine models namely BNU-ESM, CCSM4, CanESM, CAM5.1, GISS-E2-R, HadGEM2-ES, IPSL-CM5A-LR, MIROC-ESM and MPI-ESM-LR, for a period of 50 years and the graphical results for the changes in these parameters was plotted using NCAR Command Language (NCL). The results obtained from these plots were indicative of the fact that cloud area fraction and precipitation, particularly over the Indian Subcontinent, are indeed highly model sensitive parameters; where a small change in the solar radiation caused changes as high as 30% in these parameters. With the given uncertainty in the simulated parameters, it becomes crucial to have more robust modeling before implementing any decision, particularly for a country like India where the economy is largely driven by monsoon dependent agriculture and even a small change in the climate can affect severely the livelihood of millions of people. Therefore any decision, big or small, must be pondered upon carefully, to analyze the risks and the benefits being derived from it, before implementing it on a local, regional or global scale.

P-3301-02

Climate Engineering Research Trends – Results from an Expert Survey

K. Beyerl (1) ; T. Wiertz, (1)
(1) Institute for Advanced Sustainability Studies e.V., Potsdam, Germany

As international climate change mitigation efforts are progressing relatively slowly, climate engineering (CE) has been controversially discussed for several years now and often viewed with scepticism. In August 2014, the so far largest transdisciplinary conference on climate engineering CEC14 took place in Berlin, and assembled over 350 participants from 40 countries who discussed a multitude of questions associated with technical interventions in the climate system. More than one third of this expert group participated in a subsequent online survey about future research trends in CE. The presentation will summarize the outcomes of this survey and thereby give an overview of the current state and diversity of the CE debate, motivations to engage with the topic and expected future research trends. Some general results are summarized below. In the talk, the data will be presented in more detail and with regard to specific sample subgroups and technologies as each technological approach raises specific challenges.

1. Working backgrounds, motivations, hopes and concerns with regard to CE research. The vast majority of respondents named countries in Europe or North America to be their country of origin and current office location. Despite the global relevance of the topic and various attempts to increase geographic representation, scientific expertise and awareness remains very much centred in the Global North. Academic backgrounds of people working on CE cover various aspects of natural science, as well as social sciences and humanities. Social scientists seem to work more broadly on the concept of CE, whereas natural scientists focus more on specific technologies. Motivations to engage with CE are manifold, such as 1) concern about climate change and pessimism about mitigation activities, 2) a search for options to counter climate change, 3) concern about CE consequences, 4) scientific interest in the topic reaching from modelling and impact assessment to governance and policy implications, philosophical questions of decision making, to reach a robust scientific footing for decision making. Throughout the survey, participants highlighted concerns about various risks of CE technologies.

2. Expected trends in CE research. Despite the widely shared opinion that methods to remove carbon dioxide from the atmosphere (CDR) would be safer and should be researched, many of the conference participants seem to expect that research will focus on solar radiation management (SRM) in the future although they see many risks associated with SRM-techniques. Technologies that should be researched most according to the participants were for CDR: (Bioenergy with) Carbon Capture and Storage, and Direct Air Capture; and for SRM: Stratospheric Aerosol

Injections and Marine Cloud Brightening. CDR techniques are seen as currently not effective enough, too slow and too expensive. Asked for which aspects of research should get more attention, answers differed for CDR and SRM in the way that for CDR participants identified technical research and development and economics among the main aspects; for SRM, climate effects, governance and ethics where highlighted; environmental effects and impact assessment scored high for both approaches.

3. Opinions about Field Research and Governance. Whereas several participants were in favour of no field research at all, others expected field tests for CDR and/or SRM. However, the focus of research differed: For CDR, field tests were mainly suggested to test feasibility, efficiency, safety, impacts, solutions for carbon storage and recycling. For SRM, the main questions were related to atmospheric physics and chemistry, specifics of particles, engineering tests, delivery technology, impact assessment and critical factors. With regard to governance that should be in place before field testing, opinions differed from no governance and that existing governance is sufficient, to the need for an international convention or legal framework and a global body, as well as the application of national laws. Furthermore, environmental and social impact assessments (EAI and SIA) were suggested and the need for public participation in decision making and ensuring transparency was highlighted.

On a general note, most survey participants hope that CE won't be necessary at all and emphasized that climate change mitigation should be heavily intensified.

P-3301-03

Geoengineering, Preferred Climate States, and Climate Policy in the Anthropocene

J. Horton (1)
(1) Harvard University, Kennedy School of Government, Cambridge, MA, United States of America

Many social, ethical, political, environmental, and other objections to geoengineering have been raised since the taboo on public discussion was broken a decade ago. One of the key criticisms, though often unstated, is focused on the fact that geoengineering would necessarily entail making conscious, deliberate decisions about desired climate states. These states might be implicit or explicit, and might be defined in terms of temperature, radiative forcing, rate of change, atmospheric concentration, or some other metric, but choosing to intervene in the climate system is inextricably linked to choosing what the climate ought to be. This feature of geoengineering has been criticized on the grounds that it is arrogant, hubristic, unnatural, corrupt, and/or unwise. There may be merit in such criticisms, yet this line of argument overlooks the reality that, in the Anthropocene epoch, any climate policy is unavoidably premised on a preferred climate state. Mitigation rests inherently on targets, whether general (climate stability, preindustrial, Holocene) or specific (°C, ppm, GtC). From a philosophical point of view, any such target is ultimately arbitrary, in the sense that nature does not endorse one goal over another. The same is true of adaptation. Every potential climate state entails some combination of winners and losers (human and non-human), and the ethical dilemmas this presents cannot be avoided simply by excluding geoengineering as a climate policy option. The mere fact of making decisions about preferred climate states is an insufficient and unsound basis for objecting to geoengineering, and only serves to obscure the tough choices about future climate that must be made whether or not geoengineering is on the policy agenda.

Atmospheric consequences of disruption of the ocean thermocline by ocean pipe technologies

K. Lester (1) ; K. Ricke, (1) ; K. Caldeira (1)
(1) Carnegie Institution for Science, Stanford, CA, United States of America

Technologies utilising vertical ocean pipes have been proposed as a means to avoid global warming, either by providing a source of clean energy, increasing ocean carbon uptake, or storing thermal energy in the deep ocean. However, increased vertical transport of water has the capacity to drastically alter the ocean thermocline. To help bound potential climate consequences of these activities, we perform a set of simulations involving idealised disruption of the ocean thermocline by greatly increasing vertical mixing in the upper ocean. We use an Earth System Model (ESM) to evaluate the likely thermal and hydrological response of the atmosphere to this scenario. In our model, increased vertical transport in the upper ocean decreases upward shortwave and longwave radiation at the top-of-the-atmosphere due primarily to loss of clouds and sea-ice over the ocean. This extreme scenario causes an effective radiative forcing of ≈15.5-15.9W m-2, with simulations behaving on multi-decadal time scales as if they are approaching an equilibrium temperature ≈8.6-8.8°C higher than controls. Within a century, this produces higher global mean surface temperatures than would have occurred in the absence of increased vertical ocean transport. In our simulations, disruption of the thermocline strongly cools the lower atmosphere over the ocean, resulting in high pressure anomalies. The greater land-sea pressure contrast is found to increase water vapour transport from ocean to land in the lower atmosphere and therefore increase global mean precipitation minus evaporation (P-E) over land; however, many high latitude regions and some low latitude regions experience decreased P-E. Any real implementation of ocean pipe technologies would damage the thermal structure of the ocean to a lesser extent than simulated here; nevertheless, our simulations indicate the likely sign and character of unintended atmospheric consequences of such ocean technologies. Prolonged application of ocean pipe technologies, rather than avoiding global warming, could exacerbate long-term warming of the climate system.

P-3301-06

Perspectives of Climate Engineering Adoption in Africa: Analogies from International Environmental Agreements, Conventions and Treaties

C. Ngonzo Luwesi (1) ; AA. Rose (2)
(1) Kenyatta University, Geography, Nairobi, Kenya; (2) Kenya Forest Service, Climate change response programme, Nairobi, Kenya

Global warming is steadily threatening ecosystems and their biological lives across the globe. Though life in the equatorial and tropical regions is associated with hot temperatures rather than cooling, the drastic decrease of forest cover and major vegetations in the last century may be an argument for adoption of the principle of large-scale Climate Engineering (CE). Whether through Solar Radiation Management (SRM) or through Carbon Dioxide Removal (CDR), this strategy might only be acceptable as a «plan B» to climate mitigation and adaptation. CE research and technology may be scaled up to supplement African governments' efforts to reduce planned greenhouse gases (GHG) emissions and avoid suicidal climate mitigation and adaptation strategies. These schemes are cheap and effective climate "mitigation" options but may be dangerous, the safest options being expensive or simply useless. Besides, most of the countries in the African continent do not have the ability to invest in what are considered as "harebrained schemes, which impacts are yet to be ascertained". Hence, African countries will recourse to several principles found in the UNCCD, UNCBD and UNFCCC treaties and conventions, the REDD+ agreement, and the 1997 UN Convention on International

Watercourses to elicit their position vis-à-vis CE research and deployment. This paper focuses on the Intra- versus intergenerational equity and sustainability of the CE technology, the precautionary principle, the moral hazard principle linked to mitigation efforts and the binding principles of no-harm and compensatory damages. It simulates analog responses to CE research and deployment adoption based on the practice of international law in Africa.

P-3301-07

Simulating the potential impacts of reforestation on extreme rainfall over West Africa in future

RC. Odoulami (1) ; A. Babatunde (1) ; AE. Ajayi (2)
(1) University of Cape Town (UCT), Climate System Analysis Group (CSAG) - Dept. of Environmental and Geographical Science (EGS), Cape Town, South Africa; (2) Federal University of Technology Akure (FUTA), Department of agricultural engineering, Akure, Nigeria, Federal Republic of

This study investigates the impacts of reforestation on characteristics of extreme rainfall over West Africa, with a focus on the widespread extreme rainfall events (WEREs) in Savannah, under the RCP 4.5 future climate scenario. For the study, two regional climate models (RCMs: RegCM4 and WRF version 3.5.1), forced with global climate models simulations (HadGEM2 and ECHAM6 respectively), were applied to reproduce the present-day climate (PRS), and to project the future climate (2031-2064) with and without large-scale reforestation in Savannah (FUT and REF, respectively). To validate models, we compare the PRS simulations with the Global Precipitation Climatology Project (GPCP) and Tropical Rainfall Measurement Mission (TRMM) observation datasets. To examine the impacts of reforestation on future extreme rainfall events, we compare the FUT and REF simulations. The results show that, the two RCMs give credible simulations of extreme rainfall threshold (95th percentile of daily rainfall in the past climate) over West Africa. However, RegCM4 reports lower values over the Sahel and the Western Savannah, and both models simulate more WEREs than observation (TRMM) over Savannah. Both model project an increase in the occurrence of extreme rainfall events over the Guinean coast and a decrease over the Savannah and Sahel in the future. However, they show that reforestation would increase the frequency of extreme events over the Savannah, but lowers it over the Guinean coast. Results from this study may guide decision makers on climate change mitigation and adaption options in West Africa.

P-3301-08

Public perceptions of climate engineering and field test proposals in Japan

M. Sugiyama (1) ; S. Asayama (2) ; A. Ishii (3)
(1) The University of Tokyo, Policy Alternatives Research Institute, Bunkyo-ku, Tokyo, Japan; (2) National Institute for Environmental Studies, Japan, Tsukuba, Japan; (3) Tohoku University, Center for northeast asian studies, Sendai, Miyagi, Japan

There is a growing call for research on climate engineering, the deliberate intervention in the Earth's climate, particularly stratospheric aerosol injection (SAI), one of the methods of so-called solar radiation management (SRM), given the presumed inadequacy of global efforts to reduce greenhouse gas emissions and a possibility of "climate emergency". Such a call for research on SAI includes proposals of conducting small-scale outdoor experiments or field tests in the natural environment with controlled emissions of aerosols.

However, there are strong disagreements and controversies among scientists on whether and how such field tests should proceed, and importantly such debate is mainly based not on technical but social, political and ethical concerns. Advocates claim the urgent need for field tests due to concerns over "climate emergency" while critics worry about "moral hazard" caused by field tests and argue that once research was initiated, SAI would fall down a "slippery slope," eventually leading to its deployment. These concerns are relevant to broader public deliberation, and should not be confined only to debate among experts.

In this poster, we report the results of a recent online survey with Japanese citizens (N = 3000), focusing mainly on SAI field tests. Our survey design was intended to elucidate the key social, political and ethical concerns of the public regarding SAI. The respondents read a short description of SAI and answered their opinions.

The survey results show a high rate of the "unsure" or "don't know" (DK) responses — about one-third of the respondents chose DK response to the questions regarding attitudes toward SAI. At least three reasons can be considered as sources of DK response: first, lack of knowledge and awareness of SAI, as nearly two-thirds answered "neither heard of nor know at all SAI"; second, little understanding of the provided information of SAI, since about two-fifths of the respondents answered "cannot understand so much" or "cannot understand at all"; and third, the omission of middle scale option such as "neither agree nor disagree" in our survey instrument, since it might have caused those who have ambivalent or ambiguous views on SAI to be difficult to answer, resulting in a DK response. Thus, our survey results can be deemed to show the public's undecided opinions on SAI.

Nevertheless, the respondents demonstrated discernible attitudes toward SAI in some respects. First of all, a great majority of the the respondents clearly favor mitigation to SAI, and think that considering SAI before pursuing all efforts to reduce CO2 emissions is undesirable. In addition, the respondents exhibited (conditional) support of SAI research, but differentiated different modes of research. They demonstrated preference of indoor research activities such as computer simulations and lab work over outdoor field tests. The support for the deployment was limited, which is consistent with the findings of previous surveys. The respondents also showed a relatively serious concern over the risk of unpredictable side-effects of SAI and political consequences of research, i.e. the possibility of "slippery slope", although a majority of them thought that the prospect of "moral hazard" is unlikely. Regarding the governance issues on field tests, the respondents strongly favor the public consultation before field tests, the open disclosure of the results including negative information, and the international regulation of field tests instead of scientists' self-regulation. The respondents seem to endorse the importance and significance of 'Oxford Principles' of climate engineering research governance.

In our survey we controlled the information of SAI and split the sample into one with and without the "climate emergency" frame. Previous research suggests that framing of information provided to the respondents (especially, emergency framing) may influence, and therefore bias the public perception of SAI, though the results of our survey did not yield such framing effects on respondents' attitudes toward SAI with any statistical significance. We thus have reported all the results, collapsing the two groups into one.

We believe our survey results can bring important and non-Western perspectives into the wider public debate on climate engineering.

P-3301-09

The Carbon Dioxide Removal Model Intercomparison Project (CDR-MIP)

N. Vaughan (1) ; D. Keller, (2) ; A. Lenton (3) ; V. Scott (4)
(1) University of East Anglia, Tyndall Centre for Climate Change Research, Norwich, United Kingdom; (2) GEOMAR, Helmholtz centre for ocean research, Kiel, Germany; (3) CSIRO, Hobart, Australia; (4) University of Edinburgh, School of geosciences, Edinburgh, United Kingdom

Continued anthropogenic greenhouse gas emissions are changing the climate threatening "severe, pervasive and irreversible" impacts. Inadequate emissions reduction is resulting in increased attention on Climate Intervention (CI) - deliberate interventions to counter climate change that seek to either modify the Earth's radiation budget, or remove the primary greenhouse gas from the atmosphere - Carbon Dioxide Removal (CDR). The majority of future scenarios that do not exceed 2°C warming by 2100 include CDR methods. At present, there is little consensus on the impacts and efficacy of the different types of proposed CDR. In response, the Carbon Dioxide Removal Model Intercomparison Project (or CDR-MIP) is proposed. This project aims to bring together a suite of Earth System Models (ESMs) and Earth System Models of Intermediate Complexity (EMICS) in a common framework to explore the potential, risks, and challenges of different types

of proposed CDR. At present the proposed simulations for CDR-MIP include: Direct-air capture simulations, Afforestation and Ocean alkalinisation as well as a modified Diagnostic, Evaluation, and Characterization of Klima (DECK) experiment. These experiments are designed to answer key questions related to quantifying efficacy, feedbacks, response time scales, and potential side effects of specific CDR methods, as well as questions of climate "reversibility". Here we present details on the proposed experiments, and encourage feedback from the community on their design and implementation. It is anticipated that this will be the first stage of a continuing project exploring CDR, and as such we strongly encourage interested modeling groups to participate. CDR-MIP aims to commence in September 2015.

3302 - Key Energy Technologies for Low Carbon Pathways

The Role of Technology for Achieving Climate Policy Objectives: Overview of the EMF27 Study

E. Kriegler (1) ; V. Krey (2) ; J. Weyant (3)
(1) Potsdam Institute for Climate Impact Research, Potsdam, Germany; (2) IIASA, Laxenburg, Austria; (3) Director, Energy Modeling Forum (EMF), Stanford, CA, United States of America

Low-carbon technologies in the energy system have been identified as a key element for mitigating climate change. The relative importance of mitigation technologies depends not only on their techno-economic characteristics and how they develop in the future, but also on the competition with other energy technologies, the development of future energy demand and the climatepolicy architecture. Since all of these factors are interconnected and surrounded by large uncertainty, it is important to investigate technology strategies from a system perspective and under a variety of assumptions.

This presentation gives an overview of results from the Stanford Energy Modeling Forum Study 27, an inter-comparison of 18 energy-economy and integrated assessment models. The study investigated the importance of individual mitigation options such as energy intensity improvements, carbon capture and storage (CCS), nuclear power, solar and wind power and bioenergy for climate mitigation. Limiting the atmospheric greenhouse gas concentration to 450 or 550 ppm CO2 equivalent by 2100 would require a decarbonization of the global energy system in the 21st century. Robust characteristics of the energy transformation are increased energy intensity improvements and the electrification of energy end use coupled with a fast decarbonization of the electricity sector. Non-electric energy end use is hardest to decarbonize, particularly in the transport sector. Technology is a key element of climate mitigation. Versatile technologies such as CCS and bioenergy are found to be most important, due in part to their combined ability to produce negative emissions. The importance of individual low-carbon electricity technologies is more limited due to the many alternatives in the sector. The scale of the energy transformation is larger for the 450 ppm than for the 550 ppmCO2e target. As a result, the achievability and the costs of the 450 ppm target are more sensitive to variations in technology availability.

Not communicated.

K-3302-03

Is nuclear energy part of the solution?

V. Faudon (1)
(1) Société Française d'Energie Nucléaire, Paris, France

At least 80% of the world's electricity must be low-carbon by 2050 to keep the world within 2°C of warming, according to the IPCC. This is a massive global challenge that requires the use of all available low-carbon energy technologies. Nuclear energy is recognized by the IPCC as "an effective greenhouse gas mitigation option" with life cycle emissions "comparable to most renewables".

We need to take immediate steps towards reducing greenhouse gas emissions, as the world has already used up most of its carbon budget. Nuclear energy is low-carbon, available and competitive in the timeframe required. It has avoided the release of 56 gigatonnes of CO2 since 1971, two years' worth of emissions at current rates. Additional nuclear energy capacity can be built up in the world's largest emitting countries: there are more reactors under construction today than at any time in the last 25 years, with BRICS countries leading the way[i]. Existing nuclear power plants are the largest low-carbon electricity source in OECD countries. Operating them for longer is one of the most effective ways to keep greenhouse gas emissions down. Moreover, nuclear generation can operate with renewables energy in order to adapt generation to electricity demand, taking into account variability of certain renewable energy sources.

As countries are pursuing different energy policy goals, with different constraints, they should be free to choose from the full portfolio of energy technologies, including renewable energies and nuclear energy, to reduce CO2 and meet other energy objectives. Very few scenarios have been investigated with mitigation requirements to limit warming to 2C and implemention of a nuclear phase out. While they need the largest portfolio now, countries will also need the largest portfolio tomorrow: nuclear research should receive support to develop future reactors(generation 4) that will make better use of the Uranium resources, will operate in a safer way, and produce less waste. Renewable energies and Nuclear have to be considered together as part of the electricity mix on the low carbon pathways

Ocean Thermal Energy Conversion, the potential impact on microplankton of bottom water discharge at subsurface

M. Boye (1) ; M. Giraud (2) ; V. Garçon (3) ; M. Lejart (4) ; C. Auvray (5) ; M. Boeuf (4) ; D. De La Broise (6)
(1) Institut Universitaire Européen de la Mer, Laboratoire des Sciences de l'Environnement Marin, Plouzané, France; (2) IUEM-LEMAR, FEM, LEGOS, Brest, France; (3) LEGOS UMR5566, Toulouse, France; (4) France Energies Marines, Brest, France; (5) DCNS, Brest, France; (6) IUEM-LEMAR, Plouzané, France

Part of the solar energy can be harvested and used in different processes. Taking advantage of the natural temperature gradient between the surface and the deep ocean, the Ocean Thermal Energy Conversion (OTEC) process achieves this goal. However, the artificial upwelling created by the release of deep water flowing out of an OTEC plant into the sub-surface layer (whose temperature and biogeochemical composition are quite different) could locally induce alterations in ecosystem structure and functioning. The anticipated effects on the microphytoplankton were studied on a scheduled pilot site off Martinique (Caribbean Sea), within the framework of the IMPALA project.

The biogeochemical processes that participate in the artificial upwelling were addressed by simulation of the discharge using in situ microcosm experiments immersed

for 6 days. Mixing of deep water with sub-surface waters was achieved at different depths (maximum of chlorophyll and bottom of the nutricline) and mixing rates (0%, 2% and 10% of bottom water). Analyses of pigments (HPLC), picophytoplankton abundance (flow cytometry), and nutrients were performed in the microcosms and the surrounding waters to assess the natural variability of the phytoplankton assemblage and the potential shifts induced by rich deep water supply in a nutrient poor surface water.

Similar evolution over time of the phytoplankton communities was observed in the natural environment and in the microcosm without deep-water input, suggesting that microcosms can be used to assess the impact of bottom water discharge at sub-surface. The enrichment of sub-surface waters by 10% of deep seawater induced a significant shift in the phytoplankton assemblage towards the development of diatoms. This could have biogeochemical and ecological consequences since diatoms are major drivers of the biological carbon pump in the ocean.

The potential of nuclear energy to mitigate climate change

FM. Breon (1) ; A. Berger (2) ; B. Brook, (3) ; P. Hansen, (4) ; F. Livet, (4) ; H. Nifenecker (5) ; M. Petit, (4) ; G. Pierre (6) ; H. Prevot, (4) ; S. Richet, (4) ; H. Safa, (7) ; M. Schneeberger, (4)
(1) IPSL, LSCE, Gif sur Yvette, France; (2) Université Catholique de Louvain, Earth and life institute, Louvain la Neuve, Belgium; (3) University of Tasmania, Hobart, Australia; (4) Sauvons le Climat, Paris, France; (5) Sauvons le Climat, Vizille, France; (6) Bourgogne University, Dijon, France; (7) Commissariat à l'Energie Atomique, Direction de l'energie nucléaire, Gif sur Yvette, France

In the 2014 IPCC report, Working Group 3 discusses several scenarios that are consistent with RCP-2.6, with the objective of limiting the global mean surface temperature increase to less than 2 degrees. All these scenario rely on massive Carbon Capture and Storage (CCS), at the ≈10 GtC level while the few existing experiments are at the MtC level. It may appear unreasonable to assume that the geological, technology and cost requirements associated to CCS will be met.

We focus on the scenarios IMAGE, developed by the NEAA, Netherlands, and MESSAGE developed by IIASA, Austria. Both propose three sub-scenarios: (i) "Supply" that assumes a high energy consumption compliant with the needs of economic and social development. (ii) "Efficiency " which assumes a 45% smaller consumption, and (iii) "MIX" which is intermediate. All 6 scenarios assume a massive development of PhotoVoltaic (PV) energy together with a large increase of biomass. In the supply scenario, 7000 nuclear reactors are put in operation between 2060 and 2100. We suggest that the urgency of climate change argue for such development as early as 2020.

We shall describe in detail the potential and limitations of such massive nuclear development. The technology for a massive nuclear development is much more mature than that of CCS, does not suffer from the intermittency limitations of PV and wind energy, and necessitates far less material extraction than these. It requires however the generalization of breeding reactors of which only a few units currently exist. The necessity for Plutonium availability requires a partial shift from Pressurized Water Reactor (PWR) to CANDU-like reactors together with the development of fuel processing facilities.

A wide development of nuclear energy, at a pace comparable to its development in France during the 70s and 80s would allow the stabilization of atmospheric CO2 concentration at a level compatible with RCP-2.6, while providing enough energy for a growing population and without the hypothetical massive development of CCS. It makes possible a near-total ban of coal use well before the end of the century.

Analysis of substitution trade-offs among selected bioenergy pathways for different end-uses

S. Chigullapalli (1) ; AB. Rao (2) ; A. Patwardhan (3)
(1) Indian Institute of Technology Bombay, Climate Studies, Mumbai, Maharashtra, India; (2) Indian Institute of Technology Bombay, Ctara, Powai, Mumbai, India; (3) Indian Institute of Technology Bombay, Sjm som, Mumbai, Maharashtra, India

The environmental concerns (local and global) as well as the depleting reserves of the conventional energy sources have forced us to seek fuel efficient and greener alternatives for many of the traditional energy consumption approaches. Bioenergy is the traditional source of energy with renewed interest due to its carbon mitigation potential assuming CO2 neutrality, need for diversification of energy sources and the renewable nature of feedstocks. A bioenergy system or bioenergy chain / route consist of a series of conversion steps by which raw biomass feedstock is transformed into a final energy product (heat, electricity, or transport biofuel). There are many bioenergy chains as a result of the wide range of raw biomass feedstocks (wood, grass, oil, starch, fat, etc.), broad spectrum of conversion technologies and a variety of possible end-uses.

Bioenergy alternatives offer significant carbon mitigation potential (CMP), provided that the resources are utilized sustainably and that efficient bioenergy systems are used. Certain current systems and key future options including use of biomass residues and wastes and advanced conversion systems are able to deliver 80 - 90% emission reductions compared to the fossil energy baseline [IPCC, 2012].

The CMP associated with specific bioenergy options depend on intrinsic factors such as design of the bioenergy system and extrinsic factors such as source of biomass and fossil fuels they are replacing. Many bioenergy pathways can be used to convert a range of raw biomass feedstock into a final energy product. The choices we make today will affect the amount of GHGs we put in the atmosphere in the near future and for years to come.

In order to assess and compare the economic and environmental sustainability of modern bioenergy systems, there is a need for comprehensive assessment of each bioenergy pathway for cataloguing attributes of various proposed bioenergy feedstocks and conversion technologies.This article analyzes the substitution trade-offs among selected bioenergy pathways for different end-uses.

P-3302-04

The hydrogen economy: a failed concept or the future for our energy system?

P. Dodds (1)
(1) University College London, UCL Energy Institute, London, United Kingdom

Hydrogen has been proposed since the 1970s as a clean alternative to carbon-based fuels, particularly for the transport sector. This paper examines recent developments in the use of hydrogen in transport, heat provision and energy storage, and considers policy initiatives that are designed to introduce hydrogen-powered technologies into existing energy systems.

After much hype in the early 2000's, a perceived lack of progress led many to deem fuel cell vehicles (FCVs) a failure; research programmes were cut and attention switched to battery vehicles, encompassed within a broader view of predominantly electrically-powered energy systems. Yet many automotive manufacturers have continued developing FCVs, particularly in Asia, and have pushed in recent years for hydrogen-fuelled vehicles to have an important role in the future, for example through the publication of the McKinsey-coordinated "Power-trains" study [1]. It has had a significant impact, with government-industry H2Mobility programmes set up in several European countries to facilitate the introduction of FCVs. When combined with the recent launch of the first commercial FCV in Korea, and the unexpectedly poor sales of battery vehicles, it appears that FCVs will soon appear in many countries.

Another potential use of hydrogen that has received little attention is to decarbonise heat provision, particularly in those countries using natural gas combusted in boilers. Natural gas is difficult and expensive to decarbonise because the emissions cannot be captured and alternative technologies (for example, electrically-powered heat pumps) are much more expensive to buy and operate,

take more space within houses and provide an inferior customer experience. Hydrogen, on the other hand, uses a similar boiler and is carbon-free. We have examined the potential for hydrogen to be supplied to homes using existing gas network infrastructure, which would greatly reduce the cost of a heat transition and would avoid such infrastructures becoming stranded assets. We have identified the circumstances in which hydrogen could replace 20-100% of existing gas heating.

A third use for hydrogen is to support low-carbon electricity generation. Power-to-gas uses excess renewable generation to produce hydrogen that is injected into existing gas networks to partially decarbonise the gas supply, so acting as a form of energy storage. Such systems are already been tested in Germany. We have assessed the value of power-to-gas to support wind generation in the UK, compared to other novel energy storage technology options.

The "Hydrogen's Value in the Energy System" project has been assessing the value of hydrogen in all of these markets. Hydrogen is unusual as it is a zero-carbon alternative energy carrier to electricity. Our techno-economic energy system models have shown that the trade-offs between using electricity and hydrogen depend on the relative generation costs and on the net CO2 emissions from hydrogen production. We will demonstrate the importance of these trade-offs in this talk.

Innovation theory has shown that most novel technologies require support in the early stages of commercialisation in order to develop supply chains and reduce manufacturing costs through "learning by doing". Most hydrogen production and fuel cell technologies are currently unable to compete economically with incumbent energy technologies, but could do so in the future if further cost reductions are achieved [2]. One obstacle to government support for these technologies is the perception that while hydrogen is zero-carbon, the processes that produce hydrogen lead to CO2 emissions that are incompatible with the transition to a low-carbon economy. The lack of a UK definition of "green" hydrogen is a particular obstacle to policy support. We will conclude with an overview of how such a standard could be defined.

Renewable Technologies in Karnataka: Jobs Potential and Co-benefits

R. Kattumuri (1)
(1) Grantham Research Institute & India Observatory, London School of Economics, London, United Kingdom

Green technologies provide an essential starting point towards transformation for resource efficiency and a more socially inclusive low-carbon economy. As their share in the economy increases, it can hasten the required transition towards a low greenhouse gas (GHG) emissions development-path in a cost-efficient manner (UNFCCC, 2011). Beyond making the case for early climate change mitigation policy through the development and deployment of green technology, an assessment of co-benefits emphasises the potential of integrating climate change mitigation policies with other socio-economic targets such as improved health and social inclusion (Stern, Kattumuri and Rydge, 2012). Thus there are great opportunities and benefits to investigate, invest for innovation and development of green technologies in emerging economies.

This study, based on empirical study of examples of off-grid solar, wind energy and a few household sources of energy in Karnataka state in India, assesses the key opportunities and challenges presented by the transition to a low-carbon economy by accounting for both the creation of green jobs and the co-benefits arising from the development and deployment of renewable energy technologies in the state. In line with UNEP's recognition that the "greening of economies has the potential to be a new engine of growth" (2011:16) we find that a green economy may provide the necessary stimulus for a more socially inclusive development path (ADB, 2013) where co-benefits are crucial. Our research, is the first of its kind in India. It is based on primary data from households, private companies and NGOs based in Karnataka, derives estimates for jobs potential using local employment factors in Karnataka and shows strong evidence of opportunities for jobs potential.

The main objectives of the study are:

1. Identify specific renewable technologies being developed and deployed in Karnataka

2. Review the potential for green jobs in some renewable energy sectors through quantitative analyses of case studies

3. Analyse the potential co-benefits of these renewable technologies

4. Discuss the scope of these renewable technologies and further activities that could enable sustainable and inclusive development and contribute its share to national greening economy targets.

Our analysis highlights the ways in which the development and deployment of green technologies facilitate reductions in inequality through social co-benefits that are necessary for transformation at the economic and social levels, in addition to the environmental co-benefits that drive this transition. The analyses based on the state of Karnataka can provide learnings for other states in India and elsewhere.

P-3302-06

The learning curve for wind energy in China- Lessons for climate finance

Y. Liu (1)
(1) Ecole Polytechnique, Department of Economics, Palaiseau, France

Reducing greenhouse gases emissions is a two-way street that bridges finance and technology. The key issue of global climate finance is to unlock and scale up additional and predictable capital. Meanwhile, promoting renewable energy is a distinct part of the global climate regime. It is then natural to ask how climate finance interlinks with technology policy to achieve long-term environmental and energy targets.

The theory of the learning curve suggests that the cost of renewable technology falls along with knowledge accumulation based on learning-by-doing and research and development (R&D). Understanding the drivers of this endogenous technological change has important climate policy implications in two aspects. First, the optimal abatement path may vary depending on the channels of technology cost reduction. The existing literature concludes that when knowledge is gained through R&D investments, some abatement is shifted from the present to the future, but if the channel for knowledge-growth is learning-by-doing, the impact on the timing of abatement is analytically ambiguous (Goulder and Mathai 2000). Second, governments need to investigate how, if at all, climate finance can be structured in a way to provide investment subsidy necessary to make renewable energy deployment competitive with an incumbent technology.

In this study, we first assess the learning rate of China's wind energy by considering two sources of learning effect – cumulative installed capacity and technology efficiency improvement. Then, we extend the learning curve model to investigate the amount of additional capital subsidies needed to achieve grid parity of wind electricity and the distribution of this learning investment, depending on three factors – learning rate, cost target, and deployment speed. Finally, we estimate the implicit abatement cost accordingly.

Our contribution is mainly two-fold. First, we contribute to the learning rate estimates with an empirical analysis of wind energy in China. Ek and Söderholm (2013) and Del Rio and Tarancon (2012) provide a literature review on the learning rates of wind energy. Overall, the exiting literature provides few uniform conclusions. A doubling of the cumulative wind power capacity could induce cost reduction from 33% to 3%. All these studies are focused on industrialized countries. To our knowledge, only one study estimates the learning rate of wind energy in china, using the bidding electricity prices of national wind project

concession programs from 2003 to 2007. Relying on a more comprehensive panel dataset from 2004 to 2011, our study looks at the capital cost of wind projects.

Second, our quantitative analysis contributes to the current debate on a post Kyoto regime of global climate finance. We propose a new mechanism by which upfront learning investment sets up a consistency between climate finance and technology target, and thereby the leverage role of climate finance can be monitored at the sectoral level. This proposal can address two main challenges of climate finance. Uncertainty of carbon revenue calls into question the result-based approach of climate finance, which only intervenes at the project operational stage, and therefore does not generate upfront financing, much needed notably in the developing world. Another feature of global climate finance is to balance the fairness of effort sharing. Moral hazard can generate perverse incentive for firms and governments to delay or relax environment and energy policies (Millard-Ball and Kerr 2012). In fact, the debate on the additionality of climate finance has been triggered with respect to China's wind power projects supported by a policy mix including feed-in tariff (FIT) and Clean Development Mechanism (CDM) (Liu 2014). Actually, new market mechanisms for Post-Kyoto shift towards a sectoral approach of cooperation with most of developing countries (WFC 2013; Deutsche Bank 2011). Most of these initiatives are still at a conceptual level, while our analysis is quantitative and evidence-based, and thus provides a useful support to these initiatives.

P-3302-07

Electrochemical systems for a circular energy economy and carbon reuse: the SOFCOM pilot plant

M. Santarelli (1) ; A. Lanzini (1) ; M. Gandiglio (1)
(1) Politecnico di Torino, Energy, Torino, Italy

In the framework of the EU project SOFCOM (FCH JU Grant agreement no: 278798) POLITO has developed a proof-of-concept devoted to demonstrate the high interest of electrochemical systems based on high temperature fuel cells to operate as the core of future energy systems with renewable fuels and multi-product configuration, with particular care on CO2 management through C re-utilization in different processes (electrochemical, chemical, or biological as in SOFCOM).

The proof-of-concept SOFC system, installed in Torino (IT), operates with biogas produced in an industrial waste water treatment unit (WWTU) in CHP configuration, and with the CO2 separation from the anode exhaust sent to a section of CO2 recovery for Carbon reutilization in a photo-bio-reactor for C storage in form of algae (CO2 sink).

Therefore, the proof-of-concept demonstrates a poly-generation system based on the use of renewable fuels (biogas) in high efficiency electrochemical CHP generators, with complete CO2 recovery and Carbon re-use. The four products are:

1. High efficiency electric power from SOFC;
2. Thermal recovery from SOFC and other processes in the plant;
3. Clean water from photo-bio-reactor;
4. Algae: carbon stored and recovered in form of biomass.

From a more strategic point of view, the proof-of-concept demonstrates how electrochemical-based systems could represent an important cornerstone of future energy systems based on renewable fuels, with the highest achievable energy conversion efficiency, and the total recovery of main energy-related atoms (C, H, O) possibly towards a material closed cycle.

The concept of completed energy and material recovery (in particular, Carbon recovery) points towards a concept of circular economy of energy, with negative CO2 emissions: the Carbon atom is completely recirculated in the system, and its re-utilization can be looped virtually for an infinite time.

The concept demonstrated by the proof-of-concept is completely replicable in similar context, or in completely new context in which the Carbon recovery will become a must. The impacts are now at the local level (where the demonstration is applied) but in principle the impact of thee typologies of systems (with complete Carbon reuse) could be at global level once adopted.

The concept, and its proof-of-concept, will be discussed in the presentation.

P-3302-08

Hydrodynamic modeling of the hydraulic threshold El Haoureb

A. Sebai (1)
(1) National Agronomic Institute of Tunisia, Tunis, Tunisia

Groundwater is the key element of the development of most of the semi-arid areas where water resources are increasingly scarce due to an irregularity of precipitation, on the one hand, and an increasing demand on the other hand. This is the case of the watershed of the Central Tunisia Merguellil, object of the present study, which focuses on an implementation of an underground flows hydrodynamic model to understand the recharge processes of the Kairouan's plain groundwater by aquifers boundary through the hydraulic threshold of El Haoureb.

The construction of a conceptual geological 3D model by the Hydro GeoBuilder software has led to a definition of the aquifers geometry in the studied area thanks to the data acquired by the analysis of geologic sections of drilling and piezometers crossed shells partially or in full. Overall analyses of the piezometric Chronicles of different piezometers located at the level of the dam indicate that the influence of the dam is felt especially in the aquifer carbonate which confirms that the dynamics of this aquifer are highly correlated to the dam's dynamic. Groundwater maps, high and low-water dam, show a flow that moves towards the threshold of El Haouareb to the discharge of the waters of Ain El Beidha discharge towards the plain of Kairouan.

Software FEFLOW 5.2 steady hydrodynamic modeling to simulate the hydraulic threshold at the level of the dam El Haouareb in a satisfactory manner. However, the sensitivity study to the different parameters shows equivalence problems and a fix to calibrate the limestones' permeability. This work could be improved by refining the timing steady and amending the representation of limestones in the model.

Does climate change threaten the future of the PV sector in Europe?

S. Jerez (1) ; I. Tobin, (2) ; R. Vautard () ; JP. Montavez, (1) ; F. Thais, (3) ; OB. Christensen, (4) ; A. Colette (5) ; M. Déqué (6) ; S. Kotlarski, (7) ; C. Teichmann, (8) ; ME. Van (9) ; G. Nikulin, (10)

(1) University of Murcia, Department of physics, Murcia, Spain; (2) Laboratoire des Sciences du Climat et de l'Environnement (LSCE), Gif sur Yvette, France; (3) Institut de Technico-Economie des Systèmes Energétiques (I-Tésé), Saclay, France; (4) Danish Meteorological Institute (DMI), Copenhague, Denmark; (5) INERIS, Verneuil-en-Halatte, France; (6) Météo-France/CNRM, Toulouse, France; (7) Institute for Atmospheric and Climate Science - ETH Zürich, Zürich, Switzerland; (8) Climate Service Center 2.0, Hamburg, Germany; (9) Royal Netherlands Meteorological Institute (KNMI), Bilt, Netherlands; (10) Rossby Centre SMHI, Norrköping, Sweden

The bet on renewable energies is a key aspect of the mitigation strategies aimed at abating climate change, in which Europe is a world leader. In particular, PV power has been receiving large investments and its future deployment is expected to be spectacular, specially in southern countries. However, development plans remain widely blind to the potential impacts of a hereafter changed climate on renewable energy resources. In order to shed light on this issue, this study makes use of a new generation multi-model and multi-scenario ensemble of high-resolution climate simulations spanning up to the end of this century to assess changes in both PV power generation potential (PVpot) and actual production (PVprod) considering a future scenario with a high penetration of PV installations. Results show that the projected increase in the surface air temperature adversely affects the projections for PVpot, as it acts to diminish the efficiency of the PV cells. Thus, while surface solar radiation is projected to slightly increase in southern regions, PVpot is not. In the most extreme scenario considered (RCP8.5), PVpot would diminish in the range 5-15% (from South to North within Europe) by the end of this century according to the ensemble mean. In terms of production, significant changes are not expected southward but for a plausible reduction of the daily variability of the PVprod series, which would indeed be beneficial. However, further north, worse projections, with the Scandinavian region holding robust reductions in the mean production (about -10% under the RCP8.5) and uncertain projections regarding its future variability. In any case, all signals depict limited impacts indicating that climate change does not seem to pose a serious risk for the PV sector in Europe.

O-3303-02

Advances in multi-scale models to shed light on the plausibility of longterm scenarios

N. Maïzi (1)

(1) PSL, MINES ParisTech, Mathematics and Systems, Center for Applied Mathematics, Paris, France

Given the complex international situation, mitigation strategies to tackle energy-related issues need effective normative tools to deal with the different types of constraint (e.g. climate-related, financial, legal, political, technical). Various scenarios are now available to provide an insight into the challenges of energy transition under environmental constraint. However, the regional, technological and social conditions that trigger this transition require developing tools to identify the policy mixes needed for new directions in technical systems and modes of development. And this is more stringent in the electricity sector.

In particular, the aim is to reconcile and connect different scales (temporal, spatial, social) in order to understand:

- The political implications that necessarily take place at several levels, from global to local,
- The impact of phenomena with different dynamics (several decades versus seconds), and
- The central role of people (for whom the future must be acceptable and desirable, i.e. compatible with aspirations and behavior).

This multi-scale integration brings up significant methodological obstacles that we propose to examine in three stages to understand the needed reconciliation of long-term approaches employed in prospective exercises at different scales:

1. Short-term/long-term temporal scales : reconciliation involves examining the "inertia" of systems, e.g. urbanization or the composition of current mixes, versus the "instantaneousness" of usage (e.g. mobility using electric vehicles or smart grid solutions, energy efficiency) as well as the technical conditions for operating systems (i.e. network reliability, availability and stability);
2. Spatial scales : different levels of spatial issues will be tackled such as top-down versus bottom-up pledges for emerging countries, centralized versus decentralized networks, managing intermittent electricity production sources and integration into the network;
3. Societal scales : this will involve discussing the assessment of different development paradigms (degrowth/growth) and the integration of behavior as relevant modeling characteristics.

Each issue will be illustrated using specific examples.

O-3303-03

Using big data to make decisions in the electricity sector under deep uncertainty

I. Azevedo (1) ; I. Azevedo (2) ; B. Sovacool (3) ; K. Jones (4) ; M. Dworkin (5)

(1) Carnegie Mellon University, Engineering and Public Policy, Pittsburgh, PA, United States of America; (2) Carnegie-Mellon University, Department of engineering and public policy, Pittsburgh, United States of America; (3) Danish Center for Energy Technologies (Center for Energiteknologier), Herning, Denmark; (4) Vermont Law School, Vermont law school, South Royalton, United States of America; (5) Institute for Energy and the Environment, Vermont law school, South Royalton, United States of America

Creating resilient, reliable, and low-carbon electricity systems to help mitigate the effects of greenhouse gas emissions (GHG) and adapt to a changing climate remains a critical global challenge.

Electricity consumption accounts for a large portion of greenhouse gas emissions worldwide, making it one of the key sectors for climate mitigation strategies. Decarbonizing the electricity system becomes an even more daunting task given about 17% of the world population does not yet have access to energy services.

Changes in the electricity sector to move towards a low carbon energy system leave to important trade-offs in terms of costs to the overall energy system, how such costs are distributed, how to address issues related to fuel security and diversity, how to improve the level of energy services provided, and environmental consequences.

While decisions regarding different strategies to decarbonizing electricity systems may be done under deep uncertainty, in recent years the emergence of very detailed data - i.e., the big data revolution, paired with big data analytics - provides the ability to draw new insights and new ways to approach decisions.

This talk will focus on the ability to make decisions in the electricity sector under deep uncertainty in the United States. In the United States, the data from the Continuous Emission Monitoring System (CEMS), which is collected and made publicly available by the U.S. Environmental Protection Agency, provides data regarding the hourly power generation, and emissions from GHGs and criteria air pollutants, for every single fossil fuel based generator in the United States that is larger than 25MW. This data, coupled with air quality models and health and environmental valuation models, allows us today to estimate the regional effects of different interventions in the U.S. grid (such as increasing renewable (Siler-Evans et al., 2012; 2013), building codes (Gilbraith et al., 2014), storage (Hittinger and Azevedo, 2015) in a way that was not possible before. Similarly, on the consumption side, the deployment of smart meters coupled with information on energy efficiency and demand side management programs provides a new way to use big data analytics to assess whether the intended goals of the programs have been achieved (Azevedo, 2014).

In this session, we will (1) provide an overview of some of the recent big data analytics efforts that have been pursued to improve decision making under uncertainty in decisions aiming at the decarbonization of the electricity sector in the United States; (2) provide a map of data needs for several regions across the world that would be critical for one of the able to perform systematic international comparisons; (3) provide a research roadmap of the critical research questions we believe need to be addressed to make better decisions under uncertainty in the electricity sector.

Integrated pathway to decarbonizing electricity in China

S. Fu (1) ; Q. Yameng (2)
(1) Chongqing University of Arts and Sciences, Chongqing, China; (2) University of Tampere, School of information sciences, Tampere, Finland

1. Background: Economy, electricity and carbon mitigation in China

The momentum of economy growth is strong. i) urbanization; ii) poverty; iii) all-round Open-up and Reform policy; iv) 6.5-7.5% growth rate during 2016 to 2020.

Power industry faces rigorous environmental challenge. Per capita electricity is 3510 KWH and will continue to rise sharply. Energy-intensive industries are backward, which results in low energy efficiency. As 78% electricity comes from fossil fuel, CO2 intensity remains 0.514-1.246 tCO2e/MWH. Power industry discharges 39% CO2 and still appears upward trend. Pricing and universal services are far from perfect; moreover, institution has CO2 lock-in weakness.

Carbon mitigation achievements in power industry. Energy intensity per unit GDP dropped by 20.7%, reducing 1,967 million tCO2e. Non-fossil energy accounted for 8% of primary energy consumption, saving over 600 million tCO2e annually. China eliminated 80 million KW small thermal power units, reducing 166 million tCO2e every year. What more, innovation of generating technology and reformation of institutional arrangement contributed to huge CO2 abatement.

2. A big deal: China-U.S. Joint Announcement on Climate Change

Benefits and protocol. Smart action on climate can promote economic growth and broad benefits. China-U.S. will jointly propose a protocol under the COP21.

Post-2020 actions. The U.S. targets to reduce CO2 by 26-28% in 2025. By 2030, China will peak CO2 emission and increase the share of non-fossil fuels to 20%.

Technology cooperation. China-U.S. have a robust program of energy technology cooperation and will jointly invest more in clean technological innovation.

Policy dialogue and practical cooperation. The two sides announced additional measures to strengthen and expand practical cooperation in climate change.

3. Integrated pathway option: Decarbonizing electricity in China

Decarbonizing electricity goal. Chinese electricity need follow a path featuring high efficiency, less pollution as well as satisfying economy growth. At 2015 energy intensity will drop by 16% and CO2 decrease by 17%. At 2020 non-fossil energy will take 15% and CO2 lower by 40-45%.

Demand side management. China adopts key actions in electricity-saving among industry, building and transportation; actively transforms economy into capital- and technology-intensive mode. It lists technologies of energy-saving and sets energy intensity standard. China encourages green building, improves heat-supply as well as electricity-saving by public building. It also promotes green transportation, electricity-saving education; therefore, fosters a green lifestyle.

Develop renewable electricity. Renewable power is to take 30% by 2015. Hydropower will get 290 million KW, half of its potential. Currently nuclear power is 1.8%; thereafter China will endeavor to reach 40 million KW. It stresses intensive and distributed exploiting wind power; corresponding capacity will get 100 million KW. China develops diverse patterns of solar power; thereafter solar collection will exceed 400 million m2. It also actively exploits biomass electricity.

Promote clean fossil electricity. China emphasizes coal washing, shuts small thermal units, speeds up supercritical- and ultra-supercritical- technology, encourages thermoelectricity cogeneration as well as IGCC generation; actively develops circular economy. It expands power transmission from western to eastern; strengthens ultra-high voltage as well as smart grids. It will construct many CCS projects; thereafter, set up platform of national technology innovation.

Optimize institutional arrangement. China is to reform legal regime as well as regulations on electricity; especially separate transmission from distribution, revise pricing mechanism, and extend international cooperation. It will deepen electricity market and carbon market, improve CO2 auditing, diverse mitigation approaches; meanwhile, coordinate mitigation and power generation.

High-Resolution Modeling of China's Power Sector with a Particular Focus on Advanced Nuclear Technologies

AP. Avrin (1)
(1) University of California, Berkeley, Energy and Resources Group, Berkeley, CA, United States of America

Today, China's electric power sector accounts for 50% of the country's total greenhouse gas emissions and 12.5% of total global emissions. The transition from the current fossil-fuel-dominated electricity supply and delivery system to a sustainable, resource-wise system will shape how the country, and to a larger extent, the world, addresses local pollution and global climate change. While coal is the dominant primary energy source today, rapid ongoing technological changes coupled with strategic national investments in transmission capacity and new nuclear, solar and wind generation demonstrate that China has the capacity to completely alter the current trajectory. For the past decades, the country's nuclear fleet has consisted in a dozen coastal water-cooled nuclear reactors using an open fuel cycle. In addition to strong nuclear research and development programs, China's increasing deployment of renewable energies and ambitious environmental targets towards sustainability make the extent and the nature of the role of nuclear in the power sector more unclear than ever. We present an integrated model of the Chinese power sector to analyze the prospects of implementing various energy transition scenarios. SWITCH, a high resolution modeling tool under development at the University of California, Berkeley, is used to analyze least-cost generation, storage, and transmission capacity expansion pathways for the electricity mix. Using the recent announcement made by President Xi Jinping to bring the country's carbon emissions to a peak by 2030 as a framework to assess potential future profiles for the energy mix, we show that building up to 380 GW of nuclear capacity by 2030 is part of the optimal, least expensive trajectory for the power sector. While the construction of such a large fleet of reactors in about 15 years might be challenging, it proves that nuclear cannot be excluded from discussions regarding long-term planning of the electric power sector in China. Using SWITCH, we also find that a carbon price of ~$40/tCO2 would achieve the 2030 carbon peak. Such a figure has a direct impact on the level of renewables and nuclear deployment in the country and, as a consequence, on the specific reactor technologies and fuel cycle options to be developed. In particular, we investigate the role of fast-neutron reactors as part of a national plan to close the nuclear fuel cycle and present resulting pathways

for Generation IV technology deployment, according to different trajectories for CO2 emissions reduction targets and costs evolution by 2050, and different levels of variable renewable energy integration.

P-3303-02

The System Effects and Electricity Market Impacts for Germany and the EU of the Energiewende Policy in Germany

M. Blesl (1) ; J. Welsch, (2) ; M. Wiesmeth (2)

(1) IER University Stuttgart, Stuttgart, Germany; (2) University Stuttgart, Ier, Stuttgart, Germany

This energy policy, which is even internationally referred to as the "Energiewende", is based on the long-term vision of renewable energy being the primary source of future energy supply and the decarbonisation of the energy system . The road towards the new energy era is described by a set of targets: a specific share of renewables in the gross electricity generation and in the gross final energy consumption as well as an overall greenhouse gas reduction target of 80 to 90% till 2050 compared with 1990. In this context, a Pan-European TIMES energy system model (short: TIMES PanEU) points out the broader system effects and the impacts on the total costs of electricity supply and storage requirements which result from a further deployment of renewables. TIMES PanEU contains all countries of the EU-28, plus Switzerland and Norway, and covers on country level all sectors connected to energy supply and demand like the supply of resources, the public and industrial generation of electricity and heat and the sectors industry, commercial, households and transport. The scenario analysis shows that the total system costs will be more than doubled by an increasing share of renewables. The reasons for the higher total electricity supply costs are the low capacity credits of variable renewable power plants, the increased need for capacities from dispatchable power plants and the additional costs for transport and distribution. Under the current market environment ("energy only market"), it is unlikely that dispatchable power plants can be operated profitably when the share of variable renewable is increasing. New remuneration schemes would be required for the necessary balancing and capacity services. Additionally, the integration of large shares of variable renewables requires large electricity storages, power to heat, Electromobility and power to gas capacities. Thereby it is possible to map the interactions between electricity, heat and gas sector in TIMES PanEU. To this it will be examined, which temporal resolution is required for mapping different scenarios with different expansion targets of renewable energies? At first the necessary temporal resolution for mapping the availability of fluctuating renewable energies (wind and solar energy) will be determined. This is followed by an enlargement of description of energy demand and energy storage technologies. Besides, import and export and therefore energy storage requirement are affected by the temporal resolution. In this connection the error, which occurs by a lower temporal resolution, will be identified.

P-3303-03

Impact on the CO2 emissions of an increasing share of renewable energy in the French electricity mix

FM. Breon (1) ; B. Bonin, (2) ; O. Boucher (3) ; A. Laureau, (4) ; E. Merle, (4) ; J. Miss, (5) ; Y. Richet, (5) ; H. Safa, (6) ; F. Thais, (7)

(1) IPSL, LSCE, Gif sur Yvette, France; (2) CEA, Direction de l'energie nucléaire, Gif sur Yvette, France; (3) Laboratoire de Météorologie Dynamique, CNRS / IPSL, Paris, France; (4) CNRS, In2p3/Ipsc, Grenoble, France; (5) IRSN, Fontenay aux Roses, France; (6) Commissariat à l'Energie Atomique, Direction de l'energie nucléaire, Gif sur Yvette, France; (7) Institut de Technico-Economie des Systèmes Energétiques (I-Tésé), Saclay, France

The French electricity power mix is dominated by Nuclear as it provides about 75% of the total consumption. Hydroelectricity is the second main source of electricity production in France. The combination of these two decarbonized electric productions, complemented by fossil fuel power plants, leads to typical CO2 emission of less than 50 gCO2/kWh, an order of magnitude smaller than that of many other industrialized countries. Thus, the contribution to climate change of the current electric production in France is small. Yet, there is a strong ongoing debate to reduce the share of nuclear energy while increasing the share of renewable electric production such as wind and solar. It appears necessary to quantify the impact of such change in the power mix.

Although wind and solar are promising techniques to provide clean electricity, their production is intermittent. Photovoltaic electricity is null during the night and significantly smaller in winter than in summer, which is anti-correlated with the demand. Wind electricity is very much dependent on the wind, and production variations of a factor more than 100 have been observed at the French national scale. The intermittent nature of PV and wind production may necessitate the availability and use of backup solutions to insure a production in line with the demand. Yet, the requirement for backup power sources that are used at a fraction of their capacity has a direct impact on the overall production cost. In addition, to follow the intermittency of renewable energy production, it may be necessary to use CO2-emitting techniques, such as gas power plants.

We have developed a model that analyzes the electricity demand and production at the French national scale. The model accounts for the fixed and variable cost of each electricity production mean: The fixed cost does not depend on the actual production, while the variable costs are proportional to the MWh production. Similarly, the CO2 emissions have both a fixed (plant construction) and a variable component.

The model is used to estimate the impact of a larger share of renewable energy on the electricity mix at the French national scale on the overall cost and the CO2 emissions. The intermittency of PV and wind energy imposes the development of backup power that has an impact on both the cost and the CO2 emissions. The latter can be evaluated as an additional cost (such as a Carbon Tax). The optimal energy mix depends on the assumed "cost" of CO2 emitted to the atmosphere.

Degrowth through the prism of prospective macroeconomic modeling: investigating a paradigmatic change for France

F. Briens (1) ; N. Maïzi (2)

(1) PSL, MINES ParisTech, Center for applied mathematics, Sophia-Antipolis, France; (2) PSL, MINES ParisTech, Mathematics and Systems, Center for Applied Mathematics, Paris, France

About three decades ago, the Brundtland commission released its famous report entitled "Our common Future". As an attempt to conciliate development and the environment, the term "sustainable development" was coined for the first time, as a "development that meets the needs of the present without compromising the ability of future generations to meet their own needs. It contains within it two key concepts: the concept of 'needs', in particular the essential needs of the world's poor, to which overriding priority should be given; and the idea of limitations imposed by the state of technology and social organization on the environment's ability to meet present and future needs." [Brundtland, 1987]

Almost thirty years later, climate change, along with biodiversity losses, disruption of natural cycles (nitrogen, phosphorous, water), non-renewable resource depletion, and others, remains a critical issue, and seriously questions the sustainability of the intensive economic metabolism of industrialized societies. As a way out of this multifaceted crisis, many take a stand in favor of a "green growth", focusing on the idea of technology-related limitations, and with the hope that technological progress will eventually enable a decoupling of energy and material throughput and environmental burdens from economic growth. Others instead put the spotlight on the question of the "needs", and advocate for a transition towards sustainable "post-growth societies". With the Degrowth movement, the call for such a transition is consolidating into a complex and multifaceted political project. For the "wealthiest" countries, where the ecological footprint per capita is greater than the global sustainable level, this project may be envisioned as a voluntary, socially sustainable, equitable, smooth downscaling of production and consumption, and thus throughput, to an environmentally sustainable level, "that increases human

well-being and enhances ecological conditions at the local and global level, in the short and long-term''[Kallis and Schneider, 2008].

However, current literature still falls a bit short of providing detailed investigations of possible macro-socioeconomic and biophysical outcomes that may result from taking in such paths. Several questions remain unanswered. In particular, we would like to focus here on the following issues: what concrete proposals could initiate such a transition? What could such paths induce in terms of employment, public debt, energy consumption, waste and GHG emission mitigation? What structural or institutional obstacles must be overcome and how? Etc.

Using a detailed dynamic input-output simulation model of the French monetary economy, we explore different scenarios of transition towards post-growth societies. These scenarios seek to reflect contrasted "visions of sustainable societies and lifestyles", inferred from a survey conducted amongst different social groups - including in particular actors within the Degrowth movement. They involve structural and behavioral changes in consumption patterns, and integrate proposals and strategies issued from the Degrowth movement. We investigate the possible outcomes of these scenarios in terms of employment, poverty, public debt, energy consumption, waste and GHG emissions and discuss the potential strengths and weaknesses of the different visions they reflect. Our results highlight in particular the importance of cultural, social, behavioral and "non-technical" factors, and recall the critical need for the collective elaboration of a societal project.

Integrating household behavior and heterogeneity into long-term energy planning models: The TIMES-Households framework

JM. Cayla (1)
(1) EDF R&D, Paris, France

The importance of household behavior in energy consumption is regularly raised in literature. The need to take household behavior into account and to introduce heterogeneity into economy-energy models is also generally pointed out, underlining the limitations of classic models that represent energy demand by a single mean household[1][2]. In their well-known "energy paradox" article, Jaffe & Stavins[3] single out household heterogeneity as one of the main "market barriers" to energy efficiency. Similarly, heterogeneity orientates the dispersion of household behavior in terms of energy consumption and equipment purchases. Thus in order to provide useful insights to public policy debates using prospective studies, we should also consider this household heterogeneity as a kind of "model barrier" that could prevent modelers from correctly apprehending reality.

Nevertheless energy-economy long-term planning models still often represent energy demand by a single mean household and thus fail to capture household behavior. Indeed, many models developed using the TIMES modeling framework[4] are often technology oriented and provide a very detailed list of equipments on the supply side. Whereas the demand side generally consists in a single mean household with a unique level of demand for energy services. This lack of detail on the demand side usually leads to unrealistic results, especially in terms of technology diffusion. Indeed in these models small price increases may then lead to no impact or sudden technological change, sometimes called "bang-bang" effects.

We here describe the original modeling approach developed within the MARKAL-TIMES model framework in order to take household behavior and heterogeneity into account: the TIMES-Households model. This model depicts both household daily energy consumption and equipment purchasing behavior and focuses on the French residential and transport sectors. We show the importance of taking household heterogeneity into account in long-term planning models within the comparison of two energy price scenarios applied to two different models. Thanks to the highly disaggregated representation of households and their behavior in the model, we address the problem of unrealistic technology diffusion pathways often obtained when using an optimization bottom-up model. We also are able to address burden sharing issues which are very common and major issues related to the implementation of decarbonized sustainable pathways. Indeed our model helps quantifying the impact of energy polices such as carbon taxes, tax rebates or bonus/malus systems on household budget in term of investment expenditures and energy bill.

Opportunities and challenges for decarbonisation with electricity generation from nuclear energy

J. Cobb (1)
(1) World Nuclear Association, London, France

Generation of electricity from nuclear generation is a major global contributor to decarbonisation. Currently, nuclear generation meets around 11% of global electricity demand with very low lifecycle greenhouse gas emissions, avoiding in excess of two billion tonnes of carbon dioxide per year, compared to coal fired generation. Its high capacity factor and predictable output is advantageous compared to some low carbon electricity generation options.

Increased use of nuclear generation is a feature of a number of long-term climate change mitigation proposals. This presentation will review the projected emissions savings from nuclear generation, based third party studies and our own research. It will also review assessments of the lifecycle emissions of nuclear generation and how these compare to other generation options.

The presentation will examine the impact of different nuclear build scenarios on the nuclear fuel cycle, including global demand for uranium ore, uranium enrichment and fuel fabrication. It will identify where additional mining, processing and fabrication capacity may be required in these separate stages of the nuclear fuel cycle.

The presentation will also examine the scope for increasing global nuclear generation. This will include options for increasing and extending generation from existing reactors. It will also include options for new reactor technology to improve performance and better utilise the uranium resource.

Given these conditions the presentation will project what the potential contribution of nuclear generation to global greenhouse gas mitigation could be and what technical, economic and political challenges there would be to realising this contribution.

P-3303-07

The energy security implications of a low-carbon transition

E. Cox (1)
(1) University of Sussex, SPRU, Brighton, United Kingdom

In order to meet legislative targets for mitigating climate change, future energy systems will need to become secure, affordable and low-carbon – the so-called 'trilemma' of sustainable energy policy (Boston 2013). In Western Europe, the trilemma has received growing attention as energy security concerns rise up the political and public agenda, driven by declining indigenous fossil fuel reserves and increasing concerns over anthropogenic climate change (MacKerron 2009; Winstone et al 2007). As part of a growing body of research into energy security and low-carbon energy transitions, this paper assesses the future security of the UK electricity system in a low-carbon context. A new indicator framework for security of both supply and demand has been developed with the specific aim of making projections of the security of a low-carbon electricity system. Drawing upon recent research recommendations, the framework utilises a 'dashboard' approach to security analysis which is capable of identifying potential red flags for the future security of a low-carbon electricity system (Mitchell et al 2013). The paper emphasises the importance of timescales of reference when addressing energy systems, and thus focuses on assessing both short-term 'shocks' and long-term 'stresses' to the electricity system (Boston 2013; Energy and Climate Change Committee 2011). As such, the future security of the UK electricity system is assessed under four key themes: Availability (long-term), Reliability (short-term), Affordability, and Sustainability.

The security assessment framework has been applied to a set of three transition pathways, all of which aim to reduce carbon emissions from the electricity sector by 80% by 2050. The three transition pathways have been chosen to reflect the importance of the overriding governance logic and normative goals which could lead to different energy pathways. One pathway envisages deregulation and market-centrism, one envisages large-scale centralised control, and the third pathway envisages a decentralised, small-scale electricity system controlled by civil society and consumers. As such, the analysis seeks to compare the future security of some of these contrasting governance options, in an attempt to flag up areas of concern and to highlight the major trade-offs which may emerge when seeking to balance security, affordability and carbon goals in energy policy.

This presentation will introduce this new methodology for assessing the energy security of low-carbon transition pathways. Results from the empirical analysis will be presented, along with the implications of these results for the energy security of a low-carbon transition. The presentation will offer some insights of the key measures for improving low-carbon electricity security, and the key trade-offs which could emerge between the security, carbon and affordability aspects of the trilemma.

An analytic framework to explore low-carbon energy pathways in Kosovo

D. Kammen (1) ; N. Kittner (2)
(1) University of California Berkeley, Energy and resources group, Berkeley, United States of America; (2) UC Berkeley, Energy and Resources Group, Berkeley, CA, United States of America

Kosovo's power sector suffers from poor reliability and rising costs. The World Bank and other potential donors have proposed construction of a new 600 MW lignite based coal-fired power plant in 2017, despite a pledge to no longer finance coal projects except for extreme and rare circumstances. Kosovo has extensive coal resources, but also hydropower, wind, solar and biomass potential. Examination of the available options and the need to act quickly on the investment portfolio for Kosovo are critical for the local population and economy. At the same time, the financing of a coal plant in Kosovo serves as a pivotal test on the international stage for future financing of coal projects worldwide, especially in China and India. We investigate alternative low-carbon energy pathways to building the lignite coal plant and find a range of scenarios that all meet Kosovo's energy needs at lower cost than a new coal plant. We developed an analytic platform to model the electricity grid and constructed multiple scenarios for sensitivity testing. Our analytic platform looks at the cost, options, and impacts of different decarbonizing energy pathways—including a view into different energy efficiency measures, combinations of solar PV, wind, hydropower, biomass, and the introduction of natural gas. We find that a $30/ton carbon price increases costs associated with the new coal plant by at least $330 million USD (Kittner et al., under review). We find that the lignite coal plant remains the costliest option based on finances alone, even before considering the cost of carbon, health impacts, and job creation impacts. We introduce both a deterministic modeling platform to explore scenarios for Kosovo and for neighboring countries, and provide a LEAP platform version for policy makers and other interested parties to use in comparing costs, energy access, reliability, and environmental impacts of energy futures.

Decarbonizing the UK electricity sector by 2030: progress and outstanding challenges

A. Kazaglis (1) ; J. Skea (2)
(1) UK Government, Committee on Climate Change, Committee on Climate Change, london, United Kingdom; (2) Imperial College London, London, United Kingdom

The UK's Governments' statutory advisors on climate change – the Committee on Climate Change (CCC) – have advised that near-complete decarbonisation of the power sector by 2030 is part of the low cost path to meeting long term emissions targets. Through the Energy Act 2013, Parliament has now recognised the need for rapid decarbonisation of the power sector as a priority.

This talk will cover progress towards power sector decarbonisation and outstanding challenges.

Recent developments include updates in the policy framework through Electricity Market Reforms (EMR) and a step change investment in low-carbon capacity (particularly wind). The underlying emissions intensity of the UK's electricity grid – meaning the intensity that could be achieved if the grid were operated to minimize emissions – has dropped by around 40% since 2007.

However, outstanding challenges include a lack of certainty beyond 2020, which is an issue for the supply chain and investment with long lead times and the CCC recommend a legislated 2030 carbon intensity target to address this. An innovation strategy is also required for promising but currently expensive technologies (e.g. offshore wind and CCS) to clarify that there will be a market for these technologies if cost reductions can be achieved.

P-3303-10

Supplying reliable renewable electric power from desert regions to meet the electricity needs of growing economies

M. Labordena (1) ; J. Lilliestam, (1)
(1) ETH Zürich, Institute for environmental decisions, climate policy group, Zürich, Switzerland

If we are to avoid dangerous climate change, the electricity systems of the world must be largely decarbonized by mid-century. Renewable electricity sources are carbon-neutral and the resource base is, globally and on each continent, large enough to satisfy any conceivable electricity demand, however, their utilization faces numerous challenges. First, renewable sources like solar and wind are intermittent and demand-controlled, while fossil fuel power technologies are supply-controlled and can supply base load power. The intermittency of solar and wind power may cause problems when integrating these sources in the power systems. Power sources that are both renewable and supply-controlled, therefore, are of high importance. These sources are hydropower, biomass, geothermal and concentrating solar power (CSP) equipped with thermal storage. Hydropower and some bioenergy systems, however, are dependent on water availability and can increase land- or water-use competition, among other several sustainability concerns. Second, all renewable power needs extensive areas of land due to its low energy density of the primary resource, increasing concerns regarding land-use conflicts and costs for land also for solar and wind power. This is a barrier to renewable power expansion in densely populated regions, in regions with high or rapidly increasing electricity demand, and in regions competing for land for agriculture. Renewable dispatchable sources like CSP that can be deployed at large-scale in remote regions or on land with non- or low-competing land-use for agriculture would be particularly valuable.

Desert regions are, therefore, potential suitable land for CSP expansion in terms of low competition for land use and the high levels of solar irradiation. Research shows that a dispersed and coordinated fleet of CSP plants equipped with thermal storage can supply large amounts of reliable power at reasonable costs, in some desert regions around the globe (Pfenninger et al., 2014). These regions, however, are far from centres of demand where power would be consumed, requiring large transmission lines to connect generation plants to the centres of demand (Trieb et al., 2012). We therefore examine the potential of a fleet of CSP plants to supply and transport reliable renewable electric power to large centres of demand, which are large cities worldwide. The desert regions in focus are located in China, India, the United States, and North Africa and the Middle East; this last region produces solar power both for its own needs and for electricity exports to the European Union. We conduct the analysis in three steps. First, we identify the best CSP generation sites in the desert regions by means of geographic information system (GIS) analysis, applying geographical restrictions to land to minimize impact on biodiversity, soils, infrastructure due to natural hazards, and on land-use and land-cover change. Second, we identify the routes of the optimal transmission corridors from the generation plants to the centres of demand, by means of a GIS-based algorithm that minimizes economic, social and environmental costs. Third, we investigate with a multi-scale energy system model the optimal configuration and operation of the CSP plant fleet to provide reliable electric power, and calculate the costs of generating and transmitting this power to the centres of demand. Our results will show to which degree renewable reliable electric power can be supplied from CSP plants fleets in desert regions, and what the cost of this power is at the points of demand. In addition, we will show in detail the optimal siting and design of the transmission lines from the deserts to the major cities. We expect to find that the potential for desert regions to supply reliable CSP to the consumption regions in focus is large, despite the vast distances.

Spatial optimization of an ideal renewable energy system a answer to the intermittency of renewables energies ?

S. Lassonde (1) ; O. Boucher (1) ; FM. Breon (2) ; S. Jerez (3) ; I. Tobin, (2) ; R. Vautard (2)
(1) Laboratoire de Météorologie Dynamique, Cnrs / ipsl, Paris, France; (2) Laboratoire des Sciences du Climat et de l'Environnement, Saclay, France; (3) University of Murcia, Departement of physics, Murcia, Spain

The share of renewable energies in the mix of electricity production is increasing worldwide. This trend is driven by environmental and economic policies aiming at a reduction of greenhouse gas emissions and an improvement of energy security. It is expected to continue in the forthcoming years and decades. Electricity demand is related to weather and climate factors such as the diurnal and seasonal cycles of sunlight and wind, but is also linked to less predictable variability on longer time scales. The intermittency and the lack of medium to long-range predictability of the renewable electricity production (solar, wind power) could eventually hinder their future deployment. Intermittency is indeed a challenge as demand and supply of electricity need to be balanced at any time. This challenge can be addressed by the deployment of an overcapacity in power generation (from renewable and/or thermal sources), a large-scale energy storage system and/or improved management of the demand.

The main goal of this study is to provide a spatial optimization of an ideal renewable energy system at the French and European scales. We use ECMWF (European Centre for Medium-Range Weather Forecasts) ERA-interim meteorological reanalysis and meteorological fields from the Weather Research and Forecasts (WRF) model to estimate the potential for renewable energies. Electricity demand and production are provided by the French electricity network (RTE) at the scale of administrative regions for years 2012 and 2013.

Firstly we will show how the simulated production of renewable electricity compares against the measured production at the regional scale. Simulated renewable energies production (wind and solar) will then be clustered in order to highlight the temporal complementarity (or lack of) between different regions and energy sources.

Secondly, we will present preliminary results from an optimization procedure that aims to minimize the cost of an ideal system composed of renewable energies, thermal plants and increased storage, as a function of a hypothetical carbon emission penalty. The optimal spatial distribution of renewable wind and solar energy systems will be assessed at the French and European scales under the constraint of a balance between demand and supply.

Decarbonising China's electricity sector: the prospect for biomass power generation

J. Li (1) ; J. Xie (2)

(1) Curtin University of Technology, Perth, Australia; (2) South China Agricultural University, Guangzhou, China

China is struggling to accelerate its economic development transition to a lower carbon intensity trajectory. The decarbonised electricity system plays a determining role in low carbon growth in China as it has become the largest power generator in the world and power generation contributes to nearly half of the country's carbon dioxide emissions. More than two-thirds of existing electricity generation are coal-fired, making China's electric power sector the most carbon intensive in the world. Total installed generating capacity would more than double over the next 20 years. Therefore the development pathway of China's power sector has tremendous implications for global carbon emissions reduction and temperature increase stabilisation. Biomass power generation offers a promising window of opportunity to address multi-objective challenges (economic, social and environmental) in the context of fast economic and demographic growth in large emerging economies. Bioenergy can also bring about macroeconomic and environmental cobenefits such as enhanced security of energy supply, better balance sheet, improved local labour market and social welfare through green jobs creation, poverty alleviation and greenhouse gases and air pollutions mitigation. Built on lessons drawn

from the markedly rapid development of wind and solar power over the last decade, this paper attempts to shed light on the status quo, achievements, opportunities and underlying challenges of scaling up biomass-fuelled heat and power generation in China. Our analysis focuses on the strengths and weaknesses of large-scale development of biomass power generation in China's electricity market, from both technological and institutional perspective. It is emphasised that cost-effectiveness aspect needs to be mainstreamed in biomass power industry planning and development, this in return will contribute to optimising the portfolio of decarbonising China's power sector for the next decades. The paper first discusses the main achievements and prospects for China's power sector. It then investigates the role of biomass in mitigating power generation associated GHG emissions and analyses the challenges in scaling up biomass power generation in China. Drawing lessons from wind and solar power, the analysis will proceed to address the economic efficiency of biomass power by investigating the prospect of incorporating power sector in the emerging carbon markets in China to achieve cost-efficient GHG emissions mitigation. The last part offers some concluding remarks and policy implications for decarbonisation in China's electricity sector.

Asian perspectives in governing the deployment of smart grids

D. Mah (1)
(1) Asian Energy Studies Center, Hong kong baptist university, Hong Kong, Hong Kong

Climate change concerns, rising energy costs, and risks of nuclear power have heightened the urgency of a transition to a low-carbon future worldwide. Smart grids represent one of the most revolutionary developments in energy management: by integrating advanced information technology as a way to modernize existing electricity networks, smart grids have the potential to accelerate the deployment of more decentralised electricity supply systems (e.g. renewable energy) and demand-side measures. Smart grid technologies are increasingly being tested and adopted in developed and developing economies (e.g. the U.S., the U.K., Japan, and China).

Although smart grids have become an emerging theme in the energy literature, critical understandings on how and why smart grids have been developed in the ways as we observe have been lacking. The literature has also largely been based on advanced, industrialised societies in the West. The extent to which and how smart grids have been deployed in Asia, a continent of crucial importance in global energy governance, has yet been adequately addressed.

This paper aims to provide insights on the ways smart grids may evolve and enhance sustainable energy transitions in Asia. Based on preliminary results of an on-going project, we will examine the emerging interactions between the state, utilities/business, and electricity consumers, as well as the associated implications on the developments of smart grids in China and Japan. Our analysis will focus on three policy themes: (1) the development of a new regulatory framework (for rectifying utilities' disincentives to renewable energy and energy efficiency); (2) business model innovation (to develop business strategies to achieve economies of scale, cost effectiveness, and risk sharing), and (3) engaging electricity consumers. The Asian perspectives of our analysis will provide better understanding of the extent to which unique political and socio-economic conditions in some Asian countries may lead to the emergence of distinctive forms of smart grid deployment pathways that may set them apart from those in the West.

Carbon issues for power systems: a french-US crossed contribution

N. Maïzi (1) ; D. Kammen (2)
(1) PSL, MINES ParisTech, Mathematics and Systems, Center for Applied Mathematics, Paris, France; (2) University of California Berkeley, Energy and resources group, Berkeley, United States of America

Spurred by the need to address climate change while promoting economic vitality and sustainability requires a new class of energy system models that facilitate a dialog between mathematical approaches to economics, public policy and strategic thinking. This approach ideally affords a platform to integrate equally technical and social perspectives on energy systems, something that has proven particularly difficult in the past for a variety of data, analytic, and conceptual reasons. While models are inherently inaccurate representations of natural and social processes, we have found considerable value in comparative 'model complements' where different approaches are brought into dialog. To accomplish this, our two teams, based at the Ecole des Mines de Paris and at the University of California, Berkeley have initiated this comparison and conversation. The two platforms TIMES and SWITCH respectively permit different visualizations of energy choices and scenarios. These prospective modelling tools are a heritage of a long tradition of tools first created in the 1960's from the dialogue between mathematicians and economists and based on a concept of optimality. The way they support the scoping of policies on energy and climate is based on the following: a vision of transforming technical systems with the idea of an optimal timetable for employing technologies in decreasing order of merit. This can be skewed by the introduction of the internal cohesion of the energy system at technical level and, as a result, inertia, the technological barriers to remove, the benefits in endogenous learning and the macroeconomic costs of support policies are addressed.

This contribution aims to bring together parallel developments of a prospective landscape dedicated to the power sector, considered as the first GHG emitter across the world. This will bring first elements to understand to what extent technological solutions can be brought as global solutions across regions and over the long term: namely the potential of smart grid solutions as demand response, flexibility options, spread of renewable energy, and what could be their limits, if some exist.

This approach is particularly relevant to go beyond opposing theses, either for instance considering that renewable energy sources should only be used when they are competitive, or setting ambitious short- and mid-term penetration targets to bring down the cost of renewables based on technical and institutional learning processes.

This comparison will allow a greater understanding of the way long term prospective models developed in the US and in France, envisage the way countries face energy and climate long-term issues.

Power system prospective: From deep within the material to the power grid scale

V. Mazauric (1) ; N. Maïzi (2)
(1) Scneider electric and MINES ParisTech, Center for applied mathematics, Grenoble, France; (2) PSL, MINES ParisTech, Mathematics and Systems, Center for Applied Mathematics, Paris, France

To address the abysmal lack of efficiency of the electrical system (73% of losses, 45% of worldwide CO2 emissions!), an energy efficient description of electrical systems lying on a reversible interpretation of the Faraday's law is presented.

As matter of fact, the free current density flowing in the whole power grid exhibits well-split scales allowing mean-field hypothesis where the global condition of reversibility is replaced by embedded minimizations on the various scales involved by the power electrical system. Following a thermodynamic viewpoint, various scales were explored from deep within the material to the power grid scale.

At the power management level, the electromagnetic energy coupling acts to enforce synchronism – usually f = 50Hz or 60Hz – between all generation plants supplying the power grid. An X-Y lattice model is adopted to describe the interaction between the magnetic momentum carried by the rotor of a given machine and the magnetic mean-field resulting from all the others [1]. Provided a large enough resistant electrodynamic torque – simulated with a strong enough correlated lattice or actually a suitable voltage plan –, synchronism is kept under admissible load fluctuation and the kinetic energy embedded in the whole power system acts as a global and huge inertia against frequency deviation which therefore may only occur on several periods.

Given that energy conservation results from the uniformity of time for any isolated system [2], this upper-aggregated scale provides two dynamic energy-based invariants specifically shaped for power systems and suitable to address the question of reliability, namely the kinetic- and the magnetic- energies embedded in the whole power grid. Conversely, following dynamically these energy-based invariants provides a way to perform a space-aggregation and a time-reconciliation of all the scales involved in the power management of the electromagnetic energy.

Hence, a dynamic reliability constraint on kinetic energy was endogenized in the technical optimum TIMES model. Dedicated to La Reunion island:

- The potential contribution of electrochemical storage technology to the power dynamics and the reliability has been demonstrated; and
- A high share of variable renewable plants (around 50%) can be considered without jeopardize power transmission.

Costs and benefits of a greener alternative for the development of Vietnam's power sector

HA. Nguyen Trinh (1) ; M. Ha-Duong (1)
(1) CIRED/CNRS, Nogent sur marne, France

To explore pathways for Vietnam's power system until 2040, two scenarios are developed in the current study: (1) a scenario based on current trends (BAU); (2) a greener alternative with more renewable energy and higher energy efficiency (ALT). The authors estimate that the external costs of CO2, NOx, SO2 and PM10 in the power sector in Vietnam are 7-20, 1 328, 2 047 and 1 460 US$/ton, respectively. We find that the ALT scenario is more sustainable than the BAU scenario in all aspects. In the ALT scenario, the price of electricity and the domestic trade balance are less sensitive to fluctuations in the international price of coal than in the BAU scenario because imported fuel accounts for only 39% of total generation capacity in 2040, as opposed to 60% in the current policy scenario. The total costs accumulated from 2010 to 2040 would be lower in the greener alternative: 632 billion US dollars compared with 974 billion US$. This difference arises from several factors: lower investment in new capacity (226 compared with 306 billion US$); lower local pollution costs (73 compared with 137 billion US$); lower CO2 emissions; and lower expenditures on imported fuels (57 compared with 115 billion US$). The outcomes of the ALT scenario are in accord with the targets for the power sector in the most recent Green Growth Strategy of Vietnam (GGSV).

P-3303-17

Institutional change and market conditions for low-carbon electricity transition in Vietnam

HA. Nguyen Trinh (1) ; Y. Rizopoulos (1)
(1) LADYSS, Paris, France

The rapid expansion of the industrialization and urbanization processes over the last two decades has dramatically increased the demand for electricity in Vietnam. The challenges of developing new resources, enhancing high-voltage transmission lines, and reducing transmission and distribution losses imply an improvement of the current electricity system.

Considerations related to low carbon transition make part of this general context. Meanwhile, because of complex interwoven interests, major players as the powerful holding EVN (Electricity of Vietnam) seem more interested to pursue the development of fossil/fuel based power plants than to favor renewable resources. As a consequence, a low carbon transition implies a fundamental transformation of the current Vietnamese electricity system. Focusing on the institutional and governance issues, such a transition needs "actions to remove the barriers" (IEA, 2012) and "high levels of social and political innovation" (Global Carbon Project, 2010). Indeed, the institutional environment of the energy sector has its roots in the 'Doi moi' policy (1986), but also in the systemic features of Vietnam combining centralisation and fragmentation: centralisation of political power and weight of the political elite, hierarchy and informal networking, progressive decentralisation of economic management, and weak civil society.

The paper proposes a mesoeconomic approach of the low-carbon electricity transition in Vietnam. We argue that political will is a necessary but not a sufficient condition for such a change. The transition process depends on interdependent organizational decisions inside the electricity sector and implies a fundamental transformation of the stakeholder's positions and relations. In particular, it necessitates the existence of a critical mass of initiating actors perceiving the benefits of investing in renewable sources and having levers to redefine the rules of the game, modifying therefore the institutional framework and enabling the constitution of new structural interdependencies inside the electricity system. In this perspective, we proceed to the identification of key players, and point out the institutional and structural characteristics of the electricity market. Then, we propose an analytical grid to apprehend the change path by following the evolution of some focal variables. Concerning specifically wind electricity generation, wholesale market price and subsidies to the single buyer indicate the balance of power between the major stakeholders and reflect the stages of the transition process.

Our work sheds further light on the processes that determine the transition to low carbon electricity in Vietnam but several limitations should be noted given the complex multilevel/multifactor character of the game. Indeed, in-depth knowledge of vertical (government to enterprise) and horizontal (enterprise to enterprise) bargaining process or of the way foreign stakeholders intervene and interact with local actors could usefully complete the analytical grid developed here. More, we focus on the single onshore wind power as an illustration of the conditions influencing low carbon transition. The method to monitor the change process could be further improved by integrating more detailed data on electricity selling prices, as well as incentives and counter-incentives for all renewable and fossil resources.

We propose a comprehensive analysis of the factors shaping/preventing the transition to low carbon electricity in Vietnam - especially those related to interest settlements, actors' strategies, principles of governance and institutional framework - in a political economy perspective. Concerning specifically wind electricity generation, wholesale market price and subsidies to the single buyer indicate the balance of power between the major stakeholders and reflect the stages of the transition process. In addition, the paper provides a methodological contribution for the measure of structural/institutional change in the energy sector.

P-3303-18

Feasibility of a decentral renewable power system in Europe

S. Pfenninger (1) ; J. Lilliestam, (2)
(1) Imperial College London, Grantham Institute and Dept of Civil and Environmental Engineering, London, United Kingdom; (2) ETH Zürich, Human-environment systems group, department of environmental systems science, Zürich, Switzerland

The global transition of the power sector towards clean and renewable technologies is well underway. The worldwide average annual growth rate for installed wind and solar photovoltaics (PV) capacity since the year 2000 have been about 25% and 45%, respectively, with installed capacities in 2013 reaching almost 320 GW for wind and 140 GW for solar PV. Hand-in-hand with the rising importance of renewables, the idea of a more local, decentral electricity supply has gained increasing prominence and ideological support. Amongst advocates of a renewables-based electricity system, this is pitching proponents of a centralized renewables deployment (e.g.

based on large-scale desert solar power with a continental, or intercontinental, transmission system) against those who argue for decentralized generation and distribution (e.g. based on rooftop PV and small-scale wind combined with smart demand management).

The rapid deployment of both wind and PV in countries like Germany has seemingly brought this possibility of a radically different electricity system than the one we have today closer than it has ever been. Some of the potential advantages of such a decentralized system include more energy independence for individual countries or even municipalities, and more economic benefits accruing to the local communities where power is both produced and used. However, critics point to the fact that such a system would be more costly, for example, due to inefficiencies caused by the large local generation overcapacities needed to maintain system stability, the increased storage requirements, and the loss of returns to scale effects by having many small power plants instead of few large ones. Furthermore, there is the question of how technically feasible the decentralized power paradigm is for heavily populated areas, such as those found in large parts of the European Union (EU), and particularly large metropolitan areas like Paris or London.

Here, we examine the degree to which a completely decentralized power supply based on a combination of renewable energy technologies across the EU is in fact possible, answering the question of how small the smallest self-sufficient areas can be and how much interconnection (especially around cities) is needed in order to supply all electricity needed and keep the system balanced. We do this by simulating wind and solar power generation and analyzing the degrees of aggregation, interconnection and storage needed for the smallest-possible set of independent "electricity islands» across the EU to support themselves for most or all hours of the year. To do so, we use high-resolution wind and solar power plant simulations based on satellite and reanalysis data and validated against real sites across Europe, with a spatial resolution between 5 and 50 kilometers, and a temporal resolution of one hour. Using this input data, we apply the multi-scale energy systems modeling framework Calliope to determine optimal deployment scenarios for these electricity islands.

The results will show the spatial distribution of viable energy islands in Europe, how different storage and demand response availabilities influence the structure of these energy islands as well as the resulting electricity costs at different levels of supply reliability.

P-3303-19

Energy Transition in Europe. The role of communities and city-regions – some comparisons between Britain and Germany

L. Reynolds (1)
(1) L'Institut d'études avancées de Paris, Paris, France

How can city-region level public authorities in the UK help drive a low carbon energy transition? In addition, how might such a transformation of the energy regime also involve shifts in economic, social and political power?

When the energy transition in the UK is compared with the energiewende in Germany, one salient feature stands out: In Germany, new actors from local cooperatives to city authorities have become key players in the growing renewable energy sector. This may even threaten the centralised 'utility' model of the incumbent players. The UK by contrast, has historically had a more centralised political system with fewer powers for cities and regions. It has also had a more centralised energy system, along with more centralised visions for energy transition.

However, two significant recent developments may be changing this situation in the UK. First, there are the moves to devolve some central government powers to newly enhanced 'city-regions'. Secondly, comes a new government community energy strategy, which signals encouragement of the community energy model.

This paper explores the dual processes of city-regional devolution and energy transition in the UK. Drawing on early findings from a current EDF-IEA Paris Transitions énergétique study, it examines the potential for a new 'civic energy sector' in the UK, and ongoing moves by UK city-regions around this question. Drawing on theories from transition studies, the sociology of technology and urban geography, this work analyses and addresses the contested questions of scale – between community, city and region – to explore the shifting, multiple and contested pathways to energy transition. How might community and city level players reconfigure the energy transition? What limits are placed on this process – including by incumbent actors in the energy sector and government? How can we understand the different strategies and visions of energy transition today, with their different imagined scales of transition and distributions of political, economic and electrical power? The conclusions drawn can help us to understand the key role played by communities, cities and regions in the transition to a low carbon society and energy regime.

P-3303-20

Techno-economic analysis of carbon mitigation options for the fossil fuel fired power plants in India

U. Singh (1) ; AB. Rao (2) ; N. Sharma (1)
(1) National Institute of Technology Rourkela, Department of Mechanical Engineering, Rourkela, Odisha, India; (2) Indian Institute of Technology Bombay, Centre for technology alternatives for rural areas, Mumbai, India

In response to the global climate change problem, the world community today is in search for an effective means of carbon mitigation. Coal based power plants in India, with an installed capacity of over 149 GW, account for more than half of the energy production and 66% of electricity generation in the country. These plants emit approximately 665 MtCO2 annually i.e. 37.5% of the total greenhouse gas (GHG) emissions of the country. With a large number of new coal power plants (~ 500 plants with about 600 GW capacity) being proposed, the problem of GHG emissions is far from being solved.

A variety of options exist for reducing the carbon dioxide emissions from the existing coal-fired power plants in India – which are mostly sub-critical units. The most feasible approaches include fuel switching (use of low-carbon fuels such as natural gas and biomass), and efficiency improvement (by better O&M conditions – by using better quality coal which may have to be imported from outside the country, or by adoption of supercritical and ultra-supercritical or IGCC technology). Carbon Capture and Storage (CCS) is the process of extraction of Carbon Dioxide (CO2) from large-point industrial and energy related sources, transport to storage locations and long-term isolation from the atmosphere. It is being considered as a promising carbon mitigation technology, especially for large point sources such as coal power plants.

The main objective of this paper is to carry out a techno-economic analysis of the several carbon mitigation options for the fossil fuel based power plants in India. The following options would be considered:

1. refurbishing/ repowering of the existing sub-critical units with SC/USC/IGCC,
2. using imported coal with better combustion properties
3. using CCS to capture and reduce a substantial fraction of the emissions
4. a combination of any of the above strategies

However, CCS is accompanied by a huge economic and energy penalty. In case of post-combustion CO2 capture using solvents like amine and ammonia, part of the steam from the steam cycle is lost for solvent regeneration. Thus, the gross electric output of the plant is lowered. This issue can be addressed by using an auxiliary natural gas boiler. Thus, we have one more potential variant of the list of carbon mitigation options listed above.

While India has substantial coal reserves, natural gas reserves are quite low. However, recently there has been a great deal of interest in unconventional gases like shale gas and coalbed methane (CBM) in India. If shale gas and CBM can be aggressively deployed, they can serve in several avenues including in auxiliary natural gas boilers for CCS retrofits. Obviously, pricing of gas versus coal shall be an important determinant for such deployment. Moreover, if the availability and pricing of natural gas

become more favorable, then Natural Gas Combined Cycle (NGCC) plants may also be considered as a suitable option. In that case, NGCC can also be coupled with CCS.

Thus, a large number of carbon mitigation options will be analyzed so as to estimate the carbon mitigation potential as well as the associated cost of mitigation. The modeling of the plants would be done by using the Integrated Environmental Control Model (IECM-cs) developed at the Carnegie Mellon University, USA. This modeling framework enables a comparison of performance as well as the costs associated with these various plant options on a consistent basis. Sensitivity of all these scenarios towards some key parameters such as the varying levels of fuel prices, plant capacity factor and fixed charge factor on the capital investment will also be studied so as to understand the policy implications of such interventions.

P-3303-21

The drivers of investment in cleaner energy production

E. Verdolini (1) ; F. Vona (2) ; D. Popp (3)
(1) FEEM Fondazione Eni Enrico Mattei, CCSD, Milano, Italy; (2) OFCE Sciences-Po / SKEMA Business School and SciencesPo , Nice and Menton, France; (3) Syracuse University, Syracuse, United States of America

The ability to match future economic growth with reduced pressure on the environment is inextricably linked with the deployment and diffusion of low carbon technologies. An important sector that needs to be decarbonised to supply sustainable energy for all while reducing pressure on the environment is that of centralized electricity and heat production, which is among the major emitters and whose demand is project to increase significantly over the next decades, especially in developing countries (IEA, 2014).

Many "clean" technologies for electricity production are already available, but their use is hindered because they are not cost-competitive with "dirty" technologies. Such price wedge is due to at least three reasons. First, some technologies are relatively immature, and lower costs will materialize only in the future. Second, the price of dirty technologies does not internalize the cost of pollution. Third, the energy sector is characterized by long-lived capital stock and significant sunk investment in existing (dirty) plants.

The academic debate regarding the decoupling of economic growth from polluting energy sources (decarbonization) is often framed assuming a clear-cut distinction between what is clean and what is dirty and the theoretical possibility of completely substituting dirty inputs with clean ones (Acemoglu et al. 2010). Both assumptions are very strong when referring to aggregate energy systems, and more specifically to the power sector. First, emissions reductions in electricity generation can be achieved using either renewable energy resources or improving the energy (and hence carbon) efficiency of fossil-based technologies. Second, if one sets aside nuclear due to proliferation and safety considerations, there is no carbon free technology that can nowadays fully substitute fossil-based energy. Specifically, renewable energy sources strongly depend on the natural endowment (ocean, hydro, wind), are highly intermittent and seasonal (solar, wind), do not have the generation potential to meet the current demand for energy alone (wind, geothermal) or are manufactured using rare metals whose availability cannot be taken for granted (solar). Moreover, centralized electricity and heat production are peculiar in that the goods they produce (electricity and heat) are difficult to store in an economically viable way or to transport over great distances, and need to be used by consumers at the time they are produced (Battarchaya chpt10).

In this paper, we explore the implications of the peculiarities of the power sector and of available clean energy technologies. We focus on the degree of complementarity between clean and dirty electricity investment. We use data for 27 Organization for Economic Cooperation and Development (OECD) countries over the years 1990-2007 to show that to meet energy demand when the sun does not shine or the wind does not blow investments in renewable energy generation have been combined with investments in capacity of fossil power generation technologies. Specifically, our analysis confirms that systems that promote a high penetration of renewables require some backup generation capacity that is quick to react and most likely utilized under capacity for most of the time. Older coal power plants and base load plants are not good candidates in this respect, given their high capital costs, low operating costs, the inverse relation between efficiency and size and the long time needed for them to be brought on and off line. Conversely, high efficiency (gas) plants and technologies, which can be brought into operation relatively quickly and allow modular use since efficiency does not fall significantly with size, are installed to quickly compensate renewable intermittency (Battarchaya chpt10).

The implications emerging from our findings are manifold. First, at present there is no evidence that in the power sector technical change can be solely directed towards the clean input without important implications for the reliability of energy supply, energy access and energy security. Second, absent major breakthroughs in storage and grid technologies, the diffusion of renewable energy technologies may not be economically viable even if costs significantly fall due to need to balance demand and supply instantaneously. Lastly, the necessity to install peak load capacity which compensate intermittency is a further burden that is often not considered in the estimation of renewable energy costs.

P-3303-22

Global Energy and Climate Outlook: Road to Paris -Assessment from an energy system perspective of Low Emission Levels under World Action Integrating National Contributions

Z. Vrontisi (1) ; A. Kitous, (2) ; A. Labat, (3) ; M. Perry (3) ; B. Saveyn, (2) ; T. Vandyck, (2)
(1) Institute for Prospective Technological Studies, Seville, Spain; (2) European Commission (DG JRC-IPTS), Institute for prospective technological studies, Seville, Spain; (3) European Commission (DG Climate Action), Brussels, Belgium

On 25 February 2015, the European Commission has set out its Communication, «The Paris Protocol – a blueprint for tackling global climate change beyond 2020" in the EU's Energy Union package. This paper presents the modelling work undertaken in the context of the abovementioned EC communication regarding the energy system related impacts of post-2020 global climate change mitigation policies. The analysis presented here mainly lies on results from the energy systems model POLES for the purposes of the EC preparation for the global climate negotiations. It focuses on possible ways to stay below 2°C through processes established in the run-up to Paris COP21 by studying a combination of domestically determined mitigation targets for the period beyond 2020.

The POLES model is a global sectoral simulation model for the development of energy markets. It operates on a yearly basis up to 2050, with a very recent data update. Main exogenous inputs are economic growth and demographic projections for each region. POLES model provides comprehensive energy balances (demand, transformation, and supply) for the 57 countries / regions covering the world and detailed oil and gas productions for 80 countries. Energy demand in 15 sectors is driven by income and derived activity variables as well as short- and long-term energy prices.

In the POLES Baseline population and economic growth projections are based on the UN and OECD and the evolution of the energy markets, as driven by its own dynamic of production, supply and demand, is consistent with IEA projections. The projections do not consider the impacts from unabated climate change. In this Baseline scenario, global emissions would increase at unsustainable levels: from 48 GtCO2e in 2010, 61 GtCO2e in 2030 to 68 GtCO2e in 2050. Along such trajectories, the world is at risk to experience a global temperature increase of +4°C, with sizeable impacts on sustainable growth and vulnerable groups in all regions. The Global Mitigation scenario is in line with staying below 2°C, with global GHG emissions peaking in 2020 and reaching about 43 GtCO2e in 2030, still higher than in 1990 (+20%) but lower than in 2010 (-10%), and world average emissions reach 1.5 tCO2e per capita (50th percentile is 2 tCO2e per capita), roughly the level of the least emitting regions in 2010.

The modelling confirms that all regions can define domestic mitigation goals in line with 2°C, based on their current policy experiences, and that the institutions and

mechanisms put in place under the Climate Convention framework can be mobilised to deliver enhanced climate and economic benefits, especially for the countries with less capabilities. A significant transformation of the energy system is required, including energy savings, decarbonising the power sector with renewables, nuclear and fuel switching and actions to cut non-CO2 emissions in agriculture, industry or waste. It is found that Carbon Capture and Storage (CCS) becomes an important mitigation option after 2030. Europe and Asian countries see their imports in volume and monetary value decreasing substantially, North America presents a balanced energy trade and fossil fuel energy producers have to adapt to improved energy use at global level. Nonetheless, Sub-Saharan Africa and Latin America remain net fossil fuel exporters, Gulf countries and Russian Federation remain the world's dominant suppliers, and energy trade remains an important source of their income. The global investment patterns in power production are substantially modified by the introduction of ambitious GHG mitigation policies and by the related major changes in the energy mix towards renewable sources representing 40% of primary energy in 2050. Investments shift away from fossil fuels towards the power sector to tap capital-intensive mitigation opportunities. These investments enable to reduce other costs that would be required if abatement was not undertaken largely by the power sector but also by expenditure on fossil fuel imports and subsidies.

The implications of 2°C carbon budgets for global energy systems

K. Anderson (1) ; A. Bows-Larkin (1)
(1) Tyndall Centre for Climate Change Research, University of Manchester, Manchester, United Kingdom

The IPCC's fifth assessment reports (AR5) have been widely heralded as delivering unequivocal and stark messages to policy makers. Of particular relevance to this paper is the inclusion, for the first time in the IPCC's history, of explicit carbon budgets for differing probabilities of meeting a range of twenty-first century temperatures rises, from 1.5°C to 4°C. These carbon budgets provide a clear and quantifiable framework against which to assess technical and socio-economic policies for delivering the requisite rates and timeframes of mitigation.

With specific focus on CO2-only emissions from the energy system, this paper will revisit the framing of the mitigation challenge in accordance with the AR5 carbon budget range for a "likely" (66%), "likely as not" (50%) and "not likely" (33%) probability of maintaining the rise in global mean surface temperature below the 2°C characterisation of dangerous climate change. New estimates of the process-carbon emissions from the cement industry, combined with a revised carbon budget estimate for deforestation will be used to determine what CO2-only budget remains for the energy sector.

The paper will demonstrate that even assuming an unparalleled agreement at the Paris Negotiations in December 2015 (COP 21), alongside highly ambitious policies for reducing emissions from cement and deforestation, the energy-only budget of CO2 post-2020 will be radically more challenging than implied in AR5's post-2011 budgets. For a "likely" chance of 2°C, and assuming global emissions peak in 2020, mitigation of energy-only CO2 would need to rise rapidly to well over 10% p.a. by 2025 and be maintained at that rate until the virtual elimination of CO2 by 2050. The story for a 50:50 chance of 2°C though slightly less dramatic, is nonetheless beyond anything yet countenanced by policy makers and only seldom referred to in the literature.

Whilst the implications of such 2°C pathways are interpreted by some as highly regressive, this paper seeks to outline a positive solutions-oriented agenda. The scale of the challenge in the twenty-first century, with globalisation and an increasing population, demands moving beyond the reductionist disciplinary tools of the twentieth century. A systems-oriented and interdisciplinary approach designs infrastructure and develops institutions to offer resilience and facilitate iteration; a radical departure from abstract and theorised optimisation. Set within this context of unprecedented rates of mitigation and rapidly shrinking timeframes, it is this intellectually more exciting agenda, that informs the papers quantitative, technical and social-science content.

Factoring Strategic and Sustainability considerations into energy sector policy and regulation: Insights from UK expe-rience

M. Grubb (1) ; J. Hardy (2) ; J. Mills, (2)
(1) University College London, Institute of Sustainable Resources, London, United Kingdom; (2) Office of Gas and Electricity Markets, Sustainable energy policy, London, United Kingdom

The UK is widely seen as a pioneer of market liberalisation, and the UK regulator was initially established with a primary duty to promote competition, which was subsequently amended to a focus on protecting the interests of consumers. The 2000s saw growing tensions between the renamed Office of Gas and Electricity Markets (Ofgem) and the government over strategic dimensions - particularly escalating concerns about investment adequacy (for security), and decarbonisation. This paper outlines the UK development of policy and regulatory structures in support of decarbonisation, explaining the extent to which energy market structures and their regulation cannot be separated from the wider definitions of objectives and responsibilities.

Economic principles which fit one set of conditions and lead to one set of reforms may not be adequate in themselves when conditions or the balance of objectives change. Attempts to give the regulator an explicit primary duty relating to either security or the environment did not succeed. However the 2008 Energy Act 'clarified' its primary duty as being "to protect the interests of both existing and future consumers." In effect, this achieved the same thing: it gave the regulator an explicit duty to consider the longer-term implications of energy sector developments. The defining struggle within Ofgem was then its Project Discovery (2009), the findings of which were simultaneously lambasted from different camps as heresy, or derided as Ofgem finally "discovering the real world."

The conclusion that the UK electricity market structure could not guarantee security and could not deliver the scale of low carbon investment required led directly to the government developing the UK Energy Market Reform bill, which radically changes the economic structure of the UK electricity system. This paper outlines the main rationales, components and sketches the inevitable new challenges which arise.

Ofgem also underwent internal changes, setting up a Division of Sustainable Development charged in part with ensuring that the concerns of future consumers are represented at the table of regulatory decisionmaking. Analysis of the issues at stake - and practical experience - led to the conclusion that attempts to aggregate the interests of present and future consumers (and potential trade-offs) through aggregate monetised cost/benefit appraisal was unworkable and potentially obscured rather than informed good decisionmaking. Following a 2-year process of research and consultation, in July 2013 Ofgem's Board agreed a major restructuring of its Impact Assessment framework. This paper articulates this

new framework and the thinking behind it and outlines challenges in its implementation going forward.

National Plans for Utilization of Renewable Energy in Egypt

EHM. Ahmed (1) ; MW. Labib (2) ; S. Tantawi (3)
(1) Lead Author, WG III, IPCC, climate change and sustainable development, Cairo, Egypt; (2) EEAA, Climate change, Cairo, Egypt; (3) EEAA, Cairo, Egypt

Egypt has various opportunities for applying renewable energy and energy efficiency technologies. Thus to achieve sustainability in Egypt's energy sector it is important to develop an overall national energy strategy that incorporates renewable sources and acts as an umbrella for the existing renewable energy and energy efficiency plans.

This strategy should be involved in the Egyptian development plan in all sectors, as this will help to overcome the existing barriers whether institutional, technical, financial, market, awareness and information or technological barriers.

The government, the Industrial Modernization Centre (IMC) and the Ministry of Scientific Research shall allocate funds for Research and development of RE & energy efficiency technologies. Four bodies may be responsible to establish collaborative work programs for 1) RET, RE systems component design and development, 2) Human Resources Training and development and 3) National innovation on near- commercial technologies and niches.

All sectors in Egypt should be integrated with this overall strategy for harmonization in actions, hence it became necessary to raise awareness on the vital importance of Renewable Energy (RE), Research and Development (R&D), and the need to rationalize energy use in homes, factories, and various production sites and services; to make this awareness and rationalization as a rule for behavior and the lifestyle in Egypt.

O-3304-02

Present and future complementarity of wind power production in EU-28

F. Monforti (1) ; M. Gaetani (2) ; E. Vignati (3)
(1) Joint Research Centre, Institute for Energy and Transport, Cadrezzate, Italy; (2) Institut Pierre Simon Laplace, LATMOS, Paris, France; (3) Joint Research Centre, Institute for environment and sustainability, Ispra, Italy

The amount of wind energy injected in the European electricity transmission system is expected to increase in next decades following the energy transition triggered by Directive 2009/28/EC.

Nevertheless, both absolute amounts and time patterns of wind electricity supply are different in each European country because of non-homogeneous meteorological conditions, Europe being large enough to span several different climatic areas.

Indeed, different types of weather are often simultaneously present in different areas of the continent, and any planned pan-European electricity transmission grid aimed at dispatching electricity production throughout the continent has to face the challenge of balancing in real time differently intermittent and strongly inhomogeneous resources such as the wind production is.

In this study, the long term (90 years) on-shore potential wind power supply for European countries is simulated with a daily time resolution, on the basis of the wind fields provided for the period 1961-2050 by 12 regional climate models involved in the ENSEMBLES model intercomparison project.

Thanks to this data base a long term view of the evolution of potential wind power deployment will be provided. In particular, the time complementarity of wind energy production originating from different countries will be analysed with a special attention to the implications that such a complementarity is expected to have for the needs for international electrical interconnections transporting electricity from high production areas to high demand areas.

Tackling Offshore Oil & Gas GHG Emissions – Brazil's Experience

T. Bredariol (1) ; C. Guilherme (1) ; AC. Luiz (1)
(1) IBAMA, Cgpeg, Rio de Janeiro, Brazil

There is growing evidence that human pressure is substantially raising the risks of crossing planetary thresholds, such as safe CO2 concentrations in the atmosphere. A viable future depends on mitigation and adaptation efforts in multiple fields and of special importance is the energy supply sector (IPCC, 2014). Estimates for the year of 2011 account for approximately 140 billion cubic meters of natural gas being vented or flared worldwide (GGFR, 2013). Although this is a decrease of almost 20% since 2005, there is still much space for further reduction and this downward trend is in danger of being reversed by a number of factors, including increase in oil production in several countries such as Brazil (GGFR, 2013). Only a few countries have introduced detailed secondary legislation regarding flare and vent emissions, such as codes and guidelines, even though it is paramount to effectively regulate this activity (World Bank, 2004). It is also a topic that interests the private sector (CDP, 2014). This work presents the experience of a Brazilian environmental unit (CGPEG) in building such legislation and mitigating GHG emissions from offshore oil and gas exploration and production.

CGPEG is a unit of IBAMA (Brazil´s federal environmental agency) that is responsible for analyzing environmental authorization requests for seismic activities, drilling, and oil and gas production offshore. Since 2010, it has been working on climate change mitigation, limiting or requesting compensation for flare emissions – a common GHG source in offshore oil and gas production projects. Flares burn gas, mainly composed of methane, that remains after: power generation on the platforms; gas injection and/or gas lift in the wells; or gas export to land facilities – chiefly through sub-sea pipelines. In 2013, CGPEG issued a guideline regarding procedures for mitigating GHG emissions, with detailed legislation and current requirements in the environmental authorization process. Two main conditions are normally made for high emitting activities: flaring limits (daily or for another stipulated period – such as the reckoned time necessary for oil production platform's commissioning); or compensation, which may be direct (e.g. reforestation projects) or indirect (financial contribution to climate funds, such as the Amazônia Fund). As a result, over less then five years, estimates indicate that at least 225.552 tCO2eq emissions have been avoided and 3.024.160 tCO2eq compensated (equivalent to ~85,9x106 m³ of gas), generating over R$10 million funds for actions related to climate change. The industry has accompanied these developments, making gas and CO2 injection, closed flares and better commissioning plans a reality. Still there is a lot to be done towards more efficient energy practices.

Design and Construction of Domestic Jatropha Oil Pressure Cooker

C. Shonhiwa (1)
(1) University of Zimbabwe, Mechanical Engineering, Harare, Zimbabwe

Household energy for cooking accounts for a big part of overall energy consumption in developing countries such as Zimbabwe. In Zimbabwe 70% of total energy consumed is used for cooking purposes and in general wood is mainly used. The use of fire wood is resulting in deforestation of large areas creating severe ecological and environmental problems. Smoke from incomplete combustion poses health risks to humans and the environment.The Jatropha oil which is environmentally friendly is readily available in parts of Zimbabwe and can be used for cooking instead of the use of firewood, gas or electricity which are not readily and affordable to the ordinary Zimbabwean.

This work deals with the design and construction of Jatropha Oil Pressure Cooker. The design consists of the frame, piping system and air cylinder. By using the principles of Fluid Mechanics this work established the power of the cooker as 170kW and the cooker would burn 1 liter of Jatropha Oil in 4 minutes giving an energy value of 35.2MJ when operating at a constant pressure of 1.2mPa

Energy Policy, Greenhouse Gas Reduction, and Climate Negotiations

J. Sweeney (1)
(1) Stanford University, Precourt energy efficiency center, Stanford, United States of America

Nations have legitimate interests in the health and growth of their economy, in their domestic and international security, and in the environment. These are summarized as the "energy policy triangle." International agreements must respect these legitimate interests and nations are unlikely to comply with policy proposals that do not respect these interests. Nations must address both energy supply – expand low carbon energy sources – and energy consumption – reduce energy use per unit of economic activity.

There are at least seven classes of strategies to motivate energy efficiency and reductions in energy intensity: 1) Normal processes of economic innovation, 2) Information provision, 3) Nudges, 4) Stochastic rewards, 5) Financial incentives, 6) Competitions, 7) Regulation. There is no "silver bullet" for energy efficiency. This presentation will discuss these classes.

These options suggest recommended directions for international agreements: Each nation should 1) set a goal of economy-wide annual energy intensity reduction; 2) set a stronger goal of economy-wide annual carbon intensity reduction; 3) conduct/support energy efficiency and clean energy RD&D and promote open, broad communication of findings; 4) adopt some energy-efficiency behavioral incentives. Specific incentives will differ among nations, but should include among others: labeling of all major energy using equipment offered for sale; feedback of energy use to consumers; elimination of all subsidies for CO2-intense energy; internal carbon price applied broadly throughout economy.

Industry: The Gordian knot of decarbonisation on the demand side?

M. Fischedick (1)
(1) Wuppertal Institut, Wuppertal, Germany

The industry sector lies at the heart of the many governments decisions regarding the maintenance of wealth and the creation of employment. On the other hand, the industry sector accounted for over 30% of global GHG emissions in 2010. When compared to the major energy-end use sectors (transport, buildings, AFOLU), industry is currently the largest emitter of greenhouse gas (GHG) emissions. The key energy intensive material-conversion sectors (cement, iron and steel, chemicals, pulp and paper and aluminium) dominate the energy use and emissions in industry. Most scenarios envisage a continuing rise in demand for materials, by between 45% to 60% by 2050, relative to 2010 production levels.

The transition from current patterns of industrial production to a future in which goods are produced sustainably requires a holistic view that goes beyond energy efficiency. From the perspective of climate change mitigation, opportunities can be found over the whole supply chain. Although currently sometimes difficult to quantify, there are significant potentials for reduction in emissions mainly through emissions efficiency (e.g. fuel switch), material efficiency in manufacturing (through reducing yield losses, re-use of materials and recycling of products), material efficiency in product design (less material per product), product-service efficiency (in transport through car sharing) and last but not least sustainable consumption patterns.

Against this background – as we move towards the question of how to achieve sustainable development goals – a more efficient use of energy, materials and products is without alternative in the sector and has to be addressed through appropriate global and sector specific policies.

However, implementation of existing measures is not a self-dynamic process and faces various challenges, even political trade offs. This holds true particularly for more ambitious long-term decarbonisation efforts as they might require not only improvements in existing production structures, but in addition a shift to low carbon electricity, carbon capture and storage or even implementation of completely new approaches (e.g. hydrogen based steel making) or radical product innovations (e.g., alternatives to cement) which might go hand in hand with persistence forces.

The presentation addresses the portfolio of options available, gives a brief overview of their technical and economic potentials, reflects synergies and tradeoffs that mitigation in the industry sector can have with other policy objectives. Discussion of long-term decarbonisation pathways are specifically addressed as they might play a crucial role for solving the Gordian knot.

The presentation will be mainly based on recently published industry chapter of the IPCC WG III report:

Fischedick, M. et al., 2014. Industry. In Climate Change 2014: Mitigation of Climate Change. Contribution of Working Group III to the Fifth Assessment Report of the Intergovernmental Panel on Climate Change [Edenhofer, O. et al (eds.)]. Cambridge, United Kingdom and New York, NY, USA: Cambridge University Press, 2014

O-3305-01

Decarbonising demand by energy efficiency and material efficiency – why it is at the core of climate policy and how it could be achieved

S. Lechtenböhmer (1) ; LG. Giraudet (2)
(1) Wuppertal Institut für Klima Umwelt Energie, Research Group Future Energy and Mobility Structures, Wuppertal, Germany; (2) Ecole des Ponts ParisTech, Centre international de recherche sur l'environnement et le développement (cired), Nogent sur Marne, France

Decarbonising energy supply is not sufficient to achieve sustainable, low carbon energy systems. A highly efficient use of energy has to be tackled much more serious if mitigation shall leed to successful decarbonisation. Only if energy demand can be stabilised or reduced there will be a realistic chance to convert supply towards sustainable sources.

Final energy demand stabilisation needs high exploitation of potentials in all sectors by low energy buildings, highly efficient appliances and vehicles as well as mainstreaming best available technology all over industry. Basic materials production – which is responsible for a significant share of energy demand, however already operates close to physical limits of current processes in many countries. Here new processes and break through technologies will be needed to achieve significant reductions of energy use. Further, on a global scale means of more efficient use of basic materials such as material effciency as well as recycling will be indispensable.

All these challenges do need concerted action on a more streamlined policy for significantly increasing energy efficiency as well as decarbonising basic industry.

O-3305-02

A long-term, integrated impact assessment of alternative building energy code scenarios in China

S. Yu (1) ; L. Clarke (1) ; J. Eom (2) ; M. Evans (1)

(1) Pacific Northwest National Laboratory (PNNL), Joint global change research institute, College Park, MD, United States of America; (2) KAIST Business School, Graduate school of green growth, Seoul, Republic of Korea

Building energy demand continues to increase globally, generating an unprecedented amount of CO2 emissions from the sector. The trend is not likely to wane anytime soon as a less developed part of the world grows at a rapid pace demanding the standards of living that its predecessors have experienced.

China is already the world's second largest building energy user. Building energy consumption in China is expected to grow at least for the next several decades, as the country undergoes rapid income and population growth, requiring continued expansion of building floorspace and installation of energy-consuming devices. This poses substantial challenges for the Chinese government to maintain adequate supply of energy and for international society to address global climate change.

Development and implementation of building energy codes in China may be a sensible domestic strategy to fulfill building energy demand in an economically efficient way while at the same time reducing CO2 emissions. Building energy codes intend to promote energy performance of buildings by setting legal requirements on building design and their compliance provisions during construction period. They usually include standards for thermal properties of building envelope and may also cover heating, ventilation, and air conditioning, lighting, electrical power, renewable, and building maintenance. The Chinese government has implemented building energy codes since 1980s with the particular focus on the improvement of envelope insulation. All new urban residential and commercial buildings are currently required to comply with Chinese building energy codes in both design and construction stages.

This paper investigates the potential long-term impact of China's building energy codes on building energy use and CO2 emissions based on a detailed building energy model nested within the Global Change Assessment Model (GCAM). In particular, the model represents the influence of building code implementation on the improvement of buildings shell efficiency and resulting energy demands. The model disaggregates Chinese buildings into 12 different sectors—three building types in four climate zones. Specifically, the impact of building energy codes is captured through a building stock module that describes the expansion of building floorspace as a result of new construction and retirement at the regional level, as well as the interaction of the building stock with building energy codes in place, code compliance, and the degree of retrofits. This modeling approach allows for assessing the effect of building energy codes on building energy demand and associated CO2 emissions in a consistent manner, while at the same time capturing the effects of regional differences in socioeconomic development, code implementation, climate impact, and fuel choices.

In this study, we focused on the long-term impacts of various types of building energy codes that are being contemplated or could be implemented by the Chinese government. Four distinct but interrelated scenarios of Chinese building energy codes were taken into account to span possible futures of the building sector, to provide broader policy insights, and to guide the development of building codes at the regional and national level. By examining the influence of two major policy variables--the coverage by building type and the stringency of the energy codes--we suggest the pathways that next generation building codes in China are advised to take.

This study draws three important conclusions. First, the implementation of building energy codes may substantially reduce overall building energy consumption in China, and this finding remains unchanged with global climate change, modest assumptions of voluntary technological improvement, and economy-wide carbon policy. Second, the Chinese government can see significant impacts from expanding its efforts to improve building shell efficiency beyond new buildings in urban centers. In particular, promoting retrofits of poorly performing buildings and expanding building energy codes to rural areas may result in earlier and more drastic energy savings. Finally, the potential impact of building energy codes will differ by region and sector. The greatest energy savings will accrue in urban residential buildings, particularly those located in cold regions.

Directed Technological Change and Energy Efficiency Improvements

W. Jan (1)
(1) Fondazione Eni Enrico Mattei, Milan, Italy

This paper applyies the Directed Technical Change (DTC) framework to study improvements in the efficiency of energy use. We present a theoretical model which (1) highlights the drivers of innovative activity in energy intensive sectors and technologies and (2) examines the impact of such activity on the aggregate demand for energy. We then estimate the contribution of these channels through an empirical analysis of patents and energy data. Our contribution is fivefold. First, we show that information about energy expenditures, knowledge spillovers and the parameters governing the R&D process are sufficient to predict the R&D effort in efficiency-improving technologies. Second, we pin down the conditions for a log-linear relation between energy expenditure and the R&D effort. Third, the estimation of the model provides clear evidence that the value of the energy market as well as international and intertemporal spillover play a significant role in determining the level of innovative activity. Fourth, we show that innovative activity in energy intensive sectors shifts down the (Marshalian) demand for energy. Fifth, we show that due to the streamlined modelling framework we adopt, the point estimates from our regression can potentially be used to calibrate any model of DTC in the context of energy consumption.

O-3305-04

Half the material for twice as long

J. Allwood (1)

(1) University of Cambridge, Department of engineering, Cambridge, United Kingdom

The energy intensive industries, which produce that bulk materials that sustain all contemporary living, are the most energy efficient in the world. They have always paid heavily for energy, so regardless of climate or other environmental concerns, they have pursued efficiency motivated only by cost and have been very successful: the opportunities for future energy efficiency gains in the energy intensive industries are limited.

However, precisely because of their efficiency, the bulk materials are made very cheaply, and in particular are very cheap compared with labour costs in the supply chains which determine their use. As a result many decisions in construction and manufacturing are taken to minimise labour costs at the expense of increased material use. For example, in the UK we build commercial buildings with around twice the material required to meet the safety standards of the Eurocodes, and on average we replace buildings after just 40 years, when their structural integrity is absolutely sound. Our research is developing extensive evidence that we could live well by designing our buildings, infrastructure and goods to be made with half as much material and keeping them for twice as long. These two strategies, which would reduce demand for new bulk materials by 75% would be sufficient to achieve most industrial carbon mitigation targets, regardless of any future changes in the energy intensive industries themselves.

The talk will present our evidence about how to live well with much less new material, and present our current understanding of the costs of this change: as the supply chain is already seeking to optimise costs, it will cost more labour to use less material. Policy has not as yet addressed this point, but it may well prove to be a more effective mechanism for reducing industrial emissions than focusing solely on the emissions of material production.

The background to this talk is summarised in:

(1) Allwood, J.M., Cullen, J.M. and Milford, R.L. (2010) Options for achieving a 50% cut in industrial carbon emissions by 2050, Environmental Science and Technology, 44(6) 1888–1894. This paper sets out the evidence that there is limited future potential for energy efficiency in the energy intensive (bulk materials) industries.

(2) Allwood, J.M., Ashby, M.F., Gutowski, T.G, Worrell, E. (2011) Material Efficiency: a White Paper, Resources Conservation and Recycling, 55, 362–381. This paper provides a survey of the opportunity to live well with less new material production.

(3) Allwood J.M. and Cullen J.M. (2012) Sustainable Materials: with both eyes open, UIT Cambridge, England, pp 384. This popular science book, which can be downloaded for free at www.withbotheyesopen.com, sets out the detailed case for using less new material, based on a 5-year 8-person project with a 20-partner industrial consortium.

The talk will report the evidence gathered since these three publications about the implementation of Material Efficiency, in business, government and with final purchasers.

O-3305-05

"Joint crossing of the valleys of death" Exploring the need and options for formal collaboration between US ARPA-E and EU ETS' NER 400 to accelerate the commercialisation of low-carbon breakthrough technologies in the energy and industrial sectors

T. Wyns (1)
(1) Institute for European Studies, VUB, Brussels, Belgium

This paper seeks to demonstrate that there exists a policy complementarity between the US ARPA-E and the EU Emissions Trading System (New Entrants Reserve 300) funding programmes for energy innovation. Both programmes seem to be addressing two different technology market gaps. The next step is to assess if and how this complementarity could be turned into a joined opportunity for the US and the EU to accelerate the commercialisation of low-carbon breakthrough technologies in the energy and (energy intensive) industrial sectors.

Achieving decarbonisation of the EU and US economies over the next decades will require an accelerated improvement and wide-scale deployment of low-carbon energy and industrial technologies. There are two important market gaps that can impede the further development of promising breakthrough technologies. These gaps are know as the early stage "Technological Valley of Death» and the later-stage "Commercialisation Valley of Death". These barriers are strongly present in the energy sector. (Jenkins, Mansur 2010, p.3)

In 2007, the US Congress authorised the establishment of the Advanced Research Project Agency – Energy (ARPA-E). The ARPA-E, modeled on the Defence Advanced Research Projects Agency (DARPA), seeks to advance high-potential, high-impact energy technologies that are too early for private-sector investment. Since 2009, ARPA-E has funded over 360 potentially transformational energy technology projects, including projects that aim to significantly reduce energy use and greenhouse gas emissions in energy intensive industries (e.g. the non-ferrous metals and chemical sectors). However, while successfully moving technologies across the early stage valley of death to the prototype or small scale demonstration stage, the ARPA-E does lack the means to enable the commercialisation of breakthrough technologies that are emerging from its programmes (Bonvillian, Van Atta 2011, p. 471-472).

In 2008, as part of the legislative review of the EU ETS for the period 2013-2020, a new entrants reserve containing 300 million allowances (NER 300) to be auctioned under the EU ETS New Entrants Reserve was established. The revenues generated through this reserve have the goal to finance low-carbon energy demonstration projects. The programme is conceived as a catalyst for the demonstration of carbon capture and storage (CCS) and innovative renewable energy (RES) technologies on a commercial scale within the European Union. Hence, the EU ETS NER is tackling the second "commercialisation" stage of the technological valley of death. In October 2014, the European Union's head of state and government agreed to continue this NER after 2020 and to expand it to 400 million allowances and to energy intensive industrial sectors. Successful implementation of this NER 400 will depend on the availability of promising energy and industrial low-carbon breakthrough technologies at pre-demonstration stage. This is relevant since there appears to be a first stage technology market gap in the EU or at least a gap in the development of first stage low-carbon breakthrough technologies in the EU compared to US based developments and in particular the ARPA-E programmes.

These «commercialisation» and «early stage» technology market gaps, identified respectively under the ARPA-E and the EU's NER 300, can become a policy opportunity if both programmes start working together. Technologies emerging from ARPA-E could make use of the NER programme to enable full-scale commercialisation and vice versa, the EU's NER could secure a broader (and maybe lower risk) project pipeline from promising low-carbon breakthrough technologies fostered under the ARPA-E. A bilateral «technology» agreement between the U.S. government and the EU's institutions could be considered. Such agreement will need to address some specific issues, such as the use and sharing of intellectual property rights and the introduction of a waiver under the ARPA-E' s U.S. manufacturing requirement. The latter element is crucial since ARPA-E requires inventions developed under ARPA-E funding agreements to be substantially manufactured in the United States.

Jenkins, J., & Mansur, S. (2010). Bridging the clean energy valleys of death. Power.

Challenges for decarbonising basic industry: Sustainable transition of industries under competition

M. Ahman (1) ; LJ. Nilsson (2) ; S. Lechtenböhmer (3)

(1) Lund University, Department of environment and energy systems, Lund, Sweden; (2) Lund University, Department for technology and society / environment and energy systems, Lund, Sweden; (3) Wuppertal Institut für Klima Umwelt Energie, Research Group Future Energy and Mobility Structures, Wuppertal, Germany

Decarbonizing the energy intensive production of basic materials such as steel, cement, petrochemicals, and aluminum pose specific challenges.

This session presents the specific challenges for the global basic materials industry in light of the evolving global clime policy framework and discusses the opportunities that material and energy efficiency along the value chain can have. However, we also highlight the long term need for more radical shifts in energy carriers and feedstock changes that an ambitious climate policy will induce.

The energy-intensive production of basic materials are traded on a global market and the production is highly exposed to increasing energy and carbon costs. At the same time, the global framework for climate policy suggest that a level playing field in terms of a global carbon price cannot be expected the short to medium term, if ever. This fact limits the possibilities for policy makers to effectively address industrial emissions with a "price-only" approach.

The demand for basic materials are set to increase substantially with increasing material standards across the world. Recycling and material efficiency can reduced the demand growth for virgin materials. The circulation in the economy of recycled materials will offer some efficiency gains and change the energy carriers (towards eklectricity). However the production of basic materials from recycled feedstock but will still be considered an energy-intensive industry.

The energy-intensive industry is also unique in that investment cycles are very long, usually spanning over 20 to 40 years between reinvestment opportunities in core process steps.The 2 C target and the year 2050 is thus only 1 to 2 major investment decisions away. Thus, in order to make more substantial changes to process design, a long term strategy is needed.

In order to manage a smooth and both socially and politically acceptable transition for both industrialized, transitional and developing countries, we suggest that focusing on material- and energy efficiency as a win-win option. Efficiency has the potential to boost competitiveness and overall economic performances if implemented properly and should thus be at the center of a global strategy. However, efficiency has to be complemented with a technology strategy focusing on more radical changes that requires major innovation efforts and eventually new investment decisions in new basic process designs such as electrowinining, bio or electro-plastics, CCS in industry e.t.c.

Future pathways to a low carbon steel industry - The case of Germany till 2035

M. Arens (1) ; E. Worrell, (2) ; W. Eichhammer (3)
(1) Fraunhofer Institute for Systems and Innovation Research ISI, Energy Technology and Energy Systems, Karlsruhe, Germany; (2) Copernicus Institute of Sustainable Development, Department of innovation, environmental and energy sciences, Utrecht, Netherlands; (3) Fraunhofer Institute for Systems and Innovation Research ISI, Energy policy and energy markets, Karlsruhe, Germany

We analyse the diffusion factors which give explanations for innovation behaviour of individual firms in the German iron and steel industry. First, we analyse the diffusion of three energy efficient technologies for primary steelmaking (EET) from their introduction until today (top-pressure recovery turbine (TRT), basic oxygen furnace gas recovery (BOFGR) and pulverised coal injection (PCI)). We derive the uptake of these technologies both at the national level and of individual firms. Second, we analyse the impact of drivers and barriers on the decision making process of individual firms whether or not to implement these technologies. Thereby we focus on the impact of current policies (e.g. European Emission Trading System, levy for renewable energy, European Emission Directive). We give a short insight into site specific factors which shape the economics of the selected EETs. Our analysis ends with summary and conclusions.

P-3305-02

The role of the Construction Sector in decreasing global energy needs

L. Bourdeau (1)
(1) ECTP-E2BA, Brussels, Belgium

A key European employer and contributor to quality of life and a major energy

consumer and CO2 provider

Worth at least EUR 1.2 trillion of yearly turnover (2011), the European construction sector, including its extended value chain (e.g. material and equipment manufacturers, construction and service companies), is the largest European single activity (9.6 % GDP) and biggest industrial employer (14.6 million direct operatives, 30.7 % of industrial employment, 43.8 million indirect workers). The built environment affects the quality of life and work of all EU-citizens.

Buildings use 40 % of total EU energy consumption and generate 36 % of greenhouse gases in Europe. The construction sector is on its critical path to decarbonise the European economy by 2050, reducing its CO2 emissions by at least 80 % and its energy consumption by as much as 50 %. As the replacement rate of the existing stock is very small (1-2 % per year), acceleration is urgently needed.

Strategic and general objectives

The vision of the construction sector is to drive the creation of a high-tech building industry which turns energy efficiency into a sustainable business. Connecting construction industry to other built environment system suppliers and stakeholders would be the decisive step to reach economic, social and environmental goals. By creating and fostering a research driven paradigm shift, the construction industry would become competitive on a global level in the design, construction and operation of the built environment while sustaining local economies through job creation and skills enhancement, driven by the vast majority of SMEs active in the value chain. In this framework, the strategic objectives of the sector are to:

- Develop technologies and solutions enabling to speed up the reduction in energy use and GHG emission, e.g. through a higher renovation rate of the building stock at lower cost and to meet regulatory needs;
- Develop energy efficiency solutions in order to turn the building industry into a knowledge-driven sustainable business, with higher productivity and higher skilled employees;
- Develop innovative and smart systemic approaches for green buildings and districts.

This would ultimately create a solid foundation for continuous innovation in the building sector through sustainable partnerships, fostering an innovation eco-system across value chains, which is not project based with episodic innovation activities as current practices.

The Public-Private Partnership on Energy Efficient Buildings (PPP EeB)

The Energy-efficient Buildings (EeB) Public Private Partnership (PPP) is a joint initiative of the European Commission (EC) and the Energy Efficient Buildings Association (E2BA). This initiative aims to promote research on new methods and technologies to reduce the energy footprint and CO2 emissions related to new and retrofitted buildings across Europe. The EeB PPP was set up under FP7 and recognises the importance of research in Europe to achieve Europe's targets of job creation and competitiveness, and to maintain leadership in the global knowledge economy. During Horizon 2020, a contractual PPP has been agreed between the E2BA and the European Commission to continue investing in research and innovation.

The research projects respond to EU priorities for new technologies, tools and systems, materials, information

and communication technologies and retrofitting and renovation methodologies in order to achieve energy-efficient buildings. The projects demonstrate scientific and technological excellence across all levels from early stage conception through to demonstration of the potential for commercialisation.

110 projects have been funded so far through the EeB PPP under the 7th Framework Programme (FP7) for 2010, 2011, 2012 and 2013.

P-3305-03

Determination of Optimum Imbibition for the Milling Process in Sugar Factories with Consideration of Trade-offs among Sugar Extraction, Power Production, and Water Use

S. Chantasiriwan (1)
(1) Thammasat University, Mechanical Engineering, Pathum Thani, Thailand

Manufacturing of raw sugar from sugar canes requires many processes. From energy viewpoint, three important processes are milling, steam generation, and evaporation (which includes crystallization). Milling is the process in which juice is extracted from shredded sugar cane. The outputs of the milling unit are sugar juice and bagasse. Juice is sent to the evaporation process, in which, eventually, water is separated from raw sugar. Bagasse is used as the fuel in the steam generation process, which produces steam needed to evaporate juice in the evaporation process. Since the amount of bagasse required for producing process steam is much smaller than the amount of bagasse produced from the milling process, most sugar factories install high-pressure boilers so that high-pressure steam can be used to produce power in either back-pressure or extraction-condensing turbines. Low-pressure steam from turbines is then used in the process. Electrical power obtained from the cogeneration system usually exceeds the demand for internal use in the factory. The excess power is, therefore, exported to the national grid.

In order to increase juice extraction in the milling process, imbibition water is added to the milling unit. More imbibition water results in more thermal energy required to evaporate diluted sugar juice in the evaporation process. Furthermore it results in bagasse with more moisture. Combustion of wet bagasse leads to not only less production of power because some of the thermal energy from combustion is required to evaporate the moisture in bagasse but also more water loss because evaporated moisture is eventually exhausted to the environment with flue gas. Most sugar factories focus only on sugar extraction when selecting the amount of imbibition. Previous investigations have pointed out that the amount of imbibition should be reduced in order to attain the optimum mix of sugar production and power production. In fact, in terms of profit generation, imbibition should be less as the ratio of the profit from sugar production to the profit from power generation decreases.

In the current study, conservation of water is also considered, along with production of sugar and power. The direct effect of the amount imbibition on water use in form of imbibition water is apparent. It also affects water indirectly through the amount of water required to grow sugar canes. Conservation of water has rarely been taken into account by sugar factories. However, as climate change causes scarcity of fresh water in certain part of the world, sugar factories located there will eventually find it necessary to attach economic value to water, and the results of the current study will be of benefit to them. The main objective of this study is to determine the amount of imbibition that will yield the optimum mix of sugar production, power generation, and water use. To reach this objective, mathematical models of milling, steam generation, evaporation, and power generation units are developed, along with interactions between them through mass and energy balances. Results of simulation are presented in charts that show variations of optimum imbibition with important parameters.

P-3305-04

The role of energy efficiency in meeting UK carbon targets

U. Collier (1)
(1) Committee on Climate Change, London, United Kingdom

The United Kingdom was the first country to legislate ambitious climate change targets through its 2008 Climate Change Act. The Committee on Climate Change was set up to advice on the level of the carbon targets and on specific opportunities to achieve them.

This presentation will examine the role of energy efficiency in the Committee's carbon budget advice, focusing on the buildings sector. Buildings account for 37% of UK greenhouse gas emissions and with an ageing building stock, there is much scope for efficiency improvement. Furthermore, improving buildings energy efficiency has various co-benefits, including the alleviation of fuel poverty. This is of particular importance as the decarbonisation policies are expected to raise energy prices. Energy efficiency therefore plays a crucial role in keeping bills affordable.

The presentation will cover both analytical and policy issues. On the analytical side, we will discuss how the Committee estimates abatement potential from energy efficiency, what data limitations we have encountered and what work is underway to overcome them. We will also present our estimates of the impact of decarbonisation policies on energy prices and bills, and the scope for energy efficiency to offset these.

On the policy side, we will look at the UK Government's current energy efficiency policy for buildings and assess what further action is needed to meet carbon budgets. We will highlight the importance of a holistic approach to energy efficiency and heat decarbonisation.

P-3305-05

Energy Sufficiency in Rural Areas - The example of French TEPOS

M. Dreyfus (1)
(1) CNRS – CERAPS, Lille, France

Scholars and policy-makers have now widely acknowledged the key role of local governments and local initiatives in tackling climate change. In fact, for a long time climate change was seen as a global issue, ignoring the fact that its impacts are actually experienced at the local level. Yet thanks to the activities of audacious and resourceful cities as well as to the establishment of powerful transnational networks, the activities of local governments slowly got the attention of policy-makers and researchers.

In governance studies, several theoretical frameworks can be used to discuss the activities undertaken by local governments. The oldest is led by prof. Ostrom who developed with her colleagues, the concept of polycentric governance systems (Ostrom 2010, 2014). The idea is that solutions lie at the local level in the interactions of a multitude of stakeholders, public and private. Multi-level governance theories (Jordan et al. 2012; Schreurs 2008; Corfee-Morlot et al. 2009; Schroeder and Bulkeley 2009) focus on local governments and cities as important players through their responsibilities in the provision of services and infrastructures. Authors highlight the importance of the cooperation of these local authorities through transnational networks.

A common question addressed by these various theories is the relevant scale of action to address climate change. A lot of studies now report cities initiatives, a relevant field of studies because of their important contribution to greenhouse gases (GHG) emissions. Yet smaller local governments and rural authorities are also taking action. The aim of this presentation is precisely to explore what is being done in rural territories to address the challenge of climate change.

This presentation therefore introduces TEPOS ("Positive Energy Territories" or in French "Territoires à energie positive"). These are rural areas, "territories", which intend to achieve energy sufficiency. The "territory" can refer to a single commune, a group of communes or higher level of local governments' associations such as "pays"or national

parks.

The main goal of TEPOS is to increase energy efficiency and to cover the entire local demand through renewable, locally produced, energy. They have a systemic approach considering environmental benefits along with social and economic ones. The purpose is to start a transition towards less fossil-fuel energy use, involving all the stakeholders present on the territory (citizens, companies and businesses but also representatives of national and other public authorities). Excess in energy production may be delivered to other units, in particular urban areas, creating an interesting rural-urban partnership.

A network of TEPOS allows awareness-raising and sharing experiences between TEPOS and other local stakeholders. TEPOS are also part of a European network called 100% RES communities.

Many lessons can be drawn from this innovative experiment. On the basis of cases examples, I will address the following questions:

- What are the drivers of the TEPOS projects?
- What concrete measures are taken to mitigate GHG emissions?
- What concrete measures are taken to adapt to climate change?
- What legal tools (in particular what kind of companies: public ownership, semi-public, private or citizens ownerships) are used?
- How rural and urban authorities cooperate?
- How influent is the participation to a peer network?

Answers to these questions will hopefully help identifying good practices, inspiring for other stakeholders in different contexts.

P-3305-06

Impacts of Energy Efficiency Improvements in Transportation Sector on Future Emissions and Air Quality in Thailand

S. Garivait (1) ; P. Cheewaphongphan, (1) ; A. Junpen, (1) ; TBT. Pham (1) ; T. Boonman, (1) ; S. Chatani, (2)
(1) JGSEE, KMUTT, Environmental Division, Bangkok, Thailand; (2) National Institute for Environmental Studies, Tsukuba, Japan

As other developing countries in Asia, Thailand is accomplishing rapid economic growth during the last decades. The expanding economic activities have resulted in significant increase of energy consumption and carbon dioxide (CO2) emissions as well as heavy air pollution. Transportation, especially related to on-road, has been recognized as the top energy consuming sector since the beginning of 1990s. Also, it has been forecasted that energy efficiency improvements in this sector would contribute to the highest energy saving, up to more than 16,000 ktoe in 2030, and consequently to a significant national petroleum oil import reduction.

In this study, we evaluate the impacts of current and possible future on-road transport emissions on air quality in Thailand from 2010 to 2050. Ozone (O3) and particulate matter (PM) are selected as indicators of air quality, because they are recognized as the two major air pollutants both in urban and rural areas in the country. To this end, we first developed the Thailand's emission inventory of all sources using the Greenhouse Gas and Air Pollution Interactions and Synergies (GAINS)-Model. We develop two possible scenarios of future emissions: a scenario where technologies and legislations are the same as those applied in 2010 (BAU), and a scenario where energy efficiency improvements are applied following the national Energy Efficiency Development Plan 2012-2035 (EEDP). The EEDP scenario has been selected as it constitutes the latest policy formulated by the Thai government, and consequently represents the case that would possibly occur in 2030 onward. In order to analyze and evaluate the national air quality response to on-road transport emissions in 2010, 2020, 2030, and 2050, we set up an air quality modeling system using the Weather Research and Forecasting model coupled with Comprehensive Air Quality Model with Extensions (WRF/CAMx).

We will evaluate the model 2010 results with observations obtained from the 64 air quality monitoring stations operated by the Pollution Control Department (PCD), Ministry of Natural Resources and Environment (MONRE), Thailand. The emissions of carbon dioxide (CO2), carbon monoxide (CO), nitrogen oxides (NOx), non-methane volatile organic compounds (NMVOCs), primary particulate matter with diameters lesser than 10 microns and 2.5 microns (PM10 and PM2.5), and their components including black carbon (BC) and organic carbon (OC) in 2010 will be analyzed versus those found for BAU and EEDP in 2020, 2030 and 2050. The emission reductions from BAU to EEDP scenarios will be described and discussed to assess the effectiveness of energy efficiency measures put in place. Changes in O3 and PM from 2010 to 2050 will be presented and discussed to evaluate the impacts of future emissions on the air quality improvement.

P-3305-07

Sustainable building: Passive House combined with renewable energy

J. Grove-Smith (1) ; F. Wolfgang (2) ; B. Krick, (1)
(1) Passive House Institute, Darmstadt, Germany; (2) University of Innsbruck, Institute for structural engineering and material sciences, Innsbruck, Austria

This contribution will highlight the importance of energy efficiency as most important measure to address the impact of buildings on climate change. It further explores the correlations between energy efficiency and renewable energy in the context of sustainable use of available resources. Specific project examples and regional approaches will be presented to illustrate the potential impact, e.g. experiences from the EU-wide project PassREg supported by Intelligent Energy Europe.

Over a third of the total energy consumed in developed countries is required for operating buildings, especially to heat them. This consumption can be reduced by up to 90 % using Passive House technology, and the remaining demand can be met sustainably using renewable energy. The Passive House (PH) has proven itself as a reliable building standard with significant energy savings in a range of climates with more then 50 000 units built worldwide. Hence, the Passive House Standard is not just an attractive solution for the energy transition; combined with renewable energies it is also a blueprint for the Nearly Zero-Energy Building (NZEB) stipulated in the European Buildings Directive, which will come into effect in 2021.

In order to provide reliable guidance for the combination of energy efficiency and renewable energy (RE), new assessment categories are being introduced by the Passive House Institute:

- PH Classic: The established Passive House Standard
- PH Plus: Increased level of overall energy efficiency and some RE production
- PH Premium: Very high level of overall energy efficiency and significant amounts RE production

The approach for the assessment of PH classes specifically does not promote the simple annual offset of on-site energy demand and energy production in context only of the individual project. Direct offsetting disregards important aspects such as energy losses due to storage and space availability for RE production. The Passive House assessment is thus based on a contextualised methodology, which anticipates the energy transition and considers the building in an environment where only renewable energy is used. In this scenario, primary electricity is produced only from renewable sources. Some of this electricity can be used directly; storage capacities are however needed to buffer surplus RE energy so that it can be used during time periods with less RE availability. This temporary energy storage always implies losses, especially if it needs to bridge long-term energy compensations, e.g. seasonal effects from surplus RE supply during summer to cover RE shortfall during winter. Depending on the type of energy application as well as on the locally available RE resources, the amount of required storage varies, and thus the associated losses. Based on these interrelationships, new weighting factors are being introduced: the so-called PER factors (Primary Energy Renewable). The PER factor for domestic electricity use, for example, is comparatively low because the demand is fairly constant throughout the year and thus the share of electricity that can be used without

intermediate storage is high. Energy demand for heating, on the other hand, occurs only in winter, which calls for seasonal energy storage and thus results in a high PER factor.

The assessment approach emphasises the importance of efficiency when it comes to heating energy, which is exactly what the Passive House Standard stands for. Efficiency in this sector has the highest potential of putting energy resources (e.g. renewable electricity) to use responsibly and thus mitigating the impact of buildings on climate change.

P-3305-08

Integration Assessment of China's Energy Efficiency: Index Decomposition and Frontier Approach Applications

J. Jiang (1) ; Z. Tao, (1) ; R. Sheng, (1)
(1) Insitute of Quantitative and Technical Economics, CASS, Beijing, China

Policies for improving energy efficiency are one of the most effective ways to solve the contradiction between supply and demand of energy and to relieve environmental pressures for the Chinese Government. Because of several indicators to measure energy efficiency, resulting in different evaluation effects of policy implementation. First, this paper compares the energy efficiency measures from the supply side and demand side of energy, that is, a single element of energy efficiency and energy efficiency based on total factor productivity (TFP) estimates. In order to study the effects of energy efficiency change and its driving factors, the paper adopts index decomposition models and frontier approach, the former implies that production is effective, and the later provides a variety of frontier estimation methods, including non-parametric estimation of data envelopment analysis (DEA) and parameter estimation of stochastic frontier analysis (SFA). Based on China's latest available statistical data, the paper applies Divisia index decomposition to two different definition of energy intensity, e.g. final energy consumption per unit value added of industries, per capita residential energy consumption; then, using DEA of the total factor productivity estimates across-sector energy efficiency and empirical research on the driving factors of energy efficiency. Finally, based on model results, it presented energy efficiency policy implications at macro and industry level.

Taking into account the final energy consumption does not include the intermediate conversion process energy consumption, compared to the total energy consumption, this paper argues that final energy consumption can be used to more accurately reflect the energy efficiency of various industries, defines industrial energy intensity as ration to final energy consumption to industrial value added. Since only 6 industries have detailed statistical data on energy consumption by fuel type, this article analyzes only 6 industries energy efficiency; for residential energy, the average residential energy consumption defined as household energy efficiency. Energy balance tables of 1996-2012 in China energy Statistical Yearbook and other data, 6 industry and residential energy efficiency used Divisia index AMDI model decomposing, results showed that economic policy and energy policy factors in different periods on energy efficiency change play different roles with different contribution rates. In terms of per capita residential energy, economic development and the improvement of building energy efficiency play a major role.

Total factor energy efficiency, that evaluates energy efficiency during economic production process, is considered energy as one of production elements input with labor, and capital together, while also considered «bad» outputs, such as CO2, wastewater, that is, model development is under environment regulation of constraint. The paper uses directional distance function of DEA method to estimate industrial energy efficiency, and empirical analysis on effects factors of energy efficiency. Preliminary results show that overall China's energy efficiency tends to decline, but with the implementation of energy-efficiency policies in recent years, beginning in 2007 on energy efficiency has gone up. From the perspective of industry, increased industrial energy efficiency is quite obvious, while transportation, agriculture showed a downward trend. Analysis the economic development and foreign direct investment (FDI) of influencing factors shows a significant positive impact on total factor energy efficiency, while endowment structure has a negative effect, reflecting the disadvantages of excessive capital input. Industrial structure, energy prices and environmental regulation have the negative effects on energy efficiency, due to the imbalance of regional development in China, as well as the energy market is not perfect, this section needs further in-depth analysis.

Acknowledges: This paper was based on work supported by National Basic Research Program of China under Grant No. 2012CB955801, and Scholar Program of Innovation Project in Chinese Academy of Social Sciences (2014-2018).

P-3305-09

How to achieve climate stability in cultural heritage buildings despite climate changes

J. Käferhaus (1)
(1) Kaeferhaus GmbH, Vienna, Austria

In future we cannot afford any longer our energy bills especially in museums, castles and other historic buildings with need in climate stability especially under negative auspicious of climate change, which means warmer outdoor climate in future.

So far our one-dimensional thinking in 'repairing' wrong development by big machinery is no longer a suitable method because of lack of money and common cutbacks of energy budgets for cultural heritage.

As past has shown very old and unique artifacts in historic buildings have overcome very long periods of about 500 to 900 years - also with very warm periods - without any technical support or cooling units what so ever. The exceptional 'Altar of Verdun', a masterpiece of enamel work of 1188 in Stift Klosterneuburg, close to Vienna, as well as the unique collection of all kinds of artifacts of Carl Gustav Wrangel in the Swedish Castle of Skokloster and Ambras Castle, Innsbruck, with its famous painting gallery are best examples how big building masses keep valuable masterpieces in constant climate conditions in the sense of preventive conservation.

Big masses of historic buildings mostly give best shelter against summer heat. Hot summer outside temperatures mostly will be compensated by colder nights and the buffering capacity of huge walls. Often summer night cooling through natural ventilation will improve this sustainable effect.

In order to reach moderate summer indoor temperatures natural ventilation as well as best possible outside shading in accordance with monument authority's prescriptions will reduce indoor heat achieving acceptable indoor conditions when indoor loads also will be reduced accordingly.

Also winter heating in historic buildings could be reduced similar to low energy consumption buildings with pure radiation heat by warming up building masses. With pure radiation heat energy bills in historic buildings could be cut to half. Also with warm shell negative consequences of rising damp, mould or condensation on cold walls could be avoided as the following famous examples proof vividly:

Einsiedeln Monastery with an underground store room for precious, historic books and an old library, heated by waste heat of electronic data processing;

Museum of Fine Arts, Vienna, showroom IV, got rid of mould and cut energy bill by half;

Academy of Fine Arts, Vienna, and store room in the basement, heated by pure radiation heat got best indoor climate stability;

Church in Gerling in the country of Salzburg got a pure, damage preventive heating with solar support

Chapel in Schönbrunn Castle, Vienna, during EU project 'SMooHS' got simple wall heating, dry walls and indoor climate stability with only small winter heating.

Keywords: sustainability, energy-saving, indoor climate stability, museums climate, preventive conservation

P-3305-10

Promoting Renewable Energy in India for Sustainable Agriculture:Issues and Challenges

N. Kaur (1) ; R. Kaur (2)

(1) Panjab University, Public administration department, Chandigarh, India; (2) Panjab University, Public Administration Department, Mohali, Punjab, India

Agriculture and its allied sectors constitute as the largest livelihood provider to and also contributes to 18 per cent of GDP. India accounts for 17% of the world population but has only 4 % share in energy consumption and within this very less share of renewable energy usage.(Pillai and Banerjee 2009). The state of Punjab occupies less than 2 per cent of geographical area but accounts for 17 per cent of wheat and 11 per cent rice production in national pool. Inspite of green revolution, desertification, land degradation in the form of depletion of soil fertility ,reduction in groundwater table and furthermore less supply of electricity and wider gap in demand and power supply of power had aggravated the problems of the small and marginal farmers.

The statistical facts regarding degradation of land and non-availability of continuous power supply depicts the volatile picture of crumbling agriculture sector and its impact on sustainable livelihood. In order to address the problems, Government of India has formulated many policies and programmes at Union level and State level like National Mission on Energy Efficiency, Biomass Energy for Rural India, Solar and Wind Energy Projects .It had also set up various institutes and organisations i.e The Solar Energy Centre ,A Centre for Wind Energy Technology and Solar Energy Corporation of India. These institutes works for promotion of renewable energy resources and works with collaboration with State Governments and other allied departments.

An Attempt has been made in this paper to assess the implementation of various initiatives of Government of India to address the complex problem of degradation of environment and promotion of renewable energy resources. This Paper is written by using secondary sources. The data is collected from Annual Reports of Ministry of New and Renewable Energy, Government of India, Bureau of Energy Efficiency and Annual Reports of State Governments, books, journals, internet, websites of agencies who are involved in Energy Conservation in India. SWOT is used to assess the implementation of Promotion of Renewable resources in India.

The finding clearly reflects that Innovations for use of renewable energy must be promoted through community based financial organizations(CBFOs), co-operative societies and in order have to make access to these programmes to farmers. Well organised programmes must be organised at village level in order in increase awareness and access of the farmers. Building communication between people can only help in dissemination of techniques for using wind and solar energy for energy generation

Strategical interventions by the state through policies and programmes for use of renewable energy and active participation of farmers in implementation will pave the way towards the sustainable agriculture by using renewable resources of energy generation.

P-3305-11

Toward a Development and Co-Benefits Focused INDC for India

R. Khosla (1) ; N. Dubash (1) ; KR. Sharma (1) ; N. Rao (2)
(1) Centre for Policy Research, New Delhi, India; (2) IIASA, Energy, Laxenburg, Austria

India's response to global climate change is rooted in meeting the country's development needs, and aspires to be consistent with its sustainable development objectives. This is articulated as a co-benefits approach in the Intergovernmental Panel on Climate Change and in India's National Action Plan on Climate Change. The approach emphasizes measures which promote development objectives such as the ability to provide sufficient energy, ensure access to quality energy for all, address energy security and local environmental concerns such as air pollution, land and water use, while also yielding co-benefits for addressing climate change effectively. In light of this context, our paper examines recent projections for India's possible energy and climate futures by synthesizing and comparing the outcomes of seven policy salient modeling studies from India. The analysis illustrates the limited extent to which the available studies inform an achievement of co-benefits, that should underpin India's energy and emissions approach. It also identifies the basis for focusing on key areas of mitigation potential and those of uncertainty that require further analysis. The range of projections is assessed, including the reasons for the range. Based on an assessment of recent energy studies, the second part of the paper develops a methodology to overcome the existing limitations of the studies with respect to characterizing co-benefits. We delve into a single sector and use the case of energy efficiency in India's buildings, which has amongst the highest mitigation potentials, to showcase an approach to operationalizing co-benefits. A multi-criteria decision analysis framework is used. The results are based on a range of stakeholder views and a detailed evaluation of trade-offs (economic, technological, institutional) which can be required when selecting between different policy options. Approaching mitigation options using the showcased framework makes policy actions comparable and also takes into account questions of implementation and feasibility, which model results alone are not able to address. In examining the building energy efficiency case, the paper provides a proof-of-concept of operationalizing co-benefits which can be extended to other sectors. Importantly, it demonstrates how India's climate commitment in the form of an Intended Nationally Determined Contribution can be built around a bottom-up analysis of various domestic sectoral actions that achieve multiple objectives of development. In conclusion, this work presents an approach to climate and development for India that is a combination of an economy-wide metric (which does not rely on only one modeling output), and a set of analytical sectoral actions with a consideration of co-benefits and resulting tradeoffs. Such an approach lends robustness and credibility to India's domestic and international climate and development stance. The paper is amongst the early studies that attempts to further the literature beyond co-benefits conceptualization to its actual operationalization in the context of low carbon planning.

P-3305-12

ICT is part of climate change ! Can we reduce its impact and apply good practices and tools to others society domains ?

L. Lefevre (1) ; F. Berthoud (2) ; C. Gossart (3)
(1) Inria, Lyon, France; (2) CNRS, Lpmmc, umr5493, cnrs/ujf, Grenoble, France; (3) Institut Mines-Télécom, Evry, France

Information Communication and Technology comprises a variety of heterogeneous technical products : datacenters, networks and myriads of fixed and mobile terminal equipments.The power world consumption of ICT was around 112 GWatts in 2013 (divided between in near equivalent datacenters, networks and end-users equipments). The amount of dispersed CO2 is considered as equivalent to the aviation industry. This pollution and associated energy consumption is constantly and rapidly growing. As any other industrial technology and product, ICT equipments face a complex lifecycle from the design (with rare metals), transport, to the usage and (possible) recycling. This worldwide lifecycle is responsible to consequent greenhouses gases production.

This oral contribution will follow and present a complete life cycle approach applied to ICT :

- Most of numerical models do not take into account greenhouse gases production during design and transport phase. This talk will explore technological issues of an eco design of ICT equipments. The usage of rare metals and their impact on planet level must be taken into account. Potential impact for extended product life and repairing possibilities will be discussed. A focus will be provided on relevant examples from eco-aware industry.

- A lot of research initiatives (academic and industrial) are currently focused on energy efficiency during usage phase. This talk will review the most relevant ones and present their potential of impact at large scale. We will review

the challenges in energy monitoring of large distributed computing systems(from clouds to networks supporting BigData scenarios) and proposed associated metrics, code of conducts and best practices examples. Some rebound effects will be explored. Major hardware and software based energy saving capabilities will be analyzed and discussed.

- Worldwide, most of current ICT equipments are not (even partially) properly recycled. But properly processing electronic waste is mandatory if we want to efficiently influence ICT lifecyle. This talk will present some examples and explore the effect of applying good practices in recycling.

As second part, this presentation will also explore potential energy savings provided by ICT which can impact other society domains at large scale. From visio conference to social networking, ICT can support new range of services helping to reduce their potential impact on climate change. But these services must be carefuly exposed and analyzed in order to support a full understanding of their benefits.

An ex-ante quantification of the Energy Efficiency Gap

E. Ó Broin (1) ; É. Mata, (2) ; J. Nässén, (2) ; F. Johnsson, (2)
(1) CIRED, Nogent-sur-Marne, France; (2) Chalmers University of Technology, Energy and environment, Göteborg, Sweden

This work presents a methodology for estimating ex-ante the energy efficiency gap and key related energy system parameters. An ex-ante quantification of the, 'energy efficiency gap' is defined as the difference between market and techno-economic potentials. The ex-ante market potential is estimated from coefficients established with a top-down (econometric) modelling of energy demand using data from the period 1970 to 2005 (Ó Broin et al, 2015). The ex-ante techno-economic estimates are made using a bottom-up building stock model (ECCABS) that assesses the effects and cost-efficiency of various energy efficiency measures (Mata et al, 2013). We implement the method for the case of useful energy demand for space and water heating in the Swedish residential sector up to 2030.

Background: The true size of the energy efficiency gap remains unclear (Gillingham and Palmer, 2014). Findings from research on the energy efficiency gap could help policy makers generate social and private benefits from accelerating the diffusion of energy-efficient technologies (Gerarden et al., 2014). Although the general thrust of contemporary research on the energy efficiency gap is focusing on empirical studies that describe decision making among heterogeneous energy-users (Gillingham and Palmer, 2014) the authors of this work believe that there is also a need for system-level or sector-level studies which can give insights into key system-level parameters affecting the adoption of efficiency technologies, such as energy prices and discount rates. Furthermore, although the historical failure of the techno-economic energy efficiency potentials to be realised has been well documented ex-post, few, if any, studies have undertaken an ex-ante measure of potentials with the intent of learning from the comparison of the market and techno-economic potentials.

Results: In comparison to the level of energy use in 2005 (74 TWh), the top-down model predicts for 2030 reductions in demand of 21 TWh. The bottom-up model predicts corresponding reductions in demand of 31 TWh. Thus, there is an energy efficiency gap calculated of 10 TWh in 2030. An implicit discount rate of 10% would render the results from the bottom-up modelling identical to those from the top-down modelling. Conversely a doubling of the historic rate of support for technology diffusion and conservation through, for example, support schemes and regulations, would render the results from the top-down modelling identical to those from the bottom-up modelling.

Increasing energy prices as a policy measure, as implemented in this work, does not lead to significant additional savings, as shown by the top-down model. The combination of high energy prices and a long-term price elasticity of -0.29 would ceteris paribus result in a decrease in demand of only 4 TWh by Year 2030 as compared to a low energy price scenario. This suggests that while higher energy prices may achieve a global carbon target or cover the requirements of a Pigovian tax, at the residential sector level they are not so effective. The findings of this work i.e. the magnitude of the implicit discount rate; the price elasticity; and the size of efficiency gap; provide useful guidelines for policy formulation to meet individual country and regional climate and energy goals.

A design matrix for energy sustainability of buildings with double skin envelopes in warming climates in the tropics

U. Rajapaksha (1) ; H. Rupasinghe (1) ; I. Rajapaksha. (1)
(1) University of Moratuwa, Architecture, Moratuwa, Sri Lanka

Adapting buildings to extreme temperatures due to climate change, demands a collaborative effort to deal with climate, occupants and buildings. A current technology to assist with this approach is called "bio-climatic design approach". It is seen as an appropriate basis for climate responsive design which involves the way buildings filter the climate for occupants' comforts. This approach has gained recognition for the application in medium scale buildings in moderate climates. However, this is less researched and problematic due to indoor overheating potential in warm humid climates. Thus needs to be investigated in the effort of adapting buildings to warming climates.

The project will contribute to establish that building design can play a key role in combating extreme temperatures involving a shift towards new bio-climatic design solutions focusing on passive climate control with form and fabric of buildings. The method used in this research reviews trends in predicted climatic behaviors in tropics, and evaluates critical practice exemplars found in local climatic zones in Sri Lanka. The project presents a generalized matrix of evidence-based interventions from associations that publicize case studies and literature exploring the potential for adapting buildings to predicted extreme climates. Use of onsite investigations, and advanced computer-based Design-Builder simulations for assessing and predicting adaptive capabilities of buildings will become essential components of the method.

Innovative potential of envelope dependency, which optimizes the building-climate interplay for reducing the need for energy in building operation, is highlighted with the matrix. This is more complex and critical when envelope dependency is not fully resolved in buildings located in the tropics where environmental loads external to the buildings contribute more significantly to the thermal load profiles of buildings. Unresolved envelop dependency contributes to indoor overheating in many ways. The paper takes this challenge by developing a cross-dimensional performance approach of buildings focusing on the dependency of the microclimate, plan form, sectional form and envelope.

An integrated characterization of energy sustainability of buildings is proposed based on the matrix, which is a conceptualization of built environment as a building-climate-occupancy system. The matrix aims at strengthening envelope dependency of a building considering it as a bio-climatic entity contributing to

sustainability and low emission building practices. One holistic performance indicator is used for evaluating such contribution, so expressing the climate modification – the reduction from ambient to internal air temperature. Discussion on the efficacy of the matrix shows that it works as an empirical tool supporting to gaining an insight in resolving any dualities associated with performance within the envelope dependency.

The research found that most certified green buildings in the country are either of core dependent or envelope dependent but highly energy intensive. Methodology involved few field investigations of selected certified green buildings using data loggers that collected air temperature, radiation, wind flow and envelope surface temperatures and the use of a computer based Design-Builder simulation program. Empirical findings showed the criticality of the problem and unresolved duality associated with envelope dependent forms – heat gain Vs passive influence. The buildings are found to be highly energy intensive with an Energy Utility Index around 196-260-KWh/m2/a although they are certified either as Gold or Platinum. Research further showed indoor-overheating situations when buildings were allowed to run free without air conditioning.

The simulation program used to redefine the energy sustainability of the most critical case building introducing resolved envelope dependency involving a high thermal mass double skin external envelope and a vertical atrium for thermal buoyancy effect. Calibrated simulation results provide evidence of passive cooling with internal air temperatures in all multi levels of the building moving 2-3.5 degrees C below the ambient levels due to improved and resolved envelope dependency with heat removal, stack force and night ventilation. Findings showed a reduction of EUI up to 98 KWh/m2/a suggesting that the matrix can play a positive role in innovating envelope dependency for emission reduction.

P-3305-15

The importance of the sun as clean source of energy in the design of cold storage for health care facilities in africa

MRD. Seke (1)
(1) University of South Africa, Mechanical and Industrial Engineering, Gauteng, South Africa

Sun is the main source of energy to several planets, especially to the Earth and its inhabitants. It lightens the surface of the Earth free of charge, and its energy is clean.

However, we do not fully benefit from the sun's energy which is precious to the humanity and can be used as the best source of electricity. The solar energy that the Earth's atmosphere, seas, forests and soils benefit is more than billions of Joules per year.

Africa is a place of hope and has a better position in term of climate change but its population, in majority, is poor and exposed to variable viruses, diseases and threats which are still killing due to lack of access to cure and drugs of quality.

In laboratories where medicines are manufactured and in hospitals where human bloods are collected and stored to both improve and better the conditions of patients, we need their good preservation either in transit or in storage.

In rural and urban areas, solar powered cold room units would be of wide benefit to the healthcare facilities.

This study is based on theoretical analysis and calculations of Solar Powered Cold storage for healthcare facilities in Africa, as well as some comparisons made between different sources of energy to keep thermolabile medicines and blood bags in good conditions according to the pharmaceutical guides and health standards.

As the future of the Earth depends on its ecosystem, the gratuity of the solar energy is the precious fuel which led our design project.

The methodology used in the present study employs both qualitative and quantitative research techniques.

P-3305-16

Strategic policy packages to deliver energy efficiency in buildings – theoretical analysis and international evidence

S. Thomas (1) ; V. Aydin, (2) ; D. Kiyar, (2) ; L. Tholen, (2) ; M. Venjakob, (2)
(1) Wuppertal Institute for Climate, Environment and Energy, RG Energy, Transport and Climate Policy, Wuppertal, Germany; (2) Wuppertal Institute for Climate, Environment and Energy, Wuppertal, Germany

Energy efficiency in buildings and appliances has the potential to halve the energy consumption and greenhouse gas emissions from that sector by 2050, despite growth in building and appliance stock. However, this potential will not become reality without policy support, due to complex market chains with many types of actors, and a plethora of barriers they face. What are, then, effective packages of policies and measures to stimulate energy efficiency in new and existing buildings, and appliances? In recent research, we have addressed the question in a systematic way – by combining theoretical evidence on what policy support markets need, and an international comparison on which packages of policies have worked well.

On the theoretical side, the analysis starts with the barriers but also market-inherent incentives that the different types of market participants face. This enables to derive a recommended package combining the types of regulatory, economic and other policies and measures the actors need to overcome all these barriers and strengthen incentives. On the empirical side, evidence on model examples of good practice for policy packages has been collected and their design and impact compared, to check if advanced countries have indeed used the combination of policies we derived from the actor-centred analysis. Finally, the model examples, lessons learned, and the preconditions for their transferability are used to validate the generic policy package identified in the theoretical analysis.

In this way, we found that the recommendable policy package for new buildings is similar to the well-known one for appliances, but with the objective to mainstream nearly zero energy buildings. By contrast, the task for existing buildings is two-dimensional – increasing the depth of renovation first, to savings of 50 to 80%, and then the rate of energy-efficient renovation to 2% or more p.a. – and so the policy package needs more emphasis on individual advice, incentives, and financing. The paper will present the recommended packages as well as a comparison of existing national policy packages from Denmark, Germany, Singapore, Tunisia and California (USA) and what we learned from it for effective packages and implementation.

P-3305-17

Solutions for the improvement of energy efficiency in historic buildings and districts preserving their heritage value

A. Vivarelli (1) ; A. Bernardi (1) ; F. Becherini (1) ; MC. Di Tuccio (1) ; L. Pockelé (2) ; T. Broström (3) ; E. Schoenberger (4)
(1) National Research Council, Institute of atmospheric sciences and climate, Padova, Italy; (2) R.E.D. srl, Padova, Italy; (3) Uppsala University, Gotland, Sweden; (4) Fraunhofer Institute , Building physics ibp, Holzkirchen, Germany

Buildings have a significant impact on energy use and environment. Growth in population, increasing demand for building services and comfort levels, together with time spent inside buildings, assure that the upward trend in energy demand and CO2 emission will continue in the future. This situation is strongly related to the emissions from existing buildings, as 50 million buildings throughout Europe are 50 years old or more. Europe can become the leader in CO2 emission reduction by applying innovative energy efficient solutions to its built historic and cultural heritage. However, most of the current developments in energy efficiency typically address new constructions and individual buildings without considering on one hand the unique problems of historic structures and on the other hand the urban dimension.

These issues are faced within the research project EFFESUS (Energy Efficiency for EU Historic Districts' Sustainability), funded by the European Union 7FP (Grant Agreement no.

314678). Its main objectives are: i) the study of measures and tools to improve the energy efficiency of historic buildings and districts whilst protecting and preserving their cultural and historical values; ii) the development of new technologies as well as a software tool to support decisions on improvement measures. In particular a methodology is being developed for assessing the impact of implementation and selecting the most proper energy efficiency interventions in historical buildings and districts whilst ensuring the compatibility with their heritage values. This methodology is based on indicators, i.e. qualitative and/or quantitative information associated to the retrofit process under observation, which allows to verify the accomplishment of the goal or the related impact. These indicators are evaluated on a five point scale both for the initial conditions of the existing stock and for the conditions after the implementation of the interventions. The main output will be a Decision Support System (DSS), where the possible retrofit measures are prioritized in function of their potential impact, with the aim to assist stakeholders in decision-making. The DSS will be based on real data including also climatic change predictions.

The applicability of the technological developments, as well as the suitability of the DSS are being demonstrated in five case studies. In particular the following innovations are being tested: new thermal insulating mortars for use as plaster and render in Benediktbeuern (Germany); radiation selective coatings for outdoors in Istanbul (Turkey); blown-in aerogel for use in cavities behind existing wall finishes in Glasgow (United Kingdom); windows with improved insulation and ventilation, as well as intelligent indoor climate solutions through energy management algorithms in Budapest (Hungary); implementation of new control strategies to decrease the primary energy demand in historic buildings and districts in Santiago de Compostela (Spain).

The preliminary results of the performance assessment of the new technologies developed in EFFESUS will be presented mainly in function of the indoor environmental conditions and operational energy indicators on the basis of the monitoring activities carried out in the above mentioned five case studies. These activities have been launched in function of the readiness of the developed technologies and are now running for several months. The parameters, defined in function of the technology to be validated, are currently being measured simultaneously in a test area and in an equivalent reference area for reasons of comparison. The only exception is in Benediktbeuern where the comparison is performed before and after the application of the thermal insulating mortar. In particular the thermo-hygrometric conditions (temperatures, relative humidity, and air flow) and the energy related parameters (heat flows, energy consumption, associated cost of the energy, etc.) are being studied. These data are being used to assess the performance of the innovative solutions in terms of: indoor comfort expressed as PMV and PPD values (EN 15251), air quality (CO2 levels, ventilation rate), percentage of reduction of primary energy demand, reduction in energy consumption per m2, Kg CO2 emissions/m2, contribution of RES to the districts and buildings energy demand for heating/cooling, district heating contribution to the buildings/district energy demand.

P-3305-18

Fixing or transferring environmental problems in the transport sector?

HJ. Walnum (1)

(1) Western Norway Research Institute, Environmental group, Sogndal, Norway

Worldwide, the transport sector produced 7.0 GtCO2eq of direct greenhouse gas (GHG) emissions, which corresponds to approximately 23% of the total energy-related CO2 emissions. Regionally, such as in the EU, the transport sector was responsible for 25% of the energy-related GHG emissions. Although the recently adopted EU target is to reduce GHG emissions levels by 80%-95% from 1990 levels by 2050, the European Commission stated that the goal for the transport sector is 60% because of its complexity. From 1970 to 2010, the direct energy use associated with transport has grown by 250% worldwide—a growth rate that is higher than any other sector.

Based on the above it is evident that the current transport systems are not sustainable. Without a substantial change in governmental policy, this trend will continue. The scope of the thesis is to examine how rich countries, such as the U.S as well as in countries and regions in the EU and the (OECD), can achieve sustainable mobility, taking into account the problems related to various transfer effects. A reason that sustainable mobility has not been achieved could be that transfer effects have not been fully understood by policy makers nor in the sustainable mobility discourse (Holden, 2012). For example, increased technological efficiency and innovation are frequently discussed as strategies to mitigate climatic gas emissions and energy use in the transport sector. However, the idea of a technological and policy quick-fix is highly problematic because often a proposed solution by policy, innovation or technology only transfers the environmental problem to other life cycle stages, to other emissions categories, to other countries, or to increased demands across levels from the micro to the macro level and this situation is a paradox that needs to be addressed in future planning.

This abstract examines three «transfer effects»: 1. Rebound effects, 2. Environmental trade-off effects and 3. Geographical transfer effects. The following research questions are addressed in the covering essay:

- Are transfer effects the reason of why energy use and Greenhouse gas (GHG) emissions in the transport sector keep raising?
- What are the similarities and differences between the transfer effects?
- Why have such effects been overlooked in policy making?
- What could be done to mitigate them?

Studying rebound effects addresses how efficiency measures taken at the micro level do not necessarily lead to society-wide reduction. Despite improvements in intensity of grams of CO2 per kilometer for passenger cars in the EU and US, energy reduction has been outweighed by increased total kilometers travelled and sales of larger vehicles (Holden, 2012). This might be explained by rebound effects concerned with systemic and behavioral responses. For example, the cost savings from buying a fuel efficient car could be used to drive farther (a direct rebound effect) or to purchase other energy consuming activities. To fully understand rebound effects, I argue that it is necessary to take an interdisciplinary approach.

Life-cycle and energy-chain analyses, which could be considered studies of indirect rebound effects, look at products from cradle-to-grave. Both compare products at the micro level and identify environmental hotspots during production and could be used to study fuels and transport systems or to compare transport systems.

How we account for environmental transactions affects transport-emission results. Currently, international air transport of people and goods and international transport by ships are omitted from GHG-emissions inventories. They are based on the so-called Kyoto protocol way or national demarcation of accounting for GHG emissions. This implies that some of the fastest growing areas are overlooked in available GHG-emissions statistics, which are based on national territories.

P-3305-19

Reducing Methane Emissions Using a Fixed Bed Reactor Under Dynamic Condition

E. Wardhono (1) ; M. Effendy (2)

(1) University of Sultan Ageng Tirtayasa, Chemical Engineering, Cilegon, Banten, Indonesia; (2) Surabaya state university, Mechanical engineering, Surabaya, Indonesia

The production oil and gas is the largest human-made source of methane emissions in Indonesia and the fourth largest human-made source of methane emissions globally. Methane is referred to as a potent greenhouse gas because it has a Global Warming Potential, GWP of 21. This means that methane is 21 times more powerful than CO2 at trapping heat in the atmosphere over a 100-year period. Methane emissions primarily result from normal operations, routine maintenance, leaks and system upsets from connections between pipes and vessels or to valves and equipment. Reducing these emissions can have significant environmental and economic benefits.

The catalytic treatment is one of the most reliable alternatives to reduce of methane emissions. However, due to the concentration of emitted methane is low,

the flow rate changes over time and the temperature is ambient. The conventional treatment using once-through direction of fixed bed reactor operating under steady state conditions is less appropriate. For the methane content of 0.5%-v, the adiabatic temperature rise is approximately 1150C. As a result, extra external energy is required to increase the temperature of the feed gas. Reverse flow reactor was applied to overcome this problem. To increase of methane conversion may be induced by changes of the reaction rate over Pt/g-Al2O3 catalyst surface due to dynamic system operated at proper time scale. Therefore, there are two important aspects to be considered; (1) reactor design and (2) operation method. The aim of this study was to develop a new method in order to determine the reaction mechanism and rate-controlling step that occur in one dynamic cycle. The model reaction used was methane oxidation using 0,3%-wt Pt/γ-Al2O3 operated under dynamic conditions. At which the pattern of the reverse flow reactor was approached using a once-through direction of fixed bed reactor with composition modulation. It was based on the similarity of the reactor's response measured at the outlet, which is usually used for sampling.

The method used in this study was a steady state approach consisting of 4 stages; (1) the first stage was to determine the homogeneity of the continuum model of a fixed bed reactor that will be used to validate the model reaction mechanism and the rate-controlling step in dynamic conditions. (2) The second was determination of the model reaction mechanisms and rate-controlling step of the steady state condition. (3) The third was to identify the influence of the perturbation on response of the reactor in term of conversion in the dynamic condition. Furthermore, the validation of the model reaction mechanism obtained at steady state on methane conversion obtained in the dynamic operation was performed. (4) The fourth one was to establish the model reaction mechanisms and rate-controlling step that occurs in the dynamic conditions. This identification was accomplished by taking some perturbation points in term of CH4/O2 feed gas concentration ratio involved in the dynamic range to be performed the steady state experiment. The result of this identification was subsequently conducted the segmentation in order to obtain the mechanism change plots and rate-controlling step in one cycle period. Furthermore, the validation of the model reaction mechanism and dynamic kinetic parameters with dynamic experimental data were indispensable.

The influence of the perturbation on response inducing the dynamic conditions in the reactor can be expressed by the ratio of the feed gas concentration of CH4/O2 with methane conversion obtained. The use of the model reaction rate of Langmuir-Hinshelwood on pseudo-homogeneous model of mass for 1-D could not fully describe the characteristics of methane conversion obtained through experiments in the dynamic conditions. The deviation in term of error obtained was very large, i.e. 40%. In one cycle of dynamic operation, there were three mechanisms of reaction involved, i.e. the total oxidation of methane to CO2 and H2O, the partial oxidation of methane to CO2 and H2, and the decomposition of methane to C and H2O. The transition of reaction mechanism in one cycle of dynamic operation was based on the ratio changing of the concentration of CH4/O2 due to feed composition modulation applied.

P-3305-20

Mapping and Modelling multiple benefits of energy efficiency and emission mitigation in China's cement industry at the provinces level

S. Zhang (1) ; E. Worrell, (1) ; W. Crijns-Graus (1)
(1) Copernicus Institute of Sustainable Development, Department of Innovation, Environmental and Energy Sciences, Utrecht, Netherlands

China's cement industry is the second largest energy consumer and key emitter of CO2 and air pollutants. It accounts for 7% of total energy consumption in China and 15% of CO2, 21% of PM, 4% SO2 and 10% of NOx of total emissions, respectively. Provincial disparities in energy consumption and emissions of CO2 and air pollutants in China's cement industry are rarely quantified. In this study, an integrated assessment model including provincial energy conservation supply curves (ECSC) (which can shows the cost-effective and technical energy saving potential per province), the Greenhouse Gas and Air Pollution Interactions and Synergies (GAINS) model (which can be used to calculate air pollutant emissions), and ArcGIS (a geographical information system (GIS) with elaborated spatial functions) is developed and used to assess the potential of energy savings in terms of emission mitigation of CO2 and air pollutants and multiple benefits of energy efficiency measures at the provincial level during the period 2011-2030. The results show significant heterogeneity across provinces in terms of potential of energy saving as well as emission mitigation of CO2 and air pollutants (i.e. PM, SO2, and NOx) in the next two decades. Seven provinces (i.e. Shandong, Sichuan, Jiangsu, Guangdong, Zhejiang, Henan, Hebei), six of which are located in the central- and east- China, account for 47% of the total energy saving potential, equivalent to 26% of baseline energy use in 2030. The energy efficiency measures can help decrease 38% of CO2, 23% of SO2, 33% of NOx, and 26% of PM emissions in these seven provinces by 2030. This indicates that the multiple benefits should be considered when local policy makers or end users make decisions whether to use energy efficiency measures to solve environmental issues.

3306 - Transitioning from fossil fuels and avoiding lock-ins

ORAL PRESENTATIONS

K-3306-01

The role of fossil energy in conventional and carbon-constrained worlds

D. Mccollum (1)
(1) International Institute for Applied Systems Analysis (IIASA), Energy Program, Laxenburg, Austria

The transition between today's fossil-dominated energy system and one based on low-carbon supply sources will be a decades-long process. Getting from here to there will present a number of challenges, not least of which are phasing out of the ubiquitous fossil fuel infrastructure that has been built up over the past century and a half and providing the necessary incentives for foregoing the ample deposits of fossil energy lodged within the Earth's crust. In this regard, future advancements in fossil technologies, fossil resource endowments and the long-term development of fossil fuel prices are important factors that will critically influence the nature and direction of the global energy system.

This talk will summarize recent literature emanating from the global integrated assessment modeling (IAM) community which has explored the role of fossil energy (coal, oil, and natural gas) in its various energy and emissions scenarios for the twenty-first century (both in low-carbon pathways and in fossil-dominant counterfactuals). The studies to be discussed principally include those from multi-model inter-comparison projects, such as EMF27 (Energy Modeling Forum), AMPERE (Assessment of Climate Change Mitigation Pathways and Evaluation of the Robustness of Mitigation Cost Estimates), LIMITS (Low climate IMpact scenarios and the Implications of required Tight emission control Strategies), and RoSE (Roadmaps towards Sustainable Energy futures), among others.

The diverse modeling frameworks employed in these studies highlight large uncertainties in the likely development of fossil resource consumption, trade, and prices over the course of the twenty-first century and under different climate policy frameworks. A seemingly robust finding across the suite of IAMs is that the upper end of cumulative fossil fuel consumption foreseen by the models is well within the bounds of estimated recoverable reserves and resources. Hence, fossil resource constraints are, in and of themselves, unlikely to limit future GHG emissions this century. And while a vast amount of unconventional gas resources have recently become cost-competitive and could alter the future energy landscape,

the climate may be no better off because of it, given the emissions impacts elsewhere in the energy system. Further, analyses show that globally agreed mitigation policies could lead to a major reallocation of financial flows between regions, in terms of expenditures on fossil fuels and carbon; carbon leakage could become an issue in fragmented policy environments; and carbon lock-in and the eventual premature retirement of fossil infrastructure are realities to be mindful of if major mitigation efforts are delayed beyond 2020.

K-3306-02

The market and lock-in effects of new fossil fuel infrastructure, and the need to integrate supply- and demand-side climate policies

P. Erickson (1) ; L. Michael (1)
(1) Stockholm Environment Institute, Seattle, United States of America

Climate policy and analysis often focus on energy production and consumption, but seldom consider how fossil fuel supply and transportation infrastructure shape energy systems. US President Obama, among others, has recently brought these issues to the fore, stating that he would only approve the Keystone XL pipeline, connecting Canadian oil sands with US refineries and ports, if it does not significantly increase global greenhouse gas emissions. In this presentation, based on our paper in Nature Climate Change (doi:10.1038/nclimate2335) we show how such infrastructure investments, through market effects, could affect fuel use and global GHG emissions on a scale similar to national policies aimed at reducing fossil fuel consumption and GHG emissions. We contend that in order to increase the effectiveness and efficiency of meeting climate protection goals in the coming decades: (1) examination of supply-side investments and their implications for fuel markets, consumption, and emissions, needs to be undertaken widely and systematically; and (2) policies addressing the supply side need to be considered and integrated with more typical, demand-side climate policy. The presentation will synthesize insights from recent literature (e.g., Erickson and Lazarus 2014, Collier and Venables 2014, Faehn, Hagem, et al 2013, McGlade and Ekins 2015), and suggest areas for further inquiry and action for research and policy communities.

Commitment accounting of CO2 emissions: long-term consequences of current investments

S. Davis (1)
(1) University of California, Department of earth system science, Irvine, CA, United States of America

Any limit on future global warming is associated with a budget of cumulative CO2 emissions, such that annual global emissions must ultimately approach zero. Yet, unless retrofitted or retired early, currently new and existing fossil fuel-burning infrastructures commit us to future CO2 emissions over their expected lifetimes. I will highlight the results of two recent publications, Davis and Socolow [1] and Raupach et al. [2], which together describe trends in 'committed' emissions related to energy infrastructure and how these commitments compare with the remaining budgets of emissions under different climate targets and the options for sharing this budget among nations. Next, I'll show how the expansion of economic fossil fuel reserves (e.g., by exploration, innovative extraction methods, or improved transport infrastructure), may also represent commitments to extract and burn these fuels [3]. Finally, I'll discuss the required carbon intensity of new investments given the constraints of a cumulative carbon budget and existing capital stock, with explicit comparisons to a range of top-down energy-emissions scenarios. The combination of such top-down global scenarios and bottom-up appraisals of real-world trends may inform policies that minimize international carbon leakage and carbon lock-in (or stranded assets).

O-3306-01

A global abundance of natural gas increases the challenges of climate change stabilisation

J. Hilaire (1) ; N. Bauer (1) ; E. Kriegler (1) ; L. Baumstark (1)
(1) Potsdam Institute for Climate Impact Research, Potsdam, Germany

The US economic gains and carbon emission reductions associated to the recent US shale gas boom are frequently mentioned to portray natural gas as a bridge technology to a low-carbon future. Having half the carbon footprint of coal, natural gas seems indeed an attractive carbon mitigation option. As a result, several countries including China, India, Mexico, Poland and the UK are seeking to take advantage of the late technological improvements (e.g. hydraulic fracturing, horizontal drilling ...) and replicate the US development. If successful, this collective endeavour could bless the world with a global abundance of natural gas that would lead to a ''golden age of gas''. Regular upward revisions in natural gas resources – and decline in associated extraction costs – support the possibility of such future. However, should global warming be limited to below 2°C with high probability, this global gas bonanza would have to occur simultaneously with a global energy transition aiming at reducing worldwide greenhouse gas (GHG) emissions to zero or below by 2100.

Economic theory suggests that the global energy transition can be efficiently orchestrated by setting a global price on carbon emissions. Nonetheless a global carbon price regime is still subject to fierce debates during climate negotiations and will most likely be implemented with a several year delay. Currently, the climate political landscape consists of a mosaic of regional carbon markets and national technology policies. In this context, can a global abundance of natural gas facilitate the global energy transition by reducing its costs, fostering the deployment of low-carbon technologies and reducing CO2 emissions?

We address this question by generating various scenarios with a global model of the energy-economy-climate system. These scenarios differ along two dimensions: the degree of natural gas supply and the delay to implement a global carbon price consistent with a 2°C target. Our results show that seeking to expand natural gas supply whilst trying to protect the climate would bring short-term benefits such as higher GDP, lower electricity prices and reduced short-term mitigation costs. However it would also increase medium- and long-term mitigation costs substantially, owing to larger CO2 emissions and hence higher CO2 prices. Differences in aggregated discounted consumption losses over 2011-2100 between an abundant-gas and a conventional-gas world amount to more than 0.25 percentage points.

Interestingly, living under a "gloden age of gas" increases the opportunity costs of climate change mitigation, partially because of lock-ins in natural gas technologies. This can be seen by looking at differences in GDP growth reduction. Even though GDP growth is only marginally reduced by an increase in natural gas supply over 2015-2030, this reduction becomes much larger over 2031-2050. More importantly, a delay in comprehensive climate policies leads to more than a quadrupling in GDP growth reduction over 2031-2050 compared with immediate climate action. Consequently not only climate change stabilisation becomes more challenging to achieve in a gas-abundant world but it is even more difficult when climate proection is delayed.

South Africa's planned coal infrastructure expansion: drivers, dynamics and implications for carbon emissions

J. Burton (1)
(1) University of Cape Town, Energy Research Centre, Cape Town, South Africa

South Africa has both domestic climate mitigation objectives and has pledged internationally to reduce its

emissions by 34% and 42% below a business as usual baseline by 2020 and 2025 respectively. The peak of this emissions trajectory has already almost been reached. While mitigation policy has filtered into electricity planning processes, limiting demand for coal in the longer-term, both the state and private actors are at the same time investing (or planning to invest) in supply side coal-related sectors. Besides Eskom's large-scale coal-fired power plants currently under construction and the possibility of extending the lives of Eskom's older coal-fired plants, a coal-based independent power producer procurement programme has recently been announced. This power infrastructure depends on maintaining security of coal supply.

Geological factors, domestic market impacts of past high coal prices and other cost increases in the Central Basin (where most coal is currently mined) have lead, however, to serious security of physical supply and affordability concerns for Eskom in the medium to long-term. Coupled with political support for expansion of the coal sector both domestically and for export, new investments in the Waterberg coalfield are widely viewed by Eskom, the coal industry and parts of the state as the long-term future of the South African coal industry.

The presentation will briefly outline the implications of planned supply side fossil fuel investments in South Africa, using the results of an extraction-based emissions analysis of the coal industry's South African Coal Road Map scenarios.

Under these scenarios it is likely that South Africa will exceed its carbon budget to 2035. Furthermore, meeting coal demand depends on several upstream investment decisions that are being taken without consideration of either the direct impacts on emissions or the indirect effects on domestic or export coal prices, in particular new rail investment decisions. Such decisions result in increasing economic and financial lock-in of current supply systems.

Coal has historically been, and remains, key to the political economy of South Africa. Part of the explanation for the support for the Waterberg coalfield expansion lies in economic arguments put forward by the industry, which has argued that coal from the Waterberg is significantly cheaper than current and future supplies in the Central Basin. However, evidence for this claim remains limited. More broadly, political support remains important; both in supporting coal-fired electricity, liquid fuels and upstream coal mining in general, and for the Waterberg expansion in particular.

Both the major mining houses and several junior miners are connected to the new political elite; either through large-scale Black Economic Empowerment (BEE) deals, or through direct ownership interests in smaller firms. BEE policies, including Eskom procurement and rail and port access designed to encourage black-owned junior miners, contribute to linking the industry to actors in the ANC and to actors in government who are supportive of BEE as an economic policy. The Waterberg coalfield furthermore provides new investment opportunities for the mining industry, thus providing a focal point around which rail, BEE and coal interests have coalesced and leading to socio-political lock-in.

There is a mismatch between the political economy of the coal (and broader energy) sector and the mitigation efforts of certain parts of the state (based on the implementation of a carbon tax and on sectoral carbon budgets to be imposed on the economy). Despite numerous technical assessments of demand-side policy options to reduce emissions, current institutional arrangements reflect the power of coal-based economic and political interests in Eskom, Transnet, the state and politically connected elites. It appears that transformational energy policy that reduces the extraction of coal is limited by the political make-up of post-apartheid South Africa. Without the integration of supply side investment decisions with future carbon constraints, the country runs the risk of further exacerbating the systemic lock-in of South Africa's high emissions trajectory.

Unconventional Gas in the Context of Annex 1 Climate Policy

J. Broderick (1) ; K. Anderson (1) ; R. Wood, (1)
(1) Tyndall Centre for Climate Change Research, School of Mechanical, Aerospace and Civil Engineering, Manchester, United Kingdom

Recent work has illustrated the geographic distribution of 'unburnable' fossil fuel reserves under climate policy constraints (McGlade and Ekins, 2015). Natural gas is often referred to as a transition fuel but typically with little specific qualification of quantities of consumption, rates of transition and end point targets. All of these aspects can be informed by a national cumulative emissions budget approach (e.g. Friedlingstein et al, 2014). We therefore consider national and temporal dimensions of unconventional oil and gas production and consumption taking the UK case of shale gas development as an illustrative example. Recoverable quantities are found to be susbtantially lower than anticipated in UK energy policy discourses. The evidence and arguments presented are largely applicable to other unconventional gas resources such as coal bed methane (CBM), underground coal gasification (UCG) and shale oil, in other Annex 1 (industrialised) nations.

Shale gas and shale oil are fossil fuels produced by hydraulically fracturing, 'fracking', impermeable shale strata. Gas and oil residing in these and similarly impermeable reservoirs, such as coal measures, are termed "unconventional" resources. Technological developments in this area have substantially increased expectations of recoverable fossil fuel resources (McGlade et al 2013). The scope for unconventional oil and gas production and consumption in Annex 1 countries to contribute efforts to avoid the 2°C characterisation of dangerous climate change has been outlined to date (Broderick and Wood, 2014). Under reasonable assumptions of national and sectoral apportionment, the simple arithmetic of emissions budgets make it clear that Annex 1 nations require a transition to a low carbon energy system in the next two decades (Anderson and Bows, 2011). This limits the time available over which unconventional resources may be extracted and combusted and hence quantities likely to be recovered under a stringent climate regime. We quantitatively illustrate this in relation to existing UK regulations, structured by the Climate Change Act (2009), and the emissions budgets arising. Conditions for oil and gas export, including a quantitative assessment of the prospects for carbon capture and storage (CCS), are then discussed in relation to global emissions budgets and recent developments in the US energy industry.

Energy security and climate policies: An unequal marriage

J. Jewell (1) ; A. Cherp (2)
(1) International Institute for Applied Systems Analysis, Laxenburg, Austria; (2) Central European University, Department of Environmental Sciences and Policy, Budapest, Hungary

The quest for energy security and concerns over climate change caused by greenhouse gas emissions are top energy policy priorities worldwide. To complement the growing body of literature on energy security implications of climate change mitigation, this paper examines the two-way interaction between pursuing energy independence and reducing greenhouse gas emissions. Using 5 state-of-the-art energy-economy models and 6 long-term global scenarios, our analysis calls for closer and more thoughtful coordination between these policy priorities. First, we show that the pursuit of ambitious yet realistic energy independence targets would result in an insignificant reduction of greenhouse gas emissions (5%–15% over the 21st century compared to the Baseline) that will not be sufficient for achieving even the current modest climate pledges. In other words, the climate will not be saved as a 'side-effect' of energy security policies. Second, fulfilling the existing climate pledges would not significantly affect energy imports of major economies though pursuing stringent climate stabilization targets would radically reduce these imports. Third, the modeled energy independence targets could be achieved at policy costs comparable to those of the current climate pledges but ten times lower than those of the stringent climate policies. In other words, advocates of cost-efficient energy independence may have little reason to support either stringent climate policies (because of their significantly higher costs) or current climate pledges (because of their relatively minor impact on global energy.

P-3306-03

Key Issues in Energy, Climate Change and Environment

C. Lee (1) ; A. Liwayway (1) ; D. Best, (1) ; C. Hood, (1) ; E. Levina, (1)
(1) International Energy Agency, Paris, France

Policies that respond to climate change and other environmental issues will increasingly impact the development of the global energy sector. The transition to low-carbon economies will need to be carefully managed, as the provision of secure, affordable energy is critical for economic growth and social development. More than ever, there is a need for a fuller understanding of the opportunities to promote synergies between energy, environmental and climate policies.

Energy, Climate Change, and Environment: 2014 Insights helps address this need with indepth analysis of selected policy questions at the energy-climate interface, including:

- How can we accelerate the transition from (i.e., "unlock") existing high-emissions infrastructure?
- What are the best ways to design cost-effective emissions trading systems that fit with national circumstances?
- What are some alternative energy-specific metrics that support near-term emissions reductions and long-term decarbonisation of the energy sector?
- And, in the special focus of this report, can curbing local air pollution help reconcile energy priorities with environmental sustainability, including greenhouse gas mitigation?

Addressing these questions will help inform decisions that can boost decarbonisation of the energy sector while taking into account security and economic objectives. This report also features an update of key energy and emissions statistics for ten world regions that should interest energy practitioners and climate policy makers alike

P-3306-04

The 3 CRISIS: EEE (ENERGY, ECOLOGY AND ECONOMY)

G. Quartieri (1) ; E. Chavez (2)
(1) IUSR http://www.unisrita.it, PHYSICS, SAN PIETRO INFINE (Caserta), Italy; (2) National University of San Marcos, Faculty of Veterinary Medicine, OIKOS Asociation., Lima, Peru

Our common future is conditioned by three World crisis: Energy, Ecology and Economy ones. To face them it is necessary to implement an inter disciplinary approach capable to find the interlink of these three issues. The present paper wants to apply system Σ approach to discover the possible connections among energy, ecology and economy disciplines. Those linkages should be able to propose change and unveil possible hidden interlinks.

System approach implies define, operation and control of overall and global Σ system defined by its structure SΣ, its specific parameters PΣ and its variability VΣ. The system Σ depends upon EEE: Σ = f (E, E, E,). Out of the three crisis , the first and most important one is the energy that has a urgent need for real and right definition of cost, relation, availability, and proportion among fossil (oil, gas and coal), renewable and nuclear sources. Second one is the ecology with an holistic approach to the ecosystem services and their importance in the sustainability due to its inherent importance in different climate scenarios.

The third one is the economy. In this global context, paramount is the economy deception that acts and works as director. Knowledge and information economy appears to be the most probable way to cope with common future overcoming the economy deception phase and present difficulty. Quality of life has been improved according to almost exponential pattern during past ages. However, human quality of life is nowadays strongly influenced by the Standard Environmental Impact Factor I = PxAxT, in different Countries (super-developed, developed and under-developed and so on) of the World. Same approach is valid for all the biodiverse beings. There is a strong need of interlinks among these three main concepts of EEE. From the history point of view the classical main causes of World degradation, by starting with population reduction, have been wars, pestilences and famines. To cope with a better future, these main causes can and must be avoided, starting with a strong improvement of science, knowledge and information among people.

Consequently, the solution for an appropriate common future is to build a new economy based upon undeceived energy and ecology (including biodiversity) knowledge and information among people all over the World. To these purposes and to get over the EEE crisis, the holistic approach i.e. the system Σ approach has to be applied in order to delete deceptions anywhere and anytime.

3307 - Negative emissions for climate change stabilization & the role of CO2 geological storage

ORAL PRESENTATIONS

K-3307-01 (part1)

The concept of negative emissions

S. Fuss (1)
(1) Mercator Research Institute on Global Commons and Climate Change (MCC), Resources and International Trade, Berlin, Germany

Future warming is contingent on the cumulative CO2 emissions until 2100. A maximum of 1,200 GtCO2 can be emitted from 2015 onwards in order to stabilize climate below a global average of 20C above pre-industrial conditions by 2100 with a probability of 66%. At the same

time, emissions from fossil fuel combustion and cement production have increased substantially over the last decade – to 61% above their 1990 level. Reaching 2°C in a cost-effective way will demand strong mitigation action across all sectors. The further we delay mitigation, the greater the challenges will be in the future. One strategy that is currently widely discussed is the deliberate removal of CO2 from the atmosphere by human intervention; that is, not merely going carbon-neutral, but even carbon-negative. Negative emissions in the majority of Integrated Assessment Model (IAM) scenarios aiming at keeping warming below 2°C in the IPCC's Fifth Assessment Report (AR5) are mostly achieved through the production of sustainable bioenergy with carbon capture and storage (BECCS). Some scenarios also feature afforestation for carbon dioxide removal. Other options under discussion involve biochar, enhanced weathering and direct air capture. Indeed, by including negative emissions (mostly from BECCS) into our mitigation portfolios, we could effectively double the carbon quota of about 1,000 Gt CO2.

In this keynote, the concept of negative emissions will be introduced and their role in current stabilization pathways will be illustrated and discussed. Most 430-480 ppm and many 480-720 ppm CO2eq scenarios feature net negative emissions in the second half of this century. However, negative emission technologies are often deployed earlier, even if it does not lead to a net negative balance. An overview of the challenges that the reliance on negative emissions brings with it will serve to frame the individual contributions in the rest of the session. The focus here will be not only on potentials, but also on the implied tradeoffs e.g. with other policy objectives. Clearly, it is not only important to understand when negative emissions will be needed and in which form they can be sustainably and cost-effectively achieved in theory, but it also needs to be put into the context of where such options would be deployed. For example, in the case of BECCS, huge amounts of biomass will be needed as feedstock, yet the most productive areas to produce this biomass might have other policy priorities than climate change mitigation and other mitigation options such as protecting forests might be more popular for their perceived co-benefits.

K-3307-01 (part2)

Limits to negative emissions technologies

P. Smith (1)
(1) University of Aberdeen, Institute of Biological & Environmental Sciences, Aberdeen, United Kingdom

Despite two decades of effort to curb emissions of carbon dioxide and other greenhouse gases, emissions grew faster during the 2000s than in the 1990s, and reached an all-time high of ~50 thousand million tonnes of carbon dioxide equivalents in 2010. Given this level of emissions and growth trajectory, it will be challenging to meet the international goal of limiting climate warming to less than 2°C. Because of this, carbon-negative solutions – technologies that remove carbon dioxide from the atmosphere – are being proposed. In this paper I give an overview of the carbon-negative solutions available, before looking at some of the environmental and economic implications of their widespread implementation. I show that carbon-negative technologies differ greatly in their costs and n their potential environmental impacts. For example some, such as direct capture of carbon dioxide from the air by engineered chemical reactions, have limited environmental impact but are extremely expensive, while others, such as use of biomass burning to replace fossil fuels in energy production with the capture of the carbon dioxide produced by combustion (known as BioEnergy with Carbon Capture and Storage; BECCS), are inexpensive but potentially use a lot of land, putting pressure on land currently used for food production or biodiversity conservation, with a wide range of potential environmental impacts. I conclude by looking at some of the opportunities presented, and risks posed, by reliance on carbon-negative technologies for climate stabilization.

K-3307-02

Latest developments, opportunities and challenges for CO2 storage

T. Wildenborg (1)
(1) CO2GeoNet – TNO (Netherlands Organisation for Applied Scientific Research), CO2GeoNet executive committee member, Utrecht, Netherlands

Carbon dioxide Capture and Storage (CCS) is recognized in the IPCC's 5th Assessment Report as part of the mitigation technology portfolio that must be deployed in order to reduce CO2 (carbon dioxide) emissions and keep the global average temperature change to less than 2 °C relative to pre-industrial levels. Underground storage of CO2 captured at plants in the fossil-fuel energy, bioenergy and industrial sectors is a promising option to reduce emissions into the atmosphere by returning the initially extracted carbon back into the ground, and may also be used to remove CO2 from the atmosphere.

The CCS concept to mitigate emissions from fossil-fuel and biomass fired power plants and from the processing and cement industry consists of three main components; the capture installation, transport infrastructure by pipeline or ship and geological storage structures in the deep subsurface. Promising geological storage media are deep saline aquifers and depleted oil and gas fields. In Europe, the North Sea region which is rich with oil and gas reservoirs, offers a promising area for CO2 storage. Several countries around the North Sea are developing plans for CO2 storage activities including the United Kingdom, Norway, the Netherlands and Denmark. Demonstration of CCS is developing at great pace in North America. Recently, the large integrated CCS project Boundary Dam started to operate in Canada.

Inventories of storage potential presented in atlases and Geographical Information System (GIS) databases and maps have been performed in many areas of the world including the USA, Australia and Europe showing that there is great potential for CO2 storage. Storage potential in Europe has been estimated at 360 Gt CO2, 244 Gt of which is available in the offshore region (GeoCapacity project, 2009). The challenge is to test the effective storage capacity of promising geological storage media through detailed characterisation and field testing, moving from a resource estimate towards a reserve estimate.

The technology for CO2 storage is largely derived from the oil and gas industry including evaluation of reservoir performance and drilling technology. Underground storage of natural gas in diverse media is a widespread and common practice in many regions of the world. Since the nineties several storage projects have been developed e.g. the large-scale storage of CO2 in the Norwegian offshore. On land, several CO2 storage pilots, in different stages of development are present e.g. in Spain and Germany. The challenge is to demonstrate large-scale CO2 storage integrated into a full CCS chain project. Several projects for large-scale demonstration of CCS in the offshore sectors of the UK and the Netherlands are in the preparation phase.

The cost of CCS is estimated at 60 to 90 Euro per tonne CO2 in the demonstration phase (reference year 2015) which could drop to 30 to 45 Euro for projects at an early full commercial scale stage (reference year 2030; McKinsey, 2008). The costs of storage in the early commercial phase range from 4 to 12 Euro per tonne CO2 depending on the location and the type of storage structure (Mckinsey, 2008). Lowering the costs of the capture installation is the biggest challenge. Financing of CCS projects is currently faced with the low price of emission allowances of less than 7 euro per tonne CO2 (EEX, 10 March 2015). An effective CCS enabling policy with a mature emission trading market is needed.

Containment of the injected CO2 in the reservoir is a prime requirement for CCS to be an effective CO2 abatement technology. For this reason modelling and monitoring of the CO2 in the subsurface receives a lot of attention. The European CCS Directive addresses the key aspects of safe and environmentally sound CO2 storage. The current Directive seems to be fit for purpose but needs more extensive testing in real-life CO2 storage projects.

The public at large is not well informed on CCS technology and its objective of abating CO2 emissions. In onshore settings, people sometimes have shown resistance towards this new technology, like in some initiatives in Germany and the Netherlands. In other instances, like for the CO2 storage pilots near Hontomin in Spain and near Ketzin in Germany, the local people show a positive interest in these activities. Participation of the public from an early stage of project development onwards is key to making people aware of CCS and getting them engaged in these projects.

O-3307-01 (part1)

Enhanced weathering and BECCS - are carbon dioxide removal technologies complements or substitutes?

J. Strefler (1) ; N. Bauer (1) ; T. Amann (2) ; E. Kriegler (1) ; J. Hartmann (2)
(1) Potsdam Institute for Climate Impact Research, Sustainable solutions, Potsdam, Germany; (2) Universität Hamburg, Hamburg, Germany

In its fifth assessment report, the IPCC stated that scenarios which "are consistent with a likely chance to keep temperature change below 2°C relative to pre-industrial levels [...] are characterized by [...] emissions levels near zero GtCO2eq or below in 2100» (Edenhofer et al., 2014, Summary for policymakers, IPCC Fifth Assessment Report of Working Group III). To reach such low CO2eq emissions, net negative emissions will be necessary in some sectors to compensate for e.g. CH4 and N2O emissions from the land-use sector or industry process emissions. There are at least four options to achieve net negative CO2 emissions: The combination of bioenergy with carbon capture and storage (BECCS), afforestation, direct air capture, and enhanced weathering of rocks.

Enhanced weathering (EW), the deployment of finely ground minerals over forests and crop lands, could be used to remove CO2 from the atmosphere. It faces neither the technological nor the social risks of the other options. However, olivine, the mineral that is best suited, might be contaminated by potentially harmful trace elements. Other sources like basalt can have lower harmful element concentrations, but show lower CO2 sequestration potential.

Our research questions are: What are the optimal design parameters for EW? How does EW as a mitigation option interact with BECCS?

An important parameter that determines costs as well as carbon removal rate is the grain size. We first calculate an optimal grain size that maximizes profits, taking the dependency on carbon removal rate and costs into account. Second we use the calculated parameters for the implementation in the integrated assessment model REMIND and show preliminary results of EW as a mitigation option.

When EW is available as a mitigation option, it provides net negative CO2 emissions which allow for higher CO2 emissions earlier in the century. The slower reduction of CO2 emissions results in a lower CO2 price and therefore lower mitigation costs. We will analyze under which conditions EW is used as a substitute or complement to BECCS. In addition, we analyze scenarios where CCS is not available. In combination with a stringent climate target, these scenarios often show very high mitigation costs or become unachievable. We will investigate to what extent EW can substitute BECCS in this case.

O-3307-01 (part2)

Addressing technical and resource challenges in delivering negative emissions

J. Gibbins (1) ; H. Chalmers, (1) ; M. Lucquiaud, (1)
(1) University of Edinburgh, School of Engineering, Edinburgh, United Kingdom

Approaches that remove carbon dioxide from atmospheric air are likely to be an essential enabling 'backstop' technology for a world that has to keep within a fixed carbon emissions budget to avoid dangerous climate change. Such technologies must be available to be scaled up if necessary to deliver the required carbon dioxide (and other greenhouse gas) emission trajectories.

Present technology can deliver carbon dioxide removal (CDR) or 'negative emissions' using biomass with 'conventional' CO2 capture and storage (BECCS). BECCS is probably the best way to use most types of available biomass. For example, battery electric vehicles using BECCS electricity production provide a highly efficient route for using a wide range of biomass materials in transport compared to conversion to liquid fuels. Adding carbon dioxide capture and storage would give a further negative CO2 emission of about 125 g/km to set against other lifecycle emissions. In buildings, rather than using biomass directly for heating, the same amount of fuel can give similar results if used to generate electricity that can then power heat pumps, plus give negative emissions when combined with CCS.

Although BECCS can make a useful contribution to mitigating the risk of dangerous climate change it cannot be regarded as a robust backstop technology. Especially in a climate-stressed world it cannot be assumed that sufficient amounts of biomass will be available for this to be the only route. Here Direct Air Capture (DAC) by engineered systems that can be multiplied as required using mass-produced standard components appears to be an essential option for many societies.

In a number of cases DAC facilities are likely to be combined with power plants with CCS. They can share CO2 transport and storage facilities and hybrid technologies would be used also to reduce residual CO2 emissions from the fuel in the power plant to very low levels. DAC technologies can also, however, be located elsewhere. For example, developers could choose to locate DAC facilities close to CO2 storage sites to minimise time and cost associated with establishing CO2 transport infrastructure and also to optimise the use of global storage resources.

Costs for DAC technologies currently being proposed may appear high, but in the context of cancelling out emissions from hard-to-avoid liquid fuel use (as an offset or via fuel synthesis) estimated additional costs are of the order of 1 euro per litre. Some or all of this cost may be offset against reductions in oil prices if there is no other way this oil can be used. Also, when hydrocarbon fuels are used in power plants that operate in a high-renewable electricity system at low average load factors the cost of abatement using power plant CCS can increase significantly. Ultimately this can mean that power plant CCS loses its cost advantage when compared with DAC plants capturing the same amount of CO2 over an extended period of time that are able to choose to operate all of the time.

Getting to zero, or negative, global emissions is becoming accepted as the challenge the world must overcome. This paper will demonstrate that delivering carbon dioxide removal technologies beyond BECCS is key to researchers and industry helping to deliver a successful response to this challenge.

O-3307-02

The use of carbon capture and storage in mitigation scenarios – an integrated assessment modelling perspective

D. Van Vuuren (1) ; E. Kriegler (2) ; K. Riahi (3) ; M. Tavoni (4) ; B. Koelbl, (5)
(1) PBL Netherlands Environment Agency, PBL, Climate, air pollution and energy, Bilthoven, Netherlands; (2) Potsdam Institute for Climate Impact Research, Potsdam, Germany; (3) International Institute for Applied Systems Analysis, Energy Program, Laxenburg, Lower Austria, Austria; (4) Fondazione Eni Enrico Mattei , Climate change and sustainable development programme, Milan, Italy; (5) Utrecht University, Utrecht, Netherlands

Carbon capture and storage (CCS) plays an important role in the model-based scenarios consistent with stringent targets published in the literature, as emphasized in the IPCC 5th assessment report. In scenarios, CCS is partly used in combination with fossil fuels as a mean to reduce greenhouse gas emissions. CCS is also combined with bio-energy (bio-energy-and-CCS, BECCS) to create negative emissions. In the presentation, we will look at the existing literature and discuss 1) total use of CCS and associated use of storage capacity in the different scenarios, and 2) look into the use of negative emission technologies. The AR5-DB offers the opportunity to provide an in depth analysis of CCS technologies are employed for different climate targets and other assumptions. The results show that CCS is increasingly used in combination with bio-energy for increasing stringency of mitigation targets. It also shows that CCS use can be substantial in some IAM scenarios, providing a challenge from storage and transport, land use (for BECCS) and public acceptance perspective.

This presentation will consider the latest scientific developments in two key issues for carbon dioxide (CO2) storage; how can sufficient and accessible CO2 storage capacity be assured prior to any investment decision for a large-scale CO2 Capture and Storage (CCS) project; and how can CO2 storage be implemented in a manner that is safe for humans and the environment? Assured geological storage capacity that is accessible on the required timescale is a key concern for reaching a positive Final Investment Decision; storage capacity is fundamental to the success of a CCS project. There are a number of recognized methods for estimating storage capacity, ranging from simple volumetric calculations to flow models. Each of these has advantages and disadvantages in terms of accuracy, data requirements and cost. Typically, accuracy of capacity estimates increases throughout the project from screening through geological characterization to site development and operation as more data becomes available. Any uncertainties in estimated storage capacities need to be communicated effectively to stakeholders. Data is one of the key issues in assuring storage capacity; the more data defining reservoir characteristics that are available, the more accurate the assessment of storage capacity. Strategies for optimizing the use of available data for storage assessment are emerging from recent projects. Assured capacity also has a regulatory and financial dependency; the cost for accessing the storage capacity needs to be affordable (e.g. with a relatively small number of injectors and located such that the transport distance is not excessive) and storage needs to be permitted by regulations. Flexible storage solutions also raise interesting regulatory issues, for example, how will stacked storage be permitted? Strategic planning for CCS is required, assessing the national and international energy landscape and considering how to satisfy the requirements of society for affordable, dependable and sustainable energy sources with low greenhouse gas emissions. Strategic planning for geological storage of CO2 is also required to ensure the most efficient use of the subsurface. Early demonstration projects have highlighted the need to allocate sufficient time upstream for thorough geological characterization such that storage sites are available when needed; geological assessment of the potential storage site needs to start during the very early phases of the project and this in turn needs to be built on early, strategic, national assessments. Ensuring that CO2 storage is carried out in a safe manner requires actions at all stages of the CO2 storage lifecycle from thorough pre-injection risk-led geological site characterization to effective monitoring, measurement and verification (MMV) of the site during injection to understanding of long term storage site evolution during the post-injection phase. Models of the storage site are iteratively updated as new data and new techniques become available. Thorough site characterization includes testing the reservoir and seal response to CO2, for example, the threshold (capillary entry) pressure for CO2 to enter the cap-rock needs to be determined. Best practice recommendations on understanding how risks to storage site security can be mitigated have been produced by recent projects. Demonstrating the site is behaving as expected through MMV is key to ensuring the CO2 storage site is safe. New (low cost) monitoring tools specifically designed for use at CO2 storage sites have been developed and new techniques are being tested at lab-scale. For example, techniques and technologies for rapidly detecting and confirming leakage (if it occurs) are being developed and tested as are mitigation and remediation measures. Practical experience gained at pilot and test injection sites allows demonstration of innovative monitoring technologies and strategies as a first step towards new techniques that will be ready for market in the future. Experiments at natural analogue sites are also important in understanding longer-term processes and potential impacts of leakage. Onshore CO2 storage pilot projects offer an opportunity for public engagement as they are relatively easy to access, this can include communication with the general public on the safety of geological storage of CO2 and the role of CCS as a key greenhouse gas mitigation option. Pilot sites also offer the opportunity for site-specific communication activities to interact with the local community, improving public outreach strategies. Communication on geological storage of CO2 is one of the main activities undertaken by CO2GeoNet in its role as a pan-European research Association.

How much negative emission is physically needed to keep global warming below 2°C?

T. Gasser (1) ; P. Ciais (2) ; C. Guivarch (1) ; C. Jones (3) ; K. Tachiiri (4)

(1) CIRED, Nogent-sur-Marne, France; (2) LSCE, Gif-sur-Yvette, France; (3) Met Office Hadley Centre, Exeter, United Kingdom; (4) Japan Agency for Marine-Earth Science and Technology, Yokohama, Japan

RCP 2.6 is the only representative climate change scenario produced for the IPCC Fifth Assessment Report that likely limits global warming to less than 2°C above preindustrial levels. Following such a scenario needs a strong reduction in the net amount of fossil CO2 released into the atmosphere by humankind. This reduction can be achieved by a combination of «conventional mitigation», i.e. decreasing global fossil-fuel consumption, and «negative emissions», i.e. engineered removal of atmospheric CO2 (be it through on-site capture and storage, direct air capture, enhancement of natural carbon sinks, etc.). As part of the current debate on the role negative emissions might play in reaching the 2°C target, we quantify the trade-off between conventional mitigation and negative emissions in RCP 2.6. We use a three-step approach to do so. First, we take fossil CO2 emission trajectories estimated to be compatible with this scenario using Earth system models. Second, we make assumptions about maximum feasible pathways of conventional mitigation, covering a wide range of possible futures. Third, for each of these pathways, we deduce the gross negative emissions as the complementary amount of carbon that needs to be captured when conventional mitigation alone is not enough to follow the pathway compatible with the RCP2.6 scenario.

If conventional mitigation starts in 2015 at a -5% yearly rate (our best case), a maximum removal rate of 5 GtCO2/yr and a storage capacity of 550 GtCO2 are required. If conventional mitigation starts in 2030 at -1% per year (worst case), those requirements are 33 GtC/yr and 4800 GtCO2 respectively. The latter figures range from 25 to 40 GtCO2/yr and from 3500 to 6000 GtCO2 respectively, when accounting for our lack of understanding of the carbon-climate feedback. However, the ultimate product of our study is an abacus where one can make assumptions on future conventional mitigation and read the negative emission requirements - and associated uncertainty - compatible with maintaining global warming below 2°C, as estimated by state-of-the-art Earth system models.

When comparing our mass-balance estimates of gross negative emissions to those by Integrated Assessment Models (IAMs), ours fall in the lower end of the range. This logically follows our approach of always choosing conventional mitigation over negative emissions when the mitigation potential allows it. Our approach thus provides a physical lower bound of negative emission requirements for a given mitigation potential. Conversely, in integrated assessments negative emissions may be chosen over conventional mitigation at any time, depending on which

is found more economical to develop under assumed costs and technological potentials. Here, our study does not rely on assumptions about technologies and costs (but on the assumed mitigation potential). Another major difference with studies using IAMs is that ours rely on state-of-the-art Earth system models. Despite the drawback of having to set some drivers exogenously, it allows a comprehensive assessment of the uncertainty related to the future response of the carbon-climate system. Here, we show this uncertainty can be greater than the results between two different mitigation floor assumptions. It emphasizes that the uncertainty surrounding any policy decision related to negative emissions primarily comes from our lack of understanding of the future behavior of the Earth system.

To conclude, we find that negative emissions are required at significant levels (i.e. >1 GtC/yr) even for very aggressive mitigation floors. Given that negative emission technologies are still at an early stage of development, this pleads in favor of developing (financial) mechanisms to put them on a technological learning trajectory. But then, in all but the most optimistic cases, we also find negative emission requirements that have not yet been shown to be achievable: be it the flux of removal or the storage capacity. Following others, this study suggests that negative emissions alone are unlikely to be the panacea that will limit global warming below 2°C, and that conventional mitigation should remain a significant part of any climate policy aiming at this target.

P-3307-02

Negative emissions - interactions with other mitigation options

F. Kraxner (1) ; S. Fuss (2) ; P. Havlik (1) ; A. Mosnier, (1) ; S. Leduc, (1) ; P. Yowargana, (1)

(1) International Institute for Applied Systems Analysis (IIASA), Ecosystems Services and Management Program (ESM), Laxenburg, Austria; (2) Mercator Research Institute on Global Commons and Climate Change (MCC), Resources and International Trade, Berlin, Germany

Many scenarios in IPCC's recent Assessment Report (AR5) find that there is a need for negative emissions in order to stabilize at concentration levels consistent with 2°C above pre-industrial levels. This demand is under present technology assumptions largely covered by combining bioenergy with carbon capture and storage (BECCS). One major concern is that high feedstock potentials are supposed to be located in forests of the southern hemisphere, i.e. in the tropics, which is where at the same time forests are most vulnerable to deforestation. Consequently, a land-based mitigation option such as large-scale bioenergy production (w/o CCS) will interfere with options that are popular for their large co-benefits such as reduced emissions from deforestation and degradation (REDD+). Thus, based on a multi-scale bottom-up modeling approach (using an integrated land use model coupled with a global forestry model), this study aims to identify and quantify possible tradeoffs (i.e. land use-based mitigation options compete for the same land) and synergies (i.e. both options provide incentives to keep an intact and sustainably managed forest) between REDD+ and BECCS. The global results elicit the system interactions. However, they do not necessarily shed much light on the situation on the ground. Thus, a regional analysis will be carried out, zooming into Indonesia as an important tropical basin that is assessed with respect to REDD+ and BECCS interactions. This country has been chosen as a pilot region for REDD+BECCS because it looks back at decades of heavy deforestation, has established a strong palm oil sector and its remaining forests face high pressure from agriculture and a relatively developed infrastructure network. Our analysis shows that avoiding deforestation can have many implications for the establishment of sustainable bioenergy. It is therefore imperative to align REDD+ and BECCS strategies in the future for achieving optimal mitigation potentials.

P-3307-03

Incentives for the Research, Development and Deployment of Greenhouse Gas Removal Techniques

T. Kruger (1)

(1) University of Oxford, Oxford, United Kingdom

Climate models that achieve the policy objective of limiting warming to less than 2°C do so by assuming not only extremely fast reductions in emissions, but also the deployment of technologies that remove greenhouse gases from the atmosphere at a massive scale. Yet there is no substantive research to validate the assumption that such proposed Greenhouse Gas Removal (GGR) techniques could be deployed at the scale implied.

This presentation will address the issue of the incentives required for researching, developing and deploying GGR techniques. It will examine the reasons for the current absence of such incentives and explore how the development of a technology that could safely, scalably and economically remove CO2 from the atmosphere and sequester it permanently could result in a rational, moral and global carbon price.

P-3307-04

Negative emissions in sustainable transition : Which role for bioenergies and CCS?

A. Laude-Depezay (1) ; X. Galiègue (2)

(1) Université de Reims Champagne-Ardenne, Laboratoire REGARDS, Reims, France; (2) Université d'Orléans, Laboratoire d'economie d'orléans, Orléans, France

Carbon Capture and Storage (CCS) is a technology that aims to capture CO2 coming from static emitters such as coal-fired electric plants, then to transport it by pipelines until a geological reservoir (e.g. saline aquifers), where the CO2 is stored definitively. It is then an "end-of-pipe" technology, so it avoids to release pollution in the environment, but does not change the production process itself, contrary to renewable energies or improved energy efficiency. Besides, CCS needs additional energy – named energy penalty – and could reinforce the current technological lock-in in fossil energy. However, CCS could also allow a rapid decline of emissions on existing production facilities by the end of the century, when alternatives (such as renewable energies) will be fully deployed. In this case, the current sociotechnical regime based on fossil energies could be maintained for a while.

BECCS (Bioenergy and Carbon Capture & Storage) is a CCS niche that adds a CCS process on a bioenergy production unit.. Industrial sectors such as biofuels, electric generation from biomass (or coal and biomass) or paper production are concerned. BECCS could change our point of view on the CCS role into the sustainable transition, as it could provide negative emissions, which means that more GHG emissions are avoided than emitted during a production process. Instead of being released into the atmosphere during biomass transformation, carbon is definitively stored. If biomass transformation is assumed nearly carbon neutral, BECCS should effectively lead to negative emissions. This has been checked in a few cases in academic literature (IEA GHG, 2009; Laude et al., 2011). In addition, a synergy between BECCS and geothermal energy recovery has been recently explored in the CO2-DISSOLVED project (Kervévan, Beddelem, & Neil, 2013). This process is adapted to small or medium emitters, like BECCS emitters are in most cases. It could reduce significantly the energy penalty due to CCS.

The aim of this paper is then to investigate the specific role of BECCS into the sustainable transition, and more precisely its impact on its timing. This issue has been discussed mainly through Integrated Assessment Models (IAM), which compute the evolution of the worldwide energy system under climate constraint until the end of the century. IAM modeling is one of the main tools used by IPCC for its forecasts and recommendations. It is then widely considered that CCS and BECCS could be key technologies to keep temperature increase below 2°C, especially if worldwide actions are delayed.

We use here a different point of view to deal with this issue: the Multi-Level Perspective (MLP). This conceptual framework analyses transition as a mutation process from one sociotechnical regime to another, under the pressure of macro-level forces (named the landscape), and the emergence of market niches that could provide the basis of the new regime (Geels & Schot, 2007). Here, climate change could be seen as a macro pressure (with economic and social aspects), that requires a deep change of the global energy system, i.e. the socio-technical regime. It is important to point out that both CCS and BECCS remain technological solutions, even if they require policy incentives and social acceptance. According to the

typology of Arundel, Kareva, and Kemp (2011), they belong to the "techno-fix" innovations, while other solutions are available, grounded on changes in user, market, and institutional practices, as Social Innovation (change in social uses) or Transformative Innovations (both changes in social uses and technology). On the contrary "techno-fix" innovations allow preserving past habits and institutional practices through the development of new techniques, and so could contribute to the lock-in effect.

Unlike CCS, BECCS competes no more with renewable energies and could help to get a low-carbon society. Actually, BECCS is likely to become available in the second part of the century. If mitigation is delayed, it could be used to fix an overshoot of CO2 emissions in the first part of the century, thanks to negative emissions. Given the uncertainties regarding CCS and BECCS development, this last strategy could be a dangerous bet (Fuss et al., 2014). Moreover, BECCS concerns involve also biodiversity damages and the risk of higher biomass and food prices. This contribution will discuss more deeply the challenges connected to BECCS until 2100.

Development of Hybrid Coal with Bio-fuel Derived from Non-edible Resources and its Process

SJ. Park (1) ; JS. Bae (1) ; YJ. Lee (1) ; JH. Park (1) ; JG. Kim (2) ; JH. Park (3) ; YC. Choi (1)
(1) Korea Institute of Energy Research, Clean Fuel Laboratory, Daejeon, Republic of Korea; (2) Korea Institute of Energy Research, Energy saving laboratory, DaeJeon, Republic of Korea; (3) Dongwon Engineering, Ceo, Sihueng, Republic of Korea

The Korean government has implemented energy policies such as RPS and ETS to raise the share of renewable energy sources since 2012. Among the renewable sources, carbon-neutral biomass, particularly solid fuel, is immediately applicable in coal fired power plants, so a number of approaches to utilize bio-fuel by co-combustion with coal have been investigated. Hybrid Coal by Korea Institute of Energy Research (HCK) is a novel fuel for existing coal-fired power plants to cope with implementation of RPS, and we have published several articles related to the diversification of bioliquid to secure its feasibility. Many hydrophilic and hydrophobic bioliquids such as glycerol, bio-oils, and oil residues have been applied to saccharide substitutable substances, however crucial limitations of each bioliquid were found. For examples, glycerol having hydrophilic property is eligible to be impregnated in coal pores, which is primarily derived from ash, but moisture readsorption cannot be inhibited since Hybrid Coal with glycerol is not allowed to treat at desired temperature (250℃) for hydrophobicity as our previous work. Also, hydrophobic bioliquids like bio-oils and oil residues, unlike hydrophilic ones, cannot penetrate into hydrophilic coal pores, then most of them only coat the surface of coal or partially remain among coal particles. This may cause a decrease in thermal efficiency due to the heat imbalance and higher unburned carbon ratio in a power plant boiler from the difference combustion behavior between coal and biomass, consequently we have concluded saccharide is the best substance to produce Hybrid Coal. However, an ethical problem related to an edible substance might arise if a sugar cane-derived bioliquid is used. In the present paper, Hybrid Coal with bio-fuel (bio-ethanol process) derived from non-edible resources is first investigated to promote its feasibility.

P-3307-06

Can we bet on negative emissions to achieve the 2°C stabilization target even under strong carbon cycle feedbacks?

K. Tanaka (1) ; T. Yokohata (1) ; Y. Yamagata (1)
(1) National Institute for Environmental Studies (NIES), Tsukuba, Japan

Given the narrowing windows of opportunities to stay below 2°C, negative emission technologies such as Bioenergy with Carbon dioxide Capture and Storage (BioCCS) play an ever more crucial role in meeting the 2°C stabilization target endorsed by the Cancun Agreement (Fuss et al. 2014). Negative emission technologies – if deployable at a sufficiently large scale during the second half of this century – would make the 2°C target more feasible in the midst of the slow political progress and might allow current emissions unchecked for some time if stakeholders are in the process of converging to a platform to abate emissions globally. However, such technologies are currently at their infancy and their future penetrations may fall short of the scale required to stabilize the warming (Scott et al. 2013). Furthermore, the overshoot in the mid-century prior to a full realization of negative emissions would give rise to a risk because such a temporal but excessive warming above 2°C might amplify itself by strengthening climate-carbon cycle feedbacks, which are known to be positive albeit with large uncertainties (Friedlingstein et al. 2006). When one considers other classes of carbon cycle feedbacks including those with permafrost thawing and wildfire, such a risk could be even higher. It has not been extensively assessed yet how carbon cycle feedbacks might play out during the overshoot in the context of negative emissions, while the literature on carbon cycle feedbacks has burgeoned in recent years.

This study explores how 2°C stabilization pathways, in particular those which undergo overshoot, can be influenced by carbon cycle feedbacks and asks their climatic and economic consequences. We compute 2°C stabilization emissions scenarios under a cost-effectiveness principle, in which the total abatement costs are minimized such that the global warming is capped at 2°C. We employ a reduced-complexity model, the Aggregated Carbon Cycle, Atmospheric Chemistry, and Climate model (ACC2) (Tanaka et al., 2013), which comprises a box model of the global carbon cycle, simple parameterizations of the atmospheric chemistry, and a land-ocean energy balance model. The total abatement costs are estimated from the Marginal Abatement Cost functions for CO2, CH4, N2O, and BC, which are derived from Azar (2013).

Our preliminary results show that, if carbon cycle feedbacks turn out to be stronger than what is known today, it would incur substantial abatement costs to keep up with the 2°C stabilization goal. Our results also suggest that it would be less expensive in the long run to plan for a 2°C stabilization pathway by considering strong carbon cycle feedbacks because it would cost more if we correct the emission pathway in the mid-century to adjust for unexpectedly large carbon cycle feedbacks during overshoot. Furthermore, our tentative results point to a key policy message: do not rely on negative emissions to achieve the 2°C target. It would make more sense to gear climate mitigation actions toward the stabilization target without betting on negative emissions because negative emissions might create large overshoot in case of strong feedbacks. Our simple approach illuminates a need for investigating this issue further by using a range of models including coupled Earth System Model (ESM)-Integrated Assessment Models (IAMs) to serve for the framework to be agreed upon in COP21 and maintained beyond.

Developments, opportunities and challenges for Bio-CCS in order to achieve negative emissions

S. Van Der Gijp (1)
(1) TNO, Sustainable Geo-Energy, Utrecht, Netherlands

Carbon Capture and Storage (CCS) is the only way to decarbonize fossil fuel. Large scale, full-scale demonstration projects such as the one in Boundary Dam Canada prove that this is an effective technology. A

similar technological approach can be taken in the cases of (Co-)firing biomass, biogas production and other biofuel applications, all of which can contribute significantly to a more sustainable energy mix, increased security of supply and a reduction of CO2 emissions. Both combustion and gasification routes to biomass conversion can be equipped with CCS which will result in most cases in a negative CO2 foot print.

First generation biofuels have some crucial limitations. By applying a thermochemical treatment process those limitations can be largely reduced. Typical thermochemical routes include pyrolysis, gasification, torrefaction and biochemical treatments. The products obtained are in most cases a combustible gas, solid char and CO2. The options for electricity and the scale of emissions generated reflect the biomass type and conversion route. Currently the main focus is to improve operational performance such as: efficiency, power flexibility and a (further) reduction of the emissions.

Large scale biomass combustion is mainly developed for the power companies, as a substitution for coal. Also standalone 250MWe CHP based on biomass pellets has been scrutinized by those companies. So far co-feeding of biomass in coal fired power station has been successfully accomplished at a level of 10-20% weight bases. Biomass polygeneration is based on partial oxidation (indirect gasification). The resulting syngas can be used as a raw material for the production of special chemical products or the production of hydrogen. The syngas can also be used to generate electricity and heat.

The integration with CCS brings with it specific challenges. Clever process integration is required as well as understanding the specific functional requirements. The use of Biomass required specific process conditions and material properties. In addition the use creates new types of impurities in the process and flue gas that :

- causes an increase corrosion (which in its turn affect amongst others the warrantee of the power plant);
- change the generic grid code requirements and more local grid requirements regarding ancillary services (power flexibility);
- have an effect on the requirements of the CO2 capture solvent;
- have a severe impact on the economics and
- finally the different operation modes compared to traditional fossil fuel large scale power plants has an implication on the downstream CO2 infrastructure, transport, use and storage.

The EERA joined program on CCS serves as platform to share the outcomes of research of the leading research entities in Europe and their program leads the way in the future joined development of Bio-CCS.

From scenarios to reality – key issues with upscaling BECCS

N. Vaughan (1) ; C. Gough (2)
(1) University of East Anglia, Tyndall Centre for Climate Change Research, Norwich, United Kingdom; (2) University of Manchester, Tyndall centre for climate change research, Manchester, United Kingdom

Substantial amounts of biomass energy with carbon capture and storage (BECCS) are used in the majority of emissions scenarios directed at limiting climate change to 2°C. The feasibility of these scenarios is an important concern for climate policy. We used an expert elicitation methodology to explore the key explicit and implicit assumptions that underlie these scenarios' use of BECCS to deliver so-called negative emissions. The process highlighted key interlinked issues surrounding land availability, land use and land policy; timing of technology and infrastructure developments; and policy incentives, verification and social acceptability. Whilst there was agreement over the potential for BECCS to remove CO2 from the atmosphere and produce energy, claims to its capacity are potentially being over-relied upon and overstretched under the policy pressure to generate emissions scenarios that meet a 2°C limit.

A balance of 'bottom-up' and 'top-down' in linking climate policies

T. Sterner (1)
(1) Univ of Gothenburg, Dept of economics, 40530 Gothenburg, Sweden

'Top-down' climate negotiations embodied by the Kyoto Protocol have all but stalled, chiefly due to disagreements over targets and objections to financial transfers. To avoid those problems, many have shifted their focus to linkage of 'bottom-up' climate policies such as regional carbon markets. This approach is appealing, but we identify four obstacles to successful linkage: different levels of ambition; competing domestic policy objectives; objections to financial transfers; and the difficulty of close regulatory coordination. Even with a more decentralized approach, overcoming the 'global warming gridlock' of the intergovernmental negotiations will require close international coordination. We demonstrate how a balance of 'bottom-up' and 'top-down' elements can create a path toward an effective global climate architecture.

K-3308-02

Do Chinese provinces successfully implement climate mitigation policies? A political economy approach

P. Motel-Combes (1) ; JL. Combes, (1) ; M. Fodha, (2) ; MF. Renard, (3) ; S. Zhang, (4)
(1) University of Auvergne, School of Economics - CERDI, Clermont-Ferrand, France; (2) University of Paris 1 Pantheon Sorbonne, Pse, Paris, France; (3) University of Auvergne, School of economics - cerdi - idrec, Clermont-Ferrand, France; (4) Peking University, College of environmental sciences and engineering, Peking, China

China is expected to be a major actor in the design of a new global climate architecture. Its non-participation could lead to a substantial increase in GHGs concentrations by the end of 21st century (Paltsev et al. 2012). China has already managed to cut CO2 emissions in several energy intensive industries and is now endowed with good technological and scientific capacities (Rock et al. 2013). The central government has fostered the implementation of environmental policies which are now a priority of the new Chinese growth model. It has been however recognized that China's climate governance can further be improved regarding the coordination of national and provincial levels (Richerzhagen & Scholz 2008). This paper precisely intends to add to the debate between top-down and bottom-up approaches of climate mitigation policies in the context of China.

Indeed, the efficiency of climate policies in China is challenged by strong spatial i.e. provincial disparities. Provincial environmental characteristics are very different considering climate, geography, population densities, as well as urbanization and for instance, there is a very large diversity of energy intensity between provinces. The geographical distribution of China's energy intensity exhibits a characteristic of progressive increases from the eastern coastal provinces to the western provinces (Yu 2012). One of the most striking features of China is its decentralized organization and the strong power devoted to provincial governments. The leading officials have mainly focused on economic growth targets (Combes, Renard, Tapsoba, 2015) but environmental objectives are written in their responsibility contracts for few years. Local leaders sign individual responsibility contracts that embed energy or emission reduction requirements for their localities. The central government gives priorities at the national level and then assigns specific targets for the different levels (Kostka 2014).

This paper contributes to the understanding of provincial

climate mitigation policies and its aim is twofold. First an original index of climate regulation is calculated. It is devoted to the measurement of "revealed" efforts made by provinces aiming at downsizing GHGs emissions. This effort index is estimated by eliminating the impact of structural factors of CO2 emissions through a standardization equation. Second, an econometric analysis allows to a better understanding of the determinants of provincial climate policies. Policy implications are related to the need for more coordination between bottom-up and top-down policies to increase the efficiency of current practices. As the burden on provincial and national budgets may be very heavy, the choice of the level of implementation is a strong political constraint and need information on the provinces' efforts.

A public finance perspective on climate policy: Six interactions that may enhance welfare

L. Mattauch, (1) ; J. Siegmeier, (1) ; M. Franks, (2) ; D. Klenert, (2) ; A. Schultes, (2) ; O. Edenhofer (3)

(1) Mercator Research Institute for Global Commons and Climate Change, Berlin, Germany; (2) Potsdam Institute for Climate Impact Research (PIK), Potsdam, Germany; (3) Potsdam Institute for Climate Impact Research, Potsdam, Germany

Climate change economics mostly neglects sizeable interactions of carbon pricing with other fiscal policy instruments. Conversely, public finance typically overlooks the effects of future decarbonization efforts when devising instruments for the major goals of fiscal policy. We argue that such a compartmentalisation is undesirable: policy design taking into account such interdependencies may enhance welfare and change the distribution of mitigation costs within and across generations. This claim is substantiated by analyzing six interactions between climate policy and public finance that are insufficiently explored in current research: (i) reduced tax competition in an open economy, (ii) portfolio effects induced through climate policy, (iii) restructuring public spending, (iv) revenue recycling for productive public investment, (v) greater intragenerational equity through appropriate revenue recycling and (vi) intergenerational Pareto-improvements through intertemporal transfers. We thereby structure the hitherto identified interactions between climate change mitigation and public finance and show that jointly considering carbon pricing and fiscal policy is legitimate and mandatory for sound policy appraisal.

Environmental Tax Reform and Heterogenous Labor Markets: Can the Trade-Off between Environmental Quality, Efficiency and Income Distribution been Avoided?

M. Chiroleu-Assouline (1) ; D. Aubert (2)

(1) Paris School of Economics & University Paris 1 & INRA, Paris, France; (2) Université Paris 1 Panthéon-Sorbonne, Paris, France

This paper investigates the distributional and efficiency consequences of an environmental tax reform, when the revenue of the green tax is recycled by a variation of labor tax rates. We build a general equilibrium model with heterogeneous imperfect labor markets, pollution consumption externalities, and where poor households spend relatively more on polluting goods than rich households (Stone-Geary preferences). We characterize the necessary conditions for the obtainment of the environmental and welfare dividends and we analyze the distributional properties of the green tax. We show that even in the case where the reform appears to be regressive, the gains from the double dividend can be made Pareto improving by using a redistributive non-linear income tax if redistribution is initially not too large. Moreover, the use of a non-linear income tax acts on unemployment and can moderate the trade-off between equity and efficiency. We finally provide simulations highlighting the room for manoeuvre for environmental tax reforms for the French case.

K-3308-05

A Carbon tax and the Risk of Inequity

E. Combet (1)

(1) Centre International de Recherche sur l'Environnement et le Développement (CIRED), Nogent-sur-Marne, France

This paper aims at clearing up some misunderstandings about the social impacts of carbon taxes that proved to be a decisive obstacle to their further consideration in public debates. It highlights the gap between the cost of a carbon tax reform as it is spontaneously perceived by the taxpayers and the reality of its ultimate consequences: the real impact on households' poverty and inequalities is not mechanically determined by the initial burden of energy on consumption budgets and by the capacity of households to alleviate it, but also depends upon the use made of the tax proceeds and its general macroeconomic impacts. The comparison of five tax-recycling schemes highlights the existence of trade-offs between maximising total consumption, reducing unemployment, maximising the consumption of the low-income classes and reducing income inequality.

K-3308-06

Modelling of distributional impacts of energy subsidy reforms: an illustration with Indonesia

L. Campagnolo (1) ; J. Chateau (2) ; R. Dellink (2) ; O. Durand-Lasserve (2)

(1) Fondazione Eni Enrico Mattei & Centro Euro-Mediterraneo sui Cambiamenti Climatici, Venice, Italy; (2) OECD, Paris, France

Indonesia highly subsidises the consumption of electricity and oil products for both households and firms, and in 2011 was ranked the 10th country in the world in terms of total government expenditures on fossil fuel consumption subsidies (IEA, 2012). The energy subsidies represent a burden for government budget, a source of vulnerability for the economy and perform badly in terms of redistribution. Furthermore, fuel subsidies, by encouraging fossil-fuel burning, increase GHG emissions and local air pollution. This paper provides a quantitative assessment of fossil-fuel subsidy phase out in Indonesia, both at macro and micro level, with particular attention to distributional effects on households heterogeneous in terms of income structures and expenditure patterns. On this purpose, we combine a micro-level representation of households' incomes and consumption with a macroeconomic model. We enhance the dynamic global and multi-sectoral computable general equilibrium model, OECD ENV-Linkages (Chateau et al., 2014), by directly integrating a module describing the behaviour of more than 10,000 representative household groups for Indonesia. In the other regions, the final consumers are portrayed by a single representative household. The characteristics of the representative household in terms of preferences and endowments are based on national accounting data. The multi-household representation for Indonesia is based on integrating and reconciling this macroeconomic information with data from the fourth edition of the "Indonesia Family Life Survey" (IFLS4) realised in 2007 (Strauss et al., 2009).

The baseline scenario follows the macroeconomic projections of the OECD Economic Outlook and the

corresponding long-term projections (Chateau et al., 2014). All the energy policies included in the Current Policy Scenario of the World Energy Outlook 2013 (IEA, 2013) are considered except the reforms to the consumers' energy subsidies that remain at their 2011 levels. In the policy scenarios, we assume that, between 2012 and 2020, Indonesia unilaterally realises a gradual phase out of electricity and fossil fuel subsidies for households and firms. The scenarios differ by the budget-neutral compensating scheme for households they assume: cash transfers, subsidies on food products, and labour income support. An additional policy scenario envisions a global multilateral subsidy phase out and a cash transfers compensating scheme.

All the scenarios give way to positive impacts on GDP at the 2020 horizon (+0.4% to +0.7% in 2020 with respect to the baseline) due to a decrease in the deadweight loss associated with the subsidies and also, in some scenarios, to higher savings and investment. The cash transfer scenario (both unilateral and multilateral) determines the highest GDP outcome. The gains in terms of Equivalent Variation are even higher due to trade improvements consecutive to the reform, and range between 0.8% and 1.4% in 2020. The distributive direct effect of fuel price increase is regressive for households. The effects through labour and non-labour incomes are more or less distribution neutral. However, the redistribution schemes can make the total effect of the reform progressive and pro-poor. The cash transfer scenario is the most progressive among the scenarios investigated. The budget redistribution using food subsidies is less progressive than with cash transfers. Transfers proportional to labour income, as used in the labour support scenario, are regressive because the incomes from formal labour represent a higher proportion of total incomes for high-income households than for low-income households. The reform outcomes are also heterogeneous across rural and urban areas: the cash transfer and the food subsidy scenarios are more beneficial to rural than to urban households due to the lower share of energy expenditures in rural areas. The labour support scenario, in contrast, is less beneficial to the rural households, because of the greater importance of the informal sector in these areas.

The phase out of energy consumption subsidies contributes to reduce in energy-related CO2 emissions (between -10% and -12%) and GHG emissions (between -7.3%and -8.3%) in 2020 compared with the baseline. The emission reduction is mainly driven by a decrease of household energy consumption.

Optimal Environmental Taxation with Capital Mobility

G. Schwerhoff (1) ; M. Franks, (1)
(1) Potsdam Institute for Climate Impact Research (PIK), Potsdam, Germany

Climate policy exemptions for energy intensive sectors are often justified with distributional concerns. One concern is that households employed in energy intensive sectors might be affected disproportionally due to capital mobility. We find that when workers cannot move freely between sectors, a uniform carbon tax causes more inequality between the sectors when capital is mobile than when it is not. Since households benefit more directly from sector-specific labor taxes, than from carbon tax exemptions, the former are more effective in addressing the distributional wedge caused by capital mobility. In addition, we find that the differential effect of capital mobility depends on the government's degree of inequality aversion: Redistribution is more expensive when capital is mobile, so that highly inequality averse governments might even be better off without capital mobility.

How should a government take capital mobility into account when designing climate policy? There is a strong concern that climate policy affects energy intensive sectors disproportionally when capital is mobile. This motivates policy exemptions for these sectors. Papers considering exemptions usually consider one representative household. They find that exemptions are not optimal and conclude that carbon taxes should be uniform across sectors. In this paper we consider sector-specific policy as a means of addressing the sector-specific distributional effects created by the interaction of climate policy and capital mobility.

We build a model with two sectors of different energy intensity. To reflect the distributional concern we assume sectoral rigidity in labor mobility. The government maximizes a social welfare function which aggregates utility of the households working in the two sectors. The environmental objective is to reduce domestic carbon emissions, motivated for example by the objective to fulfill a carbon reduction target. We then compare the effect of environmental policy with and without capital mobility. We find that indeed climate policy introduces a bigger difference in utility of the households employed in the two sectors when capital is mobile. Based on this we determine the optimal policy package for reconciling distributional and environmental objectives. We find three major results.

The first result is that sector specific labor taxes are the most suitable instrument to redistribute among the sectors. Sector specific carbon taxes can indeed be justified, but the difference should be very small. In optimum, redistribution between sectors is mainly achieved through relatively large differences in labor taxes. When labor taxes are optimally differentiated between sectors, the difference between utility of the households employed in the different sectors is much smaller than in the case where labor taxes are constrained to be uniform.

The second result is that the reaction of the government depends strongly on its inequality aversion. A utilitarian government achieves a higher welfare under capital mobility since it benefits from the gains of (capital) trade. A strongly inequality averse government faces high cost of countering the inequality increasing effect of climate policy under capital mobility. The cost of redistribution might be so high that it could even be better off without capital mobility.

The third result is that climate policy creates a greater difference between capital and labor income under capital mobility than in autarky. The government's ability to counter this shift through labor tax cuts is weakened through capital mobility since the reduced demand for pollution means that carbon tax revenues are lower under capital mobility than in autarky.

The Cost and Benefits of Adaptation in Developing Countries: Updated Review and Insights for Policy

P. Watkiss (1) ; A. Hunt, (2) ; M. Lago, (3) ; J. Rouillard, (4) ; J. Troeltzsch, (3)
(1) Paul Watkiss Associates, Oxford, United Kingdom; (2) University of Bath, Bath, United Kingdom; (3) Ecologic Institut , Berlin, Germany; (4) Ecologic Institute , Berlin, Germany

This paper presents the findings of a major review and synthesis on the costs and benefits of adaptation in developing countries, undertaken by the ECONADAPT project, funded by the European Union's Seventh Framework Programme for research, technological development and demonstration under grant agreement no 603906*, and with co-funding from the UK Department for International Development and by the International

Development Research Centre**.

While recent reviews (IPCC, 2014) have identified a low evidence base in this area, the last few years have seen a growing number of national initiatives and risk and sector specific studies. Over 500 relevant studies have been identified, and a growing number of these are in developing countries. The paper presents a review of this evidence base, focusing on estimates and insights for least developed and middle income countries. It starts with a mapping of studies, both geographically and by risk. This shows the coverage of adaptation costs and benefits has increased when compared to previous reviews. The geographical coverage now includes Africa, South and Central America and Asia, though there remain some important regional gaps. The coverage of risks has also increased: there is a very large literature on coastal zone adaptation, and increasing studies on water management, floods and agriculture. Major gaps remain, however, for ecosystems and business/industry.

The paper then summarises a detailed review of this evidence base and draws some policy lessons , using examples. From a policy perspective, there are now three distinct set of studies, using different methods. The first uses scenario-based impact assessment (I-A) and focuses on technical adaptation. The second uses investment and financial flow analysis (IFF) and considers likely mark-ups for adaptation. The final use the more recent focus on iterative risk management, low-regret options and decision making under uncertainty. The outputs of these approaches are very different in terms of framing and importantly the types of adaptation options. They also produce very different estimates of the costs (and benefits) of adaptation, which is of particular importance in relation to National Adaptation Plans and international climate finance. A key finding is that IFF studies indicate higher costs in the short-term, due to the consideration of the existing adaptation deficit, while policy orientated studies indicate higher adaptation costs in the medium-to longer term, due to the consideration of multiple risks, uncertainty, existing policy objectives and standards, and additional opportunity, transaction and policy costs.

The paper concludes with some key policy findings and future research needs. The latter includes the need for more empirical evidence at multiple time and spatial scales, and economic analysis of adaptive capacity, non-technical measures, opportunity, transaction and policy costs, cross-sectoral/cross-cutting effects and the limits of adaptation. Further work is also needed to understand transferability of existing estimates. A key priority is to further encourage the sharing of information and good practice.

Climate change adaptation: linking policy and economics in OECD countries

M. Mullan (1) ; S. Buckle (1)
(1) OECD, Environment Directorate, Paris, France

This presentation will summarise the key findings of a forthcoming OECD publication on the Economics of Adaptation in OECD countries (released end May 2015), including a survey of these countries. By drawing upon policy-makers' experiences to date, this presentation will examine how economic analysis has informed policy development to date, and priority areas for further data gathering and tool development.

OECD countries are increasingly taking action to prepare for the effects of climate change. As of 2014, more than three-quarters of them have published, or are currently developing, national strategies for climate change adaptation. In preparing for climate change, countries are faced with the challenge of responding to a broad range of uncertain risks. The common element of their response is the emphasis on mainstreaming adaptation into government policies, with a focus upon capacity building. Based on the analysis in this paper, the following priorities emerge for evidence development and improved tools for economic analysis:

- Reducing barriers to usage: Increasingly sophisticated approaches have been developed to account for uncertainty about climate impacts, often in the context of large infrastructure investments. However, countries' experiences show that mainstreaming requires integration with existing appraisal systems for decision-making, and "light touch" approaches that are proportionate to the scale of the decision at hand.

- Achieving sufficient breadth of coverage: The evidence base on costs and benefits has significantly improved in recent years, as sectoral and national coverage has increased. However, major gaps remain in sectoral coverage. For example, impacts on businesses and ecosystems remain poorly understood. Modelling of macroeconomic interactions remains at an early stage. More evidence on these areas is needed to develop coherent responses to a changing climate

- Accounting for the distributional and normative dimension of climate change: Economic analysis provides an important input into the decision-making process, but it is also necessary to account for people's perceptions of the risks from climate change. In part, this is because decisions on how to respond to the risks from climate change frequently involve trade-offs between different values. In addition, the impacts of climate change will be felt most severely by the poor and the marginalised. Few studies based on OECD countries have accounted for these impacts to date.

Global challenge and regional analysis – Germany's vulnerability and adaptation to climate change

U. Lehr (1) ; T. Drosdowski, (1) ; A. Nieters, (1)
(1) Gesellschaft fuer Wirtschaftliche Strukturforschung, Institute for Economic Structures Research, Energy and Climate, Osnabrueck, Germany

Overview
Although climate change is a global challenge, the effects occur locally and differ by region. The large timespan and the globality of climate change often obscure rather than clarify the discussion. Germany is located in a moderate climate zone; nevertheless it is vulnerable to disruptions due to its economic dependence on high-tech production sites. The largest disturbances come from extreme weather events. Global warming not only changes the climate conditions, but its effects also challenge the way we are used to model economic development and economic growth. Dealing with this calls for climate change adaptation, and adaptation of our models to be able to simulate climate change effects as well. A feasible adaptation strategy will be developed by local decision makers, and thus needs to assess regional impacts of climate change and the socio-economic effects resulting from changing climate conditions. This contribution is based on findings from a study within the German Framework Programme "Economics of Climate Change".

Methods
The authors have applied an input-output-based macro econometric-model, adjusting it to cope with the (1) challenges of damages from extreme weather events and (2) adaptation measures. Infrastructure damages, shifts from domestic production to imports, low levels of productivity due to heat waves, and adaptation measures

are some of the topics the paper deals with. Crude data is the largest challenge we have to cope with. Results are obtained by a comparison of three scenarios – one with and one without considering extreme weather events, and finally a third one allowing for adaptation measures. These results are differences in the values of macroeconomic variables, such as GDP, exports, investment and employment as well as sector specific variables. For instance employment on the level of different economic sectors is an important indicator for the design of the appropriate adaptation measures.

Results
Extreme weather events exert slightly negative effects on economic sectors and Germany's economy as a whole. These effects intensify over time and hurt the economy. Adaptation measures reduce the damages and pay off, but the economy is still worse off with climate change. The paper provides details for economic sectors and the total economy.

Conclusion
The research on the feasibility of the IO type macro econometric model for the analysis of extreme weather events has shown that it is necessary to rethink some of the empirical evidence on reaction equations in a time series based model to model extremes in the future.

Given that Germany is in a moderately affected region, the larger challenges for an open economy as the German, will lie in climate change along the international value chain. A German adaptation strategy must consider this.

O-3309-01

Economic evaluation on the impact and cost effectiveness of climate change adaptation strategies in crop production systems (using Structural Ricardian and Decision model): Case of Northern Shewea, Ethiopia

N. Mekonnenn (1)
(1) Ethiopian Economic Policy Reserach Institute, Poverty and Agriculture and Development Division, Addis Ababa, Ethiopia

Introduction and problems: To respond to the possible impacts of climate change smallholder farmers have been using different adaptation strategies. some of the major adaptation strategies in the Woreda include use of improved variety/early maturing, use of disease tolerant crops, use of irrigation, increased use of fertilizer, use of soil and water conservation techniques, water harvesting, constructing flood control, building wind breaks etc (ibid). However, we hardly know about the economic impact of climate change adaption strategies in smallholders many of the literatures. In addition, given the limited coping capacity and resource constraint to further make investment on different adaptation strategies, we know very little about cost effectiveness of climate adaptation strategies in smallholder's crop production system. The significant part of literature on climate change adaption focus on the determinants of adaption strategies rather than the economic impact of adaption strategies and their cost effectiveness at farm level.

Objectives: The general objective of this study is to identify policy relevant issues about the impact and cost effectiveness of climate change adaptation strategies among smallholders and by way to contribute to climate resilient agricultural development. The specific objectives of the study are: 1) To assess the economic impact of climate change adaptation strategies in the selected study area 2) To conduct cost effectiveness analysis on climate change adaptation strategies in smallholder's crop production system.

Methods: The data for the research was obtained from the survey of 350 Households in two districts of North Shewa Zone in 2014. The sample households were selected randomly. The sample size in each district was determined based on probability proportion to size. The districts included in the survey were Yaya Gullel, Hidha Abote and Derra districts. The specific study sites within the districts were 18 Kebeles. A structured questionnaire was used to interview the farmers. In addition, the research employed review of secondary data at zonal level (cliamte data, agricltur production data etc).

Economic Models and result: A Decision support model and a structural Ricardian model were used to estimate the economic impact of climate change adaption strategies on smallholders and the cost effectiveness of different adaptation strategies. Thus, a comparison was also made between different adaptation strategies practiced by smallholder farmers.

The econometric results of the analysis show that adaptation to CC plays significant role in boosting food production and farm level income. In addition, the fact that the adaptation variable is positive and significant in the estimates of production model indicates that adoption of yield related adaptation strategies have vital importance in terms of ensuring food security of rural households. On the other hand, the cost effectiveness analysis (cost effectiveness ratio) using the decision support model show that while some strategies like rain water harvesting, river diversion, use of disease tolerant crops are economically preferred strategies others are not.

Recommendation:

- If the interest of the farmers lay on the achieving Climate change at the 'least cost', then provision of rain water harvesting, river diversion, use of disease tolerant crops would be the preferred cost-saving strategy
- If the farmers objective focused on "averting climate change impact ", then increasing the acceptance rate of "the provision of improved crop varieties and fertilizer use " to 62% and more should be the economical preferred strategy as compared to the other alternatives
- National adaption programs should be designed and local adaptation measures should also be contextually be introduced at smallholder's level so as that adaptation strategies can improve food production and farmers income under climate.

Climate Change and China's Agriculture: Impact and Adaptation

H. Jikun (1) ; J. Wang (1) ; X. Wei (1)
(1) Center for Chinese Agricultural Policy, Chinese Academy of Sciences, Beijing, China

China's agricultural sector is expected to face challenges in the future mainly due to rising food demand and constraints of land and water, which will be worsened by impacts of climate change. Understanding the impact of and adaptation to climate change on agriculture is critically important for climate change policy. Acknowledging the large number of studies on climate change in the literature, the overall goal of this paper is to provide additional evidence on the impacts of and adaptation to climate change on agriculture in China.

Both econometric analysis and general equilibrium modeling are applied to analyze the direct and indirect impacts of climate change. The direct impacts on major crop yields are empirically estimated using provincial data collected over the past three decades. The impacts of severe drought and flood from extreme weather events on grain production are estimated based on a large scale farm survey in 9 provinces. The indirect impact of climate change on market price response is simulated using an integrated impact assessment model under different scenarios. We identified adaptation measures taken by local governments, communities, and farmers for reducing climate risk based on primary surveys that include 3330 households from 330 villages in 9 provinces, and assessed which are the major factors that facilitate farmers to implement these measures. We also assessed the effectiveness of different measures in reducing climate risk on crop production.

Econometric results show that the effects of temperature and precipitation on crop yields are statistically significant though they differ largely among crops. Increasing temperature has a negative impact on the yield of several major crops such as wheat, rice, cotton, and sugar, though it also has a moderate positive impact on maize and rapeseed yield. However, decreasing precipitation reduces the yields of most crops. The simulation results show that overall impact of climate change on agricultural production is negative, but much less so than the direct

impact, because of responses from producers and consumers to changes in agricultural prices due to climate change. Moreover, if we consider the impacts of climate change in the rest of the world that affect China's trade and therefore domestic production, climate change impact on China's agricultural production will be further reduced.

Empirical results also show that there is a wide range of measures that can reduce climatic risks. Most of these measures are related to the water sector (e.g., water infrastructure) and farm management (e.g., crop or variety diversification, irrigation practices, adjusting field operation, etc.). Econometric analysis shows that public extension service (e.g., the provisions of early warning and prevention information), policy support (e.g., financial and technical support) against extreme weather events, and household assets such as households' social capital and wealth can improve the ability of farmers in adapting to climate change. Several major measures in the water sector and farm management significantly reduce average crop yield loss and variance of crop yield due to extreme weather events.

This study concludes with several policy implications. While China's agricultural sector will face greater challenges under climate change, there are a number of measures –particularly those related to the water sector, farm management, and agricultural markets– that can reduce the impact of climate change. As most of these measures are not new, enhancing the above measures in crops and regions that are adversely affected by climate risks and including this enhancement as one of major investment priorities in agricultural development programs are critically important in developing climate adaptation plans and policies.

3310 - Climate finance at scale: emerging opportunities?

Climate finance at scale: Overview of issues

TE. Downing (1) ; H. Mcleod (2)
(1) Global Climate Adaptation Partnership, Oxford, United Kingdom; (2) KPMG, London, United Kingdom

Climate finance is essential to reducing climate risks, and is at the heart of the UNFCCC's climate regime. Engagement with the private sector goes beyond the expectation of finance for public funds or protection against expected losses and damages. Transformation of climate resilience requires leadership in a range of private sector forms of investment and sustainability. Emerging examples of how research has informed improved access to climate finance address fundamental questions. How can research inform private sector investments in adaptation? What are the barriers limiting the scaling up of successful pilot interventions? How can adaptation plans of implementing entities be informed by research? What is the business proposition for private sector investment?

O-3310-01

Climate finance at scale: emerging opportunities?

A. Atteridge (1)
(1) Stockholm Environment Institute, Stockholm, Sweden

Climate finance is essential to reducing climate risks, and is at the heart of the UNFCCC's climate regime where developed countries have pledged to mobilize US$100 billion of climate finance per year from 2020 onwards. In parallel this year, the Post-2015 process to negotiate the Sustainable Development Goals, the Financing for Development Conference in Addis Ababa, and the Third United Nations World Conference on Disaster Risk Reduction will also agree on new financial commitments and/or principles for providing support to developing countries. While the question of how to mobilise funds is crucial, the equally important question of how to ensure their effective use has been given far less attention. At present, these different flows are governed and delivered separately, across a fragmented finance architecture, and this among other factors creates problems for using limited financial resources effectively. There is scope for much greater alignment of international public finance for development, climate change and other goals (such as for disaster risk reduction or environmental management), and yet also challenges to achieving greater alignment. What are the opportunities for post-2015 governance of climate finance in this broader context?

O-3310-02

Climate finance at scale: emerging opportunities?

R. Mechler (1) ; T. Schinko (2)
(1) IIASA, Risk, Policy, Vulnerability, Laxenburg, Austria; (2) IIASA, Risk, Policy, and Vulnerability Program, Laxenburg, Austria

Climate finance is essential to reducing climate risks, and is at the heart of the UNFCCC's climate regime where developed countries have pledged to mobilize US$100 billion of climate finance per year from 2020 onwards. In parallel this year, the Post-2015 process to negotiate the Sustainable Development Goals, the Financing for Development Conference in Addis Ababa, and the Third United Nations World Conference on Disaster Risk Reduction will also agree on new financial commitments and/or principles for providing support to developing countries. While the question of how to mobilise funds is crucial, the equally important question of how to ensure their effective use has been given far less attention. At present, these different flows are governed and delivered separately, across a fragmented finance architecture, and this among other factors creates problems for using limited financial resources effectively. There is scope for much greater alignment of international public finance for development, climate change and other goals (such as for disaster risk reduction or environmental management), and yet also challenges to achieving greater alignment. What are the opportunities for post-2015 governance of climate finance in this broader context?

Engagement with the private sector goes beyond the expectation of finance for public funds or protection against expected losses and damages. Transformation of climate resilience requires leadership in a range of private sector forms of investment and sustainability. Lessons learned in working with both large companies and SMEs highlights emerging good practise as well as major challenges for public-private cooperation.

The Warsaw Loss and Damage Mechanism holds high appeal for transforming both adaptation and mitigation, yet requires solid science-based information to become actionable. Research around the concept of climate risk management focuses on: (i) climate justice for the Loss & Damage Mechanism; (ii) climate risk management from different perspectives (objective, perceived, idealized risk), and the implications for the Loss&Damage debate; (iii) the potential for risk layering as a framework for operationalizing climate risk management, including insurance and a possible extreme climate risk layer; and (iv) attribution of losses to anthropogenic climate change and potentially robust results.

Emerging examples of how research has informed improved access to climate finance address questions such as: How can research inform private sector investments in adaptation? What are the barriers limiting the scaling up of successful pilot interventions? How can adaptation plans of implementing entities be informed by research? What is the business proposition for private sector investment?

O-3310-03

Impact Investing and unlocking Private Sector finance for climate change adaptation in Sub-Saharan Africa

N. Thaven (1)

(1) Climate Technology Initiative – Private Finance Advisory Network, Winterton, KwaZulu Natal, South Africa

There is growing consensus that with even the most rigorous of efforts to mitigate climate change it is likely that we will have to adapt to a changing climate, and that the countries least responsible for causes will bear the greatest burden. The cost estimates for adaptation vary, with more recent estimates indicating a three-fold increase in the finance required. Despite the variance, it is clear that current sources of public finance fall far short of the required resources, and that the private sector has a role to play in providing some of the required finance.

The private sector however has its own requirements for investment and many adaptation projects will not be able to respond to the return on investment, stage of development or scale requirements of investors. CTI PFAN, the Climate Technology Initiative's Private Finance Advisory Network has shown its ability to raise private sector finance for climate change mitigation, having raised in the region of $600 million to date. It is now trying to replicate this success for adaptation, supported by IDRC, and at its last Investor Forum in Johannesburg in November 2014, was able to showcase adaptation projects from Africa which have the ability to respond to some of the demands of private sector finance, with projects from multiple sectors, including water, agriculture, real estate, tourism and microfinance, at various stages of development, and various scales. Twelve projects were showcased to investors, each of which represents both public and private goods, but with in-built social and environmental credentials.

There are trillions of dollars being invested annually by the private sector and the growing call for responsible investment is part of the stimulus for the growing sector of Impact Investing. Organizations such as "100% Impact," have shown that pure impact investments have the ability to match the returns of conventional investments. Whether the investment community is aware of project categorization as mitigation, adaptation or just good development is a moot point.

The Impact Investment community represents a high potential source of private sector finance for supporting adaptation actions if the adaptation projects can demonstrate their ability to quantify their impact. The current CTI PFAN adaptation work is thus paired with a research component, managed by the Frankfurt School, which, amongst other issues such as an assessment of the policy environments and risk analysis is also looking at the metrics of adaptation.

To secure some of these private sector funds for adaptation activities, the relationship between adaptation projects and the impact investment community needs to grow, and there are four key issues which the current CTI PFAN project aims to address to achieve this:

1. The development of a pipeline of investment grade projects;
2. The leveraging of public funds to generate investment tipping points and to create a market of these types of investments;
3. Mechanisms to bring these projects into view so that they become part of the available options for investment;
4. Developing metrics for assessing adaptation activities.

O-3310-04

Private finance for adaptation: do private realities meet public ambitions?

P. Pauw (1)
(1) German Development Institute, DIE, Bonn, Germany

The private sector's role in climate finance is increasingly subject to political and scientific debate. Yet there is poor empirical evidence of private finance for adaptation and its potential contribution to the industrialised countries' mobilisation of USD 100 billion of annual climate finance from 2020 onwards to support developing countries to address climate change. Building on earlier research (e.g. on the private sector's role in adaptation in NAPAs and Zambia's agricultural sector), we will present a paper on an analysis of 101 case studies of private sector adaptation under the Private Sector Initiative (PSI) of the UNFCCC Nairobi work programme. The case studies are examined against ten 'adaptation finance criteria' that were distilled from UN climate negotiation outcomes.

Results show that private adaptation interventions complement public adaptation activities all over world, including in priority sectors in developing countries such as water and agriculture. Yet the ten adaptation finance criteria are not met, which demonstrates that the diplomatic UNFCCC conceptualisation of adaptation finance is dissonant from the private sector reality. For example, only a minority of the case studies takes place in the `prioritised' most vulnerable developing countries. And while the case studies' investments are 'new and additional' to Official Development Assistance (ODA), their 'predictability' remains unclear. And despite some commitment for 'up-scaling', plans and associated costs for doing so remain undisclosed. Developed countries' role in 'mobilising' private financial resources under the PSI seems limited.

The presenters will provide options for minor improvements to bring the private realities closer to public ambitions. Yet it is unrealistic to expect that the UNFCCC alters existing adaptation finance criteria to suit private initiatives better, or that the private sector aligns its initiatives to meet the UNFCCC criteria. We therefore advocate strict monitoring and reporting only of private investments that principally aims to finance adaptation. This practical way forward would allow private finance to meet criteria such as predictability, transparency, and mobilisation, but would drastically reduce the amount of private investment that could contribute to reaching the USD 100 billion climate finance target, which would have major political implications.

Missed Targets, Missed Opportunities! Lessons from tracking Adaptation Financing for Zambia

P. Mbozi (1)
(1) University of Zambia, Institute of Economic and Social Research, lusaka, Zambia

Who funds and who benefits from climate change adaptation (CCA) funds in Zambia? This was main question that a study commissioned by the Zambia Climate Change Network wanted answered. The study set out to map, track and analyze both domestic and foreign financial flows to CCA, as part of the global Adaptation Finance Tracking Initiative (AFTI). The goal was to improve CSO advocacy for transparency, accountability, participation and ownership of programming and financing for CCA and resilience in Zambia and help address identified institutional and structural constraints to the effective delivery of climate finance to intended beneficiary constituencies. The experience would be used strengthen tools to track and monitor adaptation and resilience finance flows from a multitude of sources down to the local level and for South-to-South learning. The study focused primarily on seven sectors which are targets of climate proofing and the extent to which these funds trickled down to the beneficiary target groups. The methodology involved review of secondary data sources including the National Budgets (Yellow Book), and sought primary information through interviews with ZCCN members, stakeholders, community leaders and local people and community based organizations at district level.

The study established three windows of financing CCA programmes in Zambia: 1. National resources; 2. Donor funds through budget support; 3. Direct programme or project support from the donors: and, 4. CSO funds from donors either through the Civil Society Environment Fund (CSEF) or through bilateral agreements between a donor or donors and a particular NGO.The study notes that funding for CCA is donor driven, with government contributing less than 1% of the total expenditure to the seven sectors; lack of prioritization for CCA; negligible and fluctuating funding; and, less CCA funds compared to mitigation. Variations between budgeted and/or pledged funds and actual disbursements is noted, including among donor finances. Lack of government policy on climate

change affects climate change financing, resulting in budget variations from year to year and lack of a budget line specifically for CCA especially for grass-root activities. Most funds go to upstream activities – salaries, workshops, etc – and CCA is lumped together with environment and other CC interventions, such as mitigation, in the national budgets. This makes it is difficult to track CCA funds and it explains why there are no visible CCA activities on the ground. The study also notes rigidity in budget lines to accommodate emerging issues, such as CCA and limited absorptive capacities among recipient sectors, resulting in variances between disbursed and utilized funds.The study found that stakeholders and ordinary people, especially at the local level, are not involved at any of the three key levels of the budget process: 1. Preparation of the budgets; monitoring expenditures from the allocated funds; and, reviewing the impact of the funded programmes, hence apparent mismatch between what the government does and what the people see as their main priorities. Further, stakeholders and local communities lack civic education about the budget and its processes and about their own rights in national resource allocation; therefore weak in demanding financial accountability and effective participation in tracking government expenditures.The study also established that the budgeting process and budgets themselves are too complicated for ordinary citizens, even professionals responsible for budgets at local level, to understand. Many people are often put off by the size of the Yellow Book and the difficulties in accessing the financial and Auditor General's reports. Further, tracking and budgeting for CCA funds is hampered by lack of knowledge of CCA funds coming into Zambia by heads and staff of government departments, stakeholders and local communities and their leaders. The study also notes lack of synergy and collaboration, especially at local level, among organizations, including CSOs that are involved in CCA in one way or the other. This weakens their capacity in advocacy.The study acknowledges the existence of various methods and tools of tracking finances for specific interventions. It recommends a cocktail of tools of tools. It recommends focused advocacy towards priortisation of CCA financing through domestic resources, more social accountability, transparency and community and stakeholder ownership participation in allocations and disbursements.

Climate Policies across Africa: Increasing Interactions and Building Resilience

A. Maupin (1)
(1) South African Institute of International Affairs SAIIA, Johannesburg, South Africa

In its quality of a worldwide well-attested phenomenon, climate change will spare no continent. This being said, Africa has started to host climate-related global conferences, such as the World Summit for Sustainable Development in Johannesburg in 2002 and the 17th Conference of the Parties (COP17) in Durban in 2011, both cities being located in South Africa. In addition, African climate-related bottom-up initiatives have played a growing role in climate negotiations, notably by shifting the climate change mindset from an environmental challenge to a development one. As a result of this more comprehensive view of climate change, numerous actions now speak to the increasing number of integrated public policies in different sectors and attempt to bridge the gap between policy development and implementation.

However, few African countries have developed comprehensive climate-related policies. More often, these policies focus on responding to extreme events on one side and managing resources on the other. For example, after Mozambique was forced to appeal for international help to rescue its people during the 2000-2001 massive floods related to the passage of several cyclones, the National Centre of Disasters Management (INGC) was created with the task to evaluate, response and adapt Mozambique to these changes. On a different note, recent provincial plans promulgated by the Democratic Republic of Congo (DRC) have mentioned the importance of including adaptation and mitigation strategies to fight climate change impacts and protect this country's environment. In South Africa, the National Climate Change Response has been conceived as a process, which provides room for stakeholders comments and scentific inputs via dialogues. This diversity of responses reaffirms not only how diverse the national contexts (notably risks and priorities) are, but also how unique the stakeholders' interactions and the locally-built initiatives have become to tackle climate change challenges.

Against this background, this paper presentation aims to provide an overview of the numerous climate-related policies that exist across African countries in order to analyse their political motives and responses to climate change. This, in turn, will contribute to develop and implement more interactive policies, which could be further scientific-and initiatives-informed at the national and regional level. Given the importance of natural resources for development and the expected global impacts of climate change on water, energy, forestry, among others, climate-related and resources-based policies would arguably become strategic components of state security. Interconnections between climate change and resources management policies already exist and cannot be ignored, when they demonstrate states' growing interests in linking future adaptation and mitigation plans with environmental concerns across Africa.

Policy Instruments to Overcome Energy Efficiency Barriers in Designated Buildings under Thailand's Nationally Appropriate Mitigation Actions (NAMAs)

Y. Asayama (1) ; B. Limmeechokchai (2)
(1) National Institute for Environmental Studies, Tsukuba, Japan; (2) THAMMASAT University, Sirindhorn International Institute of Technology, Pathumthani, Thailand

Thailand pledged its Nationally Appropriate Mitigation Actions (NAMAs) at UNFCCC COP20 in Lima, Peru, following ongoing discussions since 2012. Improvement of energy efficiency in designated buildings is one of the main countermeasures under the proposed NAMAs. Data collection on the actual energy consumption of the buildings plays a key role in determination of the scope of countermeasures as NAMAs and implementation of Measurement Reporting and Verification (MRV). However, the issue of how these countermeasures will be implemented in the context of the unsatisfactory progress of existing policy instruments, particularly the Building Energy Codes (BEC) and energy management reporting system as specified in the 2007 Energy Conservation Promotion (ECP) Act and the Energy Efficiency Development Plan (EEDP) over the period of 2011-2030 remains to be addressed.

The objective of this study is to examine the potential of policy instruments and energy-saving measures to overcome the existing barriers. Firstly the literature is reviewed, with discussion of theory-based policy instruments for building energy efficiency in order to analyze the situations and gaps in policy instruments adopted in Thailand. The means of enforcement and implementation of alternative policy options are also examined. The study also incorporates interviews with relevant stakeholders involved in the NAMA process as well as in EEDP in order to compensate for limitations in the literature available on Thailand's situation. Furthermore, good practices implemented in other countries were considered for their suitability for application in Thailand.

The necessity of addressing legal and institutional barriers in order to overcome the information barriers was clearly evident in Thailand. The literature shows that regulatory measures have been implemented since 1995 under the ECP Act. However, these have only been implemented

on an ad-hoc basis. In the case of existing buildings, there is no benchmark to identify electricity consumption involved in conducting the required energy management in each designated building. There are also limitations in the availability of information on technologies and technical information contribution to energy savings and operational management. The in-deep interviews indicated that BEC for the construction of new buildings and third-party energy audit have not as yet been implemented. The limitations in human resources and capacities to implement verification and monitoring of the submitted reports have prevented the consolidation of regulation measures as well as the revision of energy efficiency performance standards. Hence, this has given rise to a paucity of sufficient and credible data and made it difficult to achieve the understanding of the existing situation, future projections, and impact of policy instruments.

Results show that the targets of EEDP and Thailand's NAMAs will not be effectively achieved without improvement in the means of achieving compliance levels in the existing ministerial regulations. Progress on this front will be achieved through improved awareness of energy efficiency and co-benefits of implementing the actions through the development of benchmarking and information disclosure for buildings' energy performance, and providing tailor-made solutions. It is necessary to initiate process-oriented, interactive policy-making, with intensive technical training on the ground in order to enhance the credibility of governmental decisions and activities, and to collect and accumulate reliable data and information for energy efficiency toward the achievement of NAMA objectives.

Climate policies : learning from a comparison of different national experiences

P. Mallaburn (1)
(1) Climate Policy Journal, Welwyn Garden City, United Kingdom

Peter Mallaburn will give an introductory speech to the session, questioning how a comparison between different national experiences of developing climate policies can be operated, and what are the challenges we face when trying to organise a learning process between these various experiences.

O-3311-04

Price and Prejudice: The politics of carbon market establishment in Turkey

AC. Gundogan (1) ; E. Turhan (2)
(1) King's College London, Geography, London, United Kingdom; (2) Istanbul Policy Center, Sabancı University, Istanbul, Turkey

Despite increasing number of studies on carbon trading's inefficiencies and self-contradictions, it has been continually presented as the most effective climate change mitigation option and has become a huge global business. On the other hand, governments' endless support to the carbon markets has been criticised since the emission trading balloons exploded numerous times. Being an EU-accession country with no access to EU ETS (Emissions Trading Scheme) and an Annex-I country with no access to flexibility mechanisms under now defunct Kyoto Protocol, Turkey is a latecomer to the game. While being a country whose greenhouse gas emissions increased by %133 between 1990-2013 showing the highest rate of change among OECD members, Turkey's climate politics are increasingly drawn into market based climate policies particularly in the dawn of a new global climate agreement that is set to be signed in 2015. As a result of the external pressure from institutions like World Bank and private sector driven processes, Turkey has started lay down limited policy and legislative ground work in pursuit of setting up an emission trading system which then expected to be linked to the international carbon markets. However, implementation of the emission trading mechanism has never been widely discussed in Turkey hence making it a highly non-transparent process. Potential environmental and socio-economical impacts of the market-based instruments in the framework of combatting climate change are being watered down by politicians, industrialists and technocrats while illusive promises of the carbon markets are presented as the centerpiece of Turkey's position in the new climate regime. This paper critically analyzes the perceptions, promises and discourses of the emerging emission trading system in Turkey from a political ecology lens by scrutinizing different actors' (including representatives of environmental justice movements, state bureaucrats, private sector and international organizations) statements. By doing this, this research aims go beyond dominant voices on carbon market establishment in Turkey, by revealing power relations, preferential treatment of some top-down policy options and the influence of multilateral finance organizations. Such critical approaches suggest that policy preference towards carbon markets vis-à-vis carbon tax in Turkey are not necessarily a rational process lack scientific substance as well as public buy-in.

O-3311-05

Climate legislation in the UK: the Climate Change Act and the Committee on Climate Change

S. Smith (1)
(1) Committee on Climate Change, London, United Kingdom

The UK has traditionally been a progressive nation in calling for action on global warming. In 2008 it passed a Climate Change Act with strong backing from all the major political parties.

The Act set a target for national greenhouse emissions to be at least 80% below 1990 levels by 2050, created a system of 5-year carbon budgets to get there, and set a programme for adapting to climate change. It also created an independent Committee on Climate Change (CCC) to advise on these aims and monitor progress towards meeting them.

This talk will cover the Act, the role of the CCC and the various factors (such as climate science, economics and international circumstances) that inform the UK emission targets. It will show how the 2050 target is achievable, highlighting the key technologies likely to be needed and the cost involved. We will also see what policy progress has been made in the 7 years since the Act was passed and take a critical look at whether or not the UK is on track to meet the first few carbon budgets.

"Climate change adaptation strategies and disaster risk management in Bangladesh"

AMH. Akhand (1)
(1) Bangladesh Energy Regulatory Commission, Govt of Bangladesh, Joint secretary, gas and regulations, Dhaka, Bangladesh

Bangladesh is one of the most climate-vulnerable countries in the world and innocent victim, experiencing changing weather patterns of irregular temperature, rainfall and winter season-that affecting people's lifestyle. Bangladesh is already affected by climate change impact, increasing temperature of 2° C and sea level rises of 7.5 cm causing 29% higher returns of disasters (i.e. flood with permanent phenomena which is major causes of crop devastation almost every year, cyclone, storm surges, heat and cold waves, drought). Bangladesh is now suffering in water salinity, water logging, soil salinity, human health diseases, shortage of fresh drinking water and food security.

The Global Climate Risk Index 2014 covering the period 1990-2013 finds dangerous climate change affects on Bangladesh, estimates that on an average 8,241 people died each year, while the cost of damage is around US $ 1.2 billion per year and loss of GDP is 1.81%. Bangladesh is projected to face 2.0% loss of annual GDP by 2050 and more than 9% of GDP by 2100 and would experience a net increase in poverty of approximately 15% by 2030 due to climate change impacts. After the 1988 flood and 1991 cyclone, Bangladesh Government has given emphasis using satellite data to face climate change impacts. Bangladesh Space Research and Remote Sensing Organization connect the international satellite stations. Satellite images help for better prediction, and tracking

of cyclone and floods. There are also 50 thousand coastal cyclone preparedness program and 20 thousand urban volunteers are engaged in front-line rescue and awareness activities with women participation for disaster mitigation. Built coastal embankments.

Bangladesh has made remarkable efforts in 'strategies and plans' to streamline regulatory and institutional settings as a pathway for adapting climate change impacts following the existing policies and acts. Bangladesh is the first example country for taking various initiatives for the adaptation. The adaptation is the key for survival, initiatives taken in different sectors of the government. One of the six pillars in the adaptation Strategy and Plan is Low Carbon development' that puts emphasis on energy efficiency, energy conservation and utilization of renewable energy as potential mitigation options (Bangladesh is less than 0.3 ton GHG emission per year). To adapt the climate impacts, Bangladesh developed Flood Action Plan (1988), the National Water Management Plan (2004), the Standing Orders on Disasters (2010), the 'National Adaptation Program of Action' (2005, revised in 2009) and the 'Bangladesh Climate Change Strategy and Action Plan' (2009) to take necessary preparedness.

The Strategy and Plan is to strengthen adaptive capacity of the local communities and to foster innovation in climate change related technologies which would reduce poverty, generate employment, ensure security of food, water, health, energy and socio-economic well being of all citizens of the country. Bangladesh has prepared a Road map towards formulating a comprehensive NAP with a view to reducing vulnerability to the impacts of climate change by building adaptive capacity and resilience, flood and cyclone shelters.

Bangladesh Meteorological Department developed better early warning system for cyclone and other hazards using satellite data. The Flood Forecasting and Warning Centre is engaged to alert the vulnerable people about flood risk. Introduced climate tolerance (saline, drought, flood, rain-adapted) crop production. Bangladesh has established two innovative funds: Climate Change Trust Fund from the Government's own budget with an initial capital of US$ 45 million, and Bangladesh Climate Change Resilient Fund (initial fund US$188 million) with the support of development partners. Recent disaster casualties and damages shows the successful reduction compare to previous events. Satellite images are most useful as first responses to disasters and post-disaster assessment. Satellite phones/mobiles/tv channels are useful for emergency warnings. The satellite technology creates new hope and inspirations for human lives.

Forest management systems within rural communities of the north west region of cameroon, strong strategic approaches for climate change in sub-saharan africa.aw. awa (1)

(1) IMPACT CREATORS/ COMMUNITY DEVELOPMENT ALLIANCE GROUP, BAMENDA, Cameroon

In a bid to tackle some of the questions raised by climate change, this paper will discuss Sustainable Forest Management Systems within Rural Communities of the North West Region of Cameroon, strong strategic approaches for climate change in sub-saharan Africa.

Human actions on forest, such as uncontrollable harvesting of medicinal plants, felling of trees, farming, bush fires and local bee farming practices like generating smoke to drive away bees from a hive by burning fresh leaves of plants, provide negative effects on climate. This paper presents an analysis of the scientific evidence, indicating that negative influence on forest is affecting the climate in Cameroon. Sea levels are rising; rainfall has decreased by 11%, early rains, increased temperatures and flooding. The paper identifies strategic approaches that are practiced in tackling forest management and climate change in Cameroon. Examples are: tree planting, renewable energy, solar powers, water powers, etc. It describes also, generated land use systems, forests conservation methods and farming techniques, which influence climate change and the health of forest positively.

The concept of indigenous ecosystem and forest management systems used in this paper refers to a series of practices based on agreed rules, carried out by the local people, aiming at the sustained availability of products and services from trees, crops and forest through Sustainable Development for climate change. Local populations surrounding these forests understand the education of community forestry, taking an active leading role in preserving and protecting the forests, in order to ensure long term benefits and stop the ill effects of climate change in the society.

The paper concludes that this project is building these capacities in collaboration with the various stakeholders in the localities for a healthy conservation of forest and monitoring of changes in the climatic conditions of the areas. Forest management and monitoring plans are carried out using participatory methods and are designed to meet the needs of the communities and their families, while at the same time maintaining Sustainable Biodiversity and Climate change functions.

P-3311-03

The political internalization process of climate issues in Brazil and China (1992-2012)

F. Barbi (1) ; LDC. Ferreira, (2)
(1) University of Campinas, Center for Environmental Studies and Research, Campinas, Sao Paulo, Brazil; (2) University of Campinas, Center for environmental studies and research, Campinas, Brazil

In terms of climate change responses, it is argued that governments are important actors that play a key role in the development of norms, institutions and appropriate modes of governance to address these changes at different levels and scales. This paper analyzes the internalization process of the climate issue at the government level in Brazil and China. These two countries have been noted for their importance in the international arena and, above all, the importance of environmental issues at the core of their political processes. In terms of methodology, this analysis is based on three main points: i) Trajectory of greenhouse gases emissions in Brazil and China, in the period of 1992-2012; ii) Political and institutional structures mobilized to the climate issue, focusing on mitigation; iii) Political responses related to climate change, through a historical reconstruction of policies, plans, major programs and projects developed and implemented related to climate change mitigation. The starting point for this analysis is the year of 1992, more specifically the consequences of the United Nations Framework Convention on Climate Change, resulting from the United Nations Conference on Environment and Development, which marks the beginning of the involvement of both Brazil and China in international discussions and negotiations on climate change. The results of our analysis show that, in Brazil, emissions have fallen since 2008 and there has been a change in the profile of greenhouse gases emissions in the country. Land-use change and forestry sector has no longer been the most responsible for emissions since 2010. However, all other sectors have increased their emissions over the analyzed period. In the case of China, even with mitigation efforts undertaken, emissions have increased every year. However, the emission growth level has declined reflecting the country's efforts in the installation of low carbon power generation and improvements in energy intensity. In Brazil, there are robust and consolidated political and institutional structures to address the climate issue, involving other segments of society such as the private sector, civil society and research institutions, among others. Regarding political and scientific framework, there was a significant increase in the production and systematization of studies and reports, which can assist the design and implementation of policies related to the problem, and reduce the uncertainties related to climate change. China has also made some progress in this direction. The results show that, in Brazil, the climate issue internalization process is characterized by three phases: the first, marked by the establishment of political-institutional and scientific structures engaged with the issue. The second, stands out for greater understanding of this issue in the country. It is marked by the development of a political and scientific agenda around the theme and planning actions in the country. The construction of this agenda was fundamental in laying the foundations of the national policy on climate change. Finally, the third phase is marked by the development of climate policies and by strengthening the scientific agenda around the theme. The national policy agenda is focused on the implementation

of sectoral plans, to meet the voluntary mitigation targets established by the National Climate Change Policy. In the Chinese case, the internalization process of the climate issue has two phases: the first, has more focus on combating air pollution, whereas the climate issue stands as secondary focus of action and the second, more proactive regarding concrete commitments on climate change, with the establishment of the National Climate Change Program and the National Leadership Panel on Climate Change. Both Brazil and China still have challenges to be faced in relation to the set of problems that make up the environmental issue in a world characterized by global climate change. Environmental and climate concerns have difficulties to become political priorities in both countries. In any case, policy measures aimed at climate issue in these countries may lead to the reconfiguration of international negotiations about it.

P-3311-04

Agricultural biodiversity in climate change adaptation planning: An analysis of the National Adaptation Programmes of Action

A. Bedmar Villanueva (1) ; M. Halewood (1) ; Nl. López (1)
(1) Bioversity International, Roma, Italy

To guide climate adaptation policies and investments, the majority of least developed countries (LDCs) have developed National Adaptation Programmes of Action (NAPAs). This study analyzes the extent to which agricultural biological diversity is included as part of national adaptation planning in the 50 NAPAs developed by LDCs to date. Lessons learned from the NAPA development process are potentially valuable to countries that will be developing NAPs in the years to come. Agricultural biodiversity (at genetic, interspecific and ecosystem levels) can contribute to the resilience of the agricultural systems faced with increasing climatic variability, thereby reducing farmers' vulnerability. The paper presents a framework for analysis existing literature concerning climate change and adaptive capacity, agroecosystems' vulnerability and resilience and the use of biological/genetic diversity in agricultural production, plant breeding, research and development. The study identifies 48 activities included in the NAPAs that do (or at least could) increase biodiversity in agricultural production systems and/or in upstream research and development chains as part of strategies to adapt to climate change. These activities were clustered, first, by sectors (crops/forages, livestock, fisheries, forestry, agroforestry and natural resources) and then by biodiversity levels (genetic/intra-species, species and ecosystems). The analysis highlights that the exploitation and increase of agrobiodiversity is included in many of the NAPAs: 31% of all of the priority project proposals based on the NAPAs include some combination of the 48 agrobiodiversity-related activities. However, approaches taken to including agrobioversity varies considerably across the 50 NAPAs: 39% of the identified agrobiodiversity related activities are concentrated in 11 NAPAs; 20 NAPAs present the highest levels of inclusion of agrobiodiversity related activities; whereas 10 NAPAs were found to contain only between zero and 2 of the identified agrobiodiversity related activities. Eight of the identified 48 agrobiodiversity related activities accounted for the 56% of all the relevant activities mentioned overall, suggesting that relatively low range of actions were identified among the priority project proposals. The highest concentration of activities was found in the combined sector of crops/forages and at the ecosystem level; and the lowest in the fisheries sector and at the species and ecosystem levels. Only a small number of the NAPAs include a generally consistent spread of activities across the 3 levels of diversity. Interestingly, all 48 agrobiodiversity-related activities related to research, development, and production systems, and not to promotion of demand or consumption. The study concludes that a more comprehensive and organized approach to including agrobiodiversity in national adaptation planning will be important in future NAPA and NAP development. National planning teams will require capacity strengthening and tools to help them consider options and develop practical, scalable plans (there are few clearly established precedents/models for scaling up of agricultural biological diversification strategies at the national level). While it is beyond the principle scope of our analysis, the paper reflects on some of the factors that have contributed to the variable degrees to which agrobioversity has been included in some countries' NAPAs, including the influence of strong plant genetic resources for food and agriculture (PGRFA) national programs, high-profile agrobiodiversity projects, pre-existing national policies that underscore the importance of agrobiodiversity, etc. On the other hand, the paper notes that 11 countries that included highest levels of reliance on agrobiodiversity are spread across 3 continents and have very different agro-ecologies and climate-related farmer vulnerabilities.

P-3311-05

Analysis of low carbon policies in the building sector

H. Beijia (1)
(1) environmental science, shanghai, China

Building sector accounts for a large percentage of the GHG emission. It is critical to raise appropriate low carbon policies both in developing and developed countries in the building sector. This study focuses on low carbon policies in building sector by conducting a comparison study between Japan and China so that different policy implications can be recognized for countries in different development stages. Two research questions are discussed, including how effective current low carbon policies are and what obstacles exist. Both stakeholder interviews and literature reviews based on Scopus database were undertaken.

In order to address these two issues, related policies are categorized into four groups: control and regulatory instruments; economic/market-based instruments; fiscal instruments; information and voluntary actions. Policy effect analysis identifies that low carbon policies in the building sector have promoted energy saving in both Japan and China. Especially, the innovative Cap and Trade Program in Japan has greatly enhanced the GHG emission reduction. Obstacles comparison reveals that Japan and China shared many obstacles including high transaction costs and lack of applicable methodology. But certain differences also exist. For instance, the unstable political condition and the unexpected Fukushima accidents impede the Japanese government to initiate more innovative energy policies in Japan, while China is suffering from obstacles such as inefficient enforcement, and immature financial regulation system.

Based on the previous findings, common suggestions for overcoming these obstacles of low carbon policies in Japan and China are presented, such as the accurate methods of baseline identification and emission accountings, innovative incentives, and more capacity building activities. Finally more specific suggestions for both Japan and China are also added by considering their own situations so that both countries can further improve their BES policies.

P-3311-06

Rethinking Climate Change Research in Zimbabwe

S. Bhatasara (1)
(1) University of Zimbabwe, Sociology, Harare, Zimbabwe

Climate change is arguably one of the most pressing challenges confronting Zimbabwe. As such, it has received considerable attention from a wide array of scholars. Certainly, very significant contributions have come from scholars who have deployed various models to establish trends in climate change as well as assess and predict its impacts particularly on agriculture. Paradoxically, even though climate change knowledge in the country continues to grow, questions on how climate change is framed, how impacts are derived using various quantitative methods and models and, even the language used in such studies have not been adequately analysed. These facets are critical particularly because how climate change is framed has important implications for adaptation in the country.

Following the above, this paper subjects various studies on climate change in Zimbabwe to rigorous critical analysis with the intention to demonstrate how climate change and its impacts have been framed and the utility and, pitfalls of such. The important question is, what and whose frames are being activated and hence strengthened and, what are the implications for adaptation? The paper argues that climate, climate knowledge and climate change need to be unpacked and reframed by deploying new and bold ontological and epistemological positions. This involves documenting and analyzing local narratives of climate change, for instance of local farmers, living on the frontiers of such changes. This also suggests that interpretive

methods fundamentally come to the fore, even so without laying claim to principled epistemological privilege.

Although this paper centers on climate change scholarship from a developing country, it draws insights from a number of scholars working in other contexts. For instance, Brace and Geoghegan (2010), brought together the themes on landscape, temporality and lay knowledge to propose new ways of understanding climate change and its impacts. Pettinger, (2007) alludes to the social construction of climate change and how power is used to impose a hegemonic discourse on climate change. Miller et. al., (2008) argue for epistemological pluralism when it comes to understanding complex systems that embrace the human and non-human worlds and climate change is one such system. Hoffman (2011) points out that climate change is not yet a 'social consensus', drawing attention to the various contestations and divergences surrounding the framing of climate change.

P-3311-07

Mainstreaming climate adaptation-mitigation measures at local level: rifling common institutional orbit in Nepal

D. Bishwokarma (1)
(1) ForestAction Nepal, Research, Kathmandu, Nepal

Integration of climate mitigation and adaptation has now been becoming more powerful concern in climate change policy architecture to achieve synergetic outcomes. It has become more relevant especially in least developed countries (LDCs) including Nepal considering unavoidable risk of climate change but their high vulnerability. Since recent past, Nepal has been planning and implementing both adaptation and mitigation projects. Despite sectoral seclusion on planning and implementation, both adaptation and mitigation projects have chosen resourceful and independent local forestry institutions mostly community forest users groups (CFUGs) as an entry point to dispense project input at the grass root level. This article scrutinizes the potentiality of local forestry institutions to contribute on and integrate climate adaptation and mitigation. It further reconnoiters implications of and lessons to achieve synchronized outcome from adaptation and mitigation measures from existing institutional arrangements in Nepal.

This paper is the outcome of two comparative case studies of CFUGs in Dolakha and Lamjung districts where mitigation and adaptation measures have been implementing through piloting the reducing emissions from deforestation and forests degradation (REDD+) and preparing community adaptation plan (CAPs) respectively, four focus group discussions in the case study sites, four key informant interviews, five policy level expert interviews, existing climate change policy documents review, and literature review.

The research found that CFUGs have been contributing on both mitigation and adaptation through their services since before any external funds. Nonetheless, both quantity and quality of services have increased after implementing climate mitigation and adaptation projects through both government and non-governmental agencies. CFUGs have been chosen as an institutional unit to implement different mitigation measures including sustainable forests management, afforestation, and installation of smokeless stoves. The same institution has been preferred to implement adaptation measures including conservation of water holes, riverbed conservation and management, and installation of early warning systems. The research further found the overlapping of activities such as installation of smokeless stove and afforestation to achieve both mitigation and adaptation objectives. CFUGs even have funded to implement both mitigation and adaptation measures. It signifies the functional aptitude of CFUGs to integrate mitigation and adaption in practice. However, sectoral divide exists specially at the national level since adaptation and mitigation projects are being designed and implemented separately by two different sectoral ministries. We found that the operative mismatch and ghettoized dealing of adaptation and mitigation at the community and central level mechanism has been encumbering the functional contribution of CFUGs. The contradictions between climate change policies have further been stimulating for the sectoral and segregated planning and implementation of adaptation and mitigation measures. Such contradictions have further affecting on mutual coordination at the policy level. Nepal is eluding an opportunity to utilize existing and voluntarily emerging forestry institution to integrate adaptation and mitigation due to such differential interferences at the central level. This paper suggests that Nepal has a unique opportunity to be a role model of and contribute to ongoing globate debate to integrate climate mitigation and adaptation in LDCs by employing collaborative planning and implementation process at the central level and by acknowledging the potential contribution of CFUGs at the local level. However, the existing mismatches and segregated planning and implementation approach has to be addressed at the policy level. Synergetic adjustments on existing climate policies would be one primary option to create sectoral collaborative milieu for integration of mitigation and adaptation. The central level policy institution such as national planning commission having directive authority to sectoral ministries should take lead role for overall designing and planning mitigation and adaptation projects to ensure bottom-up mainstreaming, overcome mismatch at policy level, and acknowledge functional potentiality of CFUGs at local level.

P-3311-08

Towards Adaptation : Advanced scientific knowledge to better prepare for climate change

V. Bourduas Crouhen (1) ; R. Siron (2) ; L. Leclerc (2)
(1) Ouranos, Vulnerabilities, Impacts and Adaptation, Montréal, Canada; (2) Ouranos, Project coordinator, Montréal, Canada

To prepare for and cope with a changing climate, the Québec government created, in 2002, a research consortium on regional climatology and adaptation to climate change named Ouranos. The organization publishes, approximately every 5 years, a state of knowledge review on impacts resulting from climate change for Québec. The latest edition, «Towards adaptation: synthesis of knowledge on climate change in Québec» is the most thorough and up-to-date portrayal of what can be expected in the upcoming decades in the province. The synthesis is divided into three major chapters including climatic analyses and scenarios of change; vulnerabilities and impacts; and implementation of adaptation. This document helps answer questions such as «What are the effects for Québec and what options exist to cope with the expected changes?» Elaborated through a collaborative process, it involved over 80 authors and advisers and covered an immense territory (over three times the area covered by France), exposing the reality of over 17 degrees of latitude and more than 22 degrees of longitude. Since this research covers a broad area of climate types and geographic regions, multiple results from this study could be applicable or transferable in other provinces of the country and even outside Canada.

The presentation submitted for this conference will explore a few highlights from this study including the following.

Since the 1950s, the average annual temperature in Québec increased by 1 to 3°C, depending on the region. It is anticipated that by mid-century the temperature could continue to rise by 2 to 4°C and, by the end of the century, by up to 4 to 7°C in the south and 5 to 10°C in the north. In addition, extreme weather events are expected to become more frequent and/or more intense with a warming climate. A sea level rise of 30 to 75 cm in the Gulf of St. Lawrence is also considered a major threat.

Some of these climate changes could generate business opportunities while others could generate significate risks for several sectors. For example, heat waves, aggravated by the urban heat island effect, will affect public health and could increase the cases of mortality and morbidity. Other effects, such as the lengthening of the pollen season and the intensification of atmospheric pollution caused by forest fires, could aggravate respiratory and cardiovascular problems. Likewise, the decrease in ice cover as well as the increase in precipitation could result in major impacts, including erosion of the coastline and flooding. Ecosystems and biodiversity could also be deeply disturbed by the arrival and expansion of harmful invasive species. Impacts from global changes are already noted on the life cycles and distribution of trees, plants, migratory birds, salmonids and the iconic migratory caribou. Water management will be a worldwide issue in a changing climate. Conflicts of use associated with issues of quality

and availability of water are likely to increase and could have negative impacts on aquatic ecosystems and fish habitat, production of potable water in municipalities and agriculture needs among others.

To reduce the vulnerabilities and diminish the costs and magnitude of the expected risks, it is critical to take all necessary measures to adapt. Adaptation measures not only need to help people adapt, but they must be chosen carefully so that they can facilitate sustainable development and more importantly not increase greenhouse gas emissions. To achieve great adaptation measures, all stakeholders within a given system need to be included in the process. This way the multidisciplinary and sometimes multicultural teams can identify issues and search for solutions together taking into account all vulnerabilities on a territory. It is therefore easier for them to implement these adaptation measures when they are directly involved in the identification process.

Québec possesses tools and expertise that could be put to use to reduce vulnerabilities, while leveraging possible opportunities arising from global warming. Revising laws and regulations, building and maintaining infrastructure according to improved design criteria and practices as well as early warning systems to reduce impacts on human health constitute tangible examples of adaptation options already implemented. The question now is not whether we need to adapt but rather how we can optimize the way we adapt to climate change.

P-3311-09

Tracking leading indicators to understand decarbonization trends and impacts of climate policies

C. Cronin (1) ; S. Menon (1) ; S. Monteith (1)
(1) ClimateWorks Foundation, Advisory & Research, San Francisco, CA, United States of America

Over the last year, ClimateWorks Foundation with other collaborators created the Carbon Transparency Initiative (CTI) tool with the objective to provide a transparent, granular, and consistent reference scenario for greenhouse gas (GHG) emissions across regions and sectors based upon current policies, decarbonization trends, and expected investments. The CTI tool is an open-source, indicator-led methodology based upon fundamental analysis of a small number of underlying driver metrics that shape long-term emissions. It allows for comparing current regional emissions trajectories to other scenarios and government targets. It can also be used to track policy developments across nations at the sector level, and to some extent the ambition level of climate policies in different regions. Overall, it serves as a tool to evaluate the extent, pace, and efficiency of decarbonization. This presentation will review the main findings of the CTI for five focus regions, and compare scenario projections and decarbonization trends with other major modeling and tracking efforts and will evaluate the impact of specific climate policies on GHG emission reductions.

The CTI tool, as designed, provides transparency of emissions in China, the EU-28, India, Mexico, and the US, for which the methodology distinguishes between 11 sectors: power, transportation, oil and gas, buildings, steel, cement, chemicals, 'other industries', agriculture, forestry, and waste. The tool presents analysis on leading indicator statistics for each sector, and uses these metrics to both determine future emissions trajectories and benchmark current decarbonization trends. Approximately 10 additional countries are being added in 2015 in partnership with the Climate Action Tracker (CAT) group, though with less detail. All combined, the CTI will be able to evaluate decarbonization trends and impacts of climate policies in countries that account for 75% of global emissions.

Many of the highest-emitting countries are undergoing rapid changes. When extrapolating historic GHG numbers for these countries, forecasts and scenarios can fundamentally underestimate saturation and maturity effects, and cannot thoroughly capture the impacts of current and expected climate policies. CTI's methodology is uniquely designed to forecast emissions trends out to 2030, taking into account saturation points, macro and technology shifts in the economy, and climate policy implementation, and conducts fundamental analysis on a small number of key drivers of global emissions. The tool relies upon a number of trusted sources, including the International Council on Clean Transportation (ICCT), Bloomberg National Energy Finance (BNEF), International Energy Agency (IEA), and others. In addition, by providing a high level of granular visibility into its components and indicators, with all of its outputs broken by region, sector and covering the time period between 2010 to 2030, the CTI tool is designed for annual tracking of key driver metrics for the next few years that help understand and contextualize trends in decarbonization and implementation of climate policies.

P-3311-10

Greenhouse Gas Emissions and the Climate Policy Response from State and Local Governments in the United States: Comparative Analysis of California, Texas, New York, and Florida

S. Garren (1)
(1) Hofstra University, Geology, Environment, and Sustainability, Hempstead, New York, United States of America

The purpose of the session is to assess the current state of climate policy and greenhouse gas (GHG) emission trends in the four most populated states in the United States (i.e., California, Texas, New York, and Florida). Together these states comprise one-third of the total United States population. Each state faces different challenges in addressing climate change and each has historically different approaches to climate policy. The session will be organized by the three research questions that guided the research: 1) What has been the policy response to the threat of climate change from each of the four states and its local governments; 2) What were the GHG emission trends from 2000 to 2010 in the four states and its local governments?; and, 3) What were the drivers of change of greenhouse gas emissions? Research was conducted to systematically catalogue climate policy within each state and specific actions taken at the local government level. Actions taken at the local government level included participation in one or more of eight climate networks and completion of a GHG inventory and/or climate action plan. A comprehensive GHG inventory was completed for each state (2000 through 2010) and for selected local governments (2000 and 2010). GHG emissions were summarized for total GHG emissions, per capita GHG emissions, and by sector (i.e., energy, transportation, industrial processes, agriculture, waste, carbon sequestration, and for miscellaneous other categories). Data availability at the state level is robust; however, readily-available data for all local governments continues to be problematic. The research also provides recommendations on data collection improvements at the local government level to better determine the efficacy of local government policies and to make comparisons among local governments. Policymakers need accurate data and a framework by which to measure progress towards reduction targets and mitigation strategies aimed at reducing GHG emissions.

P-3311-11

Localizing climate policy responses: Explaining local government responses to climate impacts in the United States

D. Kauneckis (1)
(1) Ohio University, Voinovich School for Leadership and Public Affairs, Athens, OH, United States of America

In the context of American public policy, local and state governments have taken the lead in innovating and implementing climate change policies. This has occurred both in terms of mitigation and adaption efforts. This presentation reports results from a study of the actions of local governments in response to climate change in the United States. The study relies on a unique dataset of 1,277 public organizations at the city, county and sub-state levels engaged in climate change policymaking and implementation. The presentation focuses on climate adaptation efforts - defined for the purpose of this work as policy action taken that addresses a risk directly associated with climate impacts. The results examine the factors contributing to the likelihood that a local government organization has actively expended resources toward reducing climate vulnerability. It explores how

organizations collaborate and engage in collective action solutions that facilitate policy learning and innovative strategies to address climate risks. The variables examined include the type of policy action, exposure to real and perceived climate risks, levels of policy innovation associated with organizational collaborations, and the outcomes of these efforts. Additionally, it looks at the role of both informal and formal policy networks, sources of innovation, and the prevalence of horizontal and vertical collaboration. Findings contribute to the theoretical literature on institutional collective action, policy innovation and learning, and local public economies. The results present important lessons for local governments managing the challenges of climate change and a decentralized view of how climate policy can progress at the local level in spite of inaction at the national and international levels.

P-3311-12

Multilevel Governance and Institutional Capacity for Climate Change Responses in Latin American Cities

P. Romero Lankao (1)
(1) National Center for Atmospheric Research, Boulder, United States of America

Urban populations, economic activities and infrastructure are responsible for between 71 and 75% of global GHG emissions. However, often only a small fraction of emissions produced within a city is under the direct control of local governments. While cities are vulnerable to a suite of negative impacts that climate change is projected to aggravate, many adaptation options are also out of local reach. In these cases, other jurisdictions and actors, such as national governments or the private sector, may have control over regulations, investments and programs that drive and manage emissions and risk. Hence, in order to mitigate GHG emissions and adapt to the impacts of climate change a range of actors, across sectors and levels of government, will need to create multilevel and multisectoral coalitions for effective urban climate governance. Although mitigation and adaptation goals are, often of necessity, pursued in tandem by local governments, and urban climate policies are the product of multiscale influences, the relationship between multilevel governance and urban institutional capacity for mitigation and adaptation policies has only recently received attention, and studies focused on cities from Latin American countries are often missing altogether. We present work conducted through the ADAPTE project to explore some of the key factors or drivers shaping the institutional capacity to develop and implement mitigation and adaptation policies in the Latin American cities of Buenos Aires, Argentina, Mexico City, Mexico and Santiago, Chile. These cities have been molded by similar urbanization processes, neoliberal reforms, urban and environmental policies, and by the presence of scientific groups and multinational networks that have been instrumental in putting climate change on their policy agendas. We compare two late arrivals to the climate change policy arena (Buenos Aires and Santiago) with a frontrunner (Mexico City), and ask whether being a frontrunner is an indicator of greater institutional capacity to respond to climate change and whether barriers to creating institutional response capacity operate similarly across cities regardless of the status of their policy development.

P-3311-13

Economics of Global Climate Policies of Adaptation and Mitigation:A Review

MHB. Syed (1)
(1) Jahangirnagar University, Economics, Dhaka, Bangladesh

Climate change is uncertain all over the World. But its impact is visible everywhere.From the Arctic Ocean to the Tropics,climate is changing over the last several Decades. Greenhouse gas is the major cause of the Global climate challenges before the Mankind.It has been found that fossil fuel CO^2 is responsible for 78% of the total GHG gas emissions rise between 1970 and 2010.The concern about global warming was first raised in the UN Conference on Environment and Development(UNCED),which is also known as Earth Summit,held in Rio-De-Jenerio in 1992. Since then concerted work on climate challenges has been going on under United Nations initiatives.Conference of the Parties(COP) to the UN Framework Convention on Climate Change (UNFCCC) pledged that future Global warming should be restricted to below 2°C(3.6°F) in relation to the Pre-industrial level.This may be re-phased with a target of restricting global warming to below 1.5°C in relation to the pre-industrial level.Anthropogenic Greenhouse gases,a group of gases are responsible for golobal warming.All the Members of the United Nations are the Members of Conference of the Parties(COP). Conference of the Parties(COP) is being held at different locations of the World since 1995.The 21st COP will be held in Paris in December,2015.Now,the question is, how to adapt to the climate change and mitigate the severity of the climate change.This adaptation and mitigation policies will differ from one Country to another.However, the combined effect of the global warming has to be contained by the end of 2100 A.D.According to some others,it should be contained by 2070 A.D.Some adaptation policies are characterized as a private good as the benefit goes directly to the individuals,regions or countries that implement them.Mitigation Policies consist of switching to low-carbon energy sources for example renewable and low-carbon energy and to remove greater amounts of Carbon Dioxide from the atmosphere by enlarging forests and other «sinks».Improving insulation of the buildings may increase energy efficiency.Climate Engineering is another method of mitigation.With limitations, Economics provides mechanism for examining the merits or demerits of taking or not taking action on climate change mitigation or adaptation in obtaining competing societal goals.The Stern Review on the 'Economics of Climate Change' is a report by the Economist Nicholas Stern of the London School of Economics and the University of Leeds.The report indicates the effect of Global warming on the World economy. The Stern Review suggested fixing the accumulation of Greenhouse gas emissions in the atmosphere at a maximum of 550 CO^2e by 2050.According to the Review this amounts to cutting Greenhouse gas emissions to three quarters of 2007 levels.The costs of these cuts would be in between the range of -1 to +3.50% of World GDP(GWP) with an average estimate of approximately 1%.The revised figure by Stern is 2% of GWP.To make a comparison in 2010, the World Product(GWP) at purchasing power parity(PPP) was estimated at $74.5 trillion.Therefore, 2% of the amount is $ 1.5 trillion.The Review includes prescriptions consisting of environmental taxes to minimize the economic and social disruptions.The Stern Review's major concluding remark is that benefits of strong early action on climate change outweigh the costs of not acting.The Review points out the impacts of climate change on water, food,health and the environment.The Review says that without action the total costs of climate change will be equivalent to a loss of at least 5% GWP,each year now and forever.

Diversification: a safety net for Kenya's dryland farmers in the face of climate change

M. Okoti (1) ; P. Ketiem, (2) ; J. Wamuongo, (2) ; A. Kipkoech, (3) ; M. Barare, (4)
(1) Kenya Agricultural and Livestock Research Organization, Environment and Climate Change Research, Nairobi, Kenya; (2) Kenya Agricultural and Livestock Research Institute, Nairobi, Kenya; (3) Eldoret University, Eldoret, Kenya; (4) Kenya Agricultural and Livestock Research Institute, Kisii, Kenya

Climate change threatens livelihoods of the predominantly pastoral communities in the arid and semi-arid lands of Kenya, making about 50% of households in these areas food insecure. This will worsen given the pressures from climate change, unless there are changes in food production. In adapting to climate change, agro-pastoralism is being embraced. While this shift represents an innovation, the households are exposed to new risks and challenges in securing their livelihoods. This risks include increased drought frequencies, pests and diseases, increased temperatures and erratic rainfall. The main challenges include dwindling land sizes and limited agricultural know-how. The IDRC-funded Agricultural Productivity and Climate Change in Arid and Semi-Arid Kenya project set out to identify suitable crops for local conditions that would be readily acceptable to farmers, and to investigate water efficient farming systems that would be more productive under projected climatic changes. Localised rainfall information for the region was used to indicate current and future rainfall scenarios, forecast the onset of the planting season and identify suitable areas for different adaptation strategies. Working with 240 households, over three years, the project established demonstration field plots and farmer field schools to introduce appropriate climate adaptation strategies. These included drought tolerant crops, cover crops, use of organic and inorganic fertilizer and new production systems. Through the farmer field schools, farmers evaluated crops and assessed their acceptability. Prior to the project, households had reported a reduction in crop yields over the previous ten years by between 10% and 50%. Project interventions saw households who had planted alternative, drought-tolerant and high yielding crop varieties obtain up to 40% increase in yields. Furthermore, households started to allocate about 10% more of their arable land to food crop production, improving their household food security by 18%. Having boosted crop production, 20% of the households started to supplement their animal feeds with crop residues, increasing their feed supplies by 8%. There was a decline in the size of their livestock herds as they adopted cropping practices, but increases in crop production compensated for the reduction in livestock-based earnings. Planting in zai pits reduced crop yield losses during extreme dry weather by up to 40%. Use of organic fertilizers, increased maize yields by 50% in a normal season, fertilizers reduced losses by up to 10% during severe drought and up to 30% during mild drought. By cultivating crops in former livestock pens, production was up to three times more than unfertilized fields, showing the importance of organic fertiliser, as a way to reduce the impacts of climate variability and change. Cost and benefit projections showed that crop diversification would yield over 40 times the investment cost within the first ten years, with the potential of further significant increases in subsequent years. All targeted households influenced 3-5 other households, significantly increasing the uptake of adaptation strategies and scale of impact. Households with the highest diversity of crops traded in the market more frequently than those with fewer crops. The linkages and support from the County government extension staff greatly promoted the success of the initiatives. The county government committed to invest in competent extension services, farmer field schools and demonstration centers for supporting households in building wealth, growing income and ensuring food and nutritional security.

Picking mushrooms: how to gather adaptation science, theory and practice in order to assess progress

L. Schipper (1)

(1) Overseas Development Institute, Stockholm Environment Institute, Berkeley, United States of America

By the 1990s, adaptation scientists had developed a rather sophisticated 'typology' of adaptation (see Smit, 1993; Smit et al, 2001), which reflected adaptation's elusive character. They showed that adaptation could exist in many different temporal and spatial scales and dimensions of consciousness. One of the most useful typologies to emerge from this work is the idea of 'planned' versus 'spontaneous' adaptation, also described as 'proactive' vs. 'reactive' adaptation. This distinction has in many ways been the core notion that has given policy makers and practitioners an entry into adaptation. Yet subsequent scholarship on adaptation has been unable to develop a robust theoretical basis necessary to further a common understanding. Rather than build on existing knowledge, initiatives, publications and theories have developed in a mushroom-like fashion. This creates a rift in the three domains of adaptation science-policy-practice. In this context, this paper asks how measuring adaptation - frameworks and indicators - can be applied when the conceptual underpinnings are debated and questioned.

Adaptation tracking at global to regional scales

J. Ford (1) ; L. Berrang-Ford (1) ; R. Biesbroek (2)

(1) McGill University, Geography, Montreal, Canada; (2) Wageningen University, Public administration and policy group, Wageningen, Netherlands

Adaptation tracking seeks to characterize, monitor, and compare general trends in climate change adaptation over time and across nations. Recognized as essential for evaluating adaptation progress, there have been few attempts to develop systematic approaches for tracking adaptation, particularly at global to regional scales. This is reflected in polarized opinions, contradictory findings, and lack of understanding on the state of adaptation globally. This presentation will outline key methodological considerations necessary for adaptation tracking research to produce systematic, rigorous, comparable, and usable insights that can capture the current state of adaptation globally, provide the basis for characterizing and evaluating adaptations taking place, facilitate examination of what conditions explain differences in adaptation action across jurisdictions, and can underpin the monitoring of change in adaptation over time. We will use examples from our own work to illustrate approaches to adaptation tracking, including studies examining adaptation globally, in the EU, in the health sector, in urban areas with >1m people, and in 'hot spot' regions. The presentation will stress the importance of utilizing a consistent and operational conceptualization of adaptation, focusing on comparable units of analysis, using and developing comprehensive datasets on adaptation action, and being coherent with our understanding of what constitutes 'real' adaptation; collectively what we term the '4Cs of adaptation tracking.'

Assessing the climate change adaptive capacity at the city level, a case study: the Concepción Metropolitan Area, Chile

D. Araya (1) ; M. Metzger, (1) ; S. Neil (1) ; W. Meriwether (1) ; Á. Luis (2)

(1) University of Edinburgh, Geosciences, Edinburgh, United Kingdom; (2) Pontificia Universidad Católica de Valparaíso, Geografía, Valparaíso, Chile

Despite the growing number of studies focusing on urban vulnerability to climate change, adaptive capacity, which is a key component of the IPCC definition of vulnerability, is rarely assessed quantitatively. This research examines the capacity of generic adaptation in the Concepción Metropolitan Area (CMA), Chile. A new approach is proposed to assess the urban adaptive capacity which is based on a set of indicators and fuzzy modelling techniques through Geographic Information System (GIS) technology. A general procedure is proposed which provides consistency while allowing the required flexibility for application to cities under conditions of varying urban context, such as: information availability, resources, time, and scale. The factors understood that facilitate or constrain the process of adaptation were identified to revealed the differences between the level of adaptive capacity over time among the municipalities of the CMA. This allowed monitoring of changes in the spatial distribution of the adaptive capacity over time. This is the first extensive quantitative analysis of urban adaptive capacity in Chile.

The model of the city's generic adaptive capacity was developed through fuzzy logic operations of ArcGIS software. This is based on seventeen indicators, derived from data available for all the urban areas in Chile, which are standardized and then aggregated through a stepwise approach into six determinants. These determinants are then aggregated into three components and finally combined to provide an overall generic adaptive capacity index, which was mapped for nine municipalities within the CMA. The set of urban indicators were selected based

on the literature and created using data available at the municipality scale. As the same indicators were recorded for 1992 and 2002, they can be compared to reveal changes in the indicators over a 10 year period. This allows to understand the past conditions and factors contributing most to positive changes in adaptive capacity over the period, as well as those factors that have changed least.

Over the studied decade, it can be seen that all the municipalities increased their level of adaptive capacity. However, the relative levels of adaptive capacity between the analyzed municipalities did not change significantly, this implied that the large differences observed between the municipalities were maintained over the studied period. The results also show that municipalities with lower level of adaptive capacity in 1992 presented the highest increases in level of adaptive capacity by 2002. In contrast, those municipalities with highest level of adaptive capacity in 1992 showed less improvement. One interpretation that can be drawn is that economic factors such as the increasing income inequality found particularly in the richest municipalities may actually be reducing the potential for further increasing adaptive capacity in these municipalities. These results suggest that efforts to improve the level adaptive capacity of the municipalities should focus not only on increasing the general adaptive capacity level, but also in reducing the wide disparities observed between municipalities.

The resulting indices enable monitoring of changes in the spatial distribution of the adaptive capacity and changes over time across the city. The resulting maps help identify areas where adaptive capacity is lacking or less developed. This can stimulate dialogue amongst policymakers and stakeholders regarding how to manage urban areas/ how to prioritise resources for urban development in ways that can also improve adaptive capacity. Such discussion can contribute to the climate policy in both city planning and national planning scale, e.g. the Chilean National Adaptation Plan (NAP). It highlights the benefits of modelling using fuzzy sets to future research in the field of vulnerability to climate change since allowed the straightforward standardization and consistent aggregation of indicators. The methodology developed for CMA can be readily applied for other cities in Chile and around the world.

O-3312-03

Impact of adaptation strategies on maize productivity under climate change: Empirical evidence from the Senegal River valley

A. Beye (1)

(1) Institut Sénégalais de Recherches Agricoles (ISRA), Bureau d'Analyse macroéconomique (BAME), Dakar, Senegal

Climate change challenges require, at the microeconomic level, the adoption of effective strategies to ensure production performance for achieving food security. Adaptation strategies in the agricultural sector are essential to face issues related to climate change over the coming decades (IPCC 2007). In the literature, economists have mainly focused their interest on the impact of climate change on agriculture (Mendelsohn, Nordhaus, and Shaw, 1994; Deressa and Hassan, 2009; Deschênes and Greenstone, 2007) while the quantitative analysis of the role of adaptation remains marginally explored (Stern, 2006). In Senegal, food security depends on local agricultural capacity as agriculture, which determines the availability of food is the first element in the food safety chain (FAO, 2012). Maize (Zea mays L) is one of the major food crops in Senegal. This traditional crop has been part of Senegalese consumers' diet for centuries. However, maize cultivation is mainly rainfed. Approximately 40% of the maize growing areas are occasionally confronted with drought stress, with yield losses of 10 to 25% (Boone and al., 2008). To cope with irregular and insufficient rainfall, Senegalese farmers have adopted a range of strategies (NAPA, 2006). This paper's main concern is to identify the different types of adaptation implemented and quantify the impact of those adaptation strategies on maize productivity.

Materials and methods: This study was conducted in the Senegal River Valley which is one of the six agro-ecological zones of the country and where 8% of total arable lands are concentrated. The data used in this study was collected through surveys during the rainy season of 2013. The dataset encompasses 140 farms in the middle and upper Senegal River Valley. First, a frequency analysis is used to determine the adoption rate of coping strategies. Performing a student test, we identified strategies with a significant impact on maize productivity. Econometric estimates were then conducted for those strategies. Second, we used the endogenous switching regression model (Alene and Manyong, 2007, Di Falcao et al, 2010;. Di Falcao and Veronesi, 2011; Akpalu, 2011) to identify the determinants of the decision to adapt a given strategy. The advantage of this model is to allow for full interactions between the implementation of an adaptation strategy and the factors determining productivity. Finally, based on Sajaia and Lokshin (2004), we calculated the expected productivity in both factual and counter-factual groups to determine the impact of adaptation strategies identified on maize productivity.

Results and adaptation policy implications: The results show that 78% of farms in the middle and upper Senegal River Valley use at least one coping strategy. These strategies include the change of seeding date (implemented by 69% of farmers), the use of short cycle varieties (36%), the «cordons pierreux» (1%), the «zai» (3%), the use of trees or shrubs fertilizers (4%), the direct seeding (7%), the use of biomass (1%) and irrigation (2%). The Student test shows that the change of seeding date and the use of short cycle varieties have a positive and significant impact on maize yield. For these two strategies, the differences in yields observed between farmers who adopt a strategy and those who did not is not a hazard. Estimates of endogenous switching regression model highlight the main determinants of the decision to adapt. Farm households that use fertilizers with individual fields are found to be more likely to change the seeding date and use of short cycle varieties. Likewise, farmers who belong to a producer organization are more likely to adopt coping strategies. Therefore, dissemination of these coping strategies would be more efficient through producers' organizations than through extension services that have no impact on the decision to adopt a strategy. Results show also that in the Senegal River Valley, the change of seeding date is the best adaptation strategy to improve the maize productivity in the context of climate change. Indeed, the impact analysis shows that the change of seeding date increases the average productivity of maize by 506 kg/ha, while the use of short cycle varieties only increases it by 247 kg/ha. In terms of adaptation policy we propose the establishment of Climatic Information System which goal would be to provide information about climate to farms through a multi-stakeholder platform gathering both producer's organization and meteorological and extension services to better cope with climate change in Senegal rural area.

Formal and Informal Networks for Learning in Adaptive Risk Management in London, UK

T. Abeling (1)

(1) United Nations University / King's College London, Bonn, Germany

Since the 2003 European heatwave, risk management and early warning systems for extreme temperatures have been developed in many European cities. London, UK, a global frontrunner in urban climate change adaptation, introduced comprehensive risk planning arrangements in the context of the 2004 National Heatwave Plan. Its annual rounds of review and its application through local governments in London are the focus of the analysis in this presentation. They provide a unique opportunity to study, in a local government context, pathways and constraints for social learning as an aspect of urban resilience. Empirical evidence stems from 49 semi-structured expert interviews with risk planning officials from London local authorities, health and social care organisations. Findings suggest that the interaction of formal and informal institutions has limited social learning in heatwave planning to incremental changes that reinforced the status-quo. Informal networks and trust relationships between risk planners compensated for formal heatwave planning arrangements that were perceived as dysfunctional. This support from informal institutions to formal strategies undermined opportunities for paradigm shifts in risk planning. It suggests that social

learning can be associated with rigidity of established risk management strategies, rather than with their change. In the context of heatwave planning in London, missed opportunities for paradigm shifts concerned a consolidation of reactive risk management approaches that focused on the health implications of heat stress. This consolidation undermined the development of preventive risk management approaches that consider social, environmental and technical risk dimensions. The results of the analysis raise questions about the desirability of learning as an adaptive strategy in the context of climate change. The presentation suggests that learning is not necessarily beneficial for transformation if it is enacted through organisational systems that are inertial and resistant to change.

P-3312-02

Climate Smart Practices for Resilience and Sustainable Productivity: Sudan's NAPA Case Studies

IE. Ali Babiker (1) ; F. El-Hag, (2)
(1) Agricultural Research Corporation, Dry Lands Research Center, Khartoum, Khartoum, Sudan; (2) Agricultural Research Corporation, Dry lands research center, Khartoum, Sudan

This study aimed at documenting climate smart practices implemented by NAPA at four States (River Nile, Gedarif, North Kordfan and Darfur) in Sudan. This documentation was done through reviewing the progress attained regarding the adaptive measures undertaken to enhance the resilience of the targeted communities. Climate smart practices identified include: Sand dunes fixation, forestry and rangelands rehabilitation, micro-fences in rangelands, improved rain water harvesting practices, groundwater harvesting for establishment of community managed horticulture gardens, energy substitutes, and livestock improvement activities. Areas rehabilitated on open sand dunes with range plants and tree seeds and seedlings were over 600 ha, clay soils areas covered with agroforestry, windbreaks and rangeland rehabilitation were 105.0, 21.0 and 84 ha, respectively. Rainwater harvesting structures were constructed to improve trees and rangelands rehabilitation. Shelterbelt was established covering an area of 300 ha. Range plants seeds were, also, broadcasted inside fenced areas. This was done through communities' participation, particularly women. Rainwater harvesting technologies enables farmers to break out of the cycle of poverty through increased crop yield, enhancing their adaptive capacity through improved food security and livelihoods. Improved water harvesting practice resulted in an increased sorghum yield over 477%. Earth bund water harvesting + chisel ploughing gave an increase in sorghum yield of over 177%. Cucumber, sorghum and okra, cultivated under the improved water harvesting technique accrued a profit of over $1000. The intervention of groundwater harvesting, which involved 199 women and using solar energy operated pumps, provided a good viable practice for enhancing community adaptation to climate change through food security and income generation. Over $2500 were stated to be the revenue from the different activities of the horticultural garden due to groundwater harvesting. Cylinders and stove units were distributed relieved pressure off the fragile natural resources through provision of alternatives to tree cutting for charcoal making and for firewood collection, hence reversing resource and land degradation. Sheep and goat improvement program activities, using local breeds conducted were good practices in increasing adaptive capacities of vulnerable communities' through income generation. Improving the nutritive value of Adar grasses and crop residues helped improving livestock feed balance in these areas in view of the deteriorated rangelands, particularly during the dry season. The study revealed several success stories and learning lessons.

P-3312-03

Climate change adaptation of community-based drinking water organizations: challenges and solutions

F. Alpizar (1) ; R. Madrigal, (1)
(1) CATIE, Economics and Environment for Development Program, Cartago, Costa Rica

Due to climate change and variability, drought events are expected to be more intense and prolonged in different areas of Latin American and the Caribbean (LAC), with significant impacts in the volume, timing, and quality of water provided by water suppliers (Kundzewicz et al. 2008). Community-based drinking water organizations (CBDWO) are the most important providers of water in rural areas of LAC and play a key role in decentralization and democratization processes in the region. The inherent capacities of CBDWO to adapt to expected impacts of droughts would be much conditioned by their capacities to initiate and catalyze collective processes in the communities they represent.

The rich background of actual and historical responses that CBDWO have given to drought phenomena is an essential starting point for understanding both processes and limitations to adapt to future adverse climatic events. The complex nature of collective adaptation processes involves the identification and analysis of relationships among different actors in the communities, the governance structure in which they interact, the physical and natural resource base on which they depend and the social, economic, demographic and political setting in which they reside.

Around 1500 CBDWO provide water to 60% of people in the driest rural areas of Nicaragua and Costa Rica. We randomly selected a sample of 130 CBDWO in these two countries to collect information, through interviews to CBDWO leaders and surveys to water customers, on governance and financial characteristics, performance indicators (e.g. hours of water service), technical features of the existing infrastructure as well as adaptation investments from these water providers, among other relevant indicators. This information helped us to identify empirically the factors that influence the performance of CBDWO in the context of droughts; enumerate the adaptation measures implemented by CBDWO to deal with these disturbances and acknowledge the specific challenges and facilitating conditions for the implementation of these measures and for building drought preparedness.

We found that CBDWO implement different hard (e.g infrastructure improvement), soft (e.g. rationing) and ecosystem based (e.g. protection of recharge areas) adaptation measures to deal with droughts and water scarcity in general. One of the main factors that facilitate capital intensive adaptation measures (e.g infrastructure measures such as water metering systems at home, storage capacity augmentation) is the ability of CBDWO to mobilize internal and external financial resources, which further depends on social capital (internal and external networks) and the governance structure. In particular, some conditions seem to be necessary for adapting to driest scenarios: water fees for recovering costs and incentivizing rational consumption; external mechanisms for financing water investments; legitimate, transparent and functional governance structures at the local level; and technical expertise complementing local knowledge.

Our results suggest that in most cases external support is critical for climate change adaptation of CBDWO. This has important implications for adaptation policy design and the role for development assistance in supporting adaptive capacity. In this regard we propose a long-term integral approach minimizing the incentives to perpetuate external dependency on limited governmental funds and international donors for maintenance, replacement and expansion of water infrastructure and investment in climate change preparedness. This approach should promote the long-term financial sustainability of CBDWO through improved mechanisms for cost-recovery, accessible financial options (e.g. through public-private banking partnerships) and conditioned subsidies under critical circumstances. These efforts should be accompanied by reachable opportunities for training in administrative and technical aspects of water management. Finally, the availability of more precise and updated information on how climate change would affect local water systems is an important pillar in this approach.

P-3312-04

The Mid- and Late Holocene Climate Changes in the Amuq Plain: The Adaptive Responses to Climate Change as Indicated by Archaeological Data

B. Arikan (1)
(1) Eurasia Institute of Earth Sciences, Istanbul Technical

University, Dept. of Ecology and Evolution, Istanbul, France

Paleoenvironmental research has shown that significant climatic changes happened during the mid- and late Holocene yet it is hard to generalize changes in crucial climatic variables across the Near East. The Amuq Plain is located at the northern terminus of the Jordan Rift Valley. The region has been recognized as a hot spot for biodiversity in the modern era (ancient Antioch, the Turkish city of Hatay). The Plain has been densely settled and its resources have been used intensively in the last 10.000 years, which has become a hub for social interactions. Consequently, the Amuq Plain has a lot to offer in studying the dynamic and multifaceted history of human-environment relationships, especially the adaptive responses to climatic changes in the Holocene. Although untangling such relationships in time is essential, given the complexity of the geology of the Plain (i.e., tectonics, fluvial, and colluvial processes), spatial dimension becomes equally important. Contextualizing the range of human adaptive behavior in the Plain, across space and time, requires analyzing diverse sets of data. In addition to archaeological, economic, social, historical, and political data, environmental data are also needed to have a more accurate and complete reconstruction of adaptive patterns.

My talk will focus on correlating the results of the Macrophysical Climate Model with the long-term archaeological settlement systems on the Plain, which have been documented through traditional survey methods as well as remote sensing, geoarchaeology, and paleoenvironmental research. Macrophysical Climate Model (MCM) is one of few paleoclimatic-modeling tools that have been available to researchers. In comparison to other paleoclimate models, MCM has higher spatial resolution and the results are synoptic (i.e., local). Research in different parts of the Near East suggests that the results of MCM agree well with the results from multi-proxy based paleoenvironmental reconstructions. The model output provides quantifiable figures at centennial resolution.

In my talk, first, I will present the output from MCM that provides average annual precipitation and temperature between 12,000 and 2,000 cal. BP (ca. 10,000 B.C. - 0). Calculating annual averages at centennial resolution, changes in precipitation and temperature will be plotted. Then, I will interpret the possible impacts of climate change on the settlement systems of the Amuq Plain at spatial and temporal scales. In this comparison, the size, function, preference of land formation, and distance to the nearest water source will be analyzed using geographical information systems (GIS).

P-3312-05

Climate Change Adaptation and Household Resilience to Shocks in Ethiopia

E. Basauri Bryan (1)
(1) International Food Policy Research Institute, Washington, DC, United States of America

Rural households in Ethiopia that depend on agriculture for their livelihood are highly susceptible to climate variability and change. A number of adaptation strategies have been identified as having great potential to reduce vulnerability to climate variability and change and many of these practices have already been adopted by agricultural households. However, few studies have assessed the extent to which particular practices actually increase resilience to climate shocks, which are becoming more frequent with climate change. This paper assesses the effectiveness of key adaptation strategies in the Nile Basin of Ethiopia by examining the extent to which adoption of these practices protects household assets following a climate shock, drawing on data collected through two rounds of a survey of 1,000 agricultural households in the Nile Basin of Ethiopia.

P-3312-06

Assessing adaptation on the ground: a proposed framework to measure adaptive capacity

MA. Baudoin (1) ; G. Ziervogel (2)
(1) Climate and Development initiative, geology, cape Town, South Africa; (2) University of Cape Town, Cape Town, South Africa

Methods for evaluating adaptation projects are a growing concern, in both the applied and academic spheres of climate change adaptation (CCA). Internationally, there is increased funding for supporting adaptation projects, yet limited exploration of how this international funding is landing on the ground and impacting on adaptation. The key objective of our research is to highlight evidence of how external funding in developing countries is contributing to building adaptive capacity and implementing CCA. The core research question that guides the study is: what is the role of international funding in building adaptive capacities across scales and, especially, on the ground? This question will be addressed with a specific focus on how international funding enables or undermines adaptive capacities among local institutions (both governmental and non-governmental).

The initial phase of the study is based on a review of existing literature exploring to role of international development funding on building generic and specific adaptive capacity. The review will also serve to capture methods and approaches to measuring adaptive capacities on the ground. The literature review will inform a framework to track adaptive capacities at the local level, during the implementation of CCA programmes funded by international organisations. This first phase will be followed by the second phase that will evaluate the programme: "Taking Adaptation to the Ground: A Small Grants Facility (SGF) for Enabling Local Level Responses to Climate Change», funded by the Adaptation Fund and implemented in the Northern Cape and the Limpopo Basin, South Africa. The SGF programme's main objective is to empower local organisations so that their capacities to access external funding for CCA and to implement contextually-relevant adaptation programme are significantly enhanced.

Due to the early stage of this research, the presentation will focus on the result of its initial phase. More specifically, we will present a framework to assess adaptive capacities on the ground, among local institutions. This framework is based on a review of existing literature and on an in-depth assessment of institutional configurations within the studied area (Namakwa District in Northern Cape, South Africa). This type of research is critical to help provide an increased understanding of what constitutes an effective institutional configuration that supports the implementation of successful internationally-funded CCA strategies in developing regions. This work is important for informing future scaling up and replication of small grant-financing approaches.

P-3312-07

Climate Change Adaptation of Watershed Key Stakeholders in Talomo-Lipadas Watersheds, Davao City, Philippines

N. Branzuela (1)
(1) University of Mindanao, Department of Forestry and Environmental Studies, Davao City, Philippines

Talomo-Lipadas Watershed, Davao City, Philippines is the main groundwater source for drinking water of 99% of the urban population in Davao City, Philippines (Hearne, 2011). Yet, these watersheds are in surmountable threats because of continuous land conversion, unavoidable development, unregulated water extraction, among others. Threats are exacerbated because of potential impacts of Climate Change.

The study aims to determine Station-scale climate projections using Statistical Downscaling; groundwater recharge determination using Brook 90 hydrological model; projection of water demand using per capita method and lastly, identification of Climate Change Adaptation Strategies of three key stakeholders groups.

Results revealed that months of March and April are likely to experience intense temperature along with a low flow recharge to groundwater, and this pattern will likely sustain until the next two slice period of 2050 and 2080. Moreover, the projected water demand is increasing from 101.26%, 228.18%, and 355.10% for the slice period of 2020, 2050, and 2080; respectively. With the potential Climate Change impact to watersheds, water deficit of -31.22 and 91.52 MCM (million cubic meters) is projected for time slice period of 2050 and 2080, respectively.

Stakeholders have fragmented priorities in their adaptation strategies. Domestic water users' planned adaptations are mainly for demand-side adaptation rather than supply-side adaptation. Watershed Managers' planned adaptation is to tap surface water and tree planting. Policy makers aim to fully implement City Ordinances pertaining to Watersheds.

P-3312-08

Socio-economic aspects in the spatial differentiation of vulnerability to climate change in river basins

R. Corobov (1)
(1) EcoTiras International Association of River Keepers, Chisinau, Moldova

The measurement of vulnerability to climate change is a central moment in adaptation activity to mitigate adverse climatic impacts. Both natural and social scientists try to measure and assess such vulnerability, whether from the perspective of regions, socio-ecological systems, or individuals. Different approaches to this issue have penetrated into climate change research, and with rapid growth of attention to vulnerability, the concept itself has been re-defined, and new interpretations and approaches were developed.

Climate change represents a classic global problem characterized by infinitely diverse actors and multiple stressors at multiple scales. As a result, research on vulnerability to this phenomenon have to address at least three important challenges: (1) to improve approaches for comparing and aggregating impacts across diverse sectors and populations, (2) to model socioeconomic transformation in assessing the significance of these impacts, and (3) to account for multiple dimensions. Different challenges result in their different 'diagnoses' and different kinds of 'cures'.

Initially, the assessment of vulnerability to climate change was approached from the impacts point of view where it was defined as the degree to which a system is susceptible to and unable to cope with adverse climatic effects. However, recently the emphasis in these efforts has moved from better defining exposure and potential impacts to a better understanding of factors that affect sensitivity of societies to these impacts and their capacity to adapt. There is an increasing recognition of the importance to consider the social component of vulnerability equally with the biophysical one, thus presenting vulnerability as a function both of physical characteristics of climate change and of social systems' inherent sensitivity and adaptive capacity. Various researches try to bridge the gap between social, natural, and physical sciences' contributions to new methodologies that confront this challenge, primary under the umbrella of sustainability and resilience. On the other hand, a system of vulnerability 'measurement' should allow comparisons between different places, social groups and sectors in terms of their susceptibility to climate change risks and capacities to deal with them. Climate change consequences first of all are experienced at regional and local levels, varying between communities, social groups in a community and even between individual households.

Based on evidences that surface waters are especially sensitive to changes in climate, the main goal of this contribution is to present the pioneer assessment of socio-economic vulnerability to climate change of the Dniester River basin at its local level, namely – at the level of Moldova's administrative-territorial units (ATU). To address this task there was proposed and practically realized a relevant methodology that included development of a set of specific indicators and proxies describing the natural and socioeconomic systems sensitivity to climate change impacts and adaptive capacity to confront them. Through a ranking approach, the relative vulnerability of each ATU was calculated by summing its sensitivity and adaptive capacity ranks, arranged respectively in an increasing or decreasing order; the latter were obtained as combinations of their primary indicator ranks. To better understand the drivers of vulnerability and to compare ATUs in terms of risks, which they can face from climate change impacts, as well as their capacity to deal with their adverse consequences, the spatial models of local vulnerability and its components distribution were carried out. Corresponding mapping revealed areas that are the most vulnerable and are needed in special attention in climate change adaptation. In a final stage, the Dniester basin's "hotspots" were discussed with wide public participation.

The proposed integrated approach to local vulnerabilities assessment facilitates allocation of limited resources equitably and efficiently among different entities – regions, administrative groups or different proponents of adaptation that is especially important for transition economies, to which Moldova is attributed.

P-3312-09

Bottom-up initiatives for flood risk management in Europe: How can we evaluate governance processes and spatial outcomes? (TRANS-ADAPT research project, JPI-Climate)

A. Gatien-Tournat (1) ; M. Fournier (2) ; G. Mathilde (1) ; M. Bonnefond (2) ; S. Servain-Courant (3) ; D. Clarke (4) ; P. Driessen, (5) ; S. Fuchs (6) ; D. Hegger (5) ; H. Mees, (5) ; C. Murphy (4) ; T. Thaler (6)
(1) Université Francois-Rabelais Tours, UMR Citeres CNRS 7324, TOURS Cedex 3, France; (2) ESGT-CNAM, Le Mans, France; (3) INSA Centre Val de Loire – ENSNP, Blois, France; (4) National University Ireland Maynooth, Irish climate analysis and research units (icarus), Maynooth, Ireland; (5) Copernicus Institute of Sutainable Development, Utrecht university, Utrecht, Netherlands; (6) University of Natural resources and Life Sciences, Vienna, Austria

The aim of the proposal is to present the Trans-Adapt research project and its assessment framework that will be applied to community-led bottom-up climate change adaptation strategies. Trans-Adapt (awarded by the European Joint Programming Initiative-Climate) focuses on bottom-up initiatives to flood risk management. In the context of climate change that triggers more extreme meteorological events, including severe floods, strategies are developed by local authorities, sometimes with the collaboration of civil society. These initiatives intend to make land allocations to flood risk management more efficient and socially beneficial. Trans-Adapt project assumes that these initiatives are different from mainstream flood risk management measures, dominated by one type of use (flood protection). Our hypothesis is that bottom-up initiatives pursued by local stakeholders lead to multi-functional use of land and represent a solution of adaptation to climate change. 12 case studies are studied in four European countries: Austria, France, Ireland and the Netherlands.

The overall aim of the project is to analyse, explain and evaluate similarities and differences between the selected regions in terms of climate change adaptation performance, with a particular focus at the local-individual household level, burden-sharing and equity issues. The purpose is to understand the challenges and limitations in the on-going policy and institutional arrangements, such as benefits and costs of adaptation measures at different levels.

The proposal will present Trans-Adapt research questions and the conceptual framework for assessment and evaluation of our case studies, which will give insights to the parallel session 'Assessing adaptation' in Day 3. Preliminary results from one French case study will be used as illustration of the assessment framework application.

In order to identify the barriers and limitations of the current governance and management structures in flood risk management, the project develops an analytical and evaluation framework that focuses on efficiency, effectiveness, legitimacy, accountability, social justice and social capacity, as classical policy analysis criteria. Moreover, we carry on a reflection on feasibility and vulnerability of the risk management processes and outcomes, in a policy design concern.

The assessment framework will adapt the chosen criteria to the specific topic of flood risk management, providing operational indicators that will be used to evaluate the 12 case studies.

The final objectives of the project will be to explore the possibilities for up-scaling and replicating local initiatives in other countries and outlining the institutional change required to facilitate local initiatives, by providing a means of guiding the decision-making process at different levels of authority.

P-3312-10

Prioritizing Climate Impact Risks at the Neighborhood-level: Applying a Hazard Vulnerability Analysis for Los Angeles County

B. Moy (1) ; H. Godwin, (1)
(1) UCLA Fielding School of Public Health, Environmental Health Sciences, Los Angeles, CA, United States of America

Los Angeles presents a unique challenge in assessing local climate impacts on human health due to the county's diverse neighborhood demographics, numerous jurisdictions, and varying geography and microclimates. High-resolution climate modeling for Los Angeles County has allowed for climate impact assessments at the neighborhood-level. In order to address these impacts, it is necessary to develop a regional Climate Adaptation Plan to prioritize activities and build resiliency to climate impacts for Los Angeles County. Unfortunately, few health impact tools allow for the ability to compare the risk for a range of climate impacts at the neighborhood-level. As a case study, UCLA researchers have adapted a Hazard Vulnerability Analysis tool to compare eight different areas by which climate change impacts health (extreme heat events, sea level rise, air quality, wildfires, vector-borne diseases, water availability and quality, food security, and health systems). We applied this tool to four different neighborhoods that represent the geographic and demographic diversity of Los Angeles and observed large differences in the overall and relative risk to climate change impacts for each neighborhood. This study provides strong evidence for the need to develop priorities and implementation plans at the neighborhood-level in large, complex regions like Los Angeles, and highlights a useful tool for ensuring that this planning process is evidence-based.

P-3312-11

Stepping on agricultural biodiversity to build resilient small-holder farming systems in West African Sahel

S. N'danikou (1) ; SR. Vodouhe (1)
(1) Bioversity International, West and central africa office, Cotonou, Benin

There is evidence that the impact of climate change on agriculture will increase, under the status quo scenario. It is also advocated that agricultural biodiversity (ABD) is part of the solution to minimize the negative effects of climate change and variability on livelihoods and food security. In this paper we investigated the best adapted crop varieties to the prevailing biotic and abiotic conditions of West African Sahel. The study aimed to assess and test the adaptation potential of local genetic diversity to critical environmental conditions in the region. The field experiments were carried out using the Diversity Field Fora (DFF) participatory research approach in Mali, Niger and Burkina Faso. Each DFF consisted in a group of 25 farmers, gender mixed, which received a diversity kit (a collection of local cultivars and improved varieties grown in the contrasting environmental conditions of each country), and worked together to select preferred and adapted crop varieties to local conditions. A total of nine communities (225 farmers) participated in the DFF participatory research in the three countries. Each DFF received a minimum of six varieties or cultivars of each crop. After two cropping cycles, each community selected the three top performing crop varieties or cultivars that are best adapted to their environmental but also social and cultural contexts. This selection followed a south-north climatic gradient, dividing the study area into i) dry zones (<600 mm rainfall per year), ii) semi-arid zone (600-800 mm rainfall per year) and iii) relatively humid zones (>800 mm rainfall per year). Farmers' criteria for selecting adapted crop varieties included time to maturity, resistance to drought, resistance to diseases, yield, and food quality attributes (taste, flavour, colour, etc.). Through the DFF trained farmers selected and multiplied adapted cowpea, fonio, sorghum and millet varieties. Thanks to the capacity building activities, seeds of the farmer selected local varieties were multiplied and certified as commercial seeds in Mali and similar efforts are on-going in Burkina Faso and Niger. We concluded that cultivating adapted local and improved varieties would increase resilience of the farming systems in the region for resilient food systems.

P-3312-12

Indicaters of Vulnerabilities, Adaptations and Mitigation Strategies to Climate Change and Sustainability in Uttar Pradesh the Northern State of India

M. Nandkishor (1)
(1) Babasaheb Bhimrao Ambedkar University, Department of Environmental Science, Lucknow, Uttar Pradesh, India

Climate Change poses an unprecedented impact to the life on earth. In addition, predictions about the scale and enormity of it are continually being revised upwards so what was already a serious situation continues to look even more alarming. The atmospheric greenhouse gases and their levels too are increasing and are creating warmer temperatures, receding glaciers, sea level rise and an unpredictable climate with a range of extremely serious and hard to predict consequences.

The impacts of climate change in Indian subcontinent are important in many ways due to diverse topography, seasons etc. India in fact is considered to be highly vulnerable not only because of large physical exposure to climate related disasters 65% of India is drought prone, 12% Flood prone and 8% susceptible to cyclones are just indicative. It is a giant rain fed ecosystem and also because of its dependency for economic growth and majority of its populace on natural resources viz Water resources, agriculture, forests animal husbandry, fisheries etc. With a large land area and diversity of agroclimatic and ecological regions makes it a more vulnerable to the impending threat of climate change that threatens livelihood security of large rural masses of the country.India has been aggressively pursuing the agenda of combating climate change on two fronts namely adaptation and mitigation and to ensure coherence between the Climate change strategies on National and State levels, National and State plans have been envisaged. This is over and above the National Missions including one on climate change as a policy measure.

State of Uttar Pradesh possesses socio-cultural and geographic diversity with its eastern parts touches the foothills of Himalaya. It is one of the most populous states of the country with 16.49 % of country's total population of 1.21 billion with 7.87% of country's geographical area. The states has been divided into four zones or regions viz, Western Region, Central region, Eastern Region and Bundelkhand Region and 17 administrative divisions and almost 79% populations is residing in rural areas of 97942 inhabited villages and 114 forest villages.

Studies carried out on the indicators of Rainfall/preciptaion of five successive years of last decade particularly between 2006-2010 indicates that Bundelkhand region of the state is predominantly drought prone while some part of Eastern and Western suffers from a flood which is one of the important drivers of forced migration of workforce to other regions of country. The estimated percentage of migration of workforce who have small and marginal land holding ranges from 10 to 35% and upto 40% in the landless labourers. The nature of migration also varies in both the post and preharvest season known as rabbi and kharip. One of the observation indicated that incessant flood preceeded by long dry spell is also negetively influencing the agricuture productivity of the region. These are the areas that reflect more as negative indicators of productivity due to variety of reasons. Further climate of the region also varies from moderately temperate in the Himalayan reagion to tropical monsoon in the Ccentral plains and southern upland regions

Our analysis to assess the flood/drought dizaster risk by Latin Square Design (LSD) using statistical software SPSS reveals direct relationship of degraded ecosystems and sustainable livelihoods of the dependent population who are peasants with small land holding and agriculture labors primarily. Interestingly some measures adopted by the farmers and the state policies to resolve the ecological crisis are indicative of strategies to combat the threat. One of the means of weather based crop insurance is also felt imporatant as untimely weather fluctuations are compounding the losses to the small and marginal farmers and many have succumed over the last decade. This paper attempts to highlight impending issues in the context of Uttar Pradesh a Northern State of India focusing on issues of sustainability which is pivotal.

P-3312-13

The effects of ecosystem-based adaptation on vulnerability to climate change: evidence from semi-arid Brazil

M. Obermaier (1) ; MC. Lemos, (2) ; YJ. Lo, (2) ; AM. Bedran, (3)

(1) Universidade Federal do Rio de Janeiro (UFRJ), Instituto Alberto Luiz Coimbra de Pós-Graduação e Pesquisa de Engenharia (COPPE), Rio de Janeiro - RJ, Brazil; (2) University of Michigan, School of natural resources and environment, Ann Arbor, United States of America; (3) Faculdade de Saúde Pública (USP), Departamento de saúde ambiental, São Paulo, Brazil

Assessing the effectiveness of adaptation strategies in rural parts of developing countries is an important, but relatively understudied topic. One important question is the effect of social interventions and anti-poverty programs on vulnerability and influence the possibility of social transformation (Lemos et al. 2013, Eakin et al. 2014). While there is growing evidence that poverty is a robust predictor of vulnerability, there is also growing attention to the ways they do not overlap and/or the different ways they do overlap (Olson et al. 2014, Nelson et al. in review, Patt 2012). In this context, so-called ecosystem-based adaptation (EbA) strategies - i.e. options that combine community management of natural resources with specific agro-ecological technical assistance and production methods - have gained wider attention specifically in Latin America as means for reducing vulnerability to climatic extremes while simultaneously contributing to local sustainable development (Magrin et al., 2014). But while the role of sustainable use of biodiversity for climate adaptation is relatively unquestioned, there is little evidence on the effects on reducing social vulnerability, particularly when assessed in the context of ongoing anti-poverty programs.

This study assesses the effects of ecosystem-based sustainability projects on smallholder farmers. We focus our research on drought-vulnerable communities in Northeast Brazil where we have already carried out research and collected longitudinal data at the household (in 1998, 2012, 2013 and 2014) and municipal (in 1998 and 2012) levels at the intersection of livelihoods, technological innovation, environmental sustainability and vulnerability to drought (Lemos et al., 2002; Obermaier, 2013; Obermaier et al., 2014; Simões et al., 2010; Tompkins et al., 2008). Climate projections for NE Brazil indicate a strong likelihood of decreased precipitation, resulting in more aridization and drought (Magrin et al., 2014), which will further exacerbate social vulnerability to currently sensitive populations in the region.

Our motivation for carrying out the research in Brazil is the ability to locate the analysis in the context of a much larger social experiment in poverty elimination implemented by the Brazilian government since the late 1990s called Programa Bolsa Família. The program provides a conditional cash allowance to all households with school age children and whose income is below a minimum amount established by the government. In order to qualify for the allowance families have to enroll and keep their children in school and provide basic health care (e.g. vaccination). One hypothesis behind the Bolsa Familia program is that it will slowly eliminate severe poverty in Brazil and potentially transform the livelihoods of the segments of the population that currently live below the poverty line (below 2 dollars a day).

First evidence by our research supports the hypothesis that although Bolsa Família is necessary for families it is also insufficient to reduce vulnerability to drought. On the other hand, ecosystem-based strategies carried out through regional Conservation and Sustainable Use of Biodiversity Programs in NE Brazil seem to enable rural farmers to maintain their food security (including access and nutrition values) at higher levels as well as to contribute to income generation.

Empirical findings from this research will critically contribute to both scholarship and policymaking. Currently, there is debate among academics and practitioners alike regarding the best types of actions to reduce the risk of experiencing harm derived from extreme events particularly within the developing world where losses are expected to be significant. In order to support household adaptation, policy makers must decide whether it is more effective to invest in measures that will reduce vulnerability to a broad range of both climatic and non-climatic stressors, or whether it is best to focus on enhancing specific capacities to manage particular hazards. In terms of the livelihood framework, policy-makers must decide which types of livelihood assets should be strengthened through public investment and support. This research will contribute to this debate by providing empirical evidence of the role of anti-poverty programs in building vulnerable households' and individuals' adaptive capacity to climate impact.

P-3312-14

Water security indicators for a climate variability and climate change adaptation process in the Maipo River basin in Central Chile

A. Ocampo-Melgar, (1) ; J. Gironás, (2) ; S. Vicuna (3)

(1) Pontificia Universidad Católica de Chile, Departamento de ingeniería hidráulica y ambiental, Santiago, Chile; (2) Pontificia Universidad Católica de Chile, Centro de cambio global uc, Santiago, Chile; (3) Centro de Cambio Global UC, Pontificia universidad católica de chile, Santiago, Chile

Observed climate change effects are challenging government and societies to start thinking how to adapt to an even more extreme range of potential future changes that will impact many aspects of our lives. As this need for adaptation arises so does the practical details about how to successfully implement this adaptation process, given the socio-ecological complexity of systems involved. The Maipo river basin in the semi-arid Central Chile is an example of such systems that most likely will need to adapt in the future due to climate change. The Maipo river provides water for over six million people and to more than 200.000 hectares of agricultural land and many other productive (e.g. mining, hydropower) and not productive activities in the Santiago Metropolitan Region. Previous studies have shown that future temperature and precipitation changes will result in more stress to the already water scarce basin, but could also result in more extreme flood events due to a rising zero degree isotherm.

To face the multiple demands in an uncertain future with climate change and population increase, the public and private sectors as well as the civil society will require information and tools to concentrate efforts in the most relevant aspects of life that will need to be adapted. To respond to this need, a three-year project (2012-2015) entitled MAPA (Maipo Adaptation Plan for its initials in Spanish) is being implemented in collaboration with a multi-stakeholder platform of around 30 public, private and civil society organizations, both at the local and regional level. The objective of the project is to both identify vulnerabilities and adaptation options to potential future scenarios in the basin. To facilitate the work the scientific team and the stakeholders were grouped in three working groups (i.e. mountain/natural systems, rural sector and urban sub-sector). This project is guided by the Robust Decision Making framework that incorporates both stakeholders expertise and computational capabilities in a mutual feedback process to identify future scenarios, appropriate tools and models, adaptation measures and Performance Indicators, which are a key outcome. These indicators allow both the identification of base line vulnerability levels and the understanding of the benefits of implementing adaptation measures given uncertain scenarios.

Since water is the common link between the diversity of threats and demands at different scales in a basin, we used the Water Security definition by the U.N. to frame a participatory process to identify locally-based, multi-scale Performance Indicators, and measure climate change impacts in a way that could trigger the implementation of adaptation measures. In order to operationalize the definition into the adaptation process, we disaggregated water security into its five main sub-components (i.e. economic development, livelihoods, ecosystems conservation, protection against hazards and protection against water-borne pollution). The concept and its sub-components were intensively discussed with the working groups. A set of factors, demands and aspirations denoting water security in different spatial and temporal scales were identified by each working group (e.g. flow of water for rafting, volume of minerals extracted or turbidity in water). The indicators, relationships and casual links among them were analyzed and consolidated in order to generate a conceptual model to characterize water security

in the Maipo basin.

The guided but still highly participatory process implemented in this study identified causal links and scales of indicators, which in turns will allow defining metrics and optimum levels to be used as early signs in this adaptation plan in process. The water security conceptual model goes beyond capturing water physical manifestations, as it attempts to make visible hidden connections to ecosystem goods and services and human aspirations that represent human well-being, which could be finally impacted by climate change.

The approach has also the potential to capture the general aspirations of the different users in a basin related with economic development, ecosystem conservation, basic human needs, pollution and hazard allowing in this way not only the design of adaptation measures that have a physical water representation but also measures that are closely related to the final objectives that water security tries to achieve: human well-being.

P-3312-15

Emerging Response to climate change and Variability in Semi-Arid Areas of East Africa

E. Ogallo (1) ; E. Komutunga (2) ; G. Sabiiti (3) ; SM. Mikalitsa (1)

(1) University of Nairobi, Geography and Environmental Studies, Nairobi, Kenya; (2) National Agricultural Research Organization , Kampala, Uganda; (3) Makerere university, Kampala, Uganda

Arid and semi-arid regions are characterized by insufficient rainfall to sustain agricultural production. The rains are erratic and often come in a few heavy storms of short duration resulting in high run-off, instead of replenishing the ground water. Protective vegetation cover is sparse and there is very little moisture for the most parts of the year. Communities in these regions are particularly vulnerable to climate change not only because of their dependence on climate sensitive sectors but also due to limited capacities to anticipate and effectively respond to climate change. The main objective of this study was to determine the emerging coping and adaptation strategies of the local communities in Semi-arid Regions of East Africa with a view of enhancing their resilience and reducing vulnerability to climate change and variability. The paper is based on the synthesis and comparative analysis of coping and adaptation strategies employed by different countries in East Africa. The study found out that the communities and local governments are investing on several adaptation activities to address impacts of climate change in semi-arid areas. These include rain water harvesting for domestic, livestock and agricultural production needs. The availability of this water resource significantly reduces community vulnerability to food insecurity. The establishment of water pans and water conservation structures provide opportunities for the local community to diversify their economic activities through the cultivation of high value horticultural crops under drip irrigation systems. The pastures and improved fodder grasses planted under furrow water conservation structures provides the opportunity for the local community to produce pastures/fodders during the dry periods. The proactive responses and investment in conservation structures in ASALs is crucial towards enhancing resilience and adaption of the local communities from the adverse vagaries of climate change. Other projects such as cropping and agronomic adaptation options that promote already existing best management practices should be implemented. There is also a need for the integration of local knowledge in government climate policies to improve adaptation and enhance local adaptation strategies.

P-3312-16

Climate Change Adaptation and Vulnerability Assessment: A case Study of Lesser Himalaya

BW. Pandey (1)

(1) University of Delhi, Department of Geography, Delhi, India

Climate change and land use degradation are accelerating water induced hazards such as cloudburst, flash floods, riverine floods, surface erosion and landslides in Himalayan geosystem. Himalayas, due to their complex geological structure, dynamic geomorphology, and seasonal hydro-meteorological conditions experience very frequent natural disasters, especially water induced hazards. Natural hazards have had significant impacts on life and property in areas with high population densities and land use intensity. The escalation of risks and vulnerability has come about through population growth and land use intensification in the areas, both of which have encroached upon hazard zones and in some case, such as road construction on slopes, have exacerbated the hazard of slope failure. The association of deforestation, rainfall and steep topography was augmentative.

Climate Vulnerability Index (CVI) is being proposed to assess climate change vulnerability of communities with a case study in high mountain areas in the Beas River valley of lesser Himalaya. The index consists of household parameters of all the three dimensions of vulnerability such as Exposure, Sensitivity and Adaptive Capability. Exposure is defined by Natural disaster and Climate variability, however Sensitivity by Health, Food, and Water and Adaptive Capability by Socio demographic profile, Livelihood strategies, and Social networks.

P-3312-17

Smallholder farmers in the Great Ruaha River sub-Basin of Tanzania: coping or adapting to climate stresses?

NM. Pauline (1)

(1) University of Dar es Salaam, Institute of Resources Assessment, Dar es Salaam, Tanzania, United Republic of

Climate change and variability are pervasive contemporary realities in Africa. In this paper, we investigate the changes that have occurred in the Great Ruaha River sub-Basin (GRRB), Tanzania. By making use of a mixed-methods approach, including both quantitative and qualitative data collection methods, we demonstrate that climatic stresses have increased since the 1990s, as have limiting factors constraining effective and sustainable response options. By interrogating data from smallholder farmers focus group discussions, household questionnaire surveys and records in government institutions we show that sustainable livelihoods in this area are compromised by non-climatic stresses such as a lack of coordinated crop markets and poor access to loans, weather forecast information, and to irrigation infrastructure. Smallholder farmer responses to climatic stresses (i.e. resources utilisation, farming methods diversification) have changed over time, with corresponding changes in coping strategies that are adopted in response to specific stresses. Barriers to adaptation include limited access to irrigation water, crop markets and loans. Consequently, smallholder farmers are resorting to shorter-term coping strategies more frequently than longer-term adaptation to impacts of climatic stresses, and are thus still heavily reliant on social, economic and policy support to improve their adaptive capacity.

P-3312-18

Generating Knowledge and Capacity for Climate Change Impacts and Adaptation for Water Security

This research seeks to narrow the existing gap between scientific knowledge on climate change impacts on water resources and efforts made by national and local water management institutions in Central America and the Caribbean. Hence, from the start, these institutions were involved, in two prioritized countries, to assess climate change impacts and adaptation measures on water resources in this region. Regional, national and municipal

scales of analysis were used in a pilot basin in each of the two countries under study: the Dominican Republic and Guatemala. Research was done together with universities, ministries of environment and other stakeholders from two municipalities per basin, making it one of the key aspects that contribute to achieving the objective. This approach of incorporating decision makers, water resource managers and other stakeholders, aims to promote the application of the findings and the use of research results and to strengthen learning and management skills for beneficiaries and the organization leading the research.

For the climate change models for the region published in the IPCC Fourth and Fifth Assessment Reports (AR4, AR5), we performed a comparative analysis, in terms of future water availability. It is among the main results of the project, to date. Based on technical criteria, we chose four of the 19 General Circulation Models (GCMs) published in the last IPCC report, the new Representative Concentration Pathways scenarios (RCPs). These models were inputs to determine the impacts of future climate change on water quantity, compared to current conditions. Distinct models produced different results, especially for rainfall. Regarding erosion, the most vulnerable basins were mostly located in Haiti and Guatemala. Hydrologic and climate modeling with a Soil and Water Assessment Tool (SWAT) provided a more detailed analysis on the two basins. Results will be available in a public website, for consultation by the 22 countries in this region and can be used in their next Climate Change National Communications. Project-sponsored universities, national researchers, and students collectively performed vulnerability analyses in the pilot basins. Thru the project, a regional study was done in the countries with information available, to understand how the countries invest on climate and water resources. It showed that more than 60% of investment funding comes from external sources. From this 60%, three quarters go to the implementation of programs and costs of operation and maintenance of infrastructure. One quarter goes to actual infrastructure or hard investments. In general, countries set priorities depending on the pressure over water resources from different sectors, especially agriculture, energy generation and industry.

In the policy framework, the Roman law system prevails for Central America and in the Caribbean, the so-called common law applies. Differences in motivation are evident in the regulatory frameworks among the Caribbean Community (CARICOM) member countries and the Central American Integration System (SICA) countries. Both policy and investment studies were specific to both pilot countries. The studies were complemented by a thorough analysis of water resources management, conducted by relevant stakeholders from the pilot municipalities. It found that conflicts and gaps existed in the institutional responsibilities, policies, regulations and investments to the sectors. It identified the different local strategies that allow people to move forward in terms of water security. The municipal government scale is where findings will integrate at the end. The biophysical, economic, management and political research done will be the basis to develop Municipal Adaptation Plans. Research results plus lessons learned, will be used to prepare the guides to optimize public investment in climate change adaptation on water resources. Local stakeholders have already integrated into a «Participation Focus Group (GFP)» in each country basin in a process that promotes learning, communication and empowerment of results. They have participated in the whole process; strengthened their knowledge and perspectives; validated methodologies and monitored research outcomes, and provided recommendations. A public resource-sharing platform will complement the advances in guiding adaptation policy through knowledge built together. It will provide results and products already obtained, and the new ones we expect to obtain. This platform aims to engage and share with the rest of the regional community as a means to promote sustainability, scaling and dissemination of results.

Climate change related risks encompass an intensification of extreme weather events, such as fluvial and pluvial flooding, droughts, and heat stress. A transparent and comprehensive division of responsibilities is a necessary – but not the only – precondition for being prepared for climate change. In this paper we present, and preliminarily test, a method for the ex ante assessment of the division of public and private responsibilities for climate adaptation. This method proofs particularly suited for the assessment of adaptation responsibilities in combination with a sectoral approach. It helps identifying a number of shortcomings in divisions of responsibilities for climate adaptation. We conclude that this method is useful for identifying the expected climate change preparedness level, and recommend to combine this with ex post analyses of real-life cases of extreme events in order to assess the actual preparedness for climate change. With this method, we intend to assist policy-makers in developing and implementing adaptation plans at various levels.

Keywords: adaptation; climate change; responsibilities; ex ante assessment method; the Netherlands.
