The sustainability analysis of selected combinations of genotypes and water management practices (including water harvesting and conservation tillage) is here interpreted as an analytical approach towards the long-term perspectives. The selected combinations, specifically chosen as potential alternatives to current farming practices, should help farmers to cope with more frequent droughts induced by climate change, as well as being able to sustain their farms' activity over time. We present herein the sustainability assessment of three different Mediterranean case studies, by analysing trade-offs among environmental, economic, and social performances of farms from the Chaouia Region in Morocco, Bekaa Valley in Lebanon and in Irbid Governorate in Jordan growing mainly cereals and legumes improved varieties tolerant to water, heat and salinity stresses. Several combinations of different genotypes, fertilizers practices, tillage systems and water management options were tested and evaluated. The sustainability assessment, carried out within the activities of the project Adaptation to Climate Change of the Mediterranean Agricultural Systems (ACLIMAS, EuropeAid ENPI/2011/269-668), adopts a participatory multicriteria decision support system framework including several steps: (1) description of farming systems: identification of farmers' problems and priorities to be considered in the evaluation; (2) design of the knowledge base: identification of evaluation criteria (indicators) for the three pillars of sustainability (environment, economy, and society) in accordance to the local specificities; (3) collection of quantitative data for the selected indicators and (4) multicriteria sustainability analysis of different combinations proposed by ACLIMAS. Results demonstrate that "ACLIMAS practices" increase the three dimensions of a sustainable development and have a high rate of acceptability and a big potential of adoption.

P-3312-21

Climate Change and Adaptation Capacities in Ethiopia: Constraints and Opportunities

RB. Singh (1)
(1) Ethiopian Civil Service University, Urban Environment and Climate Change Management, Addis Ababa, Addis Ababa, Ethiopia

Assessment carried out under Ethiopian National Adaptation Program of Action (NAPA) indicates that; agricultural, water and human health are the most vulnerable sectors to climate change in Ethiopia. The present paper focus on the agriculture sector, as agriculture production complemented with pastoralist production, provide livelihood to about 80 percent of Ethiopia's population. Both of these activities are very sensitive to the changes in the climate conditions. Further, available data indicate that, in Ethiopia climate change impacts may be severe and the existing adaptation capacities are not sufficient to deal with these severe problems. Therefore, this study was designed to assess the impacts of climate change and constraints and opportunities pertaining to adaptation capacities in Ethiopia. Due to the financial limitations, the assessment was limited to two woreadas (districts) of the country-Gudura, Oromia region (predominately agricultural) and Mieso, Somali region (predominately pastoral). To achieve the objectives of the study both primary and secondary data was collected. Primary data was collected through a questionnaire survey of 100 farmers in Gudura woreda and 50 pastoralists in Mieso woreda. Further, interview was also conducted with 8 expert from federal agricultural and environmental ministries, federal and concerned regional Environmental Protection Agency (EPA), respective woreda agricultural office heads and expert of CSO named Forum of Environment, Addis Ababa. In case of farmers, for the questionnaire survey, sample respondents were selected by simple random method and experts were chosen through purposive sampling technique. Secondary data were also used to identify the types and nature of climate change impacts. To analyze the data, descriptive statistics, narration and document analyze technique was utilized. Both instrumental and proxy record have shown substantial variation in the spatial and temporal patterns of climate in the country, the UNDP climate change profile for Ethiopia shows that the mean annual temperature increased by 1.3°C between 1960 and 2006, at an average rate of 0.28°C per decade, further the results of the IPCC"s mid-range emission scenario show that compared to the 1961-1990 annual precipitation show a change of between 0.6 and 4.9% and 1.1 to 18.2% for 2030 and 2050, respectively. The percentage change in seasonal rainfall is expected to be up to about 12% over most parts of the country including the study areas. Environmental extremes are decreasing the land's productive capacity leading to a decrease in subsistence agriculture, income, assets, and a rapid decline in the health and nutritional status of the rural population and ultimately force rural people to migrate to urban centers. Latter the results of the study enable to conclude that an adaptation capacity both at household and institutional levels are very low and indicates that climate change governance framework is not properly operational. Poverty, limited resources (such as land and livestock), lack of access to credits and finance, alternative sources of income, as well as technology, knowledge and expertise, lack of integrated public policies and effective program enforcement, increase the vulnerability and adversely affect the capacity to cope with the problems. However, one can also visualize certain opportunities in the form of CRGE (Climate Resilient Green Economy) strategy, Energy Policy and Bio-fuel strategy, public sector capacity building project, southern voices capacity building program, international and Civil Society Organizations (CSOs) about 60 CSOs/NGOs formed a network-the ECSNCC (the Ethiopian Civil Society Network on Climate change), which proactively engaged in international negotiations (as observers), the generation of research based knowledge, raising of public awareness, building of local capacity and supporting adaptation efforts by vulnerable communities and regional and national government bodies. The promotion of micro finance by federal government and education, training and consultancy services available at Ethiopian Universities which may be utilized to enhance the adaptation capacity to cope with the climate change impacts. To improve the situation it is recommended to invest in climate change research and livelihood opportunities and strengthening the capacity of policymakers and institutions to enforce policies and programs.

P-3312-22

Assessing adaptation in evolving populations

T. Van Dooren (1)
(1) Institute of Ecology and Environmental Sciences, Evolutionary Ecology, team Phenotypic Variability and Adaptation (VPA), Paris, France

The current theoretical framework for the management of populations which are responding to global change lacks a systematic integration of the biological concept of adaptation. In evolutionary biology, «adaptation» describes the evolutionary process where organisms become fitted to their environments. The same term is used to denote the results of such adaptive processes: suites of evolved characteristics which are optimal in a specific sense. By using adaptive dynamics modelling, it has become possible to investigate adaptation to complex and variable environments, with interactions between individuals of the same and of different species. There is one difficulty, however, when this type of modelling is applied in the context of climate change adaptation: it assumes environments which are stationary and which are not changing with a trend.

By means of a textbook model of bet-hedging evolution, namely for plants with a seed bank and an evolving germination probability, I illustrate how concepts from adaptive dynamics modelling can still assist in predicting how natural populations would respond adaptively to climate change and in assessing adaptation. I will show that during gradual environmental change, populations will often lag behind the most adaptive response. Surprisingly, there are conditions where the adaptive state does not show a unidirectional trend. Its changes can reverse direction. The consequence is that populations which lag behind, can suddenly find themselves lagging ahead.

This model is extended with evolving phenotypic plasticity, and an exploration of evolutionary scenarios where the environmental change has a tipping point.

P-3312-23

Analysis of Spatio-temporal Climate Variability and Resulting Challenges for Household Adaptation in Lake Victoria Basin of Kenya

E. Wabwire (1)
(1) Catholic University of Eastern Africa, Geography and Environmental Studies, Nairobi, Kenya

Climate variation is one of the most challenging and intricate problem facing the world today. The resulting effects of changing climates have been of great concern to almost all sectors of the economy in Africa. This study sought to analyze spatial and temporal climate variability and the resulting challenges for household adaptation in Lake Victoria basin of Kenya. Most households in rural areas of Kenya have adaptation capability is low and this probably could result in serious challenges in as far as their livelihoods in concerned. The objectives of this study were to determine rainfall and temperature as indicators of climate variability experienced in Lake Victoria basin of Kenya. It sought to establish local awareness of climate variability, perceptions about vulnerability and observed adaptations with view to recommend effective adaptation measures.

The study presumed that rainfall and temperatures have not changed over Lake Victoria Basin of Kenya between 1973 and 2014, there was no sufficient effect of climate variability on households of Lake Victoria Basin, the residents of Lake Victoria Basin lacked sufficient knowledge on the effects of climate variations and that there are no observable adaption measures put in place in Lake Victoria Basin.

To achieve the objectives of this study, an empirical research design was employed. Climate variability was determined using rainfall and temperature data from observations and climate models over a period of 40 years, future projection were also be done for period of until 2100 in order to establish future climatic pathways. Both primary and secondary data were used in this study. The primary data was used to assess the implications of

climate variability on rural livelihood. The respondents from the study area were interviewed using a standardized interview schedule or depending on their literacy level and availability, they were supplied with a questionnaire. Focus Group Discussions were set up to explore important issues regarding livelihoods in the community.

In data analysis basic statistics of mean, standard deviation, Skewness, Kurtosis and trend were used to show the central tendency of climate. The optimal fingerprinting (Paeth and Mannig 2012) was applied in order to quantify climate change signals in the light of internal climate variability

Africa's development efforts in the continent over depend on natural resources which are vulnerable to climate change and variability. This study used multinomial logit models to analyze the effect of spatial and temporal climate variability and change on household adaptation. The Heckman model was used to assess whether households perceive climate variability and assess thier decision making process to adapt or not. The data was collected from a survey of about 400 households using semi structured questionnaires. The climatic data were obtained from Kenya Meteorological Headquarters at Dagoreti as well as from gridded observational and regional climate model data sets. This study used the newest CMIP5 and CORDEX model data sets for the assessment of climate variability and change over eastern Africa. The study was designed to have an in-depth understanding of climate variability and change at small area within on regional scale. The results of this study have been helpful in influencing the policy markers' decision making process in the face of climate variability adaptation measures at both national levels.

Households in both rural and urban settings experienced huge burden to adapt to persistent climate variations. The variations were hardly predictable within space and time and frequently they induce disasters such; as prolonged droughts or floods which have heavy burden to human livelihoods. The study established that traditionally, people used the indigenous knowledge to predict certain climate change; they also managed to cope with changing climates through applying certain adaptation measures such as planting different crop varieties, improving water conservation techniques and keeping livestock as a buffer to crop failure. Today the paradox is that people are not aware of changes in climate and the indigenous knowledge which was significant is now scanty in the face of scientific knowledge.

P-3312-24

Key climate change adaptation deficits in Indonesia: Sectoral coordination and local capacity building

R. Yoseph-Paulus (1) ; R. Hindmarsh, (2)

(1) Local Government of Buton Selatan Regency, Regional development planning agency (bappeda) and dayanu ikhsanuddin university (unidayan), Baubau, Indonesia; (2) Griffith University, Environmental politics, policy and sts griffith school of environment, and centre for governance, Brisbane, Australia

The commitment to mainstream responses to climate change in Indonesia's development agenda has been acknowledged in several government regulations. Many obstacles hinder such efforts, especially the lack of clarity over the functions of central and local governments and lack of capacity within the governments to administer new functions due to decentralization. To encourage Indonesia's participation in this global issue, there is an urgent need to identify ways to develop national capacity, including local government due to their significant roles to mainstream climate change adaptation into development agenda. This paper outlines the findings of a field trip to central and several local governments in Indonesia to seek the views of policy-makers, researchers, community representatives and other key actors related to climate change adaptation. Emphasised areas for enhanced adaptation policy development were, first, institutional strengthening through the enhancement of sectoral coordination and capacity building to ensure the adequate institutional setting and capacity. Second, for effective sectoral coordination among government agencies there needs to be elevated synchronisation of crosscutting issues, and the development of appropriate coordinating agencies and appropriate guidelines for the local level mainstreaming of climate change adaptation into development. In turn, for enhancement of capacity building there needs to be elevated local governmental and civic awareness raising; promotion of government and non-governmental partnerships; and greater availability of scientific assessment and incentives as well as inclusion of local social and traditional knowledge

P-3312-25

Assessment of Socioeconomic Vulnerability to Floods at Small Area Level in Malawi

S. Zhang (1) ; M. Bangalore (2) ; D. Schensul (1) ; S. Hallegatte (2)

(1) United Nations Population Fund, Technical Division, New York, United States of America; (2) World Bank, Climate change group, Washington, DC, United States of America

Vulnerability assessments involve indicators and measurement methodologies to assess the vulnerability of socio-ecological systems, for example to natural disasters such as floods. Flood events directly and indirectly threaten people's health, livelihoods, food security, and deepen poverty. Flood is expected to worsen with climate change, and has disproportionate impacts on different segments of the population. Poor people, women, youths, adolescents, people with disability, and migrants are more generally more vulnerable to the impacts of floods. In many urban areas, inequities will become more apparent with higher concentration of vulnerable people in less desired but higher-risk locations. There is urgent need for incorporating socioeconomic vulnerability and equity factors into climate change adaptation planning and development policies. In this paper, we examine the vulnerability to flooding in Malawi at small area levels, integrating a number of datasets.

In Malawi, we will integrate socio-demographic data with hazard data and examine vulnerability at the small-area level. We employ census data for demographic, housing quality, and service data, World Bank estimates for poverty data, and Demographic and Health Survey (DHS) data for education and nutrition data. This socio-demographic data will be merged with spatial hazard data on flood risk in Malawi, from two global hydrological models (GLOFRIS and SSBN). As socio-demographic data is at the 2nd and 3rd administrative boundary level, and hazard data is at high-resolution, the vulnerability analysis will be done at small area level, based on the level at which decision-making processes are made. The joint paper will identify a suite of indicators to develop a vulnerability index, and examine where high vulnerability coincides with high risk from flood, through spatial and statistical analysis.

The project will pilot the vulnerability index and assessment in Malawi, a country with increased pressures from population dynamics, poverty and natural disasters, where the climate data and information are sorely lacking. In addition to examining socioeconomic vulnerability, the index can be disaggregated to provide information on each dimension (demography, health, economic and flood). By disaggregating vulnerability at small geographic level over four dimensions, the project aims to better understand the socio-demographic vulnerability to floods, in a context of climate change. It is also in line with the post-2015 Sustainable Development Goals and targets by contributing to strengthening resilience and adaptive capacity to climate-related hazards and adaption, as well as providing evidenced data by small geographic location. The data, index and methodology applied in this project may also be scaled-up to more countries.

3313 - Coordinated Adaptation to Climate Change

Coordinated adaptation to future climate change, Concept and case studies in China

G. Jia (1) ; C. Fu (2) ; Z. Ma (1)
(1) Chinese Academy of Sciences, Institute of atmospheric physics, Beijing, China; (2) CAS Institute of Atmospheric Physics and Nanjing University, Beijing | Nanjing, China

Human societies have continuously adjusted themselves to meet the dynamics of climate since ancient time, long before global climate change is considered as threaten issue. Traditional approaches for climate change adaptation are often based on certain sector or administrative unit, and lack of coordination or integration across those boundaries. Such barriers among sectors and administrative units often cause conflict interests and compromised overall effects of those efforts. In some extreme cases, the adaptation strategies developed by one sector or area could even lead negative impacts on other sectors or areas. Therefore, different sectors and subregions are encouraged to work together to develop coordinated and integrated adaptation strategies at regional and global scales, in order to achieve optimal effects for sustainable development. Here we propose and discuss the possible pathways, i.e., coordinated adaptation strategies, towards integrated approaches for climate change adaptation across sectorial and administrative boundaries. Such pathways ask policy and planning at the scale of an entire region or subregion and cutting across sectorial boundaries. The proactive and coordinated adaptation planning potentially affects all sectors and all parts of a region. Cross-sectorial and cross subregion policy coordination mechanisms will also be discussed, with several case studies related to regional urban clusters and dryland watershed management in China in response to climate change.

UNEP's global adaptation strategy: from global governance to community based solutions

K. Alverson (1)
(1) PO BOX 30552, Climate Change Adaptation, Freshwater and Terrestrial Ecosystems, Nairobi, Kenya

Recognizing the need for integration across scales and sector's UNEP's adaptation portfolio includes actions on many different levels of governance (global, regional, national, sub-national, local) alongside coordinated engagement across different sectors of government, economy and society.

The presentation will first introduce UNEP's global adaptation efforts; including the 2014 United Nations Environmental Assembly Resolution on Ecosystem based Adaptation, the Global Adaptation Network, our global support programs for NAPs and access to climate finance and publications oriented towards informing global climate negotiations such as the Emissions and Adaptation Gap Reports.

The presentation will then highlight UNEP adaptation actions at the regional level including management of transboundary resources in the context of climate change and regional knowledge sharing on adaptation under the "Lima Adaptation Knowledge Initiative" pledge the Nairobi Workprogram of the UNFCCC.

Finally, the presentation will provided an overview of UNEP's portfolio of national and local projects under implementation, helping communities around the world harness ecosystems to build resilience as part of their adaptation plans and actions.

The presentation will conclude with an overview of UNEP's program of actions supporting countries in the leadup to the Paris COP.

K-3313-03

EU climate adaptation policy integration between mainstreaming and marginalisation

S. Weiland (1)
(1) Helmholtz Centre for Environmental Research - UFZ, Leipzig, Germany

Policies on climate change adaptation aim to contribute to a more climate-resilient society. In the European Union, this is pursued by ensuring that adaptation considerations are addressed in all relevant EU policies. It also promotes greater coordination and information-sharing among Member States. Such coordination of climate change adaptation measures require the vertical integration of different levels of governance (European, national, regional, local) as well as horizontal integration between different sectors of the economy and society. This 'mainstreaming' will also offer potential for synergies if adaptation policies are successfully coordinated.

Horizontal and vertical policy integration is to be seen as means to achieve policy coherence for climate adaptation. The rationale for such an approach is that cross-cutting priorities can all too often fall into the gaps that exist between narrowly specified sector objectives or lead to inconsistent or conflicting policy objectives within sectors. Integration is particularly vital for climate adaptation as climate change impacts have implications for many sectors and actors. However, adaptation concerns may get sidelined as they can be obstructed by sectoral objectives that are of more immediate concern or that appear to compete with adaptation. So while the rationale to integrate seems straightforward and desirable, implementation at sector levels is rather complex and is a potentially conflict prone process, where conflicts may arise between objectives within a sector or between sectors and broad societal objectives.

This paper explores how action on climate adaptation can be taken forward in complex policy environments such as that of the European Union. It explores the conditions for successful policy integration and coherence, which are considered to be crucially important for progressing with climate adaptation.

Integrated Trans-boundary Headwater Governance in Hindu Kush Himalaya Under Climate Change: A Coordinated Adaptation Framework for Water, Food and Energy Security in South Asia

PC. Tiwari (1)
(1) Kumaun University, Geography, Nainital, Uttarakhand, India

Hindu Kush Himalaya constitutes headwaters of some of the largest trans-boundary basins of planet. The ecosystem services, particularly the freshwater flowing down from the Himalayan headwaters sustain one-fourth global population dependent primarily on subsistence agriculture in Pakistan, India, Nepal, Bhutan and Bangladesh. Climate change has stressed hydrological regimes of Himalayan headwaters through higher mean annual temperatures, fast melting of glaciers and snow, altered precipitation patterns and increased incidences and intensity of extreme weather events causing substantial decrease in water availability and increasing frequency and severity of hydrological hazards. This may increase proportion of water, food, health and livelihood insecure population in entire South Asia which represents one of the most water stressed, food insecure and energy deficit regions, and inhabited by some of the poorest people of the world with access to less than 5% of planet's freshwater resources. This will have enormous regional implications for fundamental human endeavors ranging from poverty alleviation to environmental sustainability and climate change adaptation, and even to human security and peace in the region. A coordinated regional adaptation framework

is therefore highly imperative not only for responding to long-term impacts of climate change and achieving water, food and energy security, but also for attaining post 2015 Sustainable Developments Goals (SDGs) to provide social and economic sustainability to more than 40% global population living in the region.

The main objective of the study is to evolve a coordinated regional trans-boundary headwater management framework underlining the role and critical significance of Hindu Kush Himalayan (HKH) ecosystem services in sustaining food, water, and energy security in South Asia under climate change. In order to attain this the study: (i) appraised the mutual environmental and economic benefits of integrated trans-boundary headwater management; (ii) investigated reasons and rationale for missing regional cooperation among riparian countries; (iii) explored geo-political constraints in initiating effective regional cooperation dialogue; (iv) evolved an institutional framework for effective trans-boundary headwater governance in Hindu Kush Himalaya through the analysis of secondary data collected from varied sources. Besides, comprehensive study of available literature and media reports, interpretation of people responses obtained through interviews, interaction with political leadership and policy planners across Hindu Kush Himalayan countries formed the basis of this study. Study revealed that despite geographical and cultural contiguity South Asia is one of the geo-political hotspots as it is one of the most disintegrated regions of the world characterized by political tensions, armed conflict, and extreme political instability and economic imbalances. It was observed that political transition, threats of internal and external security, weak leadership, and long standing conflictual inter-state dynamics are important reasons for missing regional cooperation in trans-boundary water management and for freezing hydro-diplomacy in the region. Further, the results clearly indicated that the issues and challenges in the food, water, and energy sectors are interlinked in several complex ways and cannot be managed effectively without cross-sectoral integration and regional cooperation. The study also identified a range of important potential benefits of regional cooperation in integrated water resources which include: (a) sharing information for developing integrated flood forecasting and early warning system for different basins , (b) storing water in upstream river basins for flood moderation, (c) storing water resources for increasing flow in dry seasons, (d) accumulating water for inland water transport, (e) harnessing water resources to generate hydroelectricity, and (f) managing watersheds to help increase the quality and quantity of water available, irrigation, industries, drinking and sanitation by downstream users. A number of regional and local institutions, particularly International Centre for Integrated Mountain Development (ICIMOD) and South Asia Association for Regional Cooperation (SAARC) are interested to play effective role in initiating regional water cooperation in South Asia.

O-3313-02

Coordinated Regional Adaptation to Sea Level Rise -- A Case Study of Land Use and Transportation System

S. Shen (1)

(1) University of Hawaii at Manoa, Urban and Regional Planning Department, Honolulu, France

In recent years, many research efforts have been made to study the impact of climate change, especially sea level rise, on transportation system at the local level. While these studies provide many useful insights for the vulnerability of transportation system to sea level rise, few analyzed the impacts of adaptation strategies (i.e. protection, accommodation, planned retreat) on transportation system. Furthermore, the diversity of study contexts, the variety of methods utilized, and the lack of standard evaluation metrics make it difficult to compare the results of different studies. Therefore, the interaction between adaptation strategies, corresponding long term land use change, and transportation system performance are not thoroughly studied. To bridge this research gap, three adaptation scenarios with different network disruption levels and land use schemes are analyzed using Tampa, Florida as a case study. Transportation system vulnerabilities to sea level rise under three scenarios are compared using multiple performance measures. Vehicle hours travelled (VHT) shows to be the most sensitive performance measure to transportation vulnerability change. Without any adaptation strategies, the regional transportation system could have 40% VHT increase under 2ft sea level rise. Protecting up to 108 miles of freeway/bridges could prevent about 18% of VHT increase, while large scale traffic analysis zone internal capacity protection or development retreat have less than 2% contributions. Supposing the average value of travel time savings in Florida is $32 per hour, protecting up to 108 miles of freeway or bridges would generate a saving of more than $30 million per day. If the cost to elevate road is $2 million/mile, it takes about a week for the benefit to recover the cost. Consequently, even with neighborhood flood prevention and planned retreat strategies, protecting coastal freeways and important bridges would be necessary and cost-effective to adapt to sea level rise for the case study area. The results of the case study illustrate that communities outside the inundation zones or lowlying areas are also vulnerable to sea level rise because their activities are supported by critical infrastructures (i.e. transportation in this case study) within the inundation zones. Without long-term coordinated regional land use and transportation planning, adaptation strategies focus only on accommodating or relocating local vulnerable communities might not be effective at the regional level.

Making adaptation policy integration work in local government: Lessons from Australia

H. Fuenfgeld (1) ; A. Macarthur, (2)

(1) RMIT University, School of Global, Urban and Social Studies, Melbourne, Victoria, Australia; (2) RMIT University, School of global, urban and social studies / centre for urban research, Melbourne, Victoria, Australia

Considering and planning for the impacts of climate change has entered the mainstream of local government policy level, yet much experimenting is still taking place about how adaptation can meaningfully and effectively be tied in with existing policy agendas and integrated into policy making, across departmental boundaries and organisational hierarchies. Over the past decade, there has been slow recognition that, from an organisational perspective, climate change adaptation needs to be broadly anchored in an organisation; for adaptation to be effective and comprehensive, it cannot be simply be another task of environment departments or sustainability officers.

While many adaptation policy frameworks point to the need for such systematic and deep integration and recommend high-level actions, not many empirical studies exist that document the strategies that complex organisations pursue to embed adaptation, nor is there much empirical evidence assessing the success of specific strategies. While key barriers to integration are knows, many organisations still struggle to make much progress with embedding adaptation across divisions, departments or operational units.

This paper presents, for the first time, empirical findings from two research projects concerned with embedding adaptation in the local government sector in Australia. The focus of the analysis is on intra-organisational processes for embedding adaptation across an organisation, although some inter-organisational strategies will also be highlighted. The local governments that participated in these research projects are highly exposed to multiple climatic stressors and their impacts, including sea-level rise, bushfire, flooding and heatwaves. They provide interesting case studies for adaptation policy development and implementation at the local government scale, adding to our understanding of the role of institutions in climate change adaptation.

Regional climate change adaptation and mitigation in the North German Plain – a cross-sectoral analysis of land use experts' perception

T. Barkmann (1) ; R. Siebert (1) ; A. Lange (1)

(1) Leibniz Centre for Agricultural Landscape Research, Institute of Socio-Economics, Muencheberg, Germany

Climate change is beyond dispute and a crucial challenge for mankind on the global scale as well as on the regional scale. In order to successfully implement adaptation and mitigation measures towards climate change on the regional scale, the involvement of regional land use experts is very important. Moreover, cross-sectoral interdependencies of adaptation and mitigation measures on the regional scale – both synergies and conflicts – have to be taken into consideration. One crucial requirement of a successful adaptation and mitigation concept is the analysis of those measures already implemented on a regional scale, including the appropriate spatial scale for measures taken. Furthermore, coping with climate change is a multi-level policy concern. Therefore, the appropriate level of political regulation, as assessed by regional land use experts, is an important element of the analysis of adaptation and mitigation measures.

In our study we applied a qualitative, cross-sectoral approach, primarily analysing which adaptation and mitigation measures are implemented or demanded on the regional scale in the land use sectors agriculture, forestry and water resource management. The results are derived from 60 semi-structured expert interviews conducted in four case study regions in the North German Plain as well as from a subsequent survey (n=37) amongst regional land use experts. Experts involved cover a wide range of land use experts, including farm managers, forestry experts and their respective interest groups, flood protection and water body maintenance specialists as well as representatives of regional administrative bodies.

Our results show that: (1) Even if Germany may not be as affected by climate change as other countries, a number of climate change induced adaptation measures are nevertheless already implemented, (2) further measures are taken into recognition or are demanded by regional land use experts, (3) adaptation measures play an important role on the regional scale whereas mitigation measures are almost negligible, (4) water-related issues, respectively water management approaches and related measures are the linking elements between the analysed land use sectors in all case study regions and (5) in general, there is no particular spatial level favoured for the implementation of adaptation or mitigation measures. However, with regard to policy-makers' ability to exert influence on climate change related measures, the national scale is seen as the most effective level.

Our results implicate that the implementation of adaptation measures can be focussed on the regional scale, whereas efforts to mitigate climate change should be coordinated and implemented on the national or even global scale. Furthermore, cross-sectoral interdependencies between the analysed land use sectors can be shown. Therefore, an integrated, cross-sectoral approach should be further pursued, to combine the sectoral efforts to adapt to climate change, to generate synergies and to minimise conflicts.

In our study we also identified needs for further research. Whereas further analyses of interdependencies between different adaptation measures on the regional level seem to be fruitful, the analysis of regional mitigation measures is not sufficient at this point. There is further need for research on why the regional scale lacks mitigation measures and how to integrate those at the regional level. While the study's focus lies on those adaptation and mitigation measures clearly depicted as climate change related, other regional measures may also be linked to climate change. Though those were not included in our study, they should be considered in future analyses for a coherent approach. Also, further analyses on how to integrate sector-focused measures into a more comprehensive, cross-sectoral approach should be conducted.

The study was carried out within the research project „NaLaMa-nT- Nachhaltiges Landmanagement im Norddeutschen Tiefland" (Sustainable Land Management in the North German Plain) within the frame of the FONA program initiative funded by the German Federal Ministry of Education and Research (BMBF).

P-3313-02

Adaptation to climate change in Tampere Region, Finland

T. Frisk (1)
(1) Centre for Economic Development, Transport and the Environment for Pirkanmaa, Environmental Information, Tampere, Finland

Adaptation to climate change will be one of the most important issues in the different regions of Europe. Adaptation plans cannot be made only internationally or nationally but local and regional authorities must have the main be responsibility for adaptation planning. One of the four main themes of the Climate and Energy Strategy of Tampere Region is adaptation to climate change. The purpose of this presentation is to deal with the aims and the proposed actions of adaptation in Tampere Region.

In the strategy, the main general aim of adaptation is that people and different organizations of the region are reserved to governance of climate change phenomena. The aim is that Impacts of climate change have been studied, their importance has been assessed and the most important actions of adaptation have been carried out in a cost-effective way, taking into account the aims of mitigation of climate change. Another aim is that awareness of the impacts of climate change and the need of adaptation has increased. It is important that people realize that the change is permanent and the threats and also the possibilities of the changes are taken into account. For achieving the general aims, six main actions have been acknowledged:

- Research is utilized and comprehensive assessment of the impacts of climate change is made, as well as risk analyses and considerations of vulnerability.
- Skills of ordinary people in adaptation and reservation to the impacts of climate change are improved.
- Proactive and cost-effective actions of adaptation are carried out in practice.
- Adaptation to climate change is taken into account in the Biodiversity Programme of Tampere Region.
- The Centre for Economic Development, Transport and the Environment for Pirkanmaa (CETEP) is coordinating the cooperation in adaptation to climate change.
- In adaptation, the cooperation over the borders of the regions is considered.

More detailed aims have been presented for increased precipitation and humidity, increased temperature and extreme events. One of the main aims is that the risks of increased precipitation and humidity have been assessed and the most necessary actions have been carried out. Attention must be paid to the following issues for example: the amount of storm water and the capacity of sewerage systems, the condition of roads and streets, the increase of nutrient leaching from agricultural areas, regulation of lakes and rivers, and the impacts of increased humidity on houses and other constructions.

The main aims connected with increased temperature are that new animal and plant species (including cultivated plants and trees) can be utilized, harmful alien species are recognized and their distributions are monitored and restricted, and cooling of houses is carried out taking into account requirements of energy efficiency. Attention will also be paid the impacts of increased temperature on human health.

When extreme events are concerned, one of the main aims is that adaptation planning in the different sectors (local communes, industry, service, households) is sufficient. The other two main aims are that forecasts and informing about extreme events has improved and that the basic functions of society have been secured during more drastic and more often occurring extreme conditions.

For monitoring the proposed actions of the Climate and Energy Strategy of Tampere Region, a working group has been founded. The group is coordinated by CETEP and particular attention is paid to adaptation to climate change. The first report will be published in 2016.

P-3313-03

Flooding in the Urban Space: the Contribution and impact of law in relation to resilient Flood Risk Governance in the EU

S. Homewood (1)
(1) Middlesex University, Law and Flood Hazard Resaerch Centre, London, United Kingdom

This presentation will take an overview of one of the most important environmental issues affecting more than half of the world's population. How should environmental risk governance respond to climate change which is likely to have caused increasing problems of flooding in recent years and the increasing threat of flooding in the cities and urban spaces of the future? An important aspect of such governance arrangements is the impact and importance of a number of legal issues.

This paper will examine some of the law's response to the problems of the governance of flooding in England and make some comparisons with other EU Countries. This will include reference to the preliminary findings from the large 6 Million Euro EC funded STARFLOOD Research project on Flood Risk Management, with which the author and other colleagues are involved, together with 5 other European Universities.

P-3313-04

Promoting the consideration of the effects of climate change on Agriculture in Morocco

A. Laouina (1)
(1) Faculty of Human sciences, Geography, Rabat, Morocco

The effort of adaptation to climate change must be involved in the fields of resource management and governance, by the research on the possible correlations between Climate change / Management of resources / efficiency of institutions responsible for these resources, in order to better respond to the questions posed and propose ways of adaptation capable to mitigate the negative effects of the current trends.

On the political level, because of the strong interactions of the three domains, climate water and environment, it is advantageous to opt for integrated actions, winning on several plans: reduce the vulnerability, conservation of resources, development of agriculture and guaranty of water volume and quality.

Therefore propose measures with tangible effects, reform the decision-making process and place it on top of sector structures.

We can't overemphasize the importance of anticipation, ie, possess an elaborate knowledge, the result of advanced research, based on sufficient measures and studies. Careful planning is to be prepared, on the basis of a prospective based on reliable indicators. Finally, we must adopt policy choices and courageous management, by challenging truths that seemed established and proved, but recent studies seem to contradict.

Non integrated solutions with only a technical content can affect the consistency and efficiency of decisions and policies. It is necessary to collect sufficient data to validly base on the decisions and thus strengthen the links between scientific research and decision making. A sufficiently broad debate should take place, to compare the values, perceptions and views, to allow the decisions ownership by everybody. We must provide relevant and reliable scientific data and the results must be communicated to the general public and organizations, to ensure a sufficient level of awareness and commitment.

Adaptation is not exclusive to the most vulnerable farmers and most fragile lands. The rainfed land of the Atlantic plains of Morocco, considered as favorable, covered by large farms, in which aggregation of means permits to promote agriculture, and which are directed by conscious farmers, in principle, of the possible impacts of Climate change on the process of degradation, can suffer serious threats, especially because of the unexpected occurrence of large magnitude events. Irrigated land, either, are not immune to environmental crises, especially in case of water stress. So we must be prepared for any eventuality and therefore adopt a crisis management policy in the event of occurrence of major risks.

An effective integration of climate change on agriculture, as in other sectors, implies the need for a clear commitment at the highest level of the state apparatus and ensures the contribution of the private and civil society to establish the conditions for the establishment and implementation of a structured and effective strategy.

P-3313-05

Climate change and necessary actions for Sahelian rural world. What choice and what measures for responsible authorities?

A. Ndiaye (1) ; MB. Timera (1) ; SD. Badiane (1)
(1) Cheikh Anta Diop University, Geography, Dakar, Senegal

In the Sahel, rural populations are increasingly faced with a decline in agricultural production due to various inappropriate methods of production but also and especially to the influence of climate change is manifested in the form of recurring hazards: droughts, floods, dry spells, the greater wind speed, etc. However, to ensure food security, more than 80% of rural depend on a hypothetical rainy winter, very disturbed in the course of its cycle. It follows strong pressure exerted on natural resources (Sivakumar, 1993; Servat et al 1997; Etc.).

These climatic disturbances that last for almost half century affected the bio-productive system and induces degradation. It appeared everywhere, the most degraded landscapes are those affected by overgrazing, agricultural pressure, where poor farming practices; the disappearance of fallow and lack of fertilizer supply has exacerbated the phenomenon (Preliminary Report of the FAO project «Land Degradation Assessment,» FAO-CSE, April 2003), etc.

Thus, disturbances occurred on climatic factors, will have notable effects on the lifestyles of the population and socio-economic activities. They are facing, at the same time, to constantly risk situations and high vulnerability due to the lack of resources available to them to face the multiple pressures.

A diagnosis based on a field visit in 2014, with a project from F.A.O. (collection of basic information: individual interviews and focus group interviews with facilitators and leaders of structures, etc.) in Senegal, Gambia, Burkina Faso and Mali , has identified and assess the adaptive capacity of farmers to climate change in relation to their livelihoods, to identify their roles and responsibilities but also those of the various technical and administrative services that support them in their fight against the effects of the phenomenon.

It appeared at the end of our research that, the main policy advice is that both addressing food and nutrition security and building resilience in vulnerable nations and communities require an integrated approach of investing in long term production enhancement interventions, but also short term price and climate risk management strategies. Investing in responsive and sustainable safety nets that will enhance food and nutrition security can thus reduce the impact of short term risk factors. Once risk and vulnerability are not factored, hazards may reverse progress made over some years in most fragile and vulnerable countries and communities.

It appeared too, that the active participation of all stakeholders, enabling the development of the strengths and potential of rural areas and thus the assertion of economic identity, social, historical and cultural populations could assure them the well-being so aspired. Furthermore, the challenges of climate change in the context of globalization, there were proven everywhere (Smart Village, Eco-villages, etc.) that local development, will, in the future, more than in the past, a role key to play in ensuring a confirmed transformation of territories?

Ultimately, it will be discussed in the context of this paper, to succinctly analyze climate trends indispensable for socio-economic projections, to study the factors (internal and external) that exacerbate the vulnerability of farmers and finally to assess the relevance of options / more effective coping strategies in this sense the emergence of a local socio-economic consciousness and collective responsibility to build a regional project through an agreed methodology.

Rethinking Coastal Design and Planning: Integrated SLR Vulnerability Assessments, Case of Mombasa and Lamu Islands

V. Ochanda (1)
(1) Wits University, Architecture and Planning, Johannessburg, South Africa

The world coastlines are increasing in population due to their natural beauty, tourist attraction of the luxurious coastal cities leading to ever larger populations, and a vast interest in developing infrastructure at coastal areas. Sea level rise (SLR) is threatening the sustainability of coastal residents as well as the related infrastructure, The Low Elevation Coastal Zone (LECZ) defined here as the contiguous area along the coast that is less than 10 metres above sea level covers 2 per cent of the world's land area but contains 10 per cent of the world's population and 13 per cent of the world's urban population. The least developed countries have 14 per cent of their populations living in the LECZ compared with 10 per cent for the developed countries with the disparities widening in coastal urban areas at 21% and 11% respectively. Literature suggests that coastal cities in the developing world are ill prepared for the impacts arising from sea level changes and related storm surges. The Southern and Eastern African coastline (comprising the coasts of South Africa, Mozambique, Tanzania and Kenya), will regularly be affected by changes in cyclonic and other significant weather events that pose risks related to the development and infrastructure in these countries. The East African coastal Islands of Mombasa and Lamu being relatively low elevated will become increasingly vulnerable to the associated risks of increasing SLR. Urban infrastructure development, use planning and design is most likely going to be impacted by the sea level rise on the coastal built environment, these factors along the coastline will require a rethinking of coastal design and planning especially with regards to Sea level rise (SLR). The main purpose of the integrated and participatory vulnerability assessment was to identify adaptation strategies that are feasible and practical in both the local government and communities. The distinctive features of perception and adaptation analyses with this purpose are outlined, and common elements of this approach are described. The specific objectives was to assess initial SLR vulnerability levels for the coastal strip of Kenya in terms of the zones, assets, infrastructure, public services, people and activities, Use GIS-based tools and techniques to determine and map out the extent of inundation risk for Kenya's coastal strip based on localized modelling from global inundation scenarios of 1m, 3m, and 5m assessment, Appraise baseline sea level vulnerability awareness and perceptions through focus group discussions in order to understand the prevailing mitigation/adaptation practices and coping strategies now in place, co-creatively evolve intervention or mitigation policy options for subsequent action and implementation. In this case meaningful and Practical adaptations initiatives tend are enhanced when, climate is considered together with other environmental and social stresses. The important input was maily the participation of the affected communities through the mini charette on the concept of sea level rise, climate change and coastal adaptation and mitigation, especially in the context of the developing countries. The participation of the communities gave a great insight in the enhancement of the adaptation and mitigation strategies, and the absorption of climate change related mitigation and policy strategies for the two islands.

P-3313-07

Adapting to climate change through local planning: The Bolivian Andes

PL. Pacheco Mollinedo (1) ; AL. Gonzales Carrasco (2) ; C. Carafa (1)
(1) Agua Sustentable, Climate Change Adaptation, la Paz, Bolivia; (2) Agua Sustentable, Climate change, La Paz, Bolivia

The manifestations of climate change contribute to increasing threats to national development strategies. Every year more intense extreme weather impact on natural and human systems; impacting on the social and economic development in the Bolivian Altiplano. Studies by the National Climate Change Program in Bolivia (1997) and SENAMHI (1998), predict future climate scenarios in Central Altiplano of Bolivia, where variations in the cycle of rainfall and temperature increases with consequences of aridity.

Faced with this problem, there is an urgent need to build a solid foundation of scientific information, develop skills and knowledge management under which it will explore and identify the best options and tools for effective response to the impacts of change and climate variability using appropriate instruments as the rescue of knowledge, mathematical modeling, mapping rights, spatial tools, etc. To achieve this solid base of information, provide information to decision makers on the most effective use and the most appropriate destination of public investment funds and strengthen the governance structure to adapt to climate change.

An adaptation plan should address policy guidelines and adaptation to climate change in order to reduce the vulnerability of communities. In general, the policies relate to the objectives and the means of implementation, while the measures focus on actions to specific topics.

The construction of such a plan is based on social learning processes, methods and developed, adapted and tested for Sustainable Water tools, where both men and women in the communities participating in activities from the accompanying research, information gathering and building community action adaptation action plan and regional adaptation and analysis of lessons learned and planning.

Through the processes described, a methodological approach based on a sequential flow and simultaneous integrated actions in three fundamental axes parallel builds, which feed off each other 1) research, 2) Spaces of public social deliberation and advocacy and 3) Planning and investments for adaptation.

The applied, collaborative and participatory work of local actors is the key in vulnerability analysis locally and expanding to a regional analysis as well as in identifying adaptation options to climate change, some of which are re-evalued as traditional or ancestral forms of water management and some as new initiatives that are found from the research.

On the other hand, the second axis are social spaces of public deliberation. It is under this axis where the dissemination of knowledge for capacity building and strengthening works by promoting a roundtable of the basin where the actors are the same, both civilian and public. Finally, the focus of investment planning for adaptation is at the base of solutions to address climate variability and change tools built from the negotiating Regional Plan for Adaptation to Climate Change.

To meet future challenges involving climate variability and change, it is necessary a permanent improvement of the planning system (plans, programs, projects) to which this proposal raises contribute to the development of their own capabilities of the governors on the issue of adaptation. The principles of good governance imply that adaptation schemes are aimed at consensus, joint planning, effective, efficient, accountable, transparent, flexible, equitable, inclusive and law-abiding. These are basic principles to be considered to achieve reliable processes and establish legitimate institutions that lead to effective adaptation measures.

- Adaptation planning does not need to be separated aside the already known planning development actions at local levels.
- Adaptation capacities of the municipalities can be improved by better allocating the funds for adaptation actions argued by the big losses after no adaptation

Municipalities can plan adaptation actions and level up those to the Programs for development at the Regional and National level.

Dynamic coherence of risk management and adaptation strategies in cities

R. Schwarze (1)
(1) Helmholtz-Center for Environmental Research, Economics, Leipzig, Germany

Decision¬making in cities has a specific temporal character. It ranges from mainstreaming existing urban infrastructures and planning and more immediate measures to increasing theadaptive capacity of cities, to long¬term transformations of urban living and design. Scaling urban challenges of CCA in time strongly relates to the analysis of risk management andadaptation needs, measures and actions. Much knowledge is already available on the impacts of climate change and natural hazards on different sectors in cities and on associated existing vulnerabilities and risks, and many sector ¬specific CCA and DRM options are available. However, the existing methods and tools have not been studied for dynamic coherence. This paper displays the structure of risk management and adaptation need in short term direct and indirect cross¬sectoral impacts, vulnerabilities and risks of climate change, mid term levels of preparedness of cities (adaptive capacity) for these impacts, and robust long¬ term urban sustainability transformations for challenges going beyond existing adaptive capacities. It also covers the role of the private sector in short and long¬term urban resilience programmes,with a special focus on municipal climate and resilience finance.

Producing pulp and paper in 2050: from incremental improvements to breakthrough technologies

B. De Galembert (1)
(1) Confederation of European Paper Industries, Brussels, Belgium

When the European Commission announced in 2011 its ambition to reduce the EU carbon emissions by 80% by 2050, the European pulp and paper sector, represented by the Confederation of European Paper Industries (CEPI), decided on its way to achieve that ambition. After the publication of its own roadmap, specifying the ways and conditions for the paper sector to reduce its own emissions by 80% and complementing it with an ambition to increase the creation of value in the sector by 50%, CEPI launched an open-innovation process to identify concrete technologies to reduce the carbon impact of the industry. The process was called "the Two Team Project".

In November 2012, 2 teams composed of paper company representatives, experts from suppliers to the paper industry, scientists and researchers, free thinkers started to compete in identifying disruptive technologies to make pulp and paper differently and with much less energy and carbon emissions. Since the project was a competition, a pre-jury, followed by a jury had to choose a winning concept out to the eight that have been submitted by the teams. They assessed the concepts on the basis of 5 objective criteria, primarily on the contribution to the carbon emissions' reduction, but also on the contribution to value creation, the feasibility of the idea, the conditions for success, as well as the overall innovativeness of the idea.

In November 2013, a winning concept was unveiled by Connie Hedegaard, at the time European Commissioner for climate action. Since then, consortia to further develop the concepts and carry out the needed research have been established.

Among the 8 concepts for breakthrough technologies in pulp and paper making identified by the teams, 5 are listed below.

1° Deep Eutectic Solvent for pulp making - the winning concept - is an adaptation of a natural phenomenon known from plant metabolism. Glucose-based DES can dissolve wood and extract in a selective manner cellulose, lignin and hemicellulose, hence allowing their use to produce different products. The dissolving process takes place at low temperature and atmospheric pressure. By using DES, the European industry can secure a low-carbon (-20%) and low-energy (-40%) production of pulp and use the other components in bio-based products or sell them to other industries.

2° Making paper with less water and no longer using the current energy-intensive drying techniques is feasible. The concept builds on the blowing of dry fibre into highly turbulent steam and the sheet formation by flash condensation combined with steam expansion, hence requiring a thousandth of the usual water consumption. The industry can reduce its energy needs by 20% and its CO2 emissions by 50%.

3° The current paper drying technique via heated cylinders leads to evaporating water by using air as a heat carrier. Increasing temperature and humidity towards "pure vapour" allows using this "superheated steam" instead of air as heat carrier. With this, large amounts of heat can be recovered and recycled. Using superheated steam for drying would deliver 25% energy reduction and up to 50% CO2 emissions reduction.

4° The use of a very highly consistent fibre input in the headbox requires the fibre to be placed into a very viscous environment to avoid flocculation, while protecting it from shear. The sheet formation is then achieved by pressing the dry pulp components, which takes away 80% of the viscous component, and is followed by a curing technique to obtain a dry sheet. Energy demand is here reduced by 25% and CO2 emissions by 55%.

5°"Supercritical" is a stage where CO2 is neither a liquid nor a gas reached by combining a certain pressure and a certain temperature. Supercritical CO2 would allow drying paper in an autoclave with much less energy and therefore CO2 emissions. It provides the additional benefit of extracting contaminants in the recycling process. Ideally, the mill CO2 emissions could be the needed resource to run the autoclaves (carbon capture and use). The energy demand is expected to decrease by 25% and the CO2 emission by 45%.

The CEPI Two Team process has shown to be successful in showing that an open-innovation process can deliver realistic and disruptive concepts, provided the enabling conditions have been put in place.

(Con)Fusing Durability Performance of Reinforced Concrete Structures with Environmental Sustainability

O. Alao (1)
(1) University of Cape Town, Department of Civil Engineering, New Engineering Building, Cape Town, South Africa

INTRODUCTION
Concrete is one of the most extensively consumed human-made material. The annual global consumption of concrete in 2013 was estimated at 25 billion tons per year, which implied a 900 % increase in concrete consumption in comparison with that of 1950. The reasons for concrete's significant use may be attributed to its numerous benefits which include its versatility, affordability and its ability to be engineered to suit desired performance. The consumption of concrete continues to increase with increasing world population and rate of urbanization. The world population is estimated to be about 7 billion, which is a 40 % increase from the 1990 population statistic and it is projected to rise to 9 billion by the year 2050. Furthermore, with future projections of urbanization to reach 67 % in 2050 from 36

% in 1950, it is expected that there will be a consequent rise in concrete demand for infrastructure development.

However, the continued use of concrete in massive quantities has significant effects on the sustainability of the environment. Firstly, the production of cement, one of the main constituents of concrete, is responsible for 7 % of anthropogenic carbon dioxide (CO2) emissions. Secondly, the annual aggregate and water consumption for concrete production are estimated to be at about 9 billion and 1 billion tons respectively. The massive use of natural resources by the concrete construction industry is environmentally unsustainable.

Concrete is usually used as a composite material with embedded steel reinforcements because of its limited tensile force resistance. The total amount of concrete produced annually goes towards the construction of reinforced concrete (RC) structures. RC structures are prone to inevitable, time dependent ageing after construction. Hence, during their service-life repair or rehabilitation become imminent. Repair and maintenance of such structures may involve concrete patching, or in the cases of failure, reconstruction resulting in further consumption of raw materials. Statistical data on the quantity of additional raw materials consumed during infrastructure repair may not exist, however, about R 11.8 billion (US$ 1.1 billion) is required annually in South Africa for the repair and maintenance of 8,246 bridges and culverts.

MAKING CONCRETE SUSTAINABLE & DURABLE

- Zero percent cement concrete production

The removal of PC use in concrete production is also currently been advocated for by sustainability researchers. 0 % cement concrete is also referred to as geopolymer concrete and contains no PC in its production as the name implies. The concept 'geopolymer' has been in use since the 1950s but it was used to refer to alkali-activated clay-based binders in the 1970s. Geopolymers are used as an alternative to PC because of low CO2 component compared with PC production.

- Use of supplementary cementitious materials

The use of SCMs to partially replace plain PC is common because of the associated benefits with their use, which generally relates to improved economic, durability performance and sustainability properties. Binders that have chloride binding content such as fly ash (FA), ground granulated blast-furnace slag (GGBS) and condensed silica fume reduce the permeability of concrete.

CONCLUSION

The design of durable concrete for a sustainable environment must encompass the use of recycled and by-product materials, low energy requirement for cement production, low CO2 emissions from concrete production and ensure low incurred costs from maintenance. This is possible through the removal or substitution of PC in concrete production and by understanding and adequately designing for the RC structures the service environment.

O-3314-03

Dealing with the Aviation Challenge

P. Mcmanners (1)
(1) University of Reading, Geography, Reading, United Kingdom

Aviation is a growing source of carbon dioxide emissions and an enabler of the global economy leading to a polarised debate about the economic benefits versus the environmental impact. This makes the sector a barometer of the world's willingness to change economic models to deliver climate change mitigation. Currently aviation is outside the UNFCCC framework, with work on developing a way forward delegated to the International Civil Aviation Organization (ICAO). Aspirational targets have been proposed by the ICAO to limit net emissions based on a combination of shifting to bio fuel and market-based measures. However there are no plans to limit gross emissions which are expected to more than double by 2050. The research reported in this presentation has identified a way forward which requires moving away from fast-jet technology, except for an expensive First and Business Class service. Affordable flying will be on a new design of efficient and relatively slow air vehicle. Interviews with stakeholders found that passengers were generally content with the proposed changes and environmentalists were enthusiastic to shift from opposing flying to supporting the low-carbon model. Industry outside aviation was also willing to embrace the new model and focus on thinking through how they would adjust operations to suite. However, resistance was encountered from the two prime players, the aviation industry and government. The aviation industry was concerned at the impact on their business; concurring with the research which indicated that parts of the industry are likely to be bankrupted. Governmental actors did not foresee aviation coming high enough up policy priorities for them to expend political capital on taking action. In conclusion, there is a bright future for low-carbon aviation but the demand for change will have to come from society to bring the future of aviation onto the political radar so that politicians agree the policy changes required to force a reluctant industry to respond.

3315 - Energy Innovation for Climate Change: systems approaches and societal responses

ORAL PRESENTATIONS

K-3315-01

The need for energy innovation: chair's introduction

J. Skea (1) ; M. Hannon (1)
(1) Imperial College London, Centre for Environmental Policy, London, United Kingdom

Current energy technologies available to the market at scale are not capable of reducing CO2 emissions to levels compatible with achieving the UNFCCC goal of limiting global warming to 2°C. The last decade has seen a significant scaling up of both public and private sector energy RD&D efforts, but these have yet to reach the levels required to achieve climate policy goals. Indeed, much of the private sector effort will have the effect of extending the potential fossil fuel resource base leading to potential policy dilemmas.

Against this background, the objectives of the chair's introduction are to: identify the needs for investment in energy RD&D; identify patterns of investemtn in R&D in both the public and private sectors; identify investment priorities and methods for establishing them; and consider what institutional frameworks and policy instruments will be most conducive to innovation that will help the achievement of a low-carbon transition. Energy innovation systems now transcend national boundaries due to international co-operation, the mobility of human capital and the activities of multinational companies. These factors will be sketched to help frame the session Energy Innovation for Climate Change: systems approaches and societal responses.

K-3315-02

A Systemic Approach to Assess Energy Technology Innovation

A. Grubler (1)
(1) IIASA, Transitions to New Technologies, Laxenburg, Austria

A systemic framework to assess energy technology innovation efforts, the Energy Technology Innovation Systems (ETIS), is outlined. ETIS describes innovation activities within both a systems perspective of all phases of a technology's life cycle (R&D to maturity/

obsolescence) as well as all components of energy systems from supply to end-use. Within these two system boundaries innovation activities are assessed across four dimensions that represent critical inputs as well as outputs of innovation activities: knowledge generation, resource mobilization, and actor/institutional network build-up as innovation inputs, as well as improvements in technology characteristics (feasibility, performance, costs) as innovation outputs.

The ETIS framework is used to assess current global innovation efforts for climate mitigation concluding that current innovation portfolios are highly biased, resource allocation and policy focus are misaligned, as well as actor and institutional mobilization insufficiently globalized to provide for an effective innovation system that can generate and diffuse required innovations in improved resource efficiency and low-carbon technologies. Selected quantitative examples underpin the assessment presented that emerged out of work conducted within the framework of the Global Energy Assessment (GEA).

K-3315-03

Stakeholder engagement in innovation and deployment

C. Mclachlan (1) ; S. Mander (1)

(1) University of Manchester, Tyndall Centre for Climate Change Research, Manchester, United Kingdom

Low carbon energy systems will require significant infrastructural transformation, involving both novel technologies and new configurations of existing technologies. However, stakeholder 'opposition' is a frequently cited barrier to such change. Framing our research with a brief rejection of the usefulness and veracity of the dominant concept of Not In My Back Yard (NIMBY) in understanding different stakeholder positions, we draw on numerous research projects on low carbon energy siting controversy that have been undertaken at in the Tyndall Centre Manchester, UK. This body of research, undertaken over a decade, examines the local enactment of national policies, demonstrating that it is in this local deployment of technologies that the particular constellations of normative goals and power relationships come in to sharp focus. Such deployment can act as catalyst for local stakeholders to engage with, and challenge, the desirability of the dominant energy system or novel technologies for the first time. This presentation will emphasise the socio-technical nature of energy infrastructure and services, and will explore societal responses to, and engagement with, such significant changes. Issues identified and discussed by stakeholders have included: what social goals are driving policy and are these appropriate? Who are the winners and losers and what power do they have? Whose interests are protected within official impact assessments and whose are not? What kind of society does a particular energy system support or challenge?

We use case study material to explore a range of themes at the deployment stage of energy technologies and set the scene for other panel contributions which focus more on the role (and potential role) of stakeholders in determining the overarching shape of the energy system. We draw together insights from a range of disciplines addressing common themes in low carbon energy controversies such as: different interpretations of impacts and benefits; governance, consultation and engagement activities; the role of governments and businesses. In particular we draw on recent and current projects on smart grids and future energy system resilience. Exploring, for example, the impact on deployment of tensions between the visions of 'ideal' consumers used by designers and engineers to shape technology and the more messy reality of everyday energy consumption. A case study of siting a CO2 pipeline is used to examine how to engage local stakeholders, and in particular how to reconcile expressed desire for communication and engagement with a lack participation in the activities offered. Here, we find that different types and levels of engagement will be suitable for different individuals, information materials need to be tailored to different audiences and opportunities to engage should be provided through a variety of channels and methods.

We argue that there is a need to more closely examine the social assumptions within both positive and negative accounts of low carbon energy technologies and systems, as this allows for the source of controversy to be more fully understood and a wider range of ways of developing support for particular transitions to be developed. Finally, to close the presentation and frame the following panel discussion, we will reflect on the implications of our findings for those trying to deliver transitions in the energy system, particularly in the context of calls for these transitions to be achieved more rapidly.

O-3315-01

Fuel du Jour: Cutting through alternative fuel hype to decarbonize transportation

N. Melton (1) ; J. Axsen (2) ; D. Sperling (3)

(1) Navius Research Inc., Vancouver, Canada; (2) Simon Fraser University, Resource and environmental management, Vancouver, Canada; (3) University of California, Davis, Institute of transportation studies, Davis, United States of America

Achieving global climate mitigation objectives requires a substantial shift to alternative fuels such as electricity, hydrogen or biofuels for road transport. Over the past three decades, government, industry and others have repeatedly been swept up with the «fuel du jour» phenomon, believing that a particular alternative fuel vehicle (AFV) technology will succeed in replacing conventional gasoline powered vehicles. However, despite numerous periods of hype AFVs are not yet being adopted at rates sufficient to achieve deep decarbonization. The dynamics of hype and disappointment are exemplified by the ambitious statements of US presidents. For example, in 1989 President George H.W. Bush announced an Executive Order requiring 500,000 methanol vehicles to be produced by 1996. Over a decade later, President George W. Bush declared a goal of making cellulosic ethanol «practical and competitive within six years.» And in 2011, President Barak Obama made a goal of having one million electric vehicles on the road by 2015. Despite each period of hype being associated with an upswing of attention, expectations and innovation, none of these goals have been met.

Our study builds on existing science, technology and innovation research to improve awareness about the extent of hype and disappointment cycles for AFV technologies. This research has implications for all sectors where emerging technologies are important for mitigating climate change. The specific objectives of our research are to: 1) identify periods of AFV hype and disappointment by examining trends in societal attention and innovation, 2) explore the ways in which governments participate in and/or contribute to hype by examining funding, policy and political announcements, and 3) identify options for minimizing the negative effects of hype on the decarbonization of road transport. To accomplish these objectives, we analyze mass media, prototype and funding data between 1980 and 2013 for all major AFV technologies.

Hype begins with a technology breakthrough (e.g. the discovery of a new fuel cell manufacturing process) or a policy trigger (e.g. an increase in funding for fuel cell research) that attracts interest in that technology. Innovation actors such as scientists, industry and governments then communicate technological promises in order to attract attention and resources. Hype can play an important role in supporting successful innovation activities, but excessive hype increases the chance of failure. Unfulfilled promises and expectations undermine the reputation of new technologies and their developers, hamper resource mobilization and may lead to the abandonment of innovation activities.

Our research identifies and describes numerous cycles of AFV hype and disappointment, starting with methanol and natural gas in the late 1980s, moving through plug-in electric vehicles in the mid 1990s, and then turning to hybrid-electric, hydrogen and biofuels in the early 2000s. Presently, expectations about plug-in electric vehicles are particularly high (although not for the first time). We show how automotive firms, policy makers and politicians have touted the benefits of each of these AFV technologies at different times, only to lose interest and turn attention to the next technology when initial expectations fail to be met.

While some degree of hype is desirable for stimulating interest and investment in new technologies, the extreme and typically unrealistic promises related to AFVs are contrary to an efficient transition to low-carbon transportation. For policymakers seeking to induce such a transition, it therefore seems prudent to take steps to mitigate the negative impacts of hype and implement

effective policy that is relatively immune to disappointment cycles. To accelerate the adoption of low carbon technologies, we suggest that policymakers: 1) set realistic goals for AFV market penetration, 2) implement strong and consistent policies to achieve desired penetration (i.e., technology agnostic policy focused on environmental damages), and 3) establish institutional capacity to inform expectations via technology assessment. These recommendations are likely applicable to other sectors where emerging low carbon technologies is important for achieving climate mitigation objectives.

O-3315-02

What role for climate negotiations on technology transfer?

M. Glachant (1) ; A. Dechezleprêtre (2)
(1) MINES ParisTech, Paris, France; (2) Grantham Research Institute – London School of Economics , London, United Kingdom

Technology has been an important topic of international climate change negotiations since the adoption of the United Framework Convention on Climate Change in 1992, in which the parties committed themselves to "promote and cooperate in the development, application and diffusion, including transfer, of technologies". North-to-South technology transfer has been given a particularly high importance since technologies have so far been mostly developed in industrialized countries, but are urgently required to mitigate greenhouse gas (GHG) emissions in emerging economies where the bulk of future emission increases are expected.

Little progress has been made, however, in the climate negotiations on these issues. The only significant result to date is the establishment of a Technology Mechanism in 2010 in Cancun. It consists in two coordination bodies – the Technology Executive Committee (TEC) and the Climate Technology Center and Network (CTC&N) – the role of which is to elaborate and implement practical solutions to boost technology transfer and technology diffusion towards developing countries.

In this paper, we argue that this apparent lack of success has had little negative consequences on international technology diffusion until now. We even offer the perhaps controversial view that climate negotiations should continue to neglect technology issues.

We provide evidence that, despite the absence of progress on these issues, North – South technology transfer of climate change mitigation technologies has dramatically increased in the last twenty years. This has mostly concerned emerging economies which are now reasonably well connected to international technology flows. This is good news as these are the countries where most of emission increases are expected to occur in the near future. In contrast, least developed countries appear to have remained excluded from international technology flows. This evidence is based on an up-to-date analysis of the climate-related technology transfer landscape, based on a combination of patent data, bilateral trade data and foreign investment data. To the authors' knowledge, this is the first time that such a comprehensive database on climate-related technology transfer has been assembled. Existing studies essentially rely on patent data (e.g., Dechezleprêtre et al. 2011). This evolution has mainly been driven by the growing integration of emerging economies to the global economy, as technological knowledge mostly crosses borders though the international trade of capital goods and Foreign Direct Investments. Similarly, the fact that least-developed countries remain outside is explained by their little participation in the recent economic globalization.

What, then, should be the priority for international coordination on technology diffusion in the future? In the case of emerging economies, there is no reason to think that they will not continue to effectively absorb foreign technologies. In this group, certain laggards – South Asia and India in particular – will benefit from a growing participation in economic globalization. This suggests a limited role for the Technology Mechanism which should essentially provide local private and public actors with information to facilitate coordination (e.g. through technology needs assessment). In parallel, there is no reason to transfer the international regulation of market mechanisms – in particular, trade rules and Intellectual Property – from the World Trade Organization to the UNFCCC.

The situation of least-developed countries is paradoxical. On the one hand, it is more critical as they do not import green technologies; on the other hand, there is less urgency to deal with the problem as their contribution to global emissions will remain limited in the near future. In these countries, the priority is then to build technological capacities and to promote their integration into the global economy. In fact, the problem to be solved is very general: the economic under-development of certain countries and regions, in particular in Africa. We believe that the UNFCCC might not be the adequate forum to deal with what, essentially, appears as a development issue rather than a climate change-related problem.

Engaging stakeholders towards low carbon energy technology deployment

P. Ashworth (1)
(1) University of Queensland,, School of Social Sciences, Brisbane, Australia

No. 3315 Innovation, Technology Deployment and Policies FOR TYNDALL CENTRE SESSION

Like many technologies, deployment of low carbon energy technologies is a contested topic that often divides communities that previously may have coexisted harmoniously. As a result, community engagement and citizen participation have become important, if not essential components of the climate change – low carbon energy landscape. With the overriding aim of community engagement being to involve community members in decisions or policy making that is likely to affect them now or in the future (Keeney 1998), there has been a move away from the traditional one-way, top down approach to one that is far more inclusive. At the same time there has been an increase in the research literature – theoretical frameworks and models – that relate to this topic as governments and industry internationally are being held to account for their actions by their constituents and impacted communities. For example, much has been written about participatory technology assessment (pTA). Huijts, Molin and Steg (2012) proposed a framework for technology assessment with a focus on carbon capture and storage (CCS). The framework emerged from both the pTA literature and psychological theories. They have subsequently tested and refined the framework using hydrogen refuelling as their example. Key elements of their framework that influence decisions to support a technology include attitudes social norms, perceived behavioural control and personal norm. Other components include procedural and distributive fairness, perceived risks and benefits and trust. Similarly, Hall, Ashworth and Devine-Wright (2013) examined key themes that arose from an examination of seven case studies of wind farm deployment. From the qualitative interviews four common themes emerged which included trust, distributional and procedural justice and place attachment. The researchers argued that with out addressing these factors into policy development and engagement approaches wind energy is likely to be deployed for meeting new renewable energy targets. There are similar results reported for the range of low carbon energy technologies such as nuclear, geothermal, CCS and so on. Despite the similarities and overlaps across the frameworks, models and case studies successful deployment of low carbon energy technologies is still challenging and in some cases out of reach. This panel discussion will examine how the requirements for ensuring procedural and distributive justice, trust and place attachment can be met. It will also discuss responses to questions such as? Who should be included in engagement activities? What process will be used to engage? How do you ensure the process is fair? What are the components of trust? How do you evaluate success?

O-3315-04

The role of public-private partnerships in in energy innovation and technology development

I. Azevedo (1) ; I. Azevedo (2)
(1) Carnegie Mellon University, Engineering and Public Policy, Pittsburgh, PA, United States of America; (2) Carnegie-Mellon University, Department of engineering and public policy, Pittsburgh, United States of America

In order to transition to a low carbon, sustainable, energy system globally and avoid potentially dramatic effects from climate change, the work needs to reduce greenhouse gas emissions by roughly an order of magnitude.

Existing technologies and strategies, such as using energy more efficiently, scaling up of renewables, the use of nuclear and a short-term transition to natural (ensuring low leakage rates), and deployment of carbon capture and sequestration will be necessary to help with such transition.

However, there is a continuous need for innovation to help achieve these goals at lower costs. This brings us to a conundrum: the returns on public and private R&D investments and other policies (such as a carbon price or tax, production tax credits, feed-in tariffs, among others) that may lead to energy innovations and help curb the costs of climate mitigation strategies are multifaceted uncertain problems. Namely, uncertainty arises regarding 1) what will be the outcomes in terms of technology breakthroughs or improvements associated with R&D investments or other policy mechanisms that are implemented to promote innovation? 2) when will these technology breakthroughs or improvements occur and how to deal with the uncertainty regarding the timeline of such improvements? 3) if these breakthroughs or improvements occur, how fast or slow will the diffusion process be across different regions?

To address this issues requires both retrospective assessments of what outcomes have different policies and R&D investments delivered so far, as well as a forward looking perspective to enable us to make decisions for climate and energy decision under deep uncertainty.

In this talk, I will start with a retrospective analysis with the evidence from the literature regarding the outcomes of R&D investments and other policies on technology innovation and deployment in several regions of the work. In particular, I will provide examples regarding the Advanced Research Projects Agency-Energy (ARPA-E) program, the production tax credits and the renewable portfolio standard in the United States, and regarding the feed-in tariffs (and other similar policies) in many of the European Union countries, and finally assessing also the outcomes of incentives provided to wind and solar innovators in China.

While understanding the outcomes of previous policies on innovation is already a challenging task, a forward looking assessment is an even more daunting and humbling exercise: forecasts of how the energy system is likely to be shaped in the future has been proven to be quite poor, and any decision framework will be plagued by deep uncertainty. I will outline a methods that provides insight on the quality of forecasts for energy quantities and prices, and suggest a framework on how this information could be used to help identify the needs for investment in energy RD&D and to avoid "dead ends"; identify investment priorities and methods for establishing them; and consider what institutional frameworks and policy instruments will be most conducive to innovation that will help the achievement of a low-carbon transition.

Modelling Malaysia's Potential for Deployment of Biomass for Bioenergy in the Power Sector

DR. Abu Bakar (1) ; G. Anandarajah, (1) ; P. Ekins (1)
(1) Energy Institute, University College London, London, United Kingdom

Biomass is a primary source of renewable energy and accounted for about 10% of the total global primary energy supply in 2008. The Special Report of the IPCC on Renewable Energy Sources and Climate Change Mitigation (SRREN) suggested that the potential bioenergy deployment levels of biomass for bioenergy by 2050 could be in the range of 100-300 EJ; a substantial potential that could contribute to the global total primary energy supply. In the context of developing countries, this work is aimed to assess the future role of bioenergy in the power sector in Malaysia, focusing on power generation capacity and its utilisation under the scope of energy system framework analysis using TIMES (The Integrated MARKAL EFOM System) Model. The model is used to simulate scenarios based on bioenergy implementation under a number of national policies and action plans against a reference base case scenario. The biomass-based electricity promotion policies are contained in its National Renewable Energy Policy and Action Plan (2012-2050) and the National Key Economic Area (NKEA) for Palm Oil Sector under the Economic Transformation Programme. Simulations conducted include increasing biomass-based electricity production from palm oil mills under the NKEA Programme and other agricultural residue use in electricity generation. The results indicate that implementation of the NKEA programme is the most critical factor to achieve the bioenergy and environmental targets; both in terms of electricity generation capacity and in CO2 avoidance.

Grey water treatment by slanted soil system under real conditions in rural area

H. Amadou (1)
(1) International Institute for Water and Environmental Engineering, Research Direction, Ouagadougou, Burkina Faso

The Performance of the slanted soil for grey water was evaluated in light of required water quality of irrigation reuse. This study aimed to assess the treatment performance of grey water system by slanted soil and check the possibility of reuse this water treated in irrigation. The greywater was collected every week in two pilot families in "Kologondiéssé" village. The levy was made at the input and output of grey water in the treatment system and the storage tank points. Samples were submitted to physicochemical and microbiological analysis. Following changes to the treatment system, it is expected a strong improvement of purifying performance of this system. The results of this survey showed a very good purification performance of organic matters up to 89.78% for suspended solids (SS), 86.75% for chemical oxygen demand (COD) and 87% for biochemical oxygen demand (BOD). Regarding the reduction of bacterial pollution, the obtained results are greater to those of previous studies with 2.48 µlog, 3.33 µlog and 1.99 µlog respectively for E. coli, coliforms and enterococci. These results are slightly higher than the standards of reuse in irrigation.

P-3315-03

Community Investment in Wind Farms: Funding Structure Effects in Wind Energy Infrastructure Development

J. Beery (1) ; J. Day, (2)
(1) The University of Melbourne, Faculty of Architecture, Building and Planning, Parkville, Victoria, 3010, Australia; (2) The University of Melbourne, Faculty of architecture, building and planning, Parkville, Victoria 3010, Australia

Wind energy development is an increasingly popular form of renewable energy infrastructure in rural areas.

Communities generally perceive socioeconomic benefits accrue and that community funding structures are preferable to corporate structures, yet lack supporting quantitative data to inform energy policy. This study uses the Everpower wind development, to be located in Midwestern Ohio, as a hypothetical modeling environment to identify and examine socioeconomic impact trends arising from corporate, community and diversified funding structures. Analysis of five National Renewable Energy Laboratory Jobs and Economic Development Impact models incorporating local economic data and review of relevant literature were conducted. The findings suggest that community and diversified funding structures exhibit 40 to 100 percent higher socioeconomic impact levels than corporate structures. Prioritization of funding sources and retention of federal tax incentives were identified as key elements. The incorporation of local shares was found to mitigate the negative effects of foreign private equity, local debt financing increased economic output and opportunities for private equity investment were identified. The results provide the groundwork for energy policies focused to maximize socioeconomic impacts, while creating opportunities for inclusive economic participation and improved social acceptance levels fundamental to the deployment of renewable energy technology.

P-3315-04

Dew collection for water supply in Valparaíso, Chile

D. Carvajal (1) ; D. Araya Muñoz (2) ; N. Guajardo Ramírez (1) ; C. Carlesi Jara (1)
(1) Universidad Católica de Valparaíso, Escuela de ingeniería química, Valparaíso, Chile; (2) University of Edinburgh, School of geosciences, Edinburgh, United Kingdom

The availability of fresh water has become a serious problem in arid and semiarid areas of the world. There are large areas in the world, mainly in arid or semi-arid climate, with chronic shortages of fresh water, which has been aggravated consequence of climate change, population growth and, agricultural and industrial activities. As the demand for fresh water is constantly growing, vast areas that historically had no problems with availability of fresh water, have become areas with intermittent water shortages or even permanent. The problem of water shortage has been acute in Chile, particularly in the north and increasingly in the central area, affected by the intensive use of water in agriculture mainly. As a consequence of the problem of water scarcity, various technologies have been developed in order to capture not only fresh water from conventional sources such as rivers or groundwater, but also unconventional sources such as seawater treatment through processes such as distillation, reverse osmosis, nano-filtration and electro-dialysis, and from the atmosphere as is the case of fog precipitation and dew collection based on radiative cooling.

Dew formation by radiative cooling occurs when a solid surface radiates heat into sky causing its temperature becomes lower than the dew point of the water vapor contained in the surrounding air, causing condensation (liquid water). This condition usually occurs during cool nights with high relative humidity, low cloud cover and moderate or low wind speed. Once the condensation process occurs, the liquid water may be collected by natural drainage on an inclined surface (by gravity) and then stored in tanks. The water produced by the system may have uses such as irrigation or human consumption (pre purification treatment if necessary).

This work aims to assess experimentally the dew water collection based on radiative cooling using galvanized steel sheets as radiative surface. Experimental tests were carried out in the city of Valparaíso, which is located in the central coast of Chile. The amount of dew water produced was experimentally quantified, and the quality of dew water produced in the test location was analysed. The testing location included five experimental units (modules), each of which consist of galvanized steel sheets with zinc-aluminum, supported by a steel frame. Each sheet was thermally insulated on its back by Styrofoam. The sheets were coated with a paint containing an additive infra-red emitting minerals (TiO2 and BaSO4) in the atmospheric window, and a non-soluble surfactant that render the surface more hydrophilic (manufactured by OPUR, France). An experimental campaign with a total duration of 30 days was carried out.

The results indicated the following: the collectors produced amounts of dew between 0 and 89 ml/m2 per night and the analysis of dew water showed alkaline pH for all samples which may be due to the proximity of the ocean. Weather station measurements indicated significant changes in several atmospheric parameters on daily as well as hourly basis, including humidity and wind speed which could explain the variability of the amount of dew obtained. The next steps in this project include; chemical and biological analysis to determine whether dew water is potable in the study area, analysis of spatial gradient of temperature in the collectors and a test campaign of one year to determine the seasonal variability of dew yield in the study area

Acknowledgments

Interrogating the transformative power of renewable energy support instruments: the example of feed-in tariffs on photovoltaics

B. Cointe (1)
(1) CIRED, Nogent sur Marne, France

The deployment of renewable energy is considered to be a crucial part of mitigation strategies, and its promotion on the policy agenda has been largely driven by concerns related to climate change. This is particularly true of the European Union, where renewable energy policy and climate policy now go hand in hand. Besides being coupled, these two EU policy have in common their reliance on market mechanisms as means to trigger change in socio-technical systems by triggering innovation and redirecting investments towards mitigation solutions. As far as renewable energy is concerned, feed-in tariffs (FITs) have been one of the main instrument of transformation, and they have indeed proved effective in attracting investment towards renewable energy technologies, especially wind power and photovoltaics.

However, the transformations triggered by such instruments do not exactly conform to expectations: feed-in tariffs have driven the deployment of markets for electricity from renewable energy sources and the increase in renewable energy installed capacity, but they have also had many unintended effects and consequences that had to be addressed "on the go". The difficulties in managing the dynamics triggered by such mechanisms are especially striking in the case of photovoltaics, which have developed at a dramatic pace and led to political reforms and crises of varying intensities in several countries (e.g. France, Germany, Spain, UK...). Feed-in tariffs, it turns out, transform not only markets and technologies, but society and politics as well. This contribution will attempt to conceptualise the transformative power of such instruments and the issues related to its management by suggesting an alternative account of the functioning and effects of feed-in tariffs for photovoltaics.

To this end, it will rely on actor-network theory research on market-making and politicisation and on studies on governmentality. From this theoretical perspective, it will explore FIT-driven photovoltaics development in three sites, each of which sheds light on specific aspects and tensions of feed-in tariffs for photovoltaic electricity understood as political prices: the emergence and sophistication of feed-in tariffs for photovoltaics in the context of European renewable energy policy; the overflowing of the photovoltaic market that they provoked and the political crisis that ensued in France between 2009 and 2012; and the way in which they can be seized as instruments for territorial development and translated into economic and political resources. The contribution will show that feed-in tariffs for photovoltaic electricity can be described as political market agencements meant to trigger the deployment of electricity generation capacities as much as to foster innovation and experimentation around photovoltaic technologies. The articulation of this dual aim is delicate, especially since the modularity of photovoltaic technologies enables them to proliferate and spread rapidly, making their deployment hard to steer. This re-interpretation of feed-in tariffs will thus suggest ways to account for and analyse the difficulties in regulating current emerging renewable energy markets. It

will also contribute to the analysis of the implications and challenges of driving transformations through the creation and engineering of new markets that seems to characterise many climate policies.

P-3315-06

The role of public-private partnerships in energy innovation and technology development

J. Coleman (1)
(1) Energy Technologies Institute, Strategy, Loughborough, United Kingdom

Innovation is key to delivering an affordable and secure low carbon energy system. There is no time to invent and deploy a set of novel breakthrough technologies and the cost of adaptation will inevitably be higher than the cost of mitigation. So, whilst breakthrough technologies will always be welcome we cannot wait on them and neither do we need to. A transition to low carbon can be achieved by developing, commercialising and integrating known but currently underdeveloped solutions.

This means that the emphasis of technology innovation shifts from basic research and development towards scaling up, demonstration, early deployment and systems integration to prove and improve performance, drive down cost and build developer and investor confidence.

This scaling up of known but underdeveloped technologies implies different challenges and risks to earlier stage R&D and requires different skills to deliver it as well as an increase in funding levels. In a world with a functioning carbon market providing clear market signals public sector investment in early stage R&D should leverage investment from the private sector to further develop and deploy the most promising technologies. However, given the long lead times and high capital costs for many energy technologies, even with a functioning market, there is potentially a significant valley of death in which the risk/reward balance remains insufficient to attract the levels of finance needed for demonstration and early scale deployment.

Current market structures and carbon pricing appear unlikely to provide a sufficient market signal to incentive the private sector alone to deliver the level of change needed in the timeframe required. In fact the lack of a carbon price in many ways reinforces the somewhat pessimistic view from many of the larger companies in the energy sector that there is insufficient political will and co-ordination to contain global warming to 2degC, even though it is technically feasible and affordable to do so. Current policies, economic drivers and the rise of renewables, do encourage continued substantial private sector investment in improving the efficiency and performance of incumbent technologies but this alone is insufficient to deliver the scale of transition needed. An alternative is increased government-led support with penalties and incentives tailored to each sector, such as the Contracts for Difference introduced in the UK's Electricity Market Reform, to deliver a 'policy pull' until a carbon market is established. This approach is not without its challenges; not least the need to award Contracts through a transparent and competitive process in a particular sector, whilst also evaluating the value of proposals in terms of their long term contribution to decarbonising the energy system. Given the short term nature of the policy mechanism it also doesn't adequately address the valley of death for some of the large scale technology and infrastructure developments that are potentially key to an affordable transition. Moreover, private sector organisations tend to be focussed on a particular sector (or component of a sector) of the energy landscape whilst the public sector needs to integrate and assess priorities across and between sectors.

A successful transition requires the free markets efficient allocation of resources, innovation and deep technical skills to be combined with the governments ability to prioritise between sectors, its access to low cost of capital, democratic legitimacy and protection of consumers role. Without a functioning carbon market (and probably even with it) the public sector plays an essential role in providing long term funding and taking much of the risk in demonstration and early deployment of key technologies. However to be successful this must leverage financing and draw on the skills of the private sector. The UK's experience suggests that working in partnerships is a way to combine these elements that the public and private sectors need to bring to a successful transition.

LIFE programme and Climate Change

P. Fetsis (1)
(1) Neemo EEIG / AEIDL, LIFE communications team, Brussels, France

The LIFE programme was established in 1992 and is the EU's funding instrument for the environment. The general objective of LIFE is to contribute to the implementation, updating and development of EU environmental policy and legislation by co-financing pilot or demonstration projects with added value.

With 4171 initiatives supported to date, LIFE has improved the environmental performance of a wide range of sectors and fields across Europe. Pressure on water resources is being exacerbated by climate change. LIFE projects have focused on tackling water scarcity and natural water hazards, both in urban and rural contexts. Optimisation of water use through innovative water management infrastructure, water resource planning and allocation modelling, techniques for groundwater storage improvement, cost analysis and water pricing services are amongst the practices developed and tested when addressing the impact of climate change on floods, as well as on supply and availability of water.

Below you can find some examples of LIFE projects on specific themes:

Europe, flood risk management

Floodscan: The project aimed to limit flood risk by testing an innovative and cost-efficient method of mapping flood hazard areas. A web mapping service was developed to provide reliable and accurate information about flood risk not only for the general public and businesses but also for local and regional authorities, enabling them to take more effective planning decisions (e.g. to ban building in certain areas).

HydroClimateStrategyRiga: The project aimed to create a flood risk management plan for the city of Riga in order to create the means necessary to ensure that hydrological processes intensified by climate change phenomena are adequately investigated and incorporated into the city's planning system. Methodological guidelines were developed, based on existing and future flooding trends in Riga and reinforced by best practices in the identification, planning and management of flood risk zones as adopted in Rotterdam, Antwerp and Hamburg.

Mediterranean Basin / Innovation, Technology deployment & policies

Water Agenda: The main objective was to apply the Water Framework Directive principles and guidelines in order to reverse water degradation trends at a local level in the Anthemountas river basin, in Greece. A sustainable water resource management policy was developed and agreed amongst locals, demonstrating adequate social, technical, administrative and economic techniques and tools (e.g. allocation of water, real-time cost/benefit data, water pricing), mainly focusing on how to address water quantity/quality problems according to the region's development trends, natural and social characteristics.

WIZ: Developed and demonstrated an innovative online platform that includes two informative services (WIZ4All & WIZ4Planners), able to incorporate the protection and sustainable management of water in urban planning processes and local policy areas. An analysis of long-term management of drinking water integrated into land use planning was conducted, enabling water authorities to prepare investment plans and harmonize data characterising the water demands of an area. Information on water resources availability based on the effects of

climate change or active reporting on the quality of drinking water are amongst the activities making an optimum 'participatory management approach' possible.

Lost at sea? Charting wave energy's difficult journey towards commercialisation since a resurgence in UK government support

M. Hannon (1)
(1) Imperial College, Centre for Environmental Policy, London, United Kingdom

Large-scale support for wave energy innovation in the UK can be traced back to the early 1970s, a movement triggered by a sharp rise in fossil fuels following the oil crisis (Mukora et al. 2008). During this time wave energy became the principal focus for public research, development and deployment (RD&D) funding for renewable energies. However, as oil prices fell and the UK became a net exporter of oil during the 1980s and 90s funding began to decline rapidly. This shift is embodied by the termination of the UK's Wave Energy Programme in 1982, which was discontinued on the basis that official government cost estimates projected that wave energy would be more expensive in the long run compared to other promising (e.g. wind, nuclear) and established (e.g. coal) sources of energy (Ross 1996).

It wasn't until the late 1990s and early 2000s that ocean energy enjoyed a renaissance on the basis that UK government believed it could play a central role in meeting its carbon emissions reduction targets, whilst at the same time stimulating economic growth (LCICG 2012; Jeffrey et al. 2013; RCEP 2014). Subsequently, $120 million of UK public funds have been committed to ocean energy RD&D since 2000. However, despite this resurgence in support there are still no commercial wave energy devices operating in UK waters today, with no major roll-out of devices expected until at least the 2020s (LCICG 2012).

In this context the presentation explores why wave energy technology has failed to reach commercialisation in the UK despite a rich history of wave energy RD&D and a recent resurgence in public RD&D support since the turn of the millennium. It takes a detailed look at what have been the subsequent successes and failures during this period and which factors have been responsible. To answer these questions the presentation draws upon a combination of qualitative (i.e. interviews, documentary analysis) and quantitative (i.e. IEA RD&D repository) analysis to provide underpinning evidence. To conclude, some recommendations are presented to inform the design of the UK government's energy and innovation policy, with a view to accelerate the development and deployment of low-carbon technologies and help it meet its carbon emissions targets.

Device of dew and rain collectors in Guéné, Northern Benin

G. Koto N'gobi (1)
(1) Abomey-Calavi University, Physic departement, Cotonou, Benin

Dew phenomenon is a process where water vapor condenses on various types of surfaces, such as grass, crops, roofs or vehicles, which are daily experience. Dew occurs at night or early in the morning, when nocturnal radiative cooling leads to surface temperature decrease, and humid air nearby the surface condenses as its temperature falls down below the dew point temperature of the surrounding atmosphere. Dew is important in several domains and has been the focal point of various scientific researches during many years. Its ecological and social importance has been shown in arid and semiarid areas or Islands. A condenser is a surface on which dew can condense on. Three main geometrical shapes of condensers are generally presented: flat condensers, conical condensers and truncated condensers. Guéné is a semiarid village in northern Bénin with hard scarce drought conditions. The objective of this work is to present the different phases of making a truncated dew condenser, using local materials in order to pull better profit from dew water as an alternative source of water to adapt to climate severe conditions in Guéné. A device of rain water collector combined with the truncated condenser increase the amount of water that can be mobilized. During 62 days of measurements, 44 dew events and 5 rain events were observed. The results show that: (i) the truncated condenser can collect about 166 Liters, which represent about 2.7L per night, or 3.77L per dew night (ii) until 10 m3 of rain water can be stocked during the rainy season, (iii) dew amount represents about 36% of the total rain amount during dew measurement period. The collected dew and rain water represent the only source of water used in Guéné primary School for daily academic activities.

P-3315-10

The role of innovation and deployment policy mixes for innovation in renewable power generation technologies: a survey analysis of German technology providers

K. Rogge (1) ; J. Schleich, (2)
(1) Fraunhofer ISI / University of Sussex, Energy policy and energy markets / spru- science policy research unit, Karlsruhe, Germany; (2) Fraunhofer ISI / Grenoble Ecole de Management, Energy policy and energy markets, Karlsruhe, Germany

The decarbonization of energy systems constitutes one of this century's key challenges for human society in the fight against climate change (van Vuuren et al 2013). In such a transition so-called policy mixes play a crucial role in redirecting and accelerating technological change towards low-carbon solutions (Rogge and Reichardt 2013). Yet precisely how policy mixes affect technological innovation remains poorly understood. Rather, studies so far have focused on the impact of single policy instruments on environmental innovations, and also on their stringency as one of their design features (Kemp and Pontoglio 2011). However, in reality complex policy mixes are at play, implying that studies should focus on the interaction of policy instruments (Flanagan et al. 2011) and on overarching characteristics of such policy mixes, such as their consistency (Rogge and Reichardt 2013).

We address this gap in the literature by studying the case of the German Energiewende. More precisely, we analyze the role of the policy mix for firm-level innovation activities in renewable power generation technologies within the German power sector. Since this sector is supplier-driven (Pavitt 1984) we focus on German technology providers, and extend existing qualitative work in the sector (Rogge et al. 2011, Hoppmann et al. 2013) by conducting a survey of companies' innovation activities. The questionnaire for this survey was designed in line with the Community Innovation Survey, but was adjusted to the context of renewable power generation technologies and extended by a questions on companies' perceptions of the policy mix. The survey was conducted by telephone from April 9 until June 22, 2014, with interviews lasting around 30 minutes. In this time period we contacted all German renewable power generation manufacturers and suppliers and achieved a response rate of approximately 36% (n=390).

In our econometric approach we employed a bivariate Tobit model to estimate R&D expenditure equations for the years 2014 and 2015, where the error terms captured possible

correlations between R&D expenditures in different years. In this case, the use of univariate Tobit probit models can lead to biased and inconsistent parameter estimations (e.g. Greene, 2012). The simulated maximum likelihood estimations were carried out with STATA 13, relying on Barslund (2009).

Findings of our econometric analysis suggest that R&D expenditures in both years are larger for companies with higher current and expected future turnovers (including export) in the respective renewable power generation technology, which is in line with other studies on the key relevance of domestic and foreign demand pull instruments (Peters et al. 2013). Likewise, higher R&D expenditures are positively related to the amount of subsidies received for R&D from German or EU public funding bodies, thereby confirming the importance of technology push instruments for innovation. Further, future R&D spendings are larger if respondents perceive the current instrument mix to be consistent in its support of renewable energy, and if they perceive a high credibility of the overarching policy mix, as measured by the uniform cross-party support for the expansion of renewables within the German Energiewende. This confirms and extends qualitative findings for offshore wind in Germany pointing to the importance of policy mix consistency and credibility for R&D and adoption activities of emerging renewable power generation technologies (Reichardt and Rogge 2014). Finally, the time a company has been on the market for the respective renewable power technology considered is positively related to the magnitude of innovation expenditures, i.e. more experienced firms invest more in innovation.

Based on our findings we derive recommendations for policy makers on how to tailor policy mixes to support innovation in low-carbon technologies. These policy implications are not only relevant in the context of the German Energiewende but for any country aiming to promote innovation activities of domestic manufacturers in renewable power generation technologies. Such support enables the build-up and strengthening of low-carbon industries and the global deployment of innovative low-carbon technologies, thereby contributing to mitigating global climate change.

P-3315-11

The role of micro-grid on decoupling sharp fluctuations of electricity demand

P. Roque (1) ; S. Chowdhury, (2)

(1) Eduardo Mondlane University, Mechanical Engineering, Maputo, Mozambique; (2) Tshwane University of Technology, Electrical engineering, Pretoria, South Africa

Among the many human activities that produce greenhouse gases, the use of energy represents by far the largest source of emissions (IEA, 2014). This paper presents the relationships that sharp electricity demand fluctuations have with CO2 emission and describe how the shape of fluctuations interact with power dispatch, contributing to increase greenhouse gases that influence climate change. The impact on peak loading is particularly important, since occasions of extreme temperatures are likely to stress electricity systems in meeting demand (Parkpoom & Harrison, 2008). The Model for Energy Supply Strategy Alternatives and their General Environmental Impacts (MESSAGE) is used to simulate different daily load profile and thus power output can be evaluated for both centralized generation and distributed generation.

Peak demand fluctuations may occur on daily, weekly, monthly, seasonal and yearly cycles. Different power system or different categories of consumers (Residential, Industrial and Commercial) can have similar or distinct daily demand curves. Daily load profile shape has a significant influence on power dispatch and thus, during the peak hours most of power plants need to run on their maximum output. Since peak power plants are in most case fossil fuel power plants due to their operation costs, it can be assumed that the need of covering peak demand contribute to aggravate CO2 emission. The shape of the daily load curve is associated with plant capacity factor. High plant capacity factor leads to increase of power production.

Plant capacity factor = (Average annual Output/Plant capacity*8760)

In order to avoid peak demand, different measures can be implemented (energy efficiency, micro-grid system, renewable technologies etc.). According to IEA (2007), micro grid systems show strong potential to optimize asset utilization by shifting peak load to off-peak times, thereby decoupling electricity growth from peak load growth. Apart from this advantage, micro grid systems improve power quality and reliability due to decentralization of supply and better match of supply and demand. Economic operation of micro grid systems should be ensured through generation scheduling, economic load dispatch and optimal power flow operations (Chowdhury & Crossley, 2009). MESSAGE is a powerful tool for assessment of economic load dispatch and optimal power flow operations. For example, considering that renewable technologies such as solar PV and wind power plants are no dispatchable, connecting them off-grid can make those technologies competitive with other dispatchable technologies such as gas and coal power plants.

Resource-Policy-Innovation Nexus for Entrepreneurial Roles across Scales and Sectors of Low Carbon Pathway in Climate Governance

A. Tiwari (1)

(1) National Institute Of Technology, NITB, India

In the next 25 years, the world needs to invest 40 trillion dollars in infrastructure modernization. It is important to ensure that these financial resources are invested in low-carbon technology instead of conventional carbon-dependent systems. For developed economies where investments will mainly involve replacing out-of-date technology, the transition to a climate-friendly society will involve replacing existing fossil intensive systems. For developing economies, the transition to a larger extent concerns changing the course for implementing new entire systems. This brings opportunities and challenges for sustainability entrepreneurs. Nations not yet subject to fossil technology and institutional lock-in could potentially skip certain development stages (such as the fossil era), thus "leap-frogging" into the new low-carbon economy. Indeed, fast-growing economies will have to leapfrog past much fossil technology, or we will not be able to meet the climate challenge.

The study outlines the essential role of entrepreneurs to operate within resources unaccounted for effects, within which they find opportunities to create value. These efforts are easier when property rights and legal rules are clearer. Challenges to environmental entrepreneurs include environmental problems that cross international boundaries--the transaction costs and financial resource institution of dealing in different legal structures and

property rights systems are huge. As this space for environmental entrepreneurship based on property rights and win-win outcomes shrinks, the space for political entrepreneurship expands. One form of political entrepreneurship is alertness to previously unnoticed rent-seeking opportunities. Cross-boundary environmental issues are characterized by more than usual actions by political entrepreneurs. An example is the potential for climate change caused by humans producing greenhouse gasses, effects of which are globalized. This calls for consideration of effects on global emissions including from import and export.

The research utilizes the policy umbrella under which shifting from product focus to service focus will be central in establishing demand-side incentives for innovation through public procurement policies, which can play an important role as an early test market for climate technology while pushing down costs for new technology and provide low-carbon innovations in different types of businesses. Using the theoretical lenses of multi-level governance, socio-technical transitions, and corporate sustainability and sustainability entrepreneurship the paper highlights the achievement of low-carbon future through economic policy by particularly examining the climate policy within the major themes of globalization as climate objectives have more weight in economic policy than environmental policy. The climate goals manifested in economic policy for decarbonizing economies have potential clear short-term benefits, with short-term costs, and coincide with people's economic goals for greater acceptance and appreciation and in turn fostering involvement.

The study meets the challenges of institutional path dependency as existing institutions and interested parties are typically tied to existing technologies and systems, which hinder transition to the low-carbon economy by the fact that carbon emitting technology does not carry its full climate cost, or that innovations typically require higher upfront investment than fossil intensive systems—while subsequent costs for operations are lower, and due to which short-sighted financial analyses favour fossil intensive systems. In this context, the research allows for collective entrepreneurial effectiveness to be higher than the sum of individual roles in administering linear resource flows with input, process, and waste that will be replaced by cyclical flows. The outcomes favour entrepreneurial roles in dynamic interplay between nonstate, or subnational, actors (such as municipalities, state and provincial authorities, nongovernmental organizations, and civil society groups), international knowledge networks and organisations.

P-3315-13

The impact of policy and uncertainty on innovation in the wind industry: evidence from European countries

E. Verdolini (1) ; V. Bosetti (2) ; P. Jockers, (3)
(1) FEEM Fondazione Eni Enrico Mattei, CCSD, Milano, Italy; (2) Fondazione Eni Enrico Mattei, Milano, Italy; (3) Bocconi University, Milan, Italy

The 2010 moratorium on the level of feed-in-tariffs in the French solar photovoltaic industry offers one of the best illustrations of how impactful an abrupt policy change can be. Fearing the development of a "green bubble", the French government suspended the grid connection permissions for solar PV installations over 3 kilowatts peak for a period of 3 months. Since then, the French solar industry has repeatedly been described as "plunged in an induced coma" with dramatic social and economic consequences. Projects backlog reached ~3.6GW at the end of December 2010 fell by 58% as of June 2012, employment in the French photovoltaic sector declined from 32,500 in 2010 to 18,000 in 2012.

This is one of many examples highlighting the negative impact of policy uncertainty, namely of uncertainty arising from policy change and complexity. Similar anecdotal evidence and case studies can be found in the academic literature for other renewable energy technologies. For instance, Barradale (2010) describes how chronic uncertainty over the renewal of the production tax credit in the U.S. has been driving investment volatility. Meyer and Koefoed (2003) investigate how changes in the policy regime in Denmark has generated uncertainty for investors. Agnolucci (2006) shows how the introduction of a biennial revision of feed-in-tariffs in Germany through a modification of the Renewable Energy Act (EEG) may cause significant uncertainty. While praising the results achieved by the German renewable energy policy, he demonstrates that political uncertainty was behind the decrease in additional capacity in 1997-1998, 2000 and 2003.

The uncertainty surrounding policy may be a strong determinant of the development of renewable energy sources. However, a brief overview of the economic literature on climate change and energy policy shows that less attention has traditionally been devoted to its impacts than to those of economic or technological uncertainty. Moreover, most of the discussion in this respect has remained theoretical. This is a major shortcoming, as policy making and design should be informed about the negative impact on private investors decisions of changing rules, conditions, and more in general of not being able to provide a sufficiently stable policy environment.

This paper attempts to bridge a gap in the empirical literature and provide policy-relevant insight on the impact of uncertainty on wind innovation in 18 European countries over the years 1995-2009. We go a great length towards constructing sound empirical proxies for environmental policy strigenty and policy uncertainty. Inspired by the real option theory, we propose two novel proxies, one for environmental policy stringency and one for the uncertainty that charachterizes such policy. Unlike those used in previous studies on renewable energy technologies, our proxies for policy stringency and policy volatility are robust to three major concerns. First, we net out the effects of those non-policy factors which might drive capacity addition on top of government policies. Second, our proxies account for the fact that rational investors refer to expected policy and policy changes, namely future capacity additions rather than current ones, to make their decisions. Finally, and more fundamentally, we clean our proxies from the issue of potential reverse causality between installed capacity (and its volatility) and innovation. More specifically, we control for the fact that innovation may stimulate capacity additions through technology improvements resulting in greater efficiency and/or lower costs.

We confirm the positive inducement effect of environmental policy on innovation and most importantly show that indeed policy uncertainty counters such positive effect. We find that if both policy and uncertainty increase by one standard deviation in the sample, the benefits to innovation due to the increased stringency level are wiped away due to the negative effect of policy uncertainty.

P-3315-14

Scaling up technology transfer through the UNFCCC Technology Mechanism

K. Wada (1)
(1) RITE, Systems Analysis Group, Kyoto, Japan

This paper contributes to debates about technology transfer through the UNFCCC Technology Mechanism for climate change mitigation and adaptation. The purpose of this study is to understand the challenges that the current UNFCCC approach faces and to make policy recommendations on how the UN process can be brought closer to the actual need of technology to address climate change. This analysis is relevant to international negotiation in the post 2020 climate regime.

The mechanism has played a limited role in technology transfer so far, failing to materialize in actual technology deployment. Technologies can be transferred through various channels, ranging from official development assistance (ODA) to private economic activities, such as foreign direct investment (FDI). The UNFCCC, however, deals with technology transfer, as a government-to-government process and disvalues the role of private sector. This narrow focus cannot deliver a significant level of low-carbon technology required to curb GHG emissions in developing countries.

There are number of reasons why the UNFCCC needs to structuralize business activities, rather than governmental support, as a basis of technology transfer. First of all, the private sector owns most of the low carbon technologies. Without their engagement and innovative capability, the existing UNFCCC process will not deliver the scale of change that is necessary to achieve climate goal. Thus far, carbon credits via the CDM have facilitated private sector

participation, but future flexible mechanism is under uncertainty, which lacks the necessary signals to stimulate investment in low-carbon technologies. Furthermore, financial resources to support technology transfer, such as the Global Environment Facility (GEF) and Green Climate Fund (GCF), have limited availability and the eligibility criteria for the Technology Mechanism is still unclear. Lastly, but not least, about 30 developing countries with a total population of 2 billion are projected to exceed the income threshold for ODA eligibility over the period until 2030 due to their substantial economic growth, according to the OECD projection. These imply further efforts to involve private sector both in developed and developing economies are crucial.

The Technology Mechanism established in 2010 can be a potential platform to bring the UNFCCC process closer to the enabling frameworks that facilitate private sector investment. The Technology Executive Committee (TEC), together with the Climate Technology Centre and Network (CTCN), is mandated to facilitate the effective implementation of technology transfer. The CTCN strives to stimulate technology cooperation and to enhance climate technology development and transfer. CTCN operations are supposed to be conducted via partner institutions with expertise in climate technologies with an international network of academic, finance, NGO, private and public sector institutions. National Designated Entities (NDEs) are also nominated as national CTCN focal points to coordinate and submit technical assistance requests to the CTCN.

Technology has rarely been transferred explicitly yet through this premature mechanism. Hence, I would propose three specific ideas to enhance the mechanism. First, the CTCN, whose current network members are mostly public sector institutions, needs to involve more private firms that have technology solutions and financial sector, such as regional development bank, to harnesses more private sector investment. Secondly, the function of NDEs in developing countries needs to be expanded. The present role of NDEs is limited to a focal point to their technology needs to the CTCN, but it can be strengthened as a liaison between local technology needs and businesses opportunities by helping the national enabling environments that facilitate private investment. Finally, linkages between the Technology Mechanism and the Financial Mechanism of the Convention is necessary to provide grants to developing countries for the support of capacity building or adaptation technology, which are usually not covered by business activities. This item was negotiated in COP20 but the parties were unable to reach agreement, and discussed again in COP 21. The link between the two mechanisms and enhancement of the private sector involvement would be drivers of scaling up technology transfer.

P-3315-15

University-Industry-Government Collaboration for Innovation to Tackle Sustainability Challenges: Functions and Mechanisms of Stakeholder Platforms on Smart Cities

M. Yarime (1)
(1) University of Tokyo, Graduate School of Public Policy, Tokyo, Japan

Many countries have introduced policies to encourage innovation through technology transfer academia to the private sector, often with exclusive agreements on intellectual property rights. While some successful cases have been reported in transforming knowledge created by university researchers into industrial products, the existing models of university-industry-government collaboration tend to focus on narrowly-defined technical issues, mainly targeted to commercial applications. For tackling sustainability challenges, a new approach would be required to promote innovation, involving a wider variety of stakeholders with more diverse knowledge and expertise in scientific and technological fields. Smart cities and communities are particularly considered to be one of the key areas in which a variety of science and technological knowledge need to be integrated effectively through collaboration among multiple actors. A smart city would involve an advanced technological system for efficient electricity supply and applications, incorporating all the behavior of the actors involved, including generators, distributors, technology developers, and consumers, through an intelligent information network. As a smart city integrates a diverse mixture of hardware as well as software in a complex way, different approaches would be possible to introducing and implementing the concept of smart cities in practice, depending on the economic, social, and environmental conditions and purposes, such as energy efficiency, operating cost, environmental impact, resilience to external shocks and disturbances, and accessibility and inclusiveness to end users.Recently, leading research universities around the world have started to apply their expertise and sources of innovation to the goal of building smart cities and communities. In this paper, we examine approximately 80 cases of the leading initiatives led by universities through stakeholder platforms in Japan, Europe, and the United States. A particular focus is placed on smart cities and communities, involving relevant stakeholders in academia, industry, and the public sector. A close examination of the leading initiatives reveals the important functions of university-driven stakeholder platforms in implementing innovation to address societal challenges. These include the creation of future visions based on science, setting of concrete and practical goals and targets, joint scenario making with stakeholders, securing active participation and serious engagement of stakeholders, collection and analysis of data on societal needs and demands, development of new technologies and systems through social experimentation at universities as living laboratories, assessment of impacts with transparency, objectivity, neutrality, legitimation of innovation in society, provision of effective feedback to decision makers, incorporation into institutional design, and contribution to agenda setting at regional, national, and global levels. On the other hand, difference are also found with regard to the direction and process of technological development on smart cities and communities between Japan, Europe, and the United States. The Japanese approach is characterized by a strong focus on sophistication of application technologies for extensive use of home appliances and electric vehicles. In Europe an emphasis is placed on establishing a basic infrastructure in which information about the behavior of all the stakeholders is collected and distributed among the stakeholders appropriately so that the various objectives of the electricity grid are achieved in a more equitable way. In the United States a strong interest can be observed in creating and maintaining security through improvement in resilience against physical as well as virtual threats. These asymmetries in conceptualizing and implementing smart cities reflect the differences in how knowledge development, stakeholder networks, and institutional environment interact in dynamic and systemic manners. The cases highlighted in this paper provide valuable insights into potential ways forward for collaboratively designing and creating knowledge and implementing innovation to tackle sustainability challenges. For follow-up efforts and new projects in the future, however, we still need deal with remaining challenges, including how to navigate differing motivations and incentives for serious engagement and fruitful collaboration among stakeholders, to promote joint initiatives and networking that contribute to achieving desirable goals and targets and developing complementary skills and capacities, and to identify the factors and conditions required to promote their successful implementation.

P-3315-16

Re-engeneering a Flood Control in Jakarta as a capital city of Indonesia

SA. Yusuf (1)
(1) Universite Bordeaux1, Enterprise Engineering, Jakarta, Indonesia

Background: Without an integrated system and good infrastructure as well as lacks of feeling "sense of quality", these implies inconsistent in various aspects. The aversion of the goverment and company to invite along experts from Universities to optimize the system of flood control in Jakarta as capital city of Indonesia is also become an obstacle. However the need of research to solve these problems is urgently necessity, because now Jakarta attracts more investors from abroad and domestic where Jakarta is the center of all interests and decisions. Therefore a good infrastructure that guarantee safety, comfort and health can boost the condition by giving the effectivity, efficiency and also its quality.

Project: The paper is done by following the estimation of design flood and the control for 3 months by observing several values for flood routing, flood mitigation, flood forecasting, drainage system, infrastructure, maintenance

of the assets, zoning by direct observation and some interviews with officials of reservoir. The problem that occurred is always every year and mostly in the same place. Also the information that we get from the website is non-interactive.

Problem and solution:

1. Rainwater that fell and the overflow of rainwater from the higher regions provinces can not be managed properly. For instance, it rained only 5 hours it could cause flooding in several locations. It needs urgently to designing flood protection measures, Hydrology of the catchment area, it meanshow to build up a design flood based on the knowledge of hydrology of the catchment area.

2. Storage reservoirs currently not functioning optimally and manually operated. Thereafter, this required to plan re-engineering structures, its schedule of operations, so that the flood cannot cause serious damage downstream.

3. Today flooding could come suddenly without early notification to residents and may causing loss of material and human life. Further as the floodwave passes through a stream it is necessary to know how the stage varies with respect to time and distance for the design of river engineering works as well as for issuance of flood warning by the civil authorities.

4. Current water pump system is not well integrated, electricity is not equipped with backup power, so if the power fails then the pump is can not use. It is need an installing pumping facilities which comes under drainage engineering and with integration system.

Conclusion:

With this current state, it is no wonder if Jakarta famous with the flood in every year. This must be repaired and done some innovations by cooperating with universities to conduct research and continuous improvement for a greater goal. Ensure operation and maintenance personnel are part of project planning and development process including developing criteria for the initial commissioning of the project and wherever possible, choose an easily maintained system. Knowledge is considered today to be one of the main assets of a company. Together company and university can try to develop new approaches and find answers to those challenges.

3316 - Towards solutions that transcend technology and markets: The role of choices and behaviour change

ORAL PRESENTATIONS

O-3316-01

Demand-side solutions to mitigate climate change

F. Creutzig (1) ; N. Dubash (2) ; H. Helmut (3) ; Y. Mulugetta (4) ; K. Seto, (5) ; D. Urge-Vorsatz (6)

(1) Mercator Research Institute on Global Commons and Climate Change, Land use, transport and infrastructures, Berlin, Germany; (2) Center for Policy Research, New Delhi, India; (3) Uni Klagenfurt, Klagenfurt, Austria; (4) University College London, Science, Technology, Engineering & Public Policy, London, United Kingdom; (5) Yale University, School of forestry, New Haven, United States of America; (6) Center for Climate Change and Sustainable Energy Policy (3CSEP), Central european university, Budapest, Hungary

The main emphasis in assessments on climate change solutions has been on technologies and options subjected to cost-benefit analysis. However, many proposed mitigation solutions can hardly be squeezed into such categories or assessed through such analytical frameworks. Because of this mismatch such mitigation options are systematically underrepresented in integrated climate change mitigation analyses and assessments. To counteract this bias, the paper emphasizes the importance of these underreported mitigation options. First, the paper reviews the literature and taxonomies on the options available in the "mitigation space" and maps the diversity of mitigation options. Then, it reviews the key analytical frameworks that integrate mitigation options to prepare climate-related decision-making, including their strengths and shortcomings. The paper thene synthesizes examples of the underrepresented mitigation options from different sectors mostly drawing on results from the IPCC's AR5. The paper then reviews selected examples of the underrepresented mitigation options from several demand-side sectors. it calls for the need ofcomplementary analytical frameworks to cost-benefit analysis, and suggests one based on evaluating political feasibility and desirability of demand-side and infrastructure solutions that interact with endogenous preference formation. It observes that both 'hard' infrastructures, such as the built environment, and 'soft' infrastructures, such as social expectations, share behavior, and, in turn, offer significant potential for mitigating overall energy demand. The overall order of magnitude of mitigation potential of these underrepresented options can be equal to those of technologies. In contrast to the technological options, their potential depends less on economic factors but more on political will and social transformations.

O-3316-02

Show me the money (and the information)! Durability driven uptake of efficient lighting in a context of informality

A. Figueroa (1)

(1) German Development Institute / Deutsches Institut für Entwicklungspolitik (DIE), Bonn, Germany

Consumer-driven uptake of energy efficient lighting can make meaningful bottom-up and behaviour change driven contributions to address climate change challenges. The International Energy Agency (IEA) estimated that in 2005 lighting accounted for 2,650 TWh, equivalent to 19% of annual global electricity demand. This is equivalent to the power generated by all gas-fired power plants worldwide and results in annual emissions equal to 70% of world passenger vehicle emissions (IEA 2006; UNEP 2012).

Particularly among poor communities in developing countries where a light bulb is by far the most common household appliance, progress is needed to realise end-user uptake. Although light-emitting diodes (LEDs) may not always be available or affordable for these communities, compact fluorescent lamps (CFLs) offer a cost competitive means of energy efficiency uptake. CFLs use up to 80% less power and offer co-benefits such as a longer lifespan and grid load reduction which can contribute to economic welfare and development pursuits. Yet despite these potential benefits, the uptake of CFL bulbs lags. Among 800 survey respondents with an existing electricity connection in Kibera, an informal settlement in Nairobi, Kenya, only 20% have CFLs. What prevents the apparently economically rational purchase of CFLs and how might behaviour change contribute to increased uptake?

Field research in Kibera identified burdens and benefits of CFL adoption. This revealed that when power surges occur on the electrical grid serving Kibera, a majority of residents report that incandescent bulbs burst while CFLs withstand power surges. The relatively high number of power surges occurring on the grid translates to a payback period averaging six weeks, even in a context of non- or flat-rate electricity payment, common arrangements in informal settlements. However, behaviours such as a present-bias or limited self control along with quality assurance concerns such as the high presence of apparently poor performing counterfeit bulbs has reduced confidence and resulting market share for CFLs.

We employ a laboratory-in-the-field experiment (N=651) in Kibera to identify barriers and potential drivers of CFL purchase. Four elements form our research framework: a laboratory protocol testing psychological attributes; a household baseline survey evaluating demographics

and energy use; the application of a randomised control trial testing three potential drivers of CFL uptake, and household endline observation.

The treatments seek to test three hypothesised barriers to the uptake of CFL light bulbs: Awareness, liquidity, and commitment, by providing treatments anticipated to address each barrier. The awareness treatment seeks to "nudge" (Thaler / Sunstein 2008) consumers toward CFL purchase by providing information to address a perceived bias towards incandescent light bulbs. The liquidity treatment provides a subsidy to reduce the price of a CFL bulb to that of an incandescent. The commitment treatment provides a financial reward for committing to purchase a CFL and seeks to address potential barriers related to self-control by regulating this through a prior commitment. We employ a field purchase experiment that more realistically replicates the actual shopping environment that would be encountered.

The findings show that while the provision of liquidity for CFL purchase can positively impact uptake, this is more than tripled by the additional provision of salient information demonstrating the durability of CFL bulbs in comparison to incandescent bulbs. This finding is relevant for the design of behaviour-informed energy efficiency initiatives in developing countries. It demonstrates the potential "pull" of non-monetary and behavioural instruments in energy efficient lighting uptake in a context of poverty, extending the traditional focus of behaviour and energy efficiency beyond developed countries.

Perceived climate variability and water scarcity: stress experiences and survivalist responses in water resources management in Cameroon

EM. Fomba (1) ; TM. Noukeu (2)

(1) University of Dschang, PPS-Psychology, Dschang, Cameroon; (2) University of Dschang, Former student, pps-psychology, Dschang, Cameroon

Despite the interplay of many factors, climate variability has been recognised for degrading fresh water resources, destabilising human behaviours and activities; drawing in behavioural intervention as an indispensable dimension of integrated water resources management. Positioning water at the centre of human life and activities the paper regrets that human behaviour appears the least understood dimension of global change, climate variability and accompanying risks such as water related stress, thereby undermining human factors in management options and survivalist behaviours of local people. It asserts that emerging strategies in natural resources management drawn from climate variability have embraced people-centre models as core strategic values in sustainable water resources management with increased role of human factors in understanding the psychology of people as facilitators and inhibitors of effective outcomes in physical water systems. In context, increased recognition and focus on the human factor in climate variability, water crisis, stress experiences and response measures are evidenced by the critical role of human behaviours. While crisis relating to water resources management has been generally approached from physical science perspectives, the paper upholds that water management is a psychological problem, and human behaviour can provide significant insights into the antecedents and consequences of water crisis. Also, it submits that the inclusion of behavioral sciences is a prerequisite to linking the physical sciences to the broader social context while promoting water conservation behaviours capable of stress aversion. The present study investigated perceived climate variability, water scarcity and adaptive strategies of local people. A sample of 254 participants (52.4%) males, average age 28.39, (SD, 9.08), were drawn from Bangagnte, Cameroon. A self-report questionnaire with significant internal consistency was used to collect data, and descriptive and inferential statistics used for analysis. Results revealed significant relationships among study variables, except for perceived water scarcity and stress experiences, suggesting the relevance of a behavioral framework in the analysis of climate variability and sustainable use and management of water resources. Also, the relationship between perceived climate variability and water scarcity was significant, while perceived water scarcity and stress experiences were insignificant. Regression analysis confirmed perceived climate variability, water shortage and stress as significant predictors of adaptive responses and mitigation behaviors. Apart from perception of water crisis, t-test analysis showed no significant gender differences for stress level, adaptive and mitigating behaviors. From analysis, the human-centre model constitutes a pathway toward sustainable water management capable of promoting adaptive competences, strategies and actions. While the study has implications for policy, research and practice, it strongly advocates the integration of behavioral science mechanisms in addressing climate variability and natural resources management dominated by physical sciences in an anxiety-provoking era of global change.

O-3316-04

Motivation to engage in sustainable behaviour

L. Steg (1)

(1) University of Groningen, Groningen, Netherlands

Contribution to session no. 3316 (convened by Dr. Sabine Pahl)

Sustainable development implies a future in which both environmental quality and human well-being are secured. Yet, sustainable behaviour is often believed to be less attractive (e.g., more expensive, time consuming, effortful), which may inhibit sustainable choices as this may threaten individual well-being. Despite this, many people do engage in sustainable actions. Why are they willing to do so? I will argue that values are a key motivating factor in this respect. I will elaborate on which values are likely to promote or inhibit sustainable actions. Notably, hedonic values that make people focus on what makes them feel good, and egoistic values that make them focus on how to increase their resources often inhibit sustainable behaviour, particularly if such behaviour is costly or effortful. Both reflect self-enhancement values. In contrast, altruistic values that make people focus on ways to benefit others, and biospheric values that make people focus on benefiting nature and the environment generally promote sustainable behaviour; both reflect self-transcendence values. Next, I indicate via which processes values affect sustainable behaviour. More specifically, I will illustrate that values affect which behaviour consequences people find important, and how they evaluate behavioural consequences given the implications of the relevant behaviour for their important values. Moreover, values affect the activation of personal norms, that is, feelings of moral obligation to engage in sustainable behaviour, that in turn affect the likelihood of such behaviour. Also, engaging in sustainable actions make people good, and people may anticipate such positive feelings elicited by doing the right thing, which may promote sustainable actions. Finally, I will discuss factors that may activate or deactivate values, thereby affecting the likelihood that the relevant values steer sustainable choices in a given situation. Values can be activated by value-related cues, costs of sustainable behaviour, and situational cues that reflect that other people respected or disrespected norms, and acted upon their self-enhancement rather than their self-transcendence values.

O-3316-05

Behaviour change or lifestyle change? Evidence and prospects for behavioural 'spillover'

L. Whitmarsh (1)

(1) Cardiff University, School of Psychology, Cardiff , United Kingdom

Contribution to session no. 3316 (convened by Dr Sabine Pahl)

There is increasing acknowledgement that profound changes to individual behaviour are required in order to tackle climate change, and yet policies to achieve these changes have so far met with limited success. Most people are willing to make only very small changes to their lifestyle – so new ways of encouraging green behaviour which can match the scale of the climate change challenge are needed. The UK government and several psychologists have suggested behavioural 'spillover' might be a way to achieve this. Spillover is the notion that taking up one green behaviour (e.g., recycling) can lead on to other green behaviours (e.g., taking your own bags shopping). Ultimately, this might hold the key to moving beyond piecemeal behaviour change to achieving more ambitious, holistic lifestyle change. This talk will present initial work to explore when spillover does, does not, and could, occur using correlational and experimental data. First, factor analysis of UK survey data (N=551) will be presented exposing clusters of pro-environmental behaviours that co-occur, potentially indicating spillover between actions similar in difficulty and/or location. This study exposes how consistent individuals are in their behaviour and which factors (e.g., identity) might underlie spillover; it also provides some insight into which behaviours might act as 'catalyst' behaviours to trigger spillover to similar actions. Next two studies are presented which focus on the potential for specific behaviours – installing insulation and carrier bag reuse – to trigger behavioural spillover. Analysis of survey data (N=736) of Welsh homeowners' adoption of energy efficiency measures shows that those who adopt home insulation are significantly more likely to undertake other energy saving measures (e.g., turning down thermostats) in the home. This relationship holds when controlling for environmental values, suggesting behavioural spillover may be occurring in this context. Finally, a field experiment of the Welsh carrier bag change, will be presented that finds carrier bag reuse does not lead to behavioural spillover to similar (waste-related) pro-environmental behaviours. These divergent findings highlight the importance of contextual factors in facilitating pro-environmental behaviour and behavioural spillover, and a need to understand the mechanism underlying spillover. Ongoing lab experiments to induce behavioural spillover and thereby expose this underlying mechanism will briefly be discussed, along with implications for policy and practice.

O-3316-06

Global middle classes and their carbon footprints

F. Reusswig (1) ; A. Garg (2)

(1) Potsdam Institute for Climate Impact Research (PIK), Transdisciplinary Concepts and Methods, Potsdam, Brandenburg, France; (2) Indian Institute of Management Ahmedabad, Public systems group, Ahmedabad, India

While many climate change scholars from the social sciences (including economics) have paid attention to the GHG emissions contribution of different countries (including average per capita incomes and per capita emissions), we do know much less on emissions by individuals worldwide (regardless of country). But the development of the former (e.g. measured in average GDP) and the latter are linked: the richer countries get on average, the higher the income inequality, and the larger the portion of people that move from the national poor to the national middle classes. Currently, this is particularly the case in rapdily developing countries such as India and China.

We will present estimates of indivdual income by class, and of the respective carbon footprints by class. Our main reference points are Germany, the US, and India. Our basis with respect to income distribution worldwide will be the work of Xavier Sala-i-Martin and Thomas Piketty on the one hand, and national statistics on the other. The assessment of class-specific individual footprints will be based by nation-specific carbon footprint assessments and calculators.

Our results will show that while individuals from the developing world are still responsible for the vast majority of GHG emissions, upper and upper middle classes in some rapidly developing countries have now entered the global 'responsibility space', i.e. emit above per capita world average. We will discuss the implications of these findings both for national and for international climate policies.

P-3316-01

Stimulating climate aware behavior among young people in Austria

S. Chiari () ; S. Mandl, (1) ; S. Voeller, (2) ; A. Corner (3) ; O. Roberts, (3)

(1) Austrian Institute for Sustainable Development, Vienna, Austria; (2) Environment Agency Austria, Vienna, Austria; (3) Climate Outreach and Information Network (COIN), Oxford, United Kingdom

Given the latest scientific observations regarding global warming, there is an urgent need to enhance the outreach of climate change communication efforts in order to mainstream low carbon lifestyles (APCC 2014). This is specifically relevant for young people, as their future is most affected by the consequences of global warming. It is evident that the predominantly negative communication of climate change – including catastrophic imagery – simply does not positively engage (young) people in low carbon behavior (O'Neill & Nicholson-Cole 2009, Hibberd & Nguyen 2013). The ongoing research project AUTreach (funded by the Austrian Climate and Energy Fund) aims to enhance the outreach of climate communication in Austria towards young people by shifting the focus of climate communication towards environmental, personal and social benefits of climate-aware behavior, as well as towards desirable solutions for young people's daily lives. It focusses on whether and how such alternative ways of communicating climate change issues – e.g. positive framing of messages and choosing communication formats relevant to the young's needs and habits – can catalyse low carbon behavior among young people.

The project is coordinated in a transdisciplinary manner, actively involving young people and climate change communicators e.g. scientists, NGO's, lecturers, teachers, policy makers. As a first step, an extensive literature review and a quantitative online survey among young Austrians were conducted to evaluate young people's level of awareness, knowledge and engagement regarding climate change and low carbon behavior. Secondly, several workshops with young people were carried out to test possible stimulating effects of different communication formats. In these workshops also good-practice formats, which have been nominated by stakeholders before, were tested. Thirdly, three events that aimed to trigger climate engagement among this audience ("Encourage sustainability"/ lecture, "Earthtalks"/ annual evening event, "UN climate reporter"/social simulation) were evaluated in a qualitative ex-post analysis, interviewing young participants one month after the events.

In light of the conclusions of the literature review (Corner et al., submitted), and the findings of the online survey, a list of youth-specific success factors for climate communication has been derived. These success factors were further revised and supplemented by the results of the workshops and the (ongoing) ex-post evaluation. The following criteria have been identified as key in fostering behavioural change among young people through climate communication:

- frame message-content based on the values most relevant to young people
- phrase clear messages using the target group's language
- stress & strengthen perceived self-efficacy of young people
- provide concrete solutions applicable & relevant to young people's daily lives
- use formats that include social interaction & fun
- consider visual design & possible incentives

The wide spectrum of project results will be summarized concisely for stakeholders by creating an online toolbox to support them in developing youth-oriented climate communication formats. The toolbox will be co-created with young people in a one day workshop towards the end of the project and be presented in a final stakeholder workshop facilitated by young people.

Addressing the behavioural gap in energy/economy models: Outcomes of the BE4 Workshop and outlook for the state-of-the-art

H. Daly (1)

(1) UCL Energy Institute, London, United Kingdom

Energy system optimisation models (ESOMs) simulate long-term least-cost energy system trajectories with high technology resolution, and are frequently used to better understand the trade-offs of sustainable technology transition possibilities for the future energy system. ESOMs are commonly used to portray the whole energy system, depicting energy technologies at every stage in the fuel supply chain, from fuel extraction through to final end-use. These models are heavily used in national decision-making and have been influential in the design of low-carbon policies, and so bare a burden of responsibility in realistically depicting energy system dynamics.

Whole-system energy modelling approaches have been successful at capturing the technological complexity and economic feedbacks of the energy system, and are used as integrating frameworks to explore the trade-offs in climate mitigation, fuel poverty and energy security priorities. However, building sustainable energy systems requires a focus on behaviour, along with technological development: Behaviour plays a major role in the uptake and use of energy technologies, in driving energy service demand, and its treatment cannot be excluded from the analysis of long-term energy transitions. Researchers are increasingly looking to integrate insights across disciplines to increase the behavioural realism of ESOMs and include mitigation opportunities from behaviour change, along with technological and fuel solutions, in these highly influential models.

This contribution will address the growing priority of better representing behaviour in energy modelling approaches by bringing to the wider mitigation modelling community outcomes from the International BE4 Workshop, which is to be held on April 20th and 21st, 2015, at University College London*. BE4 will bring together for the first time energy system researchers with expertise and interest in representing behaviour in energy/economy/engineering/environment (E4) models, aiming to develop a common understanding of the state-of-the-art in this emerging field, to identify knowledge gaps, and for the community to gain exposure to research in other fields which has successfully integrated behaviour into other modelling approaches. The workshop will have high-profile speakers and sessions describing state-of-the-art research. BE4 is funded by IEA-ETSAP, a consortium of teams led by the IEA that actively cooperate to establish, maintain, and expand E4 model capacity, and WholeSEM, a consortium which plays an underpinning role for the UK's national strategic energy modelling activity.

BE4, and this presentation, will address the following themes:

- Heterogeneity in the population;
- Hidden costs in decision-making;
- Non-cost-optimal decision frameworks;
- Discrete choice analysis in whole-system approaches;
- Agent based modelling approaches;
- Integration of social sciences with E4 modelling.

Arising from this workshop, this conference contribution will review the challenges that face integrated energy and mitigation planning tools across temporal and spacial scales.

P-3316-03

Energy efficiency and behavioural change in Uganda's small-scale industry

B. Never (1)

(1) German Development Institute / Deutsches Institut für Entwicklungspolitik (DIE), Bonn, Germany

Energy efficiency counts as a low-hanging fruit in the combat against climate change and the transformation towards a low-carbon future. Investments in energy efficient technologies and the uptake of energy management practices offer a lot of benefits to industries in developing countries, but these are often not reaped. This so called energy efficiency gap exists in Uganda as much as elsewhere. Small-scale enterprises particularly struggle with the closure of this gap due to a combination of financial, organizational and informational barriers, as different studies have shown. This contribution will show that there is also a behavioural story to be told. Removing behavioural barriers and using psychological insights to design tailored policy packages belongs in the climate mitigation toolbox as much as in the development toolbox.

This contribution takes an innovative interdisciplinary approach combining development economics, behavioural sciences and environmental psychology to analyse the behavioural drivers and barriers of energy management in Ugandan micro- and small enterprises. The paper is an empirical contribution that draws on 45 on semi-structured interviews and focus group discussions conducted in Eastern Uganda in April 2014.

The main findings are that behavioural barriers impeding energy efficiency contribute to the limited performance of these enterprises. the cognitive focus on and preference for short-term benefits, habits and a status quo bias as well as a lack of trust impede the uptake of energy efficient technology and energy saving business practices by the MSEs. It has become clear that those entrepreneurs who have started to manage the electricity consumption of their business were supported by direct, first-hand experience with energy efficient technology and practices, followed implementation intentions taken at energy training workshops and benefited from social learning, i.e. from other, similar businesses serving as role models. The possibilities for social learning among the entrepreneurs interviewed are limited by competitiveness thinking and mistrust; at least as long as the entrepreneurs could not actually see for themselves what positive impact energy efficiency has on a neighbouring business. While the qualitative approach to this study does not allow for larger generalizations, the findings indicate a positive effect of changing energy management behaviour on business development and performance, if context conditions such as sufficient business skills and market access are provided for. Strong behavioural drivers are likely to be conducive to energy management and enterprise performance, while the strength of strong behavioural barriers negatively impacts performance. Thus, supporting behavioural change in small-scale industries can have positive effects for mitigating climate change, economic growth and development.

P-3316-04

Towards solutions that transcend technology and markets: The role of choices and behaviour change

S. Pahl (1) ; A. Pegels (2) ; Y. Mulugetta (3)

(1) Plymouth University, Psychology, Plymouth, Devon, United Kingdom; (2) German Development Institute / Deutsches Institut für Entwicklkungspolitik (DIE), Sustainable economic and social development, Bonn, Germany; (3) University College London, Science, Technology, Engineering & Public Policy, London, United Kingdom

Human choices and behaviour play a crucial role in climate change. "Human beings are the cause of the transformation, and only action by human beings can save

the world from its worst impacts" (US Secretary of State John Kerry, Sept 27, 2013). This session explores how research on choices and behaviour can facilitate interdisciplinary, integrative responses to climate change. Talks will draw on social science theories and present novel data that contribute to three types of solutions: Better engagement with the public, interventions that change behaviour, and policy responses. The explicit aim of our session is to go beyond technological and market solutions and focus on behaviour change solutions. A considerable though not exclusive focus of this session will be on energy efficiency and savings, offering solutions for the double challenge of climate change mitigation and development. The IEA estimates that 18 per cent of the global population lack access to electricity. At the same time, the energy sector accounted for over 70 per cent of global greenhouse gas emissions in 2011. Greenhouse gas emissions overall have grown more between 2000 and 2010 than in the previous three decades. Addressing carbon emissions and reforming the energy system will be vital for limiting global warming but poses different challenges for industrialised and developing countries. While technological innovation and carbon prize mechanisms will play a major role in transitioning towards a low emissions economy, it is questionable whether this technological and market frame is sufficient to realise this transition. Human decisions, behaviours and broader lifestyles are key to achieving a meaningful, acceptable and inclusive transition. Only taking a "people-focused" perspective will provide a buffer against market failures such as risk, imperfect information, hidden costs, access to capital, and split incentives. Contributions will discuss the key factors that contribute to behaviour change by presenting the results of empirical studies (e.g., interventions) and whether specific behaviours can "spill" over to other domains. We will also consider whether a behaviour change approach is too narrow in the face of broader patterns of habits and 'locked-in' lifestyles. This session will bring together social scientists including economists and psychologists, scientists, engineers and policy makers to explore the potential of behavioural, choice and lifestyle solutions to addressing climate change. The session finishes with our team working with three specialists in global environmental change. Michael Depledge (Professor of Environment and Human Health, University of Exeter, UK) will lead this discussion, drawing on his experience as advisor to the United Nations and the European Commission. Together we will sketch a map illustrating how social science theories and data might be used to enhance our responses to climate change and foster sustainable lifestyles. Six speakers are planned with 10 minutes for each presentation, plus a poster session and a panel discussion at the end.

P-3316-05

Behaviour change for household energy use: The example of visualising heat loss through thermal imaging

S. Pahl (1) ; C. Boomsma, (1) ; J. Goodhew, (1)
(1) Plymouth University, Psychology, Plymouth, Devon, United Kingdom

Energy use plays an important role in climate change and is linked to issues of energy security and fuel poverty. Householders in particular play a key role in energy conservation through the decisions they make about purchases and installations such as insulation, and through their habitual behaviour. However, energy has been described as abstract and intangible thus making it difficult for individuals to relate to in a meaningful way and know the best actions to take. The present project summarises a programme of work that visualises household energy in order to encourage behaviour change and reduce carbon emissions related to the home. The visualisation tool is "thermal imaging" which makes the invisible visible by using infrared photography. Thermal images demonstrate how heat escapes and cold air enters the home. In Study 1, householders, who received a thermal image of their own home, reduced their energy use at a 1-year follow-up, whereas householders who received a carbon footprint audit and a non-intervention control demonstrated no change. In a second study, householders were nearly 5 times more likely to install draught proofing measures after seeing a thermal image of their home. The effect was especially pronounced for actions that addressed an issue visible in the images. A third study explored the level of tailoring that is needed to change householder intentions and behaviour. Thermal images were shared with more people (social multiplication) and associated with stronger intentions and actions, when they were tailored and personal to people's own home, compared to images that showed a typical home. But seeing any thermal image (whether personal or typical) led to better memory and higher behavioural intentions, compared to text only. Finally, an update will be given on an ongoing study that tests the power of thermal images as a communication tool with 6,000 householders invited to take part in a home improvement programme. This study compares the effect of thermal images that visualise the problem ('before') with thermal images that visualise the problem together with a solution ('before' – 'after), and with a control group that does not see any images. Limitations and challenges of this applied interdisciplinary research will be discussed briefly. The potential for thermal imaging visualisation in other contexts will be highlighted. In conclusion, thermal images seem capable of overcoming the invisibility of energy said to be a barrier to behaviour change.

P-3316-06

The Environment and Data: Using Quantitative Data and Methodology to Encourage Environmental Civic Responsibility

M. Perks (1)
(1) Concordia University, Sociology & Anthropology, Montreal, QC, Canada

This paper analyzes the innovative potential of working with the Households and Environment Survey, run biennially by Statistics Canada, while proposing new instruments of measurement using this nation-wide data. Previous research has focused on small geographic areas and not in nation-wide contexts. In addition to this, the focus of research around eco-citizenship has been mainly theoretical and/or used qualitative methods. While this work has been critical to scholarly understanding of the situation and conceptualization regarding eco-citizenship, it has mainly dismissed the vast amount of aggregate data available to researchers.

This paper considers emergent innovations regarding the ways in which we might incorporate this data, as well as new quantitative methods and instruments, into environmental sociology. The data available provides a unique opportunity to create and implement an index for the analysis of our current situation regarding Canadian participation in behaviours indicative of eco-citizenship. This research will subsequently allow me to develop further instruments and tools to build upon scholarly understanding of eco-citizenship at nation-wide and global levels.

This paper will also create a framework that could be developed for use in other countries, generating new information on the status of eco-citizenship. The author looks into the civic responsibility and governance issues surrounding the use of highly statistical, government collected data and exercising what may seem to be a top-down authoritative approach compared to usual environmental approaches emphasizing horizontal authority. While initially problematic, the author believes that it is not the use of data that defines this action but how that data is used. Therefore, what is being exercised is not responsiblization through statistics, but an engagement in environmental civic responsibility to bring citizens and communities into the knowledge and process.

P-3316-07

Mobility choices and climate change: which incentives are effective?

C. Raux (1)
(1) University of Lyon, Laboratoire d'Economie des Transports, Lyon, France

Transport generated 22 per cent of anthropogenic CO2 emissions in the world in 2011 with three-quarters due to road transport and a continuous increase at least since 1990. There is a majority consensus among climate scientists and economists on a need for a sharp reduction of anthropogenic greenhouse gas emissions in the next few decades. Regarding transport it is recognized that improvements undertaken in vehicle energy efficiency will not be sufficient in the coming decades and that behavioral changes are also needed, such as shifting from individual

to public transportation or lower-emission modes per passenger-km or even reducing kilometers travelled.

Regarding behavioral changes, carbon taxes and vehicle taxes are advocated by economists as the most cost-effective instruments. Variants of economic incentives like personal carbon trading have also been proposed. Their roots can be found in the economic literature initially as a combination of economic incentive and quantity control, namely marketable or Tradable Permits. Due to the specific nature of tradable permits applied to personal consumption of fuel, potential supplementary outcomes when compared to a carbon tax are expected on psychological grounds rather than economic ones. One effect might come from making carbon visible at the end-user level, with a carbon account delivering frequent feedback on travel behavior (i.e. "carbon budgeting"). Another effect could come from the social norm associated with a personal allowance fixed within the frame of a public policy.

By the means of a series of discrete choice experiments in a transport choice context we estimate and compare the impacts of economic and psychological incentives in motivating environmentally responsible mobility behavior.

In a first experiment the potential effectiveness of personal carbon trading (PCT) in changing car travel behavior was compared to the conventional carbon tax (CT) by means of a stated preferences survey conducted among French drivers (N~300). We show evidence that PCT could effectively change travel behavior and hence reduce transport emissions from personal travel. There is however a definite reluctance to reduce car travel. We were unable to demonstrate any significant difference between the effectiveness of PCT and the CT with regard to changing travel behavior. However, in the experiment, the PCT scheme provided consistent results while this was not the case for the CT scheme. This was an indication of a potential "social norm" effect conveyed by a personal emissions allowance.

In the second series of experiments we explored the trade-off between travel price and travel time on 900 participants, while introducing in a controlled setting various effects such as information on CO2 emissions, injunctive and descriptive social norms, and fiscal incentives such as a carbon tax, a bonus-malus and a carbon trading scheme. By "framing" we mean the ways of presenting a choice based initially on objective economic properties (here the trade-off between travel price and travel time) that do change psychological aspects (information on CO2 emissions, injunctive and descriptive social norms) and sometimes economic aspects by imposing fiscal incentives (tax, quotas and bonus-malus).

Statistical evidence shows that providing CO2 information on emissions is highly effective and the injunctive norm reinforces this effect in the case of air and train. A quota scheme reinforces the injunctive norm effect in the case of these two modes. More strikingly, the amount of the financial sanction or reward has no effect on the probability of using the various travel modes, unlike the presence of the fiscal framing itself.

There are some policy implications of such results. First they confirm and reinforce the case for using psychologically positive framing effects in promoting effective pro-environmental behavior in transport choices. Providing basic CO2 emissions information on each travel alternative is likely to yield actual behavior changes. Normative messages through benchmarking (bonus-malus) or carbon budgeting (quotas) may reinforce the incentive especially for larger emitting modes. The amount of the financial (dis)incentive in itself might not matter regarding the effect on behavior change.

P-3316-08

Co-design of a place-based educational videogame on climate change: Future Delta 2.0

S. Sheppard (1)
(1) CALP, Vancouver, Canada

Contribution to session no. 3316 (convened by Dr. Sabine Pahl)

This presentation describes a co-creation and evaluation process for a community-based interactive educational videogame on local climate change solutions, developed for a case study in the coastal municipality of Delta, British Columbia, Canada.

This project uses video gaming to enable interactive exploration of local climate change threats and solutions in a real place. Delta faces challenges such as sea level rise, agricultural decline, heat-waves, and growth fuelled in part by environmental refugees. The project builds on the Collaborative for Advanced Landscape Planning (CALP) team's earlier research in Delta, collaborating with various levels of government and multiple stakeholders, and demonstrating the power of science-based visualizations in raising awareness and motivation on climate change. The aim is to make climate change science and solutions more salient and creative, in a way that conventional educational methods often fail to achieve. The videogame will allow players to visualize what their own future might look like, and explore a variety of tough choices that citizens of Delta may need to make.

Taking advantage of earlier Future Delta videogame prototypes, the co-design phase focuses on local high-schools, in partnership with Delta School district. The game design borrows from commercial videogame techniques in order to provide a compelling virtual environment for: i) place-based learning in geography and science classes, and ii) student engagement on local climate change realities, collective action and policies for adaptation and mitigation. Teachers and students will design the game collaboratively with researchers, through an iterative process of focus groups and gameplay sessions. Participants provide input on integration of class/curriculum learning objectives, the fun of game play, and storyline ideas reflecting local themes and identity.

The presentation will report on the co-design process and preliminary evaluation results on input from students, teachers, families and friends, shedding new light on responses to climate change impacts and choices in a videogame environment.

3317 - Mainstreaming low carbon consumption : challenges and opportunities

ORAL PRESENTATIONS

K-3317-01

Low carbon living and energy demand as a shared social problem: from the little to the big

G. Walker

Bringing low carbon into being evidently means far more than innovating only in technological terms. Co-evolving social change is also necessary, on a scale that extends beyond those people that are already committed, beyond individual attitudes and behaviours, to the truly collective, societal and structural. In this paper I consider the implications in terms of both how we understand the nature of much of the energy consumption that makes up the carbon burden of contemporary living, the challenges involved in achieving 'preferred' forms of low carbon social change (in both energy and social justice terms) and ways of political articulating of what is at stake in governance terms. I will draw on recent research projects focused on the relation between social practice (shared forms of everyday living at home, at work and in moving around) and energy demand, including work on the spread of air conditioning, the mainstreaming of zero carbon homes, energy use in the living spaces of older people and flexibility in the temporal patterns and rhythms of daily energy demand

O-3317-01

Daily innovations, social practices and sustainable consumption – Some insights from real life

S. Douzou (1)
(1) EDF, Research and development, Clamart, France

Daily innovations aiming at reducing C02 emissions and energy consumption constitute the cornerstone of most of scenarios and visions of the future underpinning climate change mitigation related policies and options for the residential sector. Not without reasons: the ambitious targets claimed may necessarily be achieved partly thanks to the integration of a sophisticated set of socio-technical eventual innovations. Under certain conditions however. Provided that such projections of the future will be actually performed, incorporated and eventually mainstreamed in a given real social context. This communication will stress on the "reception" and appropriation processes of such visions in order to better understand such processes related to "real" conditions of innovations insertion/co-evolution. Based on selected case and field studies we will show that these are indeed deeply anchored in a particular historical, social and evolving context of a given Society and, as such, that Home Energy related innovations are hybrid and co-shaped devices resulting from of an intertwined process of innovation and social incorporation. By nature this process is dynamic, multi-scale and multi-players. After questioning the way most current policies and measures are formulated, as well as their main underlying assumptions illustrated by such notions as "public acceptance" or "social acceptability", we will pledge for a move towards broader and more suitable concepts. We will use some key-notions mainly derived from practice-based theory as applied to energy field, in order to develop concretely our argument through concrete and socially contextualise field studies. We will finally open up the discussion about how we could (should?) think and found differently Energy related policies in order to make them more efficient and impactful.

O-3317-02

International Consultation on Consumption Patterns for Sustainable Development

CRSM. Souza (1) ; M. Poppe, (2) ; ACF. Galvão, (3)
(1) Centre for Strategic Studies and Management in Science, Technology and Innovation (CGEE), Sustainable development, Brasília – DF, Brazil; (2) Centre for Strategic Studies and Management in Science, Technology and Innovation (CGEE), Sustainable development, Brasilia – DF, Brazil; (3) Centre for Strategic Studies and Management in Science, Technology and Innovation (CGEE), Brasília – DF, Brazil

The current debate on the post-2015 development agenda and the sustainable development goals leads to a discussion of crucial points related to the definition of pathways for sustainable development, which must take into consideration how citizens, businesses and governments consume and how such patterns of consumption can be changed. With this in mind, the Brazilian Center for Strategic Studies and Management (CGEE) in cooperation with the Akatu Institute for Conscious Consumption, the Brazilian Business Council for Sustainable Development (CEBDS), the Institute for Sustainable Development and International Relations (IDDRI), the Institute of Research and Development (IRD), the Swedish Agency for Growth Analysis, the United Nations Economic Commission for Latin America and the Caribbean (ECLAC) and the World Centre for Sustainable Development (Rio+ Centre) organized the present international web-based consultation on consumption patterns for sustainable development. The consultation was addressed to a select group of people from academia, government, civil society and business sectors.

Agenda 21, adopted in 1992 at the United Nations Conference on Environment and Development (Rio 92) stated that "the major cause of the continued deterioration of the global environment is the unsustainable pattern of consumption and production" and recommended "a multipronged strategy focused on demand, meeting the basic needs of the poor and reducing wastage and the use of finite resources in the production process". In 2012, world leaders once again met in Rio de Janeiro to attend the United Nations Conference on Sustainable Development (Rio+20). The conference outcome document, «The Future We Want», reaffirmed the commitment to fully implement Agenda 21 and called for the construction of Sustainable Development Goals (SDGs) to go beyond the Millennium Development Goals (MDGs) and frame the path to sustainable development.

The survey intends to contribute to the ongoing international negotiations for the definition of the SDGs at the United Nations. This process represents an important stepping-stone towards the creation of a global model for sustainable development. It should engage and establish commitments for both developed and developing countries, as well as balance the social, economic and environmental dimensions of sustainable development, including the challenges presented by a changing climate. Therefore, the objective of the consultation is to map out society's perceptions on issues pertaining to consumption patterns in the context of sustainable development and climate change to enable a comparison of the different views, as well as to identify commonalities, in order to help bridge knowledge and information gaps that may arise in the negotiation of the SDGs and of a new international treaty on climate change in 2015.

O-3317-03

Mainstreaming low-carbon consumption: Opportunities, challenges and promising policy approaches

B. Girod (1)
(1) Group for Technology and Sustainability, ETH Zurich, Zurich, Switzerland

Consumption-oriented climate mitigation approaches account for all emissions caused by regional consumption (including imported goods), while production-oriented approaches account for all emissions attributable to regional production (including exported goods). Although currently the production-oriented approach is predominantly applied in climate policy, the consumption-oriented approach offers several advantages. These include lower carbon leakage and reduced economic competitiveness concerns over the relocation of carbon-intensive production to regions without climate mitigation requirements. However, addressing emissions via consumption also comes with several new challenges. Policies aiming at radical changes in consumption patterns or reduction of consumption levels suffer from low public acceptance. The consumption-oriented policies with the highest acceptance are those that favour changes in consumption choices towards low-carbon products such as electric cars, net zero energy buildings or sustainably produced food. These policies still face three major challenges: First, they have to account for increasing consumption levels (rebound effects). Second, emissions embodied in the products (life-cycle emissions) need to be considered. Finally, the choice of policy instruments is limited by the path dependence of policymaking as well as the feasibility and public acceptance of the different instruments.

To address these challenges, a policy framework is developed that indicates how the carbon intensity of consumption could be reduced in line with the international climate target. The framework shows how the 2 degree climate target can be translated into carbon intensity targets for products. Comparing these targets with existing low-carbon products indicates that products in line with the required emissions reductions for 2050 are available for the main consumption categories (food, shelter, mobility, goods and services). Hence, to achieve the carbon intensity targets on the product level, the timely diffusion of existing low-carbon options is key. The framework therefore also describes how such carbon intensity targets can be achieved by describing the stylized development of consumption-oriented policies that were successfully implemented in the past. These include policies for mainstreaming low-carbon cars, energy-efficient buildings and appliances as well as sustainable timber products in the European Union. Learning from these policy experiences suggests that successful policy development is a stepwise process towards increasingly stringent standards. The stepwise increase in stringency typically starts with voluntary and information measures. Public procurement and financial incentives contribute to further diffusion of the low-carbon products. This provides the basis for introducing binding standards, which are then regularly tightened. Once established, standards can

also be extended to include additional products and may become more comprehensive (e.g. also include other life-cycle emissions).

The framework helps guide future policymaking and allows the identification of the type of scientific research and policy support required to extend and improve consumption-oriented climate mitigation policy. While in the area of meat consumption and air travel the development of low-carbon innovations is necessary to provide low-carbon consumption options, most other consumption areas call for the mainstreaming of existing low-carbon options. Thus it is essential to achieve a better understanding of how to accelerate the development towards low-carbon standards for all consumption categories. International climate policy can foster this development by supporting the harmonization of carbon footprint norms for products. This will help to guide low carbon consumption, enhance conformity with international trade and facilitate the extension to embodied emissions of existing consumption-oriented climate policy.

Carbon emission mitigation by Consumption-based Accounting and Policy (Carbon-CAP)

Current climate policies are mainly shaped via territorial emission reduction approaches. Yet, growing consumption is a main driver behind rising greenhouse gas (GHG) emissions. Further, our economy is increasingly a single, global economy: international trade has risen threefold since 1990 implying pollution embodied in trade is now responsible for a significant part of total GHG emissions. Complementing territorial mitigation approaches with policies from a consumption oriented perspective hence can have added value. They can explicitly address consumption as a driver for rising GHG emissions, next to the problem of carbon leakage. However, there are significant questions about consumption based carbon accounting (CBCA) systems (Gap 1: CBCA reliability) and demand side policies (effectiveness (Gap 2) and societal impacts (Gap 3)). Stakeholders hence can easily question their added value (Gap 4).

The Carbon-CAP project aims to (1) stimulate innovative European and international demand side oriented climate policies and services due to more reliable and improved shared insights about consumption based GHG emissions, and (2) to realize a more effective policy mix for achieving the objectives of the EU Climate and Energy package and the Roadmap for moving to a competitive low carbon economy in 2050, by quantitatively analyzing the added value of consumption-oriented climate mitigating polic ies.

Carbon-CAP will deliver insights in reliability and uncertainty in Consumption based carbon accounting (CBCA) and recommendations for an approach for implementation of a robust, reliably system for CBCA. A recommendation which demand side policy instruments have most added value in complementing existing territorial mitigation approaches, with their environmental and economic implications tested via three modelling perspectives.

This presentation will be part of our process of interactive learning between the project team and key players in the policy area. We will present our intermediate findings and will stimulate discussion and reactions in order to fine tune our approach and outcomes.

Designing and experiencing social practices in LivingLab environments - A novel approach to transform routinized behaviour via materialized social innovations

C. Liedtke (1) ; C. Baedeker, (1) ; J. Buhl, (1)

(1) Wuppertal Institute for Climate, Environment and Energy, Sustainable production and consumption, Wuppertal , Germany

In recent years, theories of social practices have gained a lot of attention in the analysis of consumption. Social practices are the locus of the social, where action and structure are mediated. Social practices as a routinized type of behaviour consist of several elements, interconnected to one another: forms of bodily activities, forms of mental activities, 'things', and their use, a background knowledge in the form of understanding, know-how, states of emotion and motivational knowledge. In a nutshell: The interaction of material, skill and meaning. Social practice theories are just ideal for analysing routine behaviour. Thus consumption is not a practice itself but rather engaging in many practices requires a certain level of consumption of goods or services. Styles of consumption are interwoven with social practices of certain activities but also with daily routines i.e. in households. Consumers combine a number of different practices related to nutrition, mobility or housing and form them into lifestyles. The materials element shows how practices are directly or indirectly related to resource use for objects or infrastructures needed to engage in a given practice. Continuous engagement in a practice, rising numbers of practioners and differentiation thus keeps the engine running for continued extraction of natural resources. In order to observe, analyse and eventually identify promising interventions to support sustainable transitions of social practices, we developed a coherent research framework – the Sustainable LivingLab (SLL). In principle, a SLL is a user-centric innovation approach built on every-day practice and research, with an approach that facilitates user influence in open and real-life contexts (i.e. in households), aiming to create sustainable values and practices. Therefore, SLL approach builds on social practice theory for two reasons:

i) Social practice theories are ideal for analysing routine behaviour related to a specific case study, e.g. heating.

ii) Design processes with regard to user practices make it easier to spread sustainable social innovations such as novel product service systems (PSS). Studies in failed innovations have shown that the benefits of eco-designed products, technologies or infrastructures are hardly realised if designed without reference to user practices. In this sense, SLL aims to identify the potentials of PSS innovations to embrace social innovation . In order to employ a SLL research approach, we developed a three-phase- research design.

1) The first phase of insight research involves understanding the status quo. How do practices look like. For instance, how do people heat, how do people interact with their heating system? Which interpretative schemes do people show towards internal room temperatures? Which routines do persist unreflected? Insight research applies in-deep methods of social research. Data logging is accompanied by qualitative interviews and observations of daily routines.

2) Based on the findings from insight research, the prototyping looks out for ideas of sustainable interventions in practises. The objective is to generate ideas and to integrate participants' knowledge into the design of prototypes. PSS and transformational designs may be developed for different types of households that demonstrate rather adverse practices. Instead of automating processes, PSS or transformational designs intervene in practices and behaviour at the right spot (i.e. leaving the heating on while a window is open). We aim to trigger social learning process and support users to reflect upon their actions.

3) In addition, the prototypes developed can be validated using experimental designs and field testing via installing prototypes in a sample of households and log potential change in practices, e.g. in internal temperature or CO2 concentration. Field testing can be complemented by broad-based survey or agent based modelling. A mix and

combination of methods helps to generalise and validate small scale experimental field tests to a larger scale, such as urban transitions in quarters or cities.

The LivingLab approach and its three-phase model (insight research, prototyping, field testing) fits well for action and participatory oriented research. The methodology of research on sustainable consumption benefits substantially from experimental settings, its in-deep research of social practices and corresponding development of transformational designs. Results of action research and design will be presented.

Green Investment and Business Performance: The African Experience

OJ. Professor Adelegan (1) ; J. Adelegan (2)

(1) Lead City University, Economics, Ibadan, Oyo State, Nigeria, Federal Republic of; (2) Global Network for Environment and Economic Development Research, Department of Environment and Sustainable Development, Ibadan, Oyo State, Nigeria, Federal Republic of

Addressing a paucity of research about industrial adoption of environmentally benign technologies in Africa and, more generally, in tropical developing countries, we examined the Nigerian pulp and paper industry as a case study. Qualitative interviews with twenty upper echelon executives representing five Nigerian firms challenge conventional expectations that energy intensive industries in developing markets operate amid highly pollution-intensive conditions, within weak or non-existent formal environmental regulatory frameworks, and with limited institutional capacity. Our findings suggest a strong positive relationship between cleaner technology use and corporate financial performance of African industrial firms. Our study also suggests the adoption of classical 'win-win' integrated preventive environmental strategy, eco-efficiency and green productivity which improves industrial efficiency and profitability. Nigerian pulp and paper firms are shown to have moved beyond end-of-pipe technologies and cleaner technologies and adopted industrial ecology and "zero emission" principles with appropriate reuse of the remaining waste streams turning the production system into a sustainable industrial ecosystem.

Green Cities: Benefits of Urban Sustainability

EHM. Ahmed (1)

(1) Lead Author, WG III, IPCC, climate change and sustainable development, Cairo, Egypt

In the wake of the global financial crisis 2008-2010, the concept of a green economy was provided with fresh impetus following wide-spread discussions on a "Green" New Deal, to enable a "Green Recovery". Large investments were seen as necessary to support the recovery of the world economy. These financial investments offered an opportunity to invest in green economy sectors.

Nowadays many developed countries adopted the Green Cities concept as a new tool to face the environmental impacts in general, and the climate change impacts in particular.

With mainstreaming climate change concerns attention the world to adopt a new strategy for urban cities, we heard raising voices that asking to take GHGs reduction in account during the implementation of a new urban cities.

Regarding to the environment point of view, we have to take care about the whole natural sources we have, not to forget sustainability while we're looking for development.

Green building that the usage of a natural or green materials in its structure; saving and reduce of other resources as lighting, water consumption and waste management are the main concern to get Green Cities.

The increase of productivity of workers in green buildings could achieve labor-cost savings that maybe higher than energy cost savings; challenge in developing countries is doing away with subsidized, non-cost-reflective energy prices; the quality of life and health care are also equally significant.

City governments need to coordinate policies and decisions with other levels of government, but more importantly, they need to be equipped with strategic and integrated planning capacities. In poorer cities, the building up of such capacities is important, as is their access to financial resources for investing in the various sectors of green cities. Here it may be more prudent to adopt a more pragmatic and minimalist approach, which primarily commits municipal sectors such as water, waste, energy and transport to a limited number of overarching strategic goals.

P-3317-03

Breaking Bad: Why We Need to Target Implicit, Automatic Associations in the Fight against Climate Change

G. Beattie (1) ; L. Mcguire (2)

(1) Edge Hill University, Psychology, Lancashire, United Kingdom; (2) Edge Hill University, Psychology, Lancashire , United Kingdom

There is growing recognition of the role of consumer behaviour in the dramatic increases in global CO2 emissions and, consequently, more awareness of the critical role of consumers as a major influence on climate change itself. Some leading international figures from the commercial world have proposed that we need nothing short of a 'green revolution' in consumer behaviour to deal with the threat posed by climate change. The argument is that consumers opting for low carbon alternatives would drive demand for more environmentally friendly products, and impact on manufacturing and production with significant environmental consequences. Furthermore, many leading figures have argued that the public are ready for this 'green revolution' as they report in numerous surveys that they are keen to adapt their behaviour to mitigate the effects of climate change. This has led to campaigns in a number of countries to reduce energy use, to promote greener transportation, to highlight lower carbon footprint alternative products etc. The carbon labelling of products to guide consumer choice has now been rolled out in a number of countries, at very significant financial cost. However, these everyday consumer habits seem strangely resistant to change and many governmental, commercial, and educational campaigns have not had the desired, or anticipated, effects on actual consumer behaviour and consumer choice. For example, using eye tracking technology we found little actual gaze fixation on carbon labels on products compared to gaze fixation on the other information that features on such products (see, for example, G. Beattie, 2012, How effective is carbon labelling for the consumer? Nature Climate Change, 2, 214-217). One reason for the overall pattern of disappointing results on behavioural change in this area might be that there has been too much focus on assessing and changing explicit, self-reported attitudes rather than on more implicit attitudes, formed on the basis of underlying associative connections. For example, for years, many people have learned to associate high carbon lifestyles with societal success (partly, of course, attributable to advertising) and this association can affect actual behaviour regardless of more rational decision making about adaptation and climate change. These implicit attitudes can now be measured using the Implicit Association Test (or IAT) and outcome measures from the IAT seem to predict the attentional focus of consumers, amongst other things, in a way that self report measures do not. In this paper, we will outline new experimental data on this topic, which examines the relative importance of implicit and explicit attitudes in determining consumer choice in which the environmental consequences of the various choices are made clear to shoppers through the inclusion of various environmental labels, including features like carbon footprint, organic and Fairtrade. The research also considers other critical variables like the influence of choice under time pressure, the social context of the behavioural choice, and relevant budgetary concerns. The research demonstrates that underlying implicit attitudes are a better predictor of actual consumer choice in supermarket shopping, especially under certain circumstances, like time pressure, where the behaviour

becomes more 'automatic', and less reflective. The paper will argue that it is crucial to understand how such implicit attitudes originate and evolve if we are to deal more effectively with anthropogenic climate change. This should provide us with a more promising start point for changing resistant consumer habits, in order to attempt to reposition consumers at the centre of the necessary 'green revolution'. In this paper, we will also outline a number of particular approaches to changing these automatic, implicit attitudes, which have worked in a number of related domains, which could have a significant effect in the area of climate change.

Yves Rocher's experience: 50 years of commitments to the preservation of the environment

A. Blain (1)
(1) Groupe Rocher, sustainable development, Issy-Les-Moulineaux, France

Yves Rocher is a one-of-a-kind Brand, created over 50 years ago, that has chosen to master every aspect of its operations: Botanist, Harvester, Manufacturer and Retailer. This specificity enables the Brand to manage all the fields in its business and therefore to reduce its environmental impact at every stage of its products' life cycle.

With half a century of experience in Botanical Beauty, Yves Rocher sources almost 250 plant ingredients with a strategy based on 3 pillars: responsible sourcing, protection of natural resources and local communities, sharing of the benefits resulting from the use of plants. Yves Rocher created its Botanical Charter, illustrating its commitment to the preservation of Biodiversity. Since 2008, Yves Rocher has also actively participated in the Natural Resources Stewardship Circle (NRSC), organization of manufacturers from the beauty industry working together for a sustainable management of biodiversity in supply chains.

Besides, new exclusive active principles are created and developed every year by the Yves Rocher R&D teams, using the most environmentally-friendly extraction technology. Formulation guidelines have been implemented, and Yves Rocher, as a forerunner in the cosmetics industry has banned since 1989 all animal testing for its products and ingredients.

Furthermore, Yves Rocher eco-designs 100% of its packagings, reducing non-renewable resource consumption, designing packagings that can be recycled at existing facilities and encouraging customers to sort their packaging waste. In order to accompany teams engaged in product development, Yves Rocher developed «eco-design packaging guidelines». This tool is updated annually and is shared by marketing, purchasing, development and R&D teams. It provides instructions to follow in terms of eco-design for Yves Rocher products.

Yves Rocher industrial facilities fight global warming by reducing their fossil energy consumption, promoting renewable energies (wood-burning heating in Britanny, saving about 1600t of CO2/year), reducing CO2 emissions (-10%g CO2/product since 2010), improving water efficiency (-19% water consumed/t of bulk produced since 2010).

Since 2010, Yves Rocher has integrated biodiversity management to the company's strategy. In Brittany, 100% of the Yves Rocher industrial sites are « havens of Biodiversity ». The Brand is also a genuine Biodiversity Ambassador, hosting more than 3000 participants/year at its awareness events and programs at the Botanical Garden and its own Eco-Hotel Spa.

Environment preservation is at the heart of the Yves Rocher strategy with the support of the Yves Rocher Foundation, in order to leave a positive footprint:

Yves Rocher aims at establishing a new relationship to nature, acting with responsibility towards natural resources and being a biodiversity ambassador to its employees and its 30 million customers throughout the world.

The Yves Rocher Foundation created in 1991 by Jacques Rocher is a pioneer in positive ecology, and strives to transform the way we interact with our Planet. The Foundation- Institut de France acts through 4 sustainable programs that promote plant biodiversity through concrete initiatives in more than 50 countries throughout the world.

Through its "Plant for the Planet" program, the Yves Rocher Foundation will achieve its target of 50 million trees planted by the end of 2015, across about thirty plantations worldwide. This program is supported by the Yves Rocher brand thanks to the sales of partner products to customers and to the opening of loyalty cards to customers (1 product sold/1loyalty card created= 1 tree planted by the Yves Rocher Foundation).The Women of the Earth Award was created in 2001 to reward women for their environmental action, initiative and fight. Today, 350 women across 50 countries have received awards.

In 1992, Yves Rocher counted among the four French companies invited to the Rio Earth Summit, and Jacques Rocher, advocated the cause of forests with the «Call for tropical forests", a petition signed by 300,000 customers. Yves Rocher has also been actively involved into the UN Convention of Biodiversity and UNCTAD, and testified in the COP 10 in Nagoya in 2010, COP 11 in Hyderabad in 2012, UN Business and Biotrade events in Montréal and Geneva in 2013 and COP 12 in Pyeong-Chang in October 2014. Climate change is more than ever an urgent issue. Yves Rocher shall keep-on working to reduce its environmental footprint at every step of its value chain, in order to leave a positive footprint.

P-3317-05

Understanding the « spirit » and legitimation of Green Economy, from selective to stabilized discourses. (provisional title)

C. Serre (1)
(1) Université de Lausanne (UNIL), Institut de Géographie et Durabilité (IGD), Lausanne, Switzerland

In this paper I present an aspect of the work I am currently conducting on the performative character of the green economy (GE) and the discourses produced around this theme. I study the emergence and the impacts of the GE guidelines on environmental policies, e.g. the set of representations, discourses and practices adopted and embedded by the GE actors. According to those promoting it, GE is the path favored to accomplish sustainable development within the current context of environmental and socioeconomic global crisis. While this notion stands as a common reference for an increasing number of initiatives, a stabilized and commonly shared definition is still lacking in economic theory as well as across the international community. In fact, «in line with sustainable development and biodiversity, this notion is poorly defined enough and polysemic to be apparently the object of consensus» (Chartier and Foyer, 2012, personal translation). In fact, GE can be considered as both a discursive and socio-economic construction, as it covers a multitude of meanings that change over time and space. This is evidenced by the rhetoric deployed around this notion, showing that actors internalize different aspects of the notion depending on their interests and preferences. Actors sometimes refer to the environmental economics principles and sometimes those of ecological economics. However, the language used is indicative of different and even contradictory views of economy, human well-being, growth, environment, etc. «Green growth», "sustainable development", "green societies", «green investments», «green deal", etc., are frequently associated with the theme of GE. Utilizing a Foulcadian perspective, I question how GE discourses contribute to giving GE an existence in forming the objects of which they speak. Thus, the analysis of GE discourses through their form and content is crucial. Although drawn from ongoing research, this contribution will demonstrate preliminary findings and present one of the questions that frame this work: what do the merging and spreading of green economy rhetoric, discourses and representations tell us about the (nature of the) relationship between environment and economy, and more globally, capitalism? I consider discourse as "an ensemble of ideas, concepts and categories through which meaning is given to social and physical phenomena, and which is produced and reproduced through an identifiable set of practices" (Hajer and Versteeg 2005). In this light, discourse is seen as a social construct and a particular assemblage of discursive elements that structures realities and allows actors to understand their world. As Fairclough (1993) underlines, the role of discourse is not just of representing realities, "but of signifying the world, constituting and constructing the world in meaning". My

research explores the performative character of GE within the wider research project I am currently conducting, which aims to analyse whereby GE could contributes to (i) a shifting-produced process in the hegemonic capitalist model or, in contrast (ii) keeping, sustaining and reinforcing the capitalist dynamic ideologies through new register of justification and a new spirit in the terms of Boltanski and Chiapello (1999). In order to investigate the potential dynamic of change or continuity of the GE notion on environmental policies, the identification of the different storylines (Hajer, 2005 ; Dryzek, 2005) helps to map the discourses that encapsulates key ideas of GE. In my study, I assume that a particular and selected vision of the world is carried out through GE rhetoric and discourses, conveying imaginaries of hope and functioning with speculative argumentative thinking. To illustrate that, I will first trace the discursive and socio-historical co-construction of the GE notion through its evolution in time and space. I will then present an analysis of selected institutional discourses attempting to make sense of the different ways and options proposed to envision a "happy marriage" (Goldstein, 2014) between environment and economy: presented through "green" options and promoted via positive and appealing discourses, these propositions justify adjusting present actions to the GE promise, e.g. the increase of economic growth as "a path towards planetary salvation" (ibid). Considering how such a vision comes to be justified and formulated, gains prevalence over others and finally unfolds as coherent understandings of socioeconomic realities, prefigures in my view an attempt to construct a growing sense of belonging to a common future. Indeed, I assume that ontologies of the world are renewed through selected, then stabilized discourses and "self-evidence" (Vadrot, 2013).

P-3317-06

Obstacles: Social practice in everyday life

B. Steffensen (1)
(1) University of Applied Sciences Darmstadt, Social Sciences and Social Work, Darmstadt, Germany

"Can the Green Economy save the climate?" The answer is simple at the moment – it is: No!

To explain the strict answer I tell a short story which happened during the turn of the year from 2012 to 2013. The story: I regularly buy a coffee in the cafeteria of our student union. In December 2012 I paid for a cup of cappuccino € 1.20. Coming back after Christmas Break I was looking forward to drink my regular morning cappuccino which now costs € 1.50. Astonished about the 25% price increase I asked the till girl: "Why is the price so much higher now?" She replied: "The students' union executive body decided last autumn that they want us to provide fair trade coffee. Therefore, you get a better coffee now and that makes it more expensive!" "Oh", I said and started to think:

1. What is the price difference between a standard and a fair trade coffee?
2. How many cups of coffee does one get out of a 500gr-package of coffee?

A visit to my local supermarket revealed a price difference of about € 3.00 per package. Due to economies of scale the price difference is certainly smaller for the cafeteria. I calculated that a package of coffee will provide approximately 50 cups of cappuccino. The price increase for introducing fair trade coffee (by the way: the new and better coffee doesn't really taste or look different) should be € 0.06. My conclusion: The student union tried to make an additional profit of € 0.24. Student's protests lead them to lower the price to € 1.35. Let's accept that the additional € 0.09 covered a wage increase for the till girls. This is definitely not a scientific proof but it is an evidence for a practice of many firms.

Since the 1980 it is an established idea in the marketing literature that the green consumer will show up with increasing importance for producers and retailers. The growth rates during the last decades were disappointing and the marketing of green products was more or less a failure. But firms were successful in one aspect: Consumers are absolutely sure that green or sustainable products are imperatively more expensive than ordinary products. That the difference between ordinary and green products in many cases boils down to mere credence characteristics and only in some case to search or experience characteristics doesn't make it easier.

The multi-level approval of the transitions theory (Geels; Kemp; Shove and others) conceptualizes a transition process – i.e. towards a green economy – as a joint effort of a variety of different actors. It needs at least politicians, sometimes scientists, producers, retailers and consumers (individual households or firms in a supply chain) who have to act reciprocally and with a common interest without knowing for sure what the other will do: "do ut des!" Producers and retailers have to take entrepreneurial risks by producing "green" – consumers have to believe and trust in credence characteristics of products by consuming "green". Our own research about environmental friendly products doesn't reveal a lot of trust on both sides. In the transition from grey to green (recognizable by labeling schemes) reciprocity seems to be crucial.

One important factor in the transition process is the aspect of culture which includes norms, daily routines and taken for granteds. According to Anthony Giddens and others (Schatzki, Reckwitz, Bourdieu, Strengers, Wenger) we rely on social practices which are shaping our everyday actions. Decisions and actions of firms and individuals are based (1) on own experiences (formerly successful actions), (2) on recognized actions and decisions of relevant others, (3) on our expectations of the expectations of relevant others. Furthermore, the leeway to change behavior is (4) limited because preceding decisions and actions are binding and changes might be costly.

Conclusion: The green economy is an ambitious project which requires a massive transition. To save the climate needs a shift of the mindset of the actors mentioned above. It requires a change of routines and a growth of trust. Considering the theory of practice as an option to conceptualize routine and somehow repetitive behavior the contribution shows limits and possibilities for actually generating a transition.

3318 - Sustainable strategies to mitigate climate and improve public health in developed and developing countries

Norway's knowledge platform on SLCFs – holistic thinking and multiple benefits for climate change and air quality

V. Vestreng (1) ; MM. Kvalevåg (1) ; S. Guttu (1) ; SF. Skjellum (1)
(1) Norwegian Environment Agency, Climate department, Trondheim, Norway

Short-lived climate forcers (SLCFs) are a relatively new field in a governmental context. In 2013, Norway published its first knowledge platform on SLCFs. The key objective was to perform an integrated assessment of climate, health and environmental effects of Norwegian emissions of SLCFs and propose measures and instruments for reducing such effects by 2030. Achieving the 2-degree target relies on substantial CO2 reductions. The Norwegian knowledge platform focuses on how measures targeting SLCFs could complement CO2 mitigation measures.

The scientific knowledge was quite immature and developed rapidly in parallel with the Norwegian Environment Agency's assessment. This paper outlines methodological challenges and how these were approached to establish a framework for the analysis of measures. The development of different reduction strategies for consideration by the Norwegian Ministry of Climate and Environment, are discussed. The choice of metric to compare the climate effect of different SLCFs was a key to our analysis. Development of national BC

and OC emission inventories and valuation of health effects were other essential building blocks to enable an integrated assessment of measures. Calculation of the net climate effect of measures, i.e. taking into account both warming and cooling effects of emission reductions, is also important.

The results show that in the short term, the climate effect of Norwegian annual emissions of SLCFs is comparable to that of CO2. Measures aimed at SLCFs cannot replace CO2 measures in either the short or the long term, but reduced emissions of SLCFs will reinforce the global climate benefits of rapid reductions in CO2 emissions. Thus, both SLCFs and CO2 emissions should be mitigated in order to reduce the rate of warming over the next decades.

In some cases, we found that measures with a positive health impact had a negative climate impact. Our study concludes that integrated approaches to assess climate change and air pollution may form a better basis for policy development. Currently, the Norwegian Environment Agency is considering how the SLCFs best can be included in the analysis of greenhouse gas reductions.

K-3318-02

Improving health by acting on air pollution and climate change: the challenges faced by Chinese cities

T. Li (1)
(1) Chinese Center for Disease Control and Prevention, Institute for environmental health and related product safety, Beijing , China

As the most iconic example of the air pollution and climate change in the world, China has experienced an economic expansion during the past decades which has led to a dramatic increase in emissions of both ambient pollutants and greenhouse gases. Heavy air pollution and temperature warming has been observed in China over the past century. China is also the biggest country for its population, and is confronted with the most rigorous aging population problem in the world. Global warming and aging are emerging 21st Century challenges. In addition, haze and heat are two major threads for public health in Chinese cities, as illustrated by the situation in Beijing. The haze pollution in Beijing became more and more serious in recent years. One of the worst episode in January 2013 lead to significant excess mortality. Between January 17 to January 31, at least 164 persons died because of high PM2.5 concentrations. Respiratory and cardiovascular diseases were especially sensitive to PM2.5. Reducing PM2.5 could therefore significantly improved health and well-being in Chinese city.

We also investigated the health risk tradeoffs among heat, population aging, and adaptation under a changing climate by integrating the full range of the climate models. We estimated the exposure-response relationship between observed daily mortality of persons 65 years of age and older and the temperature data in Beijing. Then, we obtained downscaled future temperature projections from 31 climate models and two future representative concentration pathways (RCPs) scenarios for Beijing. These two inputs were then combined to estimate future mortality related to heat effects, which were compared to heat-related mortality in the baseline period (1980s). Last, we incorporated population projections under three variant scenarios and the different heat adaptation scenarios to the above two inputs to project the changes of future heat-related mortality.

Under the population high variation scenario, in the 2080s and RCP8.5, Beijing was projected to experience a median of 15894 heat-related deaths per year of persons 65 years of age and older, which is approximately 6 times the projected value for the population without variation scenario. In the 2080s, with the biggest adaptation (under the 30% adaptation scenarios), the increase in heat-related death is approximately 7.4 times and 2.6 times larger than in the 1980s in RCP8.5 and RCP4.5 respectively.

Aging population will enlarge the heat-related health risk under the warming climate. Even under the high adaptation scenario, by the 2080s, the heat-related deaths would still increase. Our results provided evidence that adaptation would diminish the magnitude of future heat-related health risk, but not completely offset the heat impact from climate change. Our findings can lead to improved understanding of public health intervention policy making and adaption strategy planning for the dual problems of climate change and aging population.

O-3318-01

Mitigating air pollution to achieve health and climate benefits

P. Kinney (1)
(1) Columbia University, Mailman School of Public Health, Climate and Health Program, New York, NY, United States of America

Air quality is a major modifiable health burden around the world, especially in rapidly developing cities. Exposure to air pollution, including fine particles (PM2.5) and ozone, has adverse effects on human health throughout the lifespan. Adverse effects of air pollution include the development of chronic diseases such as lung cancer, chronic heart and lung diseases, as well as adverse effects on the reproductive system and on neuro-development. Action to mitigate air pollution brings immediate and lasting benefits for the health and well-being of the population. In addition, well-designed air pollution mitigation actions have the potential to reduce societal impacts on the climate system. In order to inform global, regional and urban scale air pollution and climate planning, there is a need for multi-scale health impact assessments that estimate the potential health impacts and/or benefits that may result from coordinated mitigation strategies. We describe several such recent and/or ongoing efforts of this kind. For example, the recently-completed AC-HIA project estimated the influence that policies aimed at reducing air pollution emissions could have on global, regional and urban public health in 2030 and 2050, compared to 2010, taking into account the influence of climate change and alternative air pollution mitigation scenarios. Assessments were carried out across three different geographic scales with increasing spatial granularity, for the entire world, for Europe, and for the Paris metropolitan region. To mitigation scenarios were evaluated: a business as usual scenario based on national regulations already on the books, and a maximum feasible reduction scenarios based on available technologies for air pollution control. The results showed the potential for substantial increases in global deaths due to PM2.5 and ozone under the business as usual scenarios, especially in south and east Asia. On the other hand, substantial health benefits could be achieved under the maximum feasible reduction scenario. In general, health assessments carried out at finer spatial scales yielded greater health benefit estimates. This and other studies are pointing the way to a new generation of tools for integrated air quality and climate planning.

Health and climate dual impact of African anthropogenic combustion aerosol emission change in 2030

C. Liousse (1) ; L. Roblou (1) ; EM. Assamoi (2) ; M. Mallet (1) ; P. Criqui (3) ; C. Galy-Lacaux (1) ; R. Rosset (1)
(1) Laboratoire d'Aerologie, CNRS-Université Paul Sabatier UMR 5560, Toulouse, France; (2) University Felix Houphouet Boigny-Cocody-Abidjan, Physic, Abidjan, Ivory Coast; (3) CNRS and ANCRE, Pacte-edden, Grenoble, France

Fossil fuel (traffic, industries) and biofuel (domestic fires) emissions of gases and particles in Africa are expected to significantly increase in the near future, particularly due to a rapid growth of African cities and megacities.

In this study, we will present the most recent developments of African combustion emission inventories, including African specificities. A regional fossil fuel and biofuel inventory for gases and particulates described in Liousse et al. (2014) has been developed for Africa at a resolution of 0.25° x 0.25° for the years 2005 and 2030. For 2005, the original database of Junker and Liousse (2008) was used after modification accounting for updated regional fuel consumption and emission factors. Two prospective inventories for 2030 are derived based on Prospective Outlook on Long-term Energy Systems (POLES) model (Criqui, 2001). The first one is a reference scenario (2030ref) with no emission controls and the second one is for a «clean» scenario (2030ccc*) including Kyoto policy and african specific emission control. Our results

predict very large increases of pollutant emissions in 2030 (e.g. contributing to 50% of total anthropogenic organic particles), if no emission regulations are implemented.

These inventories have been introduced into RegCM4, a regional climatic model. In this paper we will focus on modelled aerosol concentrations and optical depths in 2005, 2030ref and 2030ccc* scenarios. Spatial distribution of aerosol concentrations will be presented with a zoom on a set of urban and rural sites. Finally, aerosol radiative forcing and impact on mortality rates caused by anthropogenic PM2.5 pollution increase from 2005 to 2030 will be shown for each scenarios.

To conclude, this paper will discuss the effectiveness of scenarios to improve emissions, aerosol concentrations, radiative forcing and mortality rates, underlining the need for further measurements, scheduled in the frame of the on going DACCIWA program (EU FP7).

The Importance of Revising Indonesia NAAQS for the Local Health Benefits and to Mitigate GHGs

H. Yulinawati (1)
(1) Universitas Trisakti, Jakarta, Indonesia

Indonesian government actively joins in efforts to reduce global GHGs emissions. Various regulations were issued such as Presidential Decree No. 61 of 2011 on the National Action Plan to Reduce Emissions of GHGs and Presidential Decree No. 71 of 2011 on the National GHGs Inventory System. Unfortunately, local air pollution issues seem left behind, even until these days many big cities in Indonesia do not have an adequate integrated air quality management, such as limited emission inventory, the NAAQS is not well enforced, and lack of monitoring equipment. Black carbon (BC), a constituent of fine particulate matter (PM2.5), and tropospheric ozone (O3) are harmful air pollutants associated with premature mortality that also contribute to global climate change. Recent study shows that BC and O3 emission reductions would have immediate and multiple benefits for human health. Therefore, policy designed to reduce GHGs can have co-benefits for air quality or vice versa. This study examines the current Indonesia NAAQS 1999 compared to WHO AQG 2005, mainly on particulate matter (PM) and O3. This study also evaluates ambient monitoring data of PM and O3, and Indonesia's current emission control measures targeting BC and ozone precursor. By linking these three issues above, this study simulates the impacts of mitigation measures on ambient concentrations of PM2.5 and O3 to calculate their associated changes in health-related benefits. The WHO AQG 2005 for PM2.5: 10 µg/m3 annual mean; 25 µg/m3 24-hour mean. While for PM10: 20 µg/m3 annual mean, 50 µg/m3 24-hour mean. As comparison, Indonesia NAAQS 1999 for PM2.5: 15 µg/m3 annual mean; 65 µg/m3 24-hour mean. For PM10: annual mean is not available, 150 µg/m3 24-hour mean. The WHO AQG 2005 provides interim targets as an approach to achieving the air quality guideline value. Indonesia, with higher levels of air pollution, should select a clear achievable interim target level based on air quality infrastructure. There is a substantial lack of monitoring stations for both PM2.5 and PM10; most monitored PM in Indonesia is TSP. It is very limited epidemiology studies related to air quality too. Therefore, it is not easy to show the health benefits of mitigating emissions of air pollutants and GHGs. Some mitigations exist such as emission control from industrial stacks, I/M, public transportation, and relatively new discourse on low-carbon infrastructure. Revising Indonesia NAAQS is needed to make sure public health is guaranteed. Air quality and health co-benefits, because they are mainly local and near-term, offer better motivation for transformation to a low-carbon paradigm. It will be easier to set the target to mitigate the GHGs related to air pollutants.

Health co-benefits and co-harms of reducing indoor air-pollution in Sub Saharan Africa

R. Kawan (1)
(1) Institute of Public Health (IPH), Climate change and Health, Im Neuenheimer Feld,324,heidelberg, Germany

Local air pollution harms health

Household use of solid fuel is the most widespread source of indoor air pollution worldwide. Globally, 2.6% of all ill-health is attributable to indoor smoke from solid fuels, nearly all in poor regions. Solid fuels are extensively used for cooking and home heating in developing countries, especially in rural areas. Solid fuel is usually combusted in inefficient cook stoves, producing a variety of health-damaging gases and particles, such as black carbon, organic carbon, methane, and carbon monoxide. More than 1.6 million deaths and over 38.5 million disability-adjusted life years (DALYs) were attributable to indoor smoke from solid fuels in 2000. Cooking with solid fuels is thus responsible for a significant proportion, about 3%, of the global burden of disease. Approximately 1.5 million deaths every year from respiratory infections can be attributed to the environment, including the effects of indoor air pollution. To encourage the use of cleaner burning fuels, the step is usually from wood to charcoal or kerosene and to Liquid Petrolium Gas might be effective ways to reduce air pollution exposures.

Reaping climate co-benefits by reducing climate active pollutants

Recent IPCC report stressed the role of many causative agents of Indoor air pollution,as having in addition a greenhouse gas effect, in particular black carbon. Other common pollutants such as nitrogen oxide, sulfur dioxide, particulate matter and carbon monoxide have been shown to be associated with several adverse health events such asthma attacks and incidence , chronic obstructive pulmonary diseases and lung cancer.

From a climate policy angle, reducing CAPs (Climate active pollutants) reaps Health Co -benefits. There are some evidences that stove improvements can substantially reduce indoor air pollution and the risk of lung cancer, respiratory diseases, Asthma, cataract, etc. Therefore, efforts should be made to reduce the burden of disease through public health and primary care programmes. Programmes can be designed to encourage urban and rural households that use solid fuels to move up the "energy ladder" to cleaner fuels such as kerosene or liquid petroleum gas. Household changes to improve ventilation and behavioural modifications to reduce exposure could be the cost effective interventions to reduce the burden of diseases.

Avoiding co-harm

Co-harm is a negative health effect, which has never been mentioned in this context. Without smoke, indoor abundance of mosquitoes increases and there is a higher risk of malaria transmission. 2009). There is a need to couple interventions for less smoke with those against malaria. Air pollution reduction rarely promote the twin goals of protecting health, avoiding increase in malaria and climate but can pose tradeoffs. All particles are dangerous for health, for example, some are cooling, such as sulfates, and some warming, such as black carbon. Indeed elimination of all anthropogenic particles in the atmosphere, may be a major success for health and would have only a minor net impact on climate.

Use of sattelite imageries and Numerical weather prediction output in Forecatsing Dust/Haze over West Africa

AA. Abdoul-Aziz Abebe (1)
(1) ASECNA - NIGER, NIAMEY, Niger, Republic of

Dust Haze occurrence over the sub-Saharan Africa is an annual phenomena, which has attractedquite a lot of attention from both forecasters and scientists. Between november and march,observations show that large dust plumes are transported from both the Sahara and Sahel towardsWest African Countries and accross the Atlantic Ocean. Predicting Dust haze generation should be animportant application of meteorology to development in this area both for economic and socialaspects. The main objective of the present study is to develop methodologies for betterinterpretation and use of NWP and Satellite products in forecasting Dust Haze generated

by thepredominant mechanism associated with pressure gradient tendency; improve knowledge andtechniques required to exploit potential predictability of Dust Haze;verification of weather forecasts.One should however keep in mind that atmospheric soundings are needed when other generationmechanisms are concerned.

Black carbon emissions from biomass and fossil fuels: Indo-Gangetic Plains, India

M. Arif (1) ; R. Kumar (2) ; E. Zusman (3)

(1) SHARDA UNIVERSITY, ENVIRONMENT SCIENCE, GAUTAM BUDDHA NAGAR, UP, India; (2) SHARDA UNIVERSITY, Environment science, GAUTAM BUDDHA NAGAR, India; (3) Institute for Global Environmental Strategies, Integrated policies for sustainable societies, Zushi, Japan

Most of the climate change debate and policies has focused on mitigating long-lived greenhouse gases (GHGs) to reduce global warming. But recently abating short-lived climate pollutants (SLCPs) such as black carbon (BC) has entered these discussions. BC emission from biofuel cooking in South Asia and its radiative forcing is a significant source of uncertainty for health and climate impact studies. Quantification of BC emissions in the published literature is either based on laboratory or remote field observations far away from the source. We use field measurements taken simultaneously inside urban and rural households (LPG and biomass users), ambient air and vehicular emissions from highways in area of the Indo-Gangetic-Plains region of India to establish the role of both solid biomass based cooking in traditional stoves, gas stoves and diesel vehicles in contributing to high BC. Household were also interviewed to understand barriers related to clean fuel accessibility and adoptability within users.

The major finding of this study till now is able to interpret the BC concentrations during cooking hours, both indoors and outdoors have anomalously large concentrations ranging from 3.82 µg to 105.64 µg for indoor during morning hours (05:00 to 09:00) and 1.32 µg to 130.70 µg for early evening hours (17:00 to 20:00). The BC emission during the non-cooking hours was also large, in the range of 1.05 to 95.44 µg. The peak outdoor BC concentrations are ranging from 6.54 µg to 40.81 µg in morning hours while 3.07 µg to 27.92 µg in evening hours. BC emission from transportation was also found high in morning and evening hours, have large concentration reaching 4.38 to 52.12 µg in morning hours and 1.71 to 49.02 µg in evening hours. The imprint of the cooking hour peaks were seen in the outdoor BC both in the village as well as in the highway. The results have significant implications for climate and epidemiological studies.

The Fertilizer and Carbon Sequestration Potential of an Accelerated compost in two soil types

OE. Ayanfeoluwa (1) ; VO. Aduramigba, (2) ; O. Adeoluwa, (3)

(1) Federal College of Agriculture, Department of Crop production, Ibadan, Oyo State, Nigeria, Federal Republic of; (2) Institute of Agricultural Research and Training, Department of land and water resources, Ibadan, Oyo State, Nigeria, Federal Republic of; (3) University of Ibadan, Department of agronomy, Ibadan, Oyo State, Nigeria, Federal Republic of

Compost has the potential to trap carbon in the soil while supplying the nutrients needed for the crop use. This study therefore investigated the fertilizer and carbon sequestration potential of an accelerated compost (a new commercial compost from market organic wastes and animal manure with composting accelerated with a specific microorganism). This experiment was laid out in Randomized Complete Block Design with three replications. The treatments were accelerated compost (AC) at the rate of 60, 90, 120, 150 and 180 kg N / ha. The mineral fertilizer (NPK 15-15-15) and conventional compost (CC), both at 60 kgN / ha, as well as the control (no soil additive) were the checks. Data were collected on the maize grain yields at both main and second cropping and post cropping soil organic carbon. Data were analysed using Analysis of variance and means compared with standard error of means. The result of the grain yield at the main planting showed that, on an Alfisol, the 60 kg N / ha AC (3.33 t / ha) compared favourably with 60 kg N / ha NPK (2.97 t / ha) but performed significantly ($p<0.05$) higher than 60 kg N / ha CC (2.76 t / ha). On an Ultisol, the 60 kg N / ha AC resulted into significantly higher grain yield (3.42 t / ha) than the 60 kg N / ha NPK (2.79 t / ha) and 60 kg N / ha CC (2.74 t / ha). At the residual planting, on an Alfisol, both the 60 kg N / ha AC (2.31 t / ha) and 60 kg N / ha CC (2.41 t / ha) performed significantly higher than the 60 kg N / ha NPK (2.21 t / ha), while the same trend was observed on an Ultisol. The AC sequestrated more carbon (58 % extra compared to the control) than the CC (9 % extra compared to the control) at the same 60 kg N / ha rate on an Alfisol. Also on an Ultisol, Accelerated compost sequestrated more carbon (14 % extra compared to the control) than the CC (8 % extra compared to the control) at the same 60 kg N / ha rate. It could therefore be concluded that the shortness in maturity of accelerated compost does not limit its fertilizer and carbon sequestration potential.

Modélisation de l'impact de la pollution atmosphérique urbaine aux échelles régionale et locale en Afrique de l'Ouest

D. Madina (1)

(1) university Félix Houphoôt Boigny, Physic, Cococdy, Abidjan, Ivory Coast

Regional climate modeling of the impact of urban air pollution at regional and local scales in West Africa

Mainly based on modeling, this study will highlight the impact of particulate and gaseous pollution from the West African megacities on regional climate and urban meteorology. The West African region has very large cities which promote strong anthropogenic urban air pollution. Using the Regional Climate Model (RegCM4) at the scale of West Africa will permit focus on the impact of urban air pollution on the climate of this region. Knowing that megacities affect their environment at local scales, up to the street, where RegCM4 is no more suitable, the Weather Forecast Research and its chemistry module (WFR-CHEM) with finer resolution will be used to study the chemistry of pollutants in the megalopolis. This part will focus essentially on aerosols (BC, OC, SO4 and NO3) and gases (CO2, CO, SO2 and VOC) combustion.

In the preliminary result, we have activated the dustss module to see what it brings disturbance on climate parameters. The tests with the model RegCM reproduce well the patterns of precipitation. Also we compared the temperature of the model with and without chemistry with observations. Thus the presence of dusts has a cooling effect and tends to improve the system. In further work we will characterize and quantify urban air pollution in Abidjan and Lagos. First, it will be for me to refine the inventories of particulate emissions in two megacities of West Africa (Abidjan and Lagos). Also analyze the impact of particulate and gaseous pollution on regional and local climate, while using the WRF_CHEM model for urban study.

Background: One of the most important consequences of climate change could be its impact on agriculture. While much research has focused on questions of food security, less attention has been devoted to assessing the wider health impacts of future changes in agricultural production. We estimate excess mortality due to agriculturally mediated changes in dietary and weight-related risk factors by cause of death for 155 world regions in the year 2050.

Methods: We linked a detailed agricultural modelling framework, the International Model for Policy Analysis of Agricultural Commodities and Trade (IMPACT), to a comparative risk assessment of changes in fruit and vegetable consumption, red-meat consumption, and body weight for deaths from coronary heart disease, stroke, cancer, and an aggregate of other causes. We calculated the change in the number of deaths due to climate-related changes in weight and diets for the combination of four emissions and three socio-economic pathways, which each included six scenarios with variable climatic inputs.

Findings: The model predicts that by 2050 climate change will lead to per-capita reductions of 3%, 4%, and 1% in global food availability, fruit and vegetable consumption, and red-meat consumption, respectively. Those changes were associated with 529,000 climate-related deaths globally (95% CI: 314,000-736,000), representing a 28% reduction in the number of deaths that would be avoided due to changes in dietary and weight-related risk factors between 2010 and 2050. Twice as many climate-related deaths were associated with reductions in fruit and vegetable consumption than with climate-related increases in the prevalence of underweight, and most climate-related deaths were projected to occur in South and East Asia. Adopting climate-stabilization pathways reduced the number of climate-related deaths by 29-71% depending on their stringency.

Interpretation: The health impacts of climate change from changes in dietary and weight-related risk factors could be significant, and exceed other climate-related health impacts that have been estimated. Climate change mitigation could prevent a substantial number of climate-related deaths. Strengthening public-health programmes aimed at preventing and treating diet and weight-related risk factors could be a suitable climate change adaptation strategy.

O-3320-02

Understanding the impact of international climate policies on regional food security using an Integrated Assessment Model

Y. Cui (1) ; S. Waldhoff, (2) ; E. Gilmore (1)

(1) University of Maryland, School of public policy, College Park, MD, United States of America; (2) Joint Global Change Research Institute, PNNL, College Park, MD, United States of America

We evaluate changes to regional food security under different international climate policy structures using an integrated assessment (IA) model, the Global Change Assessment Model (GCAM). Climate change mitigation policies may affect food security through complex interactions of changing food prices by altering land use patterns and changing income by influencing economic development and poverty reduction. IA models provide a consistent framework for evaluating these effects using assumptions that are consistent with the estimates of the costs and other impacts of climate policies.

First, we develop a measure of food security that can be estimated in GCAM based on economic accessibility and nutritional value. Specifically, national and regional food accessibility is approximated by the fraction of income spent on staple commodities, weighted by total food calorie availability and the share provided by staples. To better capture regional variability, we develop this measure by estimating regional consumer prices of staple commodities from the global producer prices modeled in GCAM. Second, we evaluate the implications over different socioeconomic scenarios, represented by the Shared Socioeconomic Pathways (SSPs). Finally, we estimate the impact of a universal carbon tax (UCT) on greenhouse gas (GHG) emissions to reach global climate targets reflected by the Representative Concentration Pathways (RCPs), without and with transfer payment using two illustrative allocation regimes.

We find that the socioeconomic pathway and the climate policy regime have important implications for food accessibility. More optimistic SSPs generally improve food accessibility with greater marginal benefits in poor and already food insecure regions. Second, impacts on food accessibility caused by a UCT mitigation policy differ across regions with greater impacts in developing countries. Third, regional variability of food access is further modified with payment transfers in global carbon trading. In particular, an allocation regime based on future population is expected to favor developing regions and thus moderate regional inequality of food access, while an allocation regime based on historical emissions tends to exacerbate the cross-region variability.

By exploring the magnitude and distribution of impacts on food security under alternative climate policy scenarios, we capture an important dimension of regional impacts of climate policy beyond mitigation costs.

Household and food security: what lessons can we learn from food secure households?

S. Silvestri (1) ; S. Douxchamps (2) ; P. Kristjianson (3) ; W. Foerch () ; M. Radeny (4) ; I. Mutie (1) ; C. Quiros (1) ; H. Mario (5) ; A. Ndungu (3) ; N. Ndiwa (1) ; J. Mango (3) ; L. Claessen (6) ; M. Rufino (7)

(1) International Livestock Research Institute, Nairobi, Kenya; (2) International Livestock Research Institute, Ouagadogou, Burkina Faso; (3) World Agroforestry Centre (ICRAF), Nairobi, Kenya; (4) ILRI, CCAFS East Africa, Nairobi, Kenya; (5) Commonwealth Scientific and Industrial Research Organization (CSIRO) , QLD , Australia; (6) International Crops Research Institute for the Semi-Arid Tropics (ICRISAT), Nairobi, Kenya; (7) CIFOR / CCAFS, Nairobi, Kenya

The potential impacts of climate change on food security in East Africa, while complex and variable due to highly heterogeneous landscapes, are a cause of concern. How well people are able to adapt to, or reduce climate change effects will depend on whether they are able to

change their behaviour and adopt improved agricultural technologies and management strategies.

While there is a rapidly growing literature on vulnerability and adaptation to increased climatic variability and climate change, significant knowledge gaps still exist, especially regarding the assessment of adaptation options in different environments and how these might be appropriately targeted to different types of households to reduce food insecurity.

This study therefore addresses a series of questions, such as: what are the key factors that contribute to household-level food security; what lessons can we learn from food secure households; and what agricultural interventions, options and management strategies are likely to benefit female-headed households in particular. It uses a unique dataset of 600 households to explore a wide range of indicators capturing different aspects of household performance and well-being for different types of households — female-headed, male-headed, food secure, food insecure — and assess livelihoods options and strategies and how they influence food security. The analysis is based on a very detailed farm characterisation survey carried on in three sites in Kenya, Uganda and Tanzania.

The results of this study show that food secure farmers appear to be the ones that diversify the most, have a variety of crops on their farms and are market oriented. In addition, domestic asset increases the likelihood of being food secure for female headed households. Yet, a different livelihood portfolio is pursued by men and female head of household, with women less likely to grow high-value crops then men and with a less diversified crop portfolio.

These findings can inform the targeting of national and regional policies to enhance adaptation in agricultural smallholder systems of East Africa. Implications of these findings include identifying actions that are likely to contribute more to food security and that can better enhance food security for female-headed as well as male-headed households. These usually include interventions that enable households' access to information about new technologies and practices especially though innovative communication effort, and new market opportunities.

IPCC AR5's contribution to the understanding of the future of fisheries and aquaculture and the knowledge gaps that have yet to be covered

A. Seggel (1) ; D. Soto, (2) ; C. Deyoung (2) ; T. Bahri (2)
(1) FAO, Fisheries and aquaculture department, Rome, Italy; (2) FAO, Fisheries and aquaculture, Rome, Italy

The IPCC AR5 provides highly relevant knowledge on the future implications of climate change on global fisheries and aquaculture resources. This presentation sets out to highlight how the IPCC AR5 contributes to the discussion on climate change and its direct and indirect effects on fisheries and aquaculture, our understanding of vulnerabilities within the sector and dependent communities and economies, and adaptation and mitigation options from within the sector. Furthermore, it will identify knowledge gaps of the IPCC AR5 that remain to be covered as well as provide additional knowledge not yet captured by the AR5. The presentation will provide examples of vulnerability questions and methodologies being applied from within the sector, covering inland, marine fisheries and aquaculture systems. Concrete examples of how fishers, aquaculture farmers, post-harvest systems and dependent communities are perceiving and reacting to climate variability and change will be shared. Filling knowledge gaps and up-scaling our efforts are important in order to better comprehend how food, nutrition and livelihood security as well as economic growth objectives from fisheries and aquaculture are required to change in order to be climate smart.

The abstract is submitted on behalf of the Global Partnership for Climate, Fisheries and Aquaculture (PaCFA).

Climate change impacts on the leaf miner, a major pest of the oil palm in Nigeria

T. Aneni (1)
(1) Nigerian Institute for Oil palm Research, Benin, Edo, Nigeria, Federal Republic of

This study examines application of climate variability to abundance and impacts on the leaf miner, Coelaenomenodera elaeidis, a major pest of the oil palm and its parasitoids in Africa. It analyses temperature, rainfall and relative humidity conditions from 1961 - 1970 as a reference point for baseline climatic conditions and description of same conditions between 2001 - 2010; Evaluates projections up to 2050; and describes impacts on leaf miner abundance. Leaf miner was sampled in the main station of the Nigerian Institute for Oil palm Research, between January 2009 and December 2010. Means, standard deviation, variances, covariance's, seasonal and climatic patterns for temperature, rainfall and relative humidity were computed. Least square method was used to estimate the trend in the series and the trend equation. Time series analysis was used to analyse the data and generate trend equations. The models for temperature, rainfall and relative humidity were generated. A forecast up to 2050 was generated indicating an upward trend in temperature and a downward trend in rainfall and relative humidity, with concomitant increase in leaf miner abundance between 1980 and 2010.

P-3320-02

Mapping irrigation potential from renewable groundwater in Africa: a quantitative approach

Y. Altchenko (1) ; K. Villholth (1)
(1) International Water Management Institute, Southern Africa Office, Silverton, South Africa

Groundwater provides an important buffer to climate variability in Africa. Yet groundwater irrigation contributes only approximately 1% of the cultivated land as compared to 14 % in Asia. As opposed to previous country-based estimates, this paper derives a continent-wide, distributed (0.5 degree resolution) map of groundwater irrigation potential, indicated in terms of fractions of cropland potentially irrigable with renewable groundwater. The method builds on an annual groundwater balance approach using 41 years of model data, allocating to groundwater irrigation the groundwater recharge in excess after satisfying other current human needs and environmental requirements, while disregarding any socio-economic and physical constraints in access to the resource. Due to high uncertainty of groundwater environmental needs, three scenarios, leaving 30, 50 and 70% of recharge for the environment, were implemented in a conservative estimate of the potential. In addition, current dominating crops and cropping rotations and associated irrigation requirements in a zonal approach were applied. Results show an inhomogeneously distributed gross groundwater irrigation potential across the continent, even within individual countries, reflecting recharge patterns and extent of cropland. Results further show that average annual groundwater available for irrigation ranges from 708 to 1669 km3 depending on scenario. The total area of cropland irrigable with groundwater ranges from 44.6 to 105.3 million hectares, corresponding to 20.5% to 48.5% of the cropland over the continent. Accounting for existing groundwater irrigation, residual irrigation potential remains high and relevant for poverty alleviation in the Sahel and Eastern Africa region where climate variability could have important impact on population. This could significantly increase the food production and productivity in the region from a reliable and renewable resource.

P-3320-03

Dynamics in climate change, agriculture and food security in the sub-saharan Africa: a review

MA. Awodun (1)

(1) Federal University of Technology Akure., Department of Crop, Soil and Pest Management., Ondo State, France

There have been decreases in food supply caused by extreme weather events. Regardless of where extreme weather occurs, the effects on food availability and price are disproportionately felt by the world's poor. Moreover, crop failures due to extreme weather not only affect those buying and selling in the global marketplace, but also have a direct impact on subsistence farmers. Understanding how such extreme weather events – which are predicted to become more frequent under climate change – affect both yields and total production of the world's staple food crops is thus an issue of both scientific and societal importance. Climate change is occurring more rapidly than anticipated and the increase in extreme weather events threatens more disruptive effects to agriculture. The vulnerability of food production systems has been demostrated over and over again. Food security is the state achieved when food systems operate such that «all people, at all times, have physical and economic access to sufficient, safe, and nutritious food to meet their dietary needs and food preferences for an active and healthy life». Food security is underpinned by food systems and is diminished when food systems are stressed. This stress can be caused by a range of factors in addition to global environmental change (e.g. population pressure, changes in international trade agreements and policies, migration) and may be particularly severe when these factors act in combination. Agriculture contributes on average34 percent to the GDP of Sub- Saharan Africa (SSA) countries and employs 64 percent of the labour force. It accounts for about 40percent of exports and provides various ecosystem services. Agriculture and rural development are thus the key pillars of the SSA economy. Sub – Saharan Africa is characterized by a growing population (2 – 3%) and an increasing number of households depending on farming activities. Soil degradation due to population pressure, intrinsic soil fragility and harsh climatic conditions have decreased the amount of cultivable land per capita and led to food insecurity since farmers have very limited means to purchase agricultural inputs (mineral and/or organic manure, working tools, and technical capacities, etc.) to increase soil productivity. Review of average crop yield for cereals, roots and tubers in 41 African countries showed 13 countries registering decline in cereals yield and 15 registering decline in yields for roots and tubers. Decline in rainfall has significantly altered the traditional farm calendar and soil degradation overstretched local farmers' soil management capability. Population resilence to these changes are related to several coping and adaptive strategies including crop diversification, mobility, livelihood diversification and migration. Adaptation which is a process of adjusting to a changing climate through explicit and planned interventions, or spontanous consequence of inherent flexibility, can mitigate its impacts. While adaptation to climate change is seen by most observers as the most preeminent issue for African countries. There is a strong parallel development of initiatives that aim at stabilizing GHG concentration in the atmosphere(mitigation); in reality, mitigation and adaptation should not be pursued independently as they are complementary. Most mitigation options will reduce impacts of climate change and several adaptation strategies will lead to reduction of GHG disposal in the atmosphere. With the slow progress in achieving mitigation, it is suggested that a viable option of adaptation is developed to prevent the anticipated negative imapcts of global change. Conservation agriculture, which involves minimal soil disturbance can improve water use efficiency by crops and helps in carbon sequestration processes and also improve on the capacity of crops to withstand weather stresses.Also, raising productivity through improved irrigation will likely be the key to ensuring food security as weather pattern shift.

Sustainable Agriculture and Climate Change: Producing Potatoes (Solanum tuberosum L.) and Bush Beans (Phaseolus vulgaris L.) for Improved Food Security and Resilience in a Canadian Subarctic First Nation Community

C. Barbeau (1) ; M. Oelbermann, (1) ; J. Karagatzides, (2) ; L. Tsuji, (3)

(1) University of Waterloo, Environment and Resource Studies, Waterloo, Ontario, Canada; (2) Georgian College, School of environmental studies, Barrie, Canada; (3) University of Toronto, Health studies and the department of physical and environmental sciences, Scarborough, Canada

Aboriginal people in Canada's northern regions are vulnerable to climate variability in addition to experiencing disproportionately high rates of diet-related illnesses including obesity, diabetes, and heart disease. Food insecurity is a contributing factor along with a loss of traditional lifestyles. Current food systems within these regions rely heavily on imported foods that are expensive (when available), and unsustainable. A warming subarctic and arctic climate offers the opportunity for local agricultural production that can increase food security and promote a more sustainable food system. In this study the feasibility of sustainably growing potatoes (Solanum tuberosum L.) to enhance food security in remote subarctic communities is explored through a case study in Fort Albany First Nation in northern Ontario, Canada. Potato crops were grown over a two-year period and rotated into plots that had been planted with green bush beans (Phaseolus vulgaris L.) Results showed that potatoes and bush beans could be grown successfully in the subarctic with yields comparable to more traditional agricultural methods. In subarctic Canada, sustainable local food production helps to promote social capital, healthier lifestyles, and food security.

P-3320-05

Weather, Climate and Food Security

T. Beer (1)

(1) President, IUGG Union Commission on Climatic and Environmental Change, CSIRO; PB1, Aspendale, Vic. , Australia

Safety and Security, though almost synonymous opposites of "risk", can have different meanings. Thus, for example, food safety is only one of the nine attributes of food security.

To meteorologists, food security is dominated by the impacts of weather and climate on food systems. But the link between the atmosphere and food security is more complex. Extreme weather events such as tropical cyclones impact directly on agriculture, but they also impact on the logistical distribution of food and can thus disrupt the food supply chain, especially in urban areas. A holistic approach is required to understand the phenomena, to forecast catastrophic and to predict their societal consequences.

In the Food Security recommendations of the Rio+20 Forum on Science, Technology and Innovation for Sustainable Development it states that it is important "To understand fully how to measure, assess and reduce the impacts of production on the natural environment including climate change, recognizing that different measures of impact (e.g. water, land, biodiversity, carbon and other greenhouse gases, etc) may trade-off against each other..."

The International Union of Geodesy and Geophysics (IUGG), through its Union Commission on Climatic and Environmental Change (CCEC) is leading the WeatCliFS consortium of international scientific unions to examine weather, climate and food security as well as to look at the interaction of food security and geophysical phenomena. The following fundamental question underpins WeatCliFS: What technologies and methodologies are required to assess the vulnerability of people and places to hazards [such as famine] – and how might these be used at a variety of spatial and temporal scales? This poster will review the work undertaken to date.

P-3320-06

International Joint Laboratory Patho-Bios, an efficient observatory of Plant Pathogens in West Africa in the context of climate change

C. Brugidou (1) ; E. Traoré (2) ; F. Tiendrébéogo (3) ; J. Néya (3) ; D. Sérémé (3) ; I. Wonni (4) ; M. Bangratz (5) ; C. Tollenaere (5) ; L. Nitiema (6) ; P. Nikièma (6) ; E. Zida (6) ; L. Ouedraogo (4) ; S. Nacro (6) ; O. Traoré (6)

(1) IRD, Département Environnement Ressources, Montpellier, France; (2) INERA, Ouagadougou -Kamboinsé,

Burkina Faso; (3) INERA, Ouagadougou-Kamboinsé, Burkina Faso; (4) INERA, Bobo Dioulasso, Burkina Faso; (5) IRD, Département environnement et ressources, Montpellier, France; (6) INERA, Ouagadougou, Burkina Faso

The International Joint Laboratory (LMI) entitled observatory of Plant Pathogens in West Africa: Biodiversity and Biosafety (LMI-Patho-Bios) has been formally launched in Burkina Faso on the 30th January 2014. LMI-Patho-Bios was initiated by the national research institute of Burkina faso, "Institut de l'Environnement et de Recherches Agricoles (INERA)" and the French Research Institute for Development (IRD) which have signed a memorandum of understanding to drive a five years research project on bio surveillance of plant pathogens. LMI-Patho-Bios is established at INERA on two sites. It is mainly located at Kamboinse research station of INERA (Ouagadougou) with a secondary location at Farako-Ba research station (Bobo-Dioulasso). LMI-Patho-Bios is interested on all important crops in West Africa including cereal crops (rice, maize, sorghum, millet), root and tuber crops (yam, cassava, sweet potato and potato), legume crops, vegetable crops and fruits. Its main goal is to develop a powerful open field observatory platform for bio surveillance in order to study plant pathogens interactions, diversity and evolution of pathogen populations in the context of global warming change which is expected to lead to major changes in plant diseases epidemic risks. Rice is used as model crop in such a platform which will significantly contribute for better understanding of the emergence of new plant diseases in a context of continuing climate change. Surveys will be made on common experimental plots located in different agroecological area in Burkina Faso and in West Africa to follow the dynamics and aggressiveness of pathogen populations. The major activities consist on diagnosis and characterization of plant bio-aggressors as well as epidemiology study of rice pathogens: viruses (RYMV, RSNV), bacteria (Xanthomonas oryzae, Burkholderia sp), fungi (Magnaporta grisea), and nematodes (Meloidogyne spp.). LMI-Patho-Bios has also developed a strong regional network with several national research systems (NARS) and Universities in Sub-Saharan Africa (SSA) and contribute in the capacity building of researchers, research technicians, students and agricultural extension officers. Finally, the joint laboratory will train and promote knowledge dissemination to farmers and extension officers on good agricultural practices in terms of recognition and proper management of bio-aggressors. Furthermore, LMI-Patho-Bios will contribute to develop strategic technological tools to help African farmers to better adapt to, and to mitigate the effects of climate change.

P-3320-07

Post harvest challenges & economic consequences and opportunities. Case study of Rwanda

H. Cesar (1) ; T. Doucha (1) ; T. Ratinger (1)
(1) Czech University of Life Sciences in Prague, Economic and Development, 16500 Praha 6, Suchdol, Czech Republic

The total agricultural product loss of 23.5% in Rwanda is due to poor post-harvest processing of agricultural products, when valued in monetary terms reflects a tremendous loss in the economy. Deficits in food items or financial loss should not have occurred if post-harvest losses were reduced through proper processing and preservation from harvest to consumption. Such a situation does not only reduce the national income but also it generates a problem of malnutrition in population, 43% in children in Rwanda is subjected to malnutrition. The loss ranges from 5 to 40% of production in Sub Saharan Africa. This exceeds the total food aid received by countries in Sub Saharan Africa.

Both government and private institutions needs to invest in much effort in research and extension toward improving and modernizing post-harvest facilities for attaining more efficient market infrastructure and distribution channels. The aim of this research is evaluation of post harvest losses of different cereals crops, evaluation of the economic impact caused by post harvest losses by quantifying the price discounts which small farmers face when selling damaged cereal and establishment of a postharvest model that can tackle the postharvest losses.

Different methods will be applied and include quantitative methods and qualitative methods. Interview, use of algorithm that operates on two data sets of a set of postharvest loss profiles and a set of seasonal data to assess the post harvest losses level. The double-hurdle model and standard regression models will be used to identify the level of impact of post harvest losses damages to evaluate the economic loss caused by this damage.

P-3320-08

For a sustainable agriculture according to land suitability, dietary needs and climate scenarios

A. Di Paola (1) ; MC. Rulli, (2) ; M. Santini (3)
(1) Euro-Mediterranean Center on Climate Change (CMCC), Impacts on Agiculture, Forests and Ecosystems Services (IAFES), Viterbo, Italy; (2) Politecnico di Milano, Department of civil and environmental engineering, Milano, Italy; (3) Centro Euro-Mediterraneo sui Cambiamenti Climatici, Impacts on agriculture, forests and ecosystem services, Viterbo, Italy

A large portion of agricultural production is funneled into animal feed or biofuels despite widespread hunger and undernutrition. Predictions foresee global demand for biofuels increasing from 81 billion of litres in 2008 to 172 billion litres in 2020, coinciding with an additional 40 million hectares of land converted for biofuel crops. According to the Milan protocol (http://www.milanprotocol.com/), a third of the global food production is used to feed livestock. Of the some 7 billion people on earth, 1 billion are without access to drinking water, which causes the death of 4,000 children each day. In contrast, 15,000 litres of water are needed for the production of a single kilogram of beef. In this work we tried to evaluate the advantages and feasibility of options to optimize the production, promotion and distribution of food with a high protein content (so as to remain equal nutritional quality of the meat) to reduce the footprint of water consumption and GHGs' emissions from the agricultural sector and to recover the availability of agricultural land as well. As example it is recognize that if the same amount of plant protein produced from protein-rich legumes is used directly for human consumption rather than for feed (currently 95%) up to 75 times the land currently required to grow feed crops could be recovered, up to 40·103 cubic meters of water could be saved per each recovered hectare and, also, emissions should be contained thanks to the nitrogen-fixing behavior of promising protein-rich crops.

By means of crop modeling coupled with emission-climate and diet scenarios, and adopting an ensemble approach that favors robust evaluations comprehensive of uncertainty flagging, we show how to it is possible to formulate different agri-food solutions for a sustainable agriculture compatibly to land suitability, water availability, dietary needs and climate projections. In particular, agri-food options we investigate include i) identification of protein-rich legumes and their suitable area of culture according both with the current and projected climate, ii) their contribution to limit environmental footprints (GHG, water, land) and iii) the optimal compromise of crop production used for human consumption vs feed such as to ensure a balanced diet between meat and lacto-ovo-vegetarian consumptions compatible to climate change, water consumption and land recovery issues.

P-3320-09

Predetermination of floods in the Senegal River Valley: application between Bakel and Matam

Y. Dieme (1) ; S. Sambou (2) ; VB. Traoré (2) ; MT. Cissé (1) ; C. Diatta (2) ; M. Bop (1)
(1) Laboratoire Hydraulique et Mécanique des Fluide /FST/ UCAD, Physique, Dakar, France; (2) Laboratoire Hydraulique et Mécanique des fluides, Physique, Dakar, Senegal

The risk of flooding in the valley of the Senegal River remain important. These floods more and more recurrent can be explained by a combination of several factors. Extreme weathers due to climate change have significantly increased the intensity of the rain causing flooding in many regions and countries around the world. Important contributions uncontrolled tributaries of BAKOYE and FALEME, releases made at Manantali representing approximately 40% of volumes sold, but also the low volume of water released downstream of the Diama dam contribute to inundation. The consequences of these floods are sometimes heavy in terms of loss of life, of health, of education, of economy

and of infrastructure. The determination of flood risk areas is important to anticipate and protect populations. For this we used coupled models HECRAS and ARC-GIS to determine the areas likely to be flooded between Bakel and Matam. These flood risk were studied with decennial, centennial and millennial flows. The results are promising and suggest that HEC-RAS with ArcGIS can be used to set up an early warning system on the Bakel, Matam reach.

P-3320-10

Modelling the current and future dry-season distribution of Encosternum delegorguei (Hem., Tessaratomidae) in sub-Saharan Africa

C. Dzerefos (1) ; E. B. (1) ; W. E. (1) ; G. D. (2)
(1) University of the Witwatersrand, School of Animal, Plant and Environmental Sciences, Johannesburg, South Africa; (2) SANBI, Climate change and bio-adaptation division, Cape Town, South Africa

Rural communities in South Africa, Malawi and Zimbabwe annually harvest from winter aggregations of the edible stinkbug Encosternum (=Haplosterna) delegorguei Spinola. Using a regional maximum entropy modelling method (MAXENT) for winter field records of E. delegorguei, current and future climate scenarios were identified. Winter precipitation and to a lesser degree summer precipitation and winter temperature were the climatic variables found to limit the regional distribution of E. delegorguei. The receiver operating characteristic analysis (ROC) yielded an AUC (area under the curve) value of 0.995, indicating a reliable model although interpretations must consider the influence of elevation for this insect. A testable hypothesis regarding future distribution of E. delegorguei in the face of climate change has been formulated for its winter range. Predator-prey relationships and food source are also influencing the occurrence of E. delegorguei and may override the influence of climate. The modelled current distribution identifies potential new sites in areas of similar climate which may be unknown to harvesters. Areas for mini-livestock pilot studies provide opportunities for extending commercial potential and ensuring a sustainable nutritional food during a period of food scarcity.

P-3320-11

Economic implications of climate change in Sub-Saharan agricultural system: short term impacts and opportunities for irrigation

F. Eboli (1) ; F. Bosello (2) ; L. Campagnolo (3) ; M. Mistry (4) ; R. Parrado (5) ; RD. Ponce (6)
(1) Euro-Mediterranean Center on Climate Change, Economic analysis of Climate Impacts and Policy Division, Venice, Italy; (2) University of Milan, FEEM, and CMCC, Dep. of economics, Milan, Italy; (3) Fondazione Eni Enrico Mattei, Venice, Italy; (4) Ca' Foscari University and FEEM, Department of economics, Venice, Italy; (5) FEEM, Venice, Italy; (6) Ca' Foscari University of Venice, Economics, Venice, Italy

This research examines the climate related impacts and adaptation options in Sub-Saharan Africa agriculture in a recursive dynamic Computable General Equilibrium (CGE) framework with world coverage. Differently from most of the global CGE models treating the land supply in a very simplistic way, here we introduce land heterogeneity differentiating between rainfed and irrigated cropland. The irrigation production function is built upon the estimates on unitary investments from FAO and considering the current level of irrigation in Sub-Saharan Africa. Under this new specification, each agricultural sector can substitute rainfed land with an irrigated bundle composed of irrigated land and capital and allows considering differentiated climate change impacts.

The first step of the analysis is the assessment of the climate change impacts. The reference scenario is the SSP5, to ensure consistency with the climate scenario described below. It is worth mentioning that the time frame of the analysis is 2030, even though climate change impacts are expected to increase more than proportionally later than 2030. However, aadaptation strategies imply decisions in the very short term and can lead to delay in taking actions against future climate change. For the impact assessment, two climate scenarios in line with RCP8.5 are analyzed. The first assumes constant CO2 (1960 level, 316.27 ppm), while in the second scenario CO2 increase over time mirroring RCP8.5 concentration. Biophysical changes in land productivity by crop and land type are taken by the LPJ-ML model run according to the CanESM General Circulation Model and are exogenously introduced in the CGE model.

Without "CO2 fertilization effect", due to the short term considered, a few countries/regions, namely Nigeria, Senegal, Madagascar, Botswana and Rest of West Africa are better off in terms of agricultural production; on the other hand, Malawi, Mozambique and the Rest of South Central Africa are the most damaged countries in terms of yields reduction. Where agricultural production drops, the dependence from imports increases, clearly highlighting the effects of economic vulnerability to climate change. The overall effect on Sub-Saharan African economies is summarised by the GDP growth change compared to the reference scenario and ranges between -1.6% (Mozambique) and +1.6% (Nigeria). The "CO2 fertilisation effect" scenario has uniformly a positive effect on yields. Mozambique is the only country with production losses in all agricultural sectors compared to the reference scenario. The impact on GDP is generally positive; only Mozambique and Rest of South Central Africa experience a GDP loss of 0.6 and 0.1%, respectively.

Overall, when the «CO2 fertilization» effect is not accounted for, Eastern and South Central Africa experiments negative changes in yields also in such a short time horizon. Extending irrigation practices represents a key strategy to cope with climate change and at the same time to favour development. We compute ex-ante the additional irrigation required such to compensate the production losses due to climate change and recover the output of the "no climate change" scenario. This information is combined with country specific unitary costs of irrigation projects from FAO to estimate the required amount of investments. Such an additional flow of capital for irrigation in the agricultural sectors is subtracted to the rest of the economic system. This approach allows highlighting the inherent trade-off within adaptation plans: allocating more investments to agriculture deteriorates the capital stock available for developing the rest of the economic system.

The outcome of increased irrigation in the country targets is heterogeneous. In most cases, irrigation provides higher benefits than costs. This is explained by the higher marginal productivity of capital for irrigation than in other productive sectors, reflected by the large increase in crop yields when cropland is equipped with irrigation systems. Nevertheless, in Mozambique and Rest of South Central Africa, the most vulnerable countries to climate change, extending irrigation is not sufficient to bring back production to the reference scenario levels. This lack of responsiveness can be explained by the low degree of internationalization of the agricultural sectors that limits the expansion of exports in spite of higher productivity.

P-3320-12

The contribution of fruits and vegetables production to poverty alleviation, nutrition and environment in Africa

D. Feliciano (1)
(1) Institute of Biological and Environmental Sciences, School of Biological Sciences, Aberdeen, United Kingdom

Over the last 20 years, the demand for fresh fruits and vegetables, both in their crude and processed form, has significantly increased. According to Mal et al. (n.d.), it is only in recent years that there is an increasing awareness of the potential of native tropical fruit species as sources of dietary vitamins, minerals and energy. Rising incomes and growing consumer interest in product variety, freshness, convenience and year round availability are among the main reasons for this increasing demand (Diop & Jaffee, date). Ruel et al. (2005) recognises that the consumption of fruits and vegetables increase when gross domestic product per capita goes up, but cautions that this is not a fully linear relation as the overall percentage of the food budget allocated to fruits and vegetables is low (4-16%). Fruit and vegetables are rich sources of micronutrients, needed by children for optimal growth and development (WHO/FAO, 2004). Energy, protein, vitamins (A, C, D, and B-complex), and minerals (iron, zinc, iodine) are required for the growth of muscle tissue and bones, brain development, and bodily functions such as the immune

system or co-factors for enzymes. WHO (2009) estimates that 250 million preschool children are vitamin A deficient and as a consequence between 250 000 to 500 000 become blind every year. Most national and international dietary guidelines are in agreement that consumption of fresh fruit and vegetables is a healthy food choice and generally needs to be increased. The World Health Organisation recommends a minimum daily intake of 400 g of fruit and vegetables especially for children, and many countries have programmes to promote consumption (FAO/WHO, 2004).Several initiatives have recognised the importance of the consumption of fruits and vegetables to deal with micronutrient deficiencies. One of these is the Global Fruit and Vegetable for Health Initiative (PROFAV/PROFEL), launched by FAO and WHO in 2003. This was followed by the elaboration framework for action in 2004 which objective was to guide the development of cost-effective interventions to promote adequate consumption of fruits and vegetables for health at national or sub-national level (FAO/WHO, 2004). In addition, regional workshops have been held between 2004 and 2014 promoting the consumption of fruits and vegetables, within healthy diets and lifestyles, in the different continents. In 2007, the World Vegetable Centre (AVRDC) submitted a pre-proposal on High-Value Crops - Fruits and Vegetables to the Consultative Group on International Agricultural Research (CGIAR). The objective of this proposal was broader since it aimed at helping the poor to take advantage of the economic and nutritional value of high-value fruit and vegetables for income generation, job creation, food security and health, taking into account environmental sustainability. However, this proposal did not go ahead.

This papers reviews the literature and analyse FAOSTAT database to investigate how the production of fruits and vegetables contribute to:

1. Poverty alleviation;
2. Improved nutrition and health;
3. Improved natural environment and ecosystem services

The focus of the paper is Africa. Food consumption patterns have been progressively analysed in developing countries over the past 30 years. However, food production and consumption patterns remain poorly understood in Africa, particularly for fruits and vegetables.

P-3320-13

Using phosphorites mine wastes to improve soil fertility and crop production in Togo and in the West African region for food security in a context of climate change

K. Gnandi (1)
(1) University of Lome, Dpt of Geology, Lome, France

Phosphorites are been mined in the areas of Hahotoe-Kpogamé (Southern Togo) in the Tertiary coastal basin since 1960. The exploited raw phosphorite is naturally enriched with trace metals (Cd, Pb, Cr, Cu, Ni, V, Zn, Ba, Sr, F, U) and rare earths. Phosphorites are transported to the factory of Kpémé close to the beach where they are washed by seawater using sieving and hydrocyclone separation techniques. It results from this process coarser waste and muddy fine grained clayey phosphorites tailings. The solid waste is disposed on soil, on the beach and the muddy waste fraction is dumped directly into the sea without any treatment..About 2.9 million of tons of mining waste are dumped annually into the coastal waters of Togo and causes transboundary marine pollution between Togo, Benin and Nigeria, coastal habitat degradation and the reduction of fish stock.

The phosphorite factory of Kpeme Togo has 5 chains for the treatment of raw phosphorite to commercial pure phosphorite. Each chain produces 1600 tons of muddy phosphorite waste per day. Chemical analysis showed that phosphorites waste contain up to 18 % P_2O_5, clay minerals and numerous nutritive elements such as Co, Cu, Ni, Cr, Fe, Zn, Mo, Se. and can be used for soil fertilization and crops productivity according laboratory and field experiment. Coagulation and flocculation methods in big decantation basins, or decantation in hydrocyclones are necessary to recover high amounts of solid waste that can be treated and use directly for soil fertilization in Togo and other countries in the West African region for food security in a context of climate change.

P-3320-14

Marriage of traditional knowledge and modern science to build the resilience of food security systems in Pacific Island Countries

V. Iese (1) ; J. Maeke (1) ; M. Wairiu (1) ; M. Nand (1) ; E. Holland (1)
(1) The University of the South Pacific, Pacific Centre for Environment and Sustainable Development, Suva, Fiji

Pacific Island Countries prioritized increase agricultural production as a way for sustainable development. Agricultural products can also contribute to energy security as demonstrated by many developed and developing countries in the world. However, the question remains as to how we can increase agricultural productivity against increasing pressures and uncertainties and with limited information on soil, climate and crops or how we can optimize crop productivity and get the best outcomes from our crop management practices and limited arable land areas. . Research conducted on both high islands and atolls reveal different level of vulnerabilities including types of crops they cultivate and methods and technologies used. Understanding the vulnerability of the food security systems at the community level is very important in order to strategically build their resilience. Farmers in studied countries in the Pacific apply both traditional practices and modern innovations to improve their resilience. Employing the holistic approach including climate and weather information (current and future), soil information (physical and chemical), crop or variety suitability and optimized integrated crop management (traditional and modern practices) to improve crop productivity is the way forward for a resilience food security system.

P-3320-15

Agriculture is neither the culprit, nor the solution, to climate change

R. Kröbel (1) ; H. Janzen (1)
(1) Lethbridge Research Center, Science and Technology Branch, Agriculture and Agri-Food Canada, Lethbridge, Alberta, Canada

It may be obvious, but agriculture's primary function is to produce food. It is in the nature of agricultural systems that they do leak greenhouse gases as part of the food production function, and they undoubtedly contribute to climate change. However, any greenhouse gas component that is emitted was prior fixated from the atmosphere and will be recycled to and from atmosphere eventually. This is fundamentally different from the process of burning fossil carbon compounds that adds ever more carbon dioxide to the atmosphere for an everlasting effect of climate warming. Carbon sequestration is seen as solution to this problem, and one option that has been widely promoted is the increase and (long-term) storage of soil carbon in agricultural soils. Thus (based on the past versus now principle of life cycle analysis approaches), producers can now promote their production as environmentally friendly when they increase the carbon stock in their soils. The problem is that soil carbon cannot increase endlessly, and so this approach benefits producers who switch away from systems with bad environmental performance rather than producers that were environmentally friendly all along. On top of that, soil carbon gains only make up a minor fraction of the carbon fixated by agricultural systems initially. Therefore, we propose the following concepts to re-assess the role agriculture plays in climate change:

- Producers benefits should be based on the amount of soil carbon stored (and thus also benefit from increasing them), but the emphasis would be on maintaining the soil carbon stock
- Greenhouse gas emissions from agriculture should be charged against the carbon the system fixated in total (net primary productivity - nitrous oxide - enteric methane - soil respiration), as tremendous amounts of fixated carbon are exported from farms each year to feed the human population

The onus should not be on the farmer to responsibly store the carbon resource they produce, similar to the oil industry that is not responsible to educate the consumer towards responsible consumption and utilization of its

products. However, if it is our goal to remove carbon from the atmosphere, utilizing the tremendous amounts of biomass produced each year on agricultural soils might be a more suitable solution for long-term storage than highly technical and energy consuming alternatives. For this purpose, storage of nutrient depleted crop straw or already collected and concentrated manure and waste products could prove to be cheaper and more successful.

P-3320-16

Fitting neglected and underutilised crops into climate change adaptation strategies

T. Mabhaudhi (1) ; A. Modi, (1)
(1) University of KwaZulu-Natal, Crop Science, School of Agricultural, Earth and Environmental Sciences, Pietermaritzburg, South Africa

Agriculture is the predominant activity sustaining livelihoods in sub-Saharan Africa with about 70% of the region's population relying on agriculture for their sustenance. In this region, about 95% of agriculture is primarily rainfed and relies mainly on a few starchy cereal and root and tuber crops for dietary provision. Climate change and variability are expected to result in increased variability of rainfall as well as severity and intensity of extreme weather events such as drought and floods. This places pressure on food and nutritional security within a region that is already behind with achieving Millennium Development Goal - 1. Consequently, there has now been movement across the region to develop climate change adaptation strategies at various levels. These strategies, which include climate smart agriculture, are mainly focussing on the major crops. There is a need to include alternative crops - the neglected and underutilised crop species (NUCS). These are crops that have historically formed the rich tapestry of the agro-biodiversity that exists within the region. By definition, NUCS are crops that have not been previously classified as major crops, have previously been under-researched, currently occupy low levels of utilisation and are mainly confined to smallholder farming areas. Historically, NUCS have played an important role in ensuring community and household food and nutrition security through providing healthy alternatives when the main crop failed or during periods in-between subsequent harvests. The promotion of a few major crops during the Green Revolution subsequently led to their relegation to their current although they still offer much potential. Across much of SSA, water availability remains the major limiting factor to crop production, threatening food security of vulnerable groups. It is also expected that water would be the primary medium through which impacts of climate change and variability would be experienced. Most NUCS are believed to be resilient and adapted to a range of ecological niches, low input agriculture and may have tolerance to abiotic stresses such as drought. This makes them important future crops for SSA's smallholder farmers on marginalised lands especially under predicted climate change. Their inclusion in climate change adaptation strategies would offer sustainable solutions built upon existing agro-biodiversity of communities within the region.

P-3320-17

L'eau virtuelle des produits agricoles d'importation : Un moyen de contrecarrer le problème du manque d'eau en Algérie

B. Mouhouche (1)
(1) Ecole Nationale Supérieure Agronomique (ENSA) ex INA, Génie Rural (Hydraulique Agricole), Alger, Algeria

L'Algérie est classée parmi les 17 pays qui souffrent le plus du manque d'eau à travers le monde.

En effet, avec moins de 300 m3/habitant/an d'eau renouvelable, l'Algérie dispose de moins de 30% du seuil théorique de rareté fixé par la Banque Mondiale à 1000 m3 /hab./an.

Etant dans l'impossibilité d'étendre sa SAU et/ou d'augmenter les surfaces irriguées, pour combler le déficit alimentaire, l'Algérie a recours à des importations massives de produits alimentaires, particulièrement les céréales et leurs dérivés.

Ajouté à cela les produits agricoles non-alimentaires.

Ces importations, bien qu'elles représentent une hémorragie financière très importante pour le pays, elles ont au moins un aspect positif représenté par les quantités impressionnantes d'eau virtuelles qu'elles procurent à l'Algérie estimées à plus de 40 milliards de m3 pour l'année 2012.

C'est dans ce cadre que s'inscrit notre étude dans laquelle nous essayons de quantifier ces quantités d'eau virtuelles qui contribuent grandement à soulager temporairement le pays de son problème de manque d'eau.

P-3320-18

Small farmers and their perceptions of climate, environmental and social changes: the stories behind vegetable production that could affect food and nutritional security in Brazil

C. Nolasco (1) ; FS. Pacheco, (1) ; LS. Soler (2) ; J. Ometto (1) ; M. Lahsen, (1)

(1) National Institute for Space Research (INPE), Earth system science centre (ccst), São José dos Campos, SP, Brazil; (2) National Center for Monitoring and Early Warning of Natural Disasters (CEMADEN), Sao Jose dos Campos, Brazil

Brazil's National Council for Food and Nutrition Security (CONSEA) defines and advocates food security as "the realization of everyone's right to regular and permanent access to quality food in sufficient quantity without compromising access to other essential needs, based on health promoting food practices that respect cultural diversity and that are socially, economically and environmental sustainable." The Brazilian Federal Constitution has institutionalized the right to adequate food as a Citizens Social Right. Even so, access to adequate food is far from a reality in Brazil. Results of a Health Ministry's study (2009) shows that only 18.9 % of the population consumes five servings daily (400 grams of vegetables/day) as recommended by the World Health Organization. In a context of rapid urbanization, an ever greater majority of the Brazilian population is concentrated in urban areas, where food demand thus rises. The increasing distance between the cultivation sites and where they are consumed results in increased food losses due to the high perishability of vegetables. This, together with the greater need for packaging, refrigeration and transportation raises prices, reducing the poorer populations' access to these foods which are crucial for a healthy human diet. Studies suggest that the intake of more than five portions of fruit and vegetables a day significantly reduces risk of death. Oyebode et al. (2014) found that vegetables had the strongest health protective effect compared to other foods, with each daily portion reducing overall risk of death by 16%. In this sense, the Brazil Health Ministry recently (2014) launched a new nutritional guide which emphasizes the consumption of natural or minimally processed foods in great variety, noting that especially foods of plant origin are "the basis for diets that are nutritious, delicious, appropriate, and supportive of socially and environmentally sustainable food systems.» Diets link environmental and human health (Tilman and Clark, 2014), and the incentive for vegetables consumption should rely on a well-organized food system that can provide the population with healthy products, produced in a sustainable manner and resilient against the effects of climate change and other environmental stresses. However, olericulture production in Brazil is marked by a profound lack of reliable data about the number of farmers, their cultivation methods, use of natural resources, etc. There is an even greater lack of knowledge about the human dimension of the food system, including factors and experiences which will influence whether small farming will be sustained and able to contribute in meeting the future demand and the governmental prescriptions for a healthy diet.

Based on field research in the micro-region of São José dos Campos in the state of São Paulo, Brazil, this work investigates who the vegetable producers are and how they are experiencing and adapting to the changes in market-related, environmental and socio-economic conditions affecting their work and lives. The micro region studied is composed of eight municipalities, with 1,406,315 inhabitants, and is part of the Expanded Metropolitan Complex of São Paulo, one of the most populous urban agglomerations in the world with more

than 20 million inhabitants. The field research, conducted between 2013 and 2015, included an initial investigative phase to locate the farmers within the micro region, followed by more in-depth field visits to the agricultural sites and semi-structured interviews with the farmers. The method adopted was the narrative analysis focusing on the stories told by the farmers. Some data extracted from the interviews was also georreferenced using GIS tools in Arc GIS 10.1 to assist in the visualization of the producers' characteristics along the study area. The results showed beyond the economic, health and environmental aspects involved in the management of their crops. It shows their beliefs and values related to their activity; the role of the institutions in their productive condition; their perceptions about the recent extreme events affecting the Brazil's Southeast Region and how their production is being affected; the pressures related to urbanization and population concentration, such as elevation of land prices and insecurity due theft and violence; and difficulties to perpetuate their activity and keep the interest of their heirs in the face of changes in consumption patterns, market channels and the globalization process in the food system.

P-3320-19

Traditional faming practices and water management for Climate change adaptation in Sri Lanka

RU. Piyadasa (1)
(1) University of Colombo Sri Lanka, Geography Department, Colombo, Sri Lanka

Sri Lanka is one of the few countries in the world that has had a thriving and vibrant irrigation based civilization for over two thousand years. The cascade system, they used for traditional organic cultivation of paddy, harmonized environment and development in an environmentally sound and sustainable manner. Sri Lankan history is deeply connected with its hydraulic civilization and its erroneously named as a community based cascade ecosystem irrigation. In Sri Lanka water is collected using man-made interconnected cascade tanks ecosystems in dry areas mainly for paddy cultivation. These tanks comprise of various components of ecological importance. Tank cascade ecosystems were constructed mainly in two ways, either by impounding a river or by diverting the river through canals. In early days villages were built around tanks to allow easy access to water for agricultural purposes. Tanks were also important for cultural, spiritual and religious reasons, as water is a symbol of life and purity. While the challenges are daunting, they also provide opportunities for local communities, business and government to innovate for the benefit of communities, economies and the global environment. The cascade ecosystems, throughout the Sri Lanka in particular, are under unprecedented pressure, threatening prospects for sustainable development. Tanks were constructed mainly in two ways, either by impounding a river or by diverting the river through canals. In early days villages were built around tanks to allow easy access to water for organic agricultural purposes. Tanks were also important for cultural, spiritual and religious reasons, as water is a symbol of life and purity. Cascade ecosystems were originated within the community and practiced over many generations. Presently managed by community Farmer Organizations and government. The all the cascade ecosystem based irrigation systems were operated and managed by the community and responsibility rested with the chief of the village community based organization. Ecosystem that helped the community in passing through the difficult times during the droughts; a system that nurtured the development of drought insurance through animal husbandry and fragmented land ownership; and that provided opportunities for inland fishing and human and animal nutrition. The ecosystem operate with collection of rainwater harvesting technology; a soil moisture and groundwater maintaining technology; a soil erosion and siltation control technology; a technology that ensured the maintenance of ecological balance; a technology that promoted social cohesion and need for community leadership; a system that accommodated spiritual development which promoted egalitarian attitudes. On the basis of their form and appearance, the cascading systems would have operated as an ideal community based adaptation to climate change.

P-3320-20

Agriculture Adaptation to Climate Change in Brunei Darussalam: A Step towards Food Security

S. Shams (1)
(1) Institut Teknologi Brunei, Civil Engineering, Bandar Seri Begawan, Brunei Darussalam

The world's population is increasing rapidly and expected to reach 8 billion by the year 2020. The standard of living is also increasing with the advancement of new technologies and thus increasing the life span of individuals. The demand for food production will increase too and particularly the developing countries will face a new set of challenges. The impact of increased demand for food production will significantly felt in the agricultural sector. Rural economies, which are based upon and dominated by agricultural, pastoral and forest production, are highly sensitive to climate variations and change. So too are the livelihoods and food security of those who participate directly in these activities, supply inputs to them, or use their outputs to produce other goods and services. The climate change is a major threat to the existing agricultural practice in many developing countries. The continuous increase in temperature with intensive precipitation over a short period will have adverse affect on the agricultural output of Brunei Darussalam. There were 115 reported cases of flooding and 105 landslides during the last rainy season, the worst and most severe rainfall ever happened in Brunei. Over the past few decades, Brunei is experiencing a rapid change in climatic condition particularly on the increased temperature (0.0375oC) and rainfall (37.62 mm) received annually. The economy of Brunei is mostly relying on oil and gas sector which consist of up to 90% of the country exports. In 2007, Brunei's oil production saw a reduction of 11.5% to approximately 193,000 barrels per day compare to the output in 1979, which surpassed 240,000 barrels per day. Wawasan Brunei 2035 (Brunei's National Vision) has been established by Brunei Economic Development Board (BEDB), as to give awareness to the population not to rely fully on oil and gas productions. The vision formulates a plan to increase employments, enhancing the current education and upskill the labour force by introducing more institutions to the related work, and initiate a more sustainable economy. Due to ample amount of land availability, Brunei can make use of the land resources as potential assets. An improved and regulated country's agriculture can give a better and sustainable future, not just to the population but also increase the government revenues. Intensification of agriculture and the associated increase in productivity has already saved about one billion hectares of wildlife habitat across the world (Pratley, 2008). Therefore, the study aims to synthesize the relationship between climate change and agriculture production in Brunei Darussalam. The study focus on the adaptation or coping strategies with emphasis on training to agricultural extension workers and farmers to ensure increased productivity, a step towards food security. Technical change is one of the key elements that influence the pace of agricultural growth in the developing countries. Agriculture in Brunei Darussalm must undergo a transformation to become 'climate-smart' in order to prevent climate change from further exacerbating food insecurity. To adapt to climate change, farmers need new and improved technologies, skills and knowledge, or in many cases, to be linked to existing technologies which are currently inaccessible. These may include, for example, improved water management using rainwater harvesting or soil stabilization techniques; soil conservation and erosion control through terracing and agro forestry; and greater use of renewable energy through biogas and solar PV.

P-3320-21

Genetic analysis of drought tolerance among selected bread wheat (triticum aestivum) lines

H. Shimelis (1) ; T. Tsilo (2) ; M. Learnmore (3)
(1) University of KwaZulu-Natal, Acci, Pietermaritzburge, South Africa; (2) ARC, Small grains, Bethelehem, South Africa; (3) University of KwazuluNatal , Acci, Pietermaritzburge , South Africa

Wheat production in most parts of the world including the Sub-Saharan Africa is currently being threatened by the

increasing incidences of periodical droughts emanating from climate change. This is causing the entire continent, including South Africa, which is the region's largest producer of the crop to increasingly depend on imported wheat. There is, therefore, a need to continuously search for useful variation for drought tolerance improvement among wheat breeding stocks within the local seed banks and among international nurseries. Currently, there is little documentation of the potential genetic contribution of these lines with reference to drought tolerance. This is limiting the development and adoption of better adapted varieties which is causing a decline in dry land wheat production and productivity. The use of biochemical selection methodologies and next generation sequencing technologies such as genotyping by sequencing (GBS), can greatly contribute to the understanding of the genetic bases of drought tolerance in wheat which have a huge and complicated genome. This study therefore, evaluates 100 genotypes for drought tolerance under controlled water application. Ninety (90) of the lines are from the CIMMYT germplasm of which 30 are from the drought, and 60 are from the heat nurseries. Ten are commercial check varieties. The specific objective of this study is to determine the genetic diversity present among the selected wheat lines for drought tolerance based on phenotypic, biochemical (proline and mannitol accumulation due to drought stress) and molecular (genotyping by sequencing (GBS) analysis. The greenhouse experiments are being carried out at the University of KwaZulu Natal and the field experiments are at Ukulinga Research Farm. Biochemical quantification is done at the University's Analytical Chemistry laboratories, while genotyping is being done at the Agriculture Research Council (ARC) of South Africa. Data collection for these three aspects of the study is underway and all the data analysis will be done by end of April. This study will recommend further evaluation of lines which will be found to be having considerable drought tolerance coupled with high yields for dry land commercial cultivation. Also, some drought tolerant lines will be selected to be parents for crossing with high yielding but susceptible commercial cultivars to transfer the drought tolerance traits (genes).

P-3320-22

How can food insecure smallholders gain the full potentials of climate smart agriculture (CSA)

E. Simelton (1) ; P. M. (2)
(1) World Agroforestry Centre (ICRAF), Hanoi, France; (2) Chalmers University of Technology, Physical resource theory, Gothenburg, Sweden

Integrated farming systems are often mentioned as strong contender of Climate-smart agriculture (CSA) for meeting food security, adaptation and mitigation objectives. Studies on CSA-adoption typically identify two strands of recommendations: One strand finds that "Farmers' are already doing climate-smart practices" and some add "... so let's learn from them". The other strand concludes that "Farmers are not yet optimizing the full potential of CSA", meaning "more training or awareness-raising is needed". Thus to optimize the full potential of integrated farming systems for CSA, we hypothesize that lessons be exchanged between the two strands. Therefore, to identify factors that can reduce the gap between these two categories, we synthesized household survey results from over 800 households in semi-tropical Viet Nam. We characterize households in 25 villages across northern and central Viet Nam who have adopted and those who have not adopted integrated farming systems, including agroforestry, home gardens, and rice-fish cultures. The data was using direct measurements or proxies for food security status, adaptive measures, and biophysical inventory including biodiversity and carbon stock covering.

We highlight several gaps between farmers' practice and scientific knowledge in each of the three pillars of CSA, relating to differences between adopters and non-adopters of integrated farming systems. Households with integrated farming systems are able to make synergies between a stable household economy (food security) and adaptation. In particular, households with agroforestry had shorter economic recovery period after natural disasters than those without. In contrast, food insecure households had smaller land area, fewer integrated farming systems and less diverse production.

Land use policies have a strong influence on farmers' crop choice through designated land uses, subsidies and seedling supply. Home gardens, which are excluded from land us policies, were an underestimated resource for diversity. In particular, food secure households with home gardens were more benign to experiment. Lastly, as no mitigation mechanisms in place, farmers benefited neither from the carbon sink potentials of tree plantations nor greenhouse gas emission-reducing agricultural practices.

The study concludes that realizing the full potential of CSA-synergies requires (1) a carefully selected portfolio of context-specific technologies and improved local practices, (2) that farmers and local land use planners are able to estimate costs-and-benefits of business-as-usual versus adaptation and mitigation options, and (3) an enabling policy environment streamlined towards CSA.

P-3320-23

Clam farming in the Lagoon of Venice. How to adapt to local and global changes?

C. Solidoro (1) ; G. Cossarini, (1) ; F. Giorgi (2) ; MC. Donata (1)
(1) Istituto nazionale di Oceanografia e di Geofisica Sperimentale OGS, oceanography, Trieste, Italy; (2) International Centre for Theoretical Physics (ICTP), Earth system physics (esp) section, Trieste, Italy

Culture based fisheries and aquaculture deeply rely on the coastal and marine environmental conditions and can be highly vulnerable to anthropogenic pressures and to climatic changes. Adaptation and mitigation measures to local and global changes need to be supported by information and assessments..

With this aim, a downscaling experiment linking a regional atmospheric model to local ecosystem and a target species population dynamic model was conducted to evaluate the effects of IPCC climate change scenarios on a temperate coastal lagoon ecosystem, the lagoon of Venice, along with goods and services provided by this ecosystem. Our results indicate that the changes in water temperature and reduction in plankton productivity caused by the modification of seasonal precipitation patterns will affect habitat suitability for clam growth and aquaculture. Our simulations show that aquaculture will suffer under projected future climate conditions and indicate that implementation of site- and condition-specific adaptive aquaculture management policies can mitigate the adverse effects of GC. This conclusion can be generalised to other temperate coastal systems and might be of particular importance in ecological- social-economic systems where clam farming is crucial for a self-sustaining economy.

P-3320-24

Climate-smart Agriculture put into Practice: The case of Rice Production in Southeast Asia

R. Wassmann (1) ; R. Reinke (1) ; BO. Sander (1) ; P. Ficarelli, (1)
(1) International Rice Research Institute, Los Banos, Philippines

The concept of Climate-smart Agriculture (CSA) encompasses both mitigation and adaptation practices that are fused into one comprehensive approach for devising sustainable farming systems. Rice production is an ideal model crop to illustrate the coherence of these principles as the CSA approach can draw upon a wealth of knowledge and previously developed farming practices for coping with adverse climatic conditions (to be tapped for adaptation) and for increasing resource use efficiencies (to be tapped for mitigation). Plant breeding has a proven track record to increase resilience of the rice crop against drought, submergence, salinity and heat stress. New biotechnology tools allow expeditious and precise changes in rice varieties that increase their performance under climatic stresses.

Rice is a major source of the Greenhouse Gases (GHGs) methane and - to a lesser extent - methane. Given that high rice yields are imperative to food security, the key to reducing GHGs is increasing resource-use efficiencies, namely of water and fertilizer. Methane is produced by the microbial community in flooded soils. In turn, water saving techniques such as Alternate Wetting and Drying (AWD) can be deployed to effectively reduce methane emissions while

– if implemented properly – rendering several co-benefits such as reduced input costs and stable yields in water scarce years. More judicious use of nitrogen fertilizers decreases emissions of nitrous oxides; this approach is now incorporated into interactive mobile phone apps to convey site-specific recommendation to farmers in several rice-growing countries.

Given the significance of rice production in Southeast-Asia, this production system also constitutes the key component of comprehensive initiatives for upscaling CSA technologies, such as the recently established 'Climate-Smart Villages'. In these villages, the entirety of land use is assessed in terms of interventions towards increased climate resilience and mitigation options through participatory action research. Thus, the previous and ongoing initiatives on rice production offer to derive meaningful 'lessons learnt' for future CSA dissemination of rice as well as for other land use systems.

P-3320-25

Potential Contribution of Supplemental Irrigation as a key Strategy of Local Adaptation to Climate Change in small holder farming in the Sudan Savanna zone of West Africa

ON. Worou (1) ; BJ. Naab (1)
(1) WASCAL, Agriculture, Ouagadougou, Burkina Faso

Irrigation is a key strategy to help farmers to adapt to potentially drier and shorter growing season projected for climate change effects in most parts of Africa, especially West Africa. Field experiments were conducted during the 2013 and 2014 in order to evaluate supplementary irrigation strategies for improving water productivity. Maize was planted on different sowing dates either rainfed or with supplemental irrigation using rainwater harvested. In general the date of sowing highly significantly affected on weight of grain under both rainfed and irrigated plots. Application of irrigation caused an significant increase in weight total dry matter biomass in 2013. In 2014, water productivity was 11.71 kg/ha/mm, 7.16 kg/ha/mm and 5.40 kg/ha/mm at early, medium and late dates respectively. A simulation study was done using the Decision Support systems for Agrotechnology Transfer (DSSAT 4.6)-CERES model in order to optimize irrigation level at 3 option of sowing dates. Model´s predictive capability was first verified by using some yield, phenelogy and treatments from current experiment. Simulations were then carried out for 31 years period with measured daily climatic data derived from 2 stations. The modeling showed that a window of sowing date can be implemented when it is associated with supplemental irrigation. Application of a higher amount of water or higher frequency of limited amount of water to rainfed maize could substantially increase crop yield and make it stable over years.

ORAL PRESENTATIONS

O-3321-01

From here to there: promises and perils in scaling up health adaptation

K. Ebi (1) ; D. Mariam Otmani (2)
(1) University of Washington, Department of Global Health, Seattle, WA, United States of America; (2) World Health Organization, Phe, Geneva, Switzerland

Objective: document lessons learned and identify opportunities and barriers to scaling up health adaptation projects in low- and middle-income countries to address current and future climate variability and change

Data sources: evaluation reports and other materials covering the first five years of implementation (2008-2013) of three multinational health adaptation projects covering fourteen countries (Albania, Barbados, Bhutan, China, Fiji, Jordan, Kazakhstan, Kenya, Kyrgyzstan, Macedonia, Philippines Russia, Tajikistan, and Uzbekistan) and qualitative data collected through a focus group consultation and interviews with 19 key informants purposively selected for their expertise and role in health adaptation to climate change

Methods: a qualitative review and synthesis of documents for evidence and examples of: attaining objectives and planned results of interventions; sustainability; stakeholder participation and community engagement; country ownership and socio-political constraints; human resources and capabilities; replicability and scalability; and health adaptation monitoring and evaluation

Main conclusions: The national projects increased resilience for particular weather-sensitive health outcomes by focusing on incremental improvements in policies and programs to address the current adaptation deficit associated with climate variability, and by beginning to establish enabling environments for additional adaptation. Irrespective of resource constraints, low and middle-income countries need to prepare for climate change through better understanding of potential risks, strengthening health systems, ensuring adequate policies and legislation, facilitating institutional support, and public education and awareness programs, including disaster preparedness measures. However, no project planned nor considered how to scale up successful community-based activities. Further, the activities undertaken may not be sufficient to address significant increases in climate variability and change. National health plans and budget processes need to move beyond focusing on shorter-term activities to address climate variability to also promoting mitigation and to transforming adaptation policies and programs into multi-faceted, collaborative (multi-disciplinary), and iterative activities, with support for capacity building, knowledge communication, and institutionalized monitoring and evaluation.

Climate change impact on heat-related mortality under some RCP scenario

Y. Honda (1) ; H. Kim (2)
(1) University of Tsukuba, Faculty of Health and Sport Sciences, Tsukuba, Japan; (2) Seoul National University, School of Public Health, SEOUL, Republic of Korea

Background: In 2014, we reported the future heat-related excess mortality projections as Chapter 2 of the book by World Health Organization. In this projection, we used SRES A1B scenario and the target was elderly population, i.e., 65+ years. We updated the projection using RCP scenario and for all age groups combined.

Methods: We defined excess mortality identical to the WHO book: The relation between daily maximum temperature and mortality is V-shaped, and the temperature at which the mortality is lowest is called «optimum temperature (=OT).» When the temperature is higher than OT, the mortality risk is higher than that at OT. We define this difference between the mortality at higher temperature and that at OT as excess mortality.

For projection, we used RCPs 2.6, 4.5, 6.0 and 8.5 with SSPs 1, 2 and 3 Target periods were 1981-2000 as the baseline, 2020s, 2050s and 2080s. The general circulation models (=GCMs) we used are GFDL-ESM2M, HadGEM2-ES, IPSL-CM5A, MIROC-ESM-CHEM and Noresm1-M. As of now, RCP&SSP-specific mortality rate has not been publicly available. Thus, we calculated mortality using IIASA SSP-specific population data by country, sex and 5-yaer age category.

Results: Regardless the GCM, excess mortality increased along with the time, and large increase was observed in China, India and Europe. Along with the temperature rise, the increase in excess mortality varied with the GCM, but the difference was smaller for nearer future. The difference due to the SSP appeared smaller compared with the difference due to the model.

Discussion: Impact of climate change on heat-related excess mortality will occur not only developing countries but also developed countries. This is specific to heat-related mortality, unlike other major health impacts such

as malnutrition, malaria, dengue fever, diarrhea and deaths due to coastal floods. Although «autonomous adaptation,» i.e., optimum temperature becomes higher along with the warming climate without specific adaptation policy, would occur, this ubiquitous impact all over the globe would require us to take actions for mitigation and adaptation.

Conclusion: Heat-related excess mortality would affect both developing and developed countries, and shows a good example of the necessity of cooperation all over the world.

Acknowledgements: This study was supported by the Environment Research and Technology Development Fund (S8 & S10) of the Ministry of the Environment, Japan, and the Global Research Laboratory (grant K21004000001-10A0500-00710) through the National Research Foundation of Korea (NRF), funded by the Ministry of Education, Science, and Technology, Korea.

O-3321-03

Global Risk Assessment of the Effect of Climate Change on Selected Causes of Death in 2030s and 2050s

S. Kovats (1) ; S. Hales (2) ; D. Campbell-Lendrum (3) ; J. Rocklov, (4) ; Y. Honda (5) ; S. Lloyd, (6)

(1) London School of Hygiene and Tropical Medicine, Social and Environmental Health Research, London, United Kingdom; (2) University of Otago, Wellington, New Zealand; (3) World Health Organization, Public Health, Environmental and Social Determinants of Health, Geneva, Switzerland; (4) Umeå University, Umeå centre for global health research, Umea, Sweden; (5) University of Tsukuba, Faculty of Health and Sport Sciences, Tsukuba, Japan; (6) London School of Hygiene and Tropical Medicine, London , United Kingdom

Climate change is likely to affect human health with important differences by world region. As climate change is likely to affect proximal and distal (upstream) risk factors for a wide range of health outcomes, the quantification of these risks and burdens is complex, and few global models are available. We will report the finding of a global assessment of the impact of climate change on selected mortality outcomes undertaken for the World Health Organization.

Future cause-specific mortality in 2030 and 2050 (in the absence of climate change) was estimated using regression methods for three development futures: base case, high growth and no-growth scenarios. Global climate-health models were developed for a range of health outcomes known to be sensitive to climate change: heat-related mortality in elderly people, mortality associated with coastal flooding, mortality associated with diarrhoeal disease in children aged under 15 years, malaria population at risk and mortality, dengue population at risk and mortality, undernutrition (stunting) and associated mortality. Future climate change was characterized by a medium-high emissions scenario (A1b) run through three climate models. The counterfactual was a future world with population growth and economic development but with baseline (1961-1990) climate. The annual burden of mortality due to climate change was estimated for world regions. For most pathways considered, the results reflect both positive and negative impacts on health.

Compared with a future without climate change, the following additional deaths are projected for the year 2030: 38 000 due to heat exposure in elderly people, 48 000 due to diarrhoea, 60 000 due to malaria, and 95 000 due to childhood undernutrition. WHO projects a dramatic decline in child mortality, and this is reflected in declining climate change impacts from child malnutrition and diarrhoeal disease between 2030 and 2050. On the other hand, by the 2050s, deaths related to heat exposure (less than 100 000 per year) are projected to increase. Impacts are greatest under a low economic growth scenario because of higher rates of mortality projected in low- and middle-income countries. By 2050, impacts of climate change on mortality are projected to be greatest in south Asia. These results indicate that climate change will have a significant impact on child health by the 2030s.

A main limitation of this assessment is the inability of current models to account for major pathways of potential health impact, such as the effects of economic damage, major heatwave events, river flooding and water scarcity. The assessment also did not consider the impacts of climate change on human security. Current models can capture only a subset of potential causal pathways, and none account for the effects of major discontinuities in climatic, social or ecological conditions.

Global climate change is projected to have substantial adverse impacts on future mortality, even considering only a subset of the expected health effects, and under optimistic scenarios of future socioeconomic development and with adaptation. This indicates that avoiding climate-sensitive health risks is an additional reason to mitigate climate change. The results indicate that significant impacts of climate change cannot be avoided, and supports the case for strengthening programmes to address health risks including undernutrition, diarrhoea, vector-borne disease, and heat extremes, and for including consideration of climate variability and change within programme design. The strong effect of socioeconomic development on the projections of future risks emphasizes the need to ensure that economic growth, climate policies and health programmes particularly benefit the poorest and most vulnerable populations.

O-3321-04

Managing climate-sensitive health risks in vulnerable Pacific Island communities with minimal adaptive capacity: Lessons from Rabi Island

H. Bambrick (1) ; S. Moncada (2)

(1) University of Western Sydney, School of medicine, Sydney, Australia; (2) University of Malta, Institute for european studies, Msida, Malta

In coming years, the Pacific is expected to experience increasing climate extremes as periods of drought and heavy rainfall, cyclones and heat become more frequent and intense, oceans become warmer and more acidic, and sea-level rise affects artesian water causing flooding. Pacific Island communities are especially susceptible to the health impacts of climate change due to their isolation, limited land area, low lying topography, and generally high levels of inherent vulnerability, together with poverty and widespread reliance on subsistence farming. The poorest communities especially are inadequately resourced to manage current climate and health risks, and have even less capacity to prepare for and adapt to long-term climatic changes. Despite the acceptance that communities in the Pacific are highly vulnerable, very little is known about how these risks may best be managed with so few resources and the structural disadvantages typical of small island developing states. Existing data in the region relevant to climate and health is sparse, may not be relevant to particular communities, and may miss important local features. This study is an in-depth assessment of vulnerability on Rabi Island. We document current health concerns, especially in relation to climate-relevant health risks. We evaluate contemporary coping mechanisms and capacity for adaptation, in order to develop feasible and acceptable strategies in the context of extremely limited resources.

Rabi Island is a small volcanic island in Fiji situated to the east of Vanua Levu, one of Fiji's two main islands. Rabi is home to around 5000 Banaba Islanders who were brought there from Kiribati 70 years ago, displaced by phosphate mining on their home island. The islanders have maintained their Banaba culture and language and have dual Kiribati-Fijian citizenship. In many ways, Rabi is typical of Pacific vulnerability to climate change – underlying poor health, poverty and exposure to extreme events such as cyclones – but with the added complexity of being an ethnic minority population that is especially isolated from the rest of the country. Income is very low, houses are crowded, and islanders rely on fishing and subsistence farming. Aside from coconuts that are collected for processing, there is a single cash-crop, kava, that generates most of the income on the island. Vector-borne disease, food- and water-borne and other communicable diseases, ciguatera (fish poisoning), malnutrition and direct physical trauma during extreme events are current health problems. Existing climate vulnerabilities, including threats to food security, are likely to be amplified with climate change.

We present the findings from our vulnerability assessment using data from a detailed random household survey (156 item questionnaire, 200 households, yielding data on 1500 individuals) and from focus groups of women and men in each village using Participatory Rural Appraisal

methods. We explore locally feasible opportunities to boost community resilience in the face of climate change and adaptation interventions to minimise adverse health outcomes. We discuss the relevance of our findings to other vulnerable communities in the Pacific and elsewhere.

O-3321-05

Impacts of Climate Change on Vector Borne Diseases in the Mediterranean Basin - Implications for Preparedness and Adaptation Policy

S. Paz (1) ; M. Negev, (2) ; M. Green (2)
(1) University of Haifa, Geography and Environmental Studies, Haifa, Israel; (2) University of Haifa, School of public health, Haifa, Israel

The Mediterranean region is vulnerable to climatic changes. A warming trend exists with an increase in warm days and nights, longer and warmer summers, an increase in the frequency and the severity of heat waves and a reduction in rainfall amounts. Therefore, it is expected that vector-borne diseases (VBD) in the region will be influenced by climate change since the ecology, development, behaviour, and survival of insects and the transmission dynamics of the diseases they transmit are strongly influenced by climatic factors (especially temperature, rainfall, and humidity). The same factors also play a crucial role in the survival and transmission rate of the pathogens.

The main parameter that affects the rate of multiplication in the insect is temperature. When the temperature increases, it tends to cause an upsurge in the growth rates of mosquito populations, decrease the interval between blood meals, shorten the incubation time from infection to infectiousness in mosquitoes and accelerate the virus evolution rate.

Most cities in the Mediterranean are densely populated. Air conditioning is used, but as part of the local mentality windows remain open for most of the hot months. Many activities, particularly social gatherings, occur in outdoor locations such as shaded balconies and outdoor restaurants - all ideal for contact with the vector.

For some disease emergence in the Mediterranean basin (i.e. West Nile virus) the linkage with climate change was proved recently; for others (such as dengue) the risk for local transmission is real.

Consequently, adaptation and preparation for changing patterns of VBD distribution is crucial for the Mediterranean countries.

We analyzed nine representative Mediterranean countries and found that they have started to prepare for this threat, but the preparation levels among them differ greatly. Policy mechanisms at the regional level are limited, and depend on international organizations.

The Mediterranean countries should enhance collaboration in order to address cross-border aspects of vector transmission since the vectors of infectious diseases know no political borders.

Based on the Mediterranean Action Plan (MAP)'s success in advancing national legislation and regional cooperation, we suggest that this existing framework will address the risk of VBD transmission.

Regional-level policy mechanisms should include: monitoring and surveillance systems, capacity building in and across environment and health sectors, and stakeholder awareness and participation. Regional vector management should be advanced by the Mediterranean countries before the VBD develop into regional outbreaks.

O-3321-06

A vulnerability/resilience framework approach

LP. Briguglio (1) ; S. Moncada (2)
(1) University of Malta, Islands and Small States Institute, Msida, Malta; (2) University of Malta, Institute for european studies, Msida, Malta

The presentation will draw on the literature on the health impacts of climate change, and will re-position the arguments in a vulnerability/resilience framework. It will be argued that many communities are located in territories that are inherently prone to being negatively affected by global warming in terms of health and this will have major negative impacts on human capital in these territories. This will be the vulnerability side of the argument. The resilience side of the argument will relate to what can be done, policy-wise, to strengthen the ability of communities to evade health problems and survive, recover from, and even possibly improve their health condition, in the face of global warming. These could include adaptation and mitigation measures. The outcome of inherent vulnerability and policy induced resilience could result in a net strengthening of human capital.

O-3321-07

Adaptation to potential shifts in malaria breeding sites: larvicide application in Sub-Saharan Africa, guided by risk maps based on remote sensing

I. Traore (1) ; A. Sié, (2) ; V. Machault (3) ; C. Vignolles (4) ; R. Sauerborn (5) ; P. Dambach (5) ; N. Becker (6)
(1) Centre de Recherche en Santé de Nouna, Service Formation Recherche et Communication, Nouna, Region Boucle du Mouhoun, Burkina Faso; (2) Centre de Recherche en Santé de Nouna, Direction, Nouna, Burkina Faso; (3) Laboratoire d'Aérologie, Toulouse, France; (4) CNES, Toulouse, France; (5) Heidelberg University, Institute of public health, Heidelberg, Germany; (6) German Mosquito Control Association, Heidelberg, Germany

Climate change is likely to lead to shifting patterns of temporal and spatial distribution of many vector borne diseases, such as malaria. Firstly, this could lead to new areas becoming suitable for malaria transmission, particularly in higher altitudes and latitudes. Secondly we could observe epidemic patterns of malaria transmission and thirdly within the area of current endemicity, we could see e.g. a prolongation of the transmission period and a change in the productivity of breeding sites.

In Sub-Saharan Africa, significant progress has been made in providing access to bed-nets impregnated with insecticides and in offering subsidized, but still expensive malaria treatment. Both control measures are likely to have less than optimal effectiveness: Health care seeking drops drastically in the high transmission /high agricultural work season due to high time costs of farmers and an ebb in household cash resources before the next harvest. Second, many farmers sleep in makeshift straw huts in the midst of their fields and are thus not protected by bed nets. Unfortunately the third pillar of control, blocking larval production in breeding sites through applying larvicides, has hardly been used for malaria control. Larviciding was abandoned due to the large biological side effect of the then used DDT. However, biological larvicides, derived from Bti (Bacillus thuringiensis israeliensis) and others have been developed in the meantime. They have been effectively applied for decades in high and middle-income countries in larval control programs without showing any adverse human or biodiversity side effects. In Africa however, larviciding is largely absent in malaria control. This is generally attributed to the perceived high costs of biological larvicides and the high cost of treating all breeding sites around human settlements every two weeks during the rainy season.

We developed and validated a technique using SPOT-5 satellite images to predict which breeding sites would carry Anopheles larvae and at which larval productivity. The remote sensing predictions were tested and validated with field entomological and ecological data until a high degree of agreement was achieved. We used this novel technique to test two separate hypothesis that (i) applying larvicides is a cost-effective measure for malaria control, compared to currently applied control measures; and (ii) that it makes cost-effectiveness sense to apply the larvicides only to the breeding sites with the highest larval productivity.

We present first cost and effectiveness results of a three-armed cluster-randomized trial with three arms: (i) larvicidal treatment of all breeding sites within a radius of 1,5 km of the village borders; (ii) larvicidal treatment of only those 50% of breeding sites which are identified and validated as high-productivity sites: and (iii) control clusters of villages with no larvicide application of any

kind. All study arms receive the current national routine malaria control measures.

The results show that larvicidal treatment is highly effective both in larvae removal for 2 weeks under field conditions and to significantly reduce adult mosquito abundance in reference villages. First cost data indicate that the costs of locally adapted larviciding compare favorably to those of impregnated bed nets and that the targeted 50% larvicidal intervention is about 35% less costly. Analysis of data on the effect of malaria transmission to children under five years is under way.

The Effect of Training on Health: Biogas Development Interventions to Enhance Health Resilience to Climate Change in Informal Urban Settlements in Ethiopia

S. Moncada (1) ; H. Bambrick (2)
(1) University of Malta, Institute for european studies, Msida, Malta; (2) University of Western Sydney, School of Medicine, Penrith, Australia

This paper measures the impact of community-level Overseas Development Assistance (ODA) on public health, specifically focusing on the provision of training. It is often the case that biogas programmes do not include any training component accompanying the intervention, believed to be either too expensive or simply overlooked. However, improved sanitation facilities do not automatically translate into better health standards, unless increased awareness and education can support behavioural changes to ensure long-lasting development.

The context of this research is an informal urban settlement in Ethiopia, characterised by extreme poverty, poor sanitation and exposure to climate-sensitive risks, where a biogas sanitation project funded by ODA was implemented in 2013. The development intervention included environmental and sanitation training, provided to 45 heads of the 200 beneficiary households of the project. Quasi-experimental techniques with propensity score matching methods are applied using two waves of panel data, generated from a dedicated survey conducted among all the households.

The study finds that training, provided within the biogas and sanitation development intervention, had positive effects on a number of health indicators including self-assessed health and lower use of contaminated water from the river. Although training beneficiaries carries additional costs during implementation, the benefits are significant, suggesting long-term behavioural changes. Participants who live closer to the biogas facilities enjoyed further health benefits, reinforcing arguments for the scaling-up of biogas development and sanitation interventions inclusive of training in informal urban settlements to enhance health resilience to climate change.

P-3321-01

Assessment of health-related impact of climate change in Taiwan

CC. Chen (1)
(1) National Health Research Institutes, Institute of Population Health Sciences, Zhunan, Miaoli, France

Objective: To provide a general framework of health impact assessment due to climate change in Taiwan. Health impacts such as heat or air pollution-related mortality and hospital admissions of cardiovascular disease and respiratory diseases, variability of meteorological factors on the dengue fever and diarrhea incidents, will be assessed for the projected climate change in 2020 to 2050.

Methods: Meteorological records during the past few decades will be collected from the Data Bank for Atmospheric Research of Taiwan. Hospital admissions and mortality data will be obtained from the National Health Insurance (NHI) dataset and Multiple Cause of Death Automated Data Entry System. Environmental monitoring data will be obtained from the Taiwan EPA website. The comparative risk assessment (CRA) method of the World Health Organization will be employed for comparisons of risk factors (such as frequency and intensity of extreme heat waves, storms, and droughts) and climate-sensitive health outcomes. Dose-response relationships for baseline climate during the period 1990-2010 will be determined and climate-attributable burden of disease (the numbers of deaths and disability adjusted life years, DALYs) for different climate scenarios predicted for the future period 2020-2050, as well as avoidable burden resulting from the effects of mitigation of GHG will be estimated. Quantitative statistical methods will be developed for uncertainties in the health impact assessment.

P-3321-02

Climate Change and the use of Serious Games: responses for Neglected Tropical Diseases in Southwestern Amazonia

M. Cesario (1) ; L. Saturnino (2) ; M. Masoodian (3) ; RR. Cesario (4)
(1) Academia Magdala, Franca, São Paulo, Brazil; (2) Trinity College Dublin – University of Dublin, School of computer sciences – o'reilly institute, Dublin, Ireland; (3) University of Waikato, School of computer science, Hamilton, New Zealand; (4) University of Franca, Medical school, Franca, Brazil

In the Brazilian Amazon Region, Land Use/Cover Change – the main contributor to the national emissions of Green House Gases and, therefore, to climate change – equals to deforestation through anthropogenic forest-fires. The associated biodiversity loss affects the spread of vector-borne Neglected Tropical Diseases (NTDs), due to the susceptibility of infectious diseases' vectors to environmental degradation, which in turn disrupt natural cycles. Balanced ecosystems, where those natural cycles occur, act as buffer zones between zoonosis and susceptible human populations – the Ecosystem Service known as "Infectious Diseases Regulation". This paper addresses the potential benefits of using a "serious game" as part of community-based healthcare practices, to educate local citizens and health professionals about ways of controlling and reducing the spread of NTDs in remote regions, especially in the tri-national South-western Amazonia. American Cutaneous Leishmaniasis represents an ideal challenge for the application of complex ludic educational tools, because its complex and poorly understood transmission cycle involves humans, their dogs, insect vectors, sylvatic reservoirs and other domestic animals (chicken, pigs, etc.) that attract both vectors and sylvatic reservoirs to the peri-domicile. The existing efforts to control American Cutaneous Leishmaniasis' transmission have relied, so far, on the development of either drugs (to break disease transmission with the appropriate treatment of humans and, in some countries, dogs, or to prevent people and dogs being infected, by the use of insect repellents) or vaccines (for dogs, so far). These chemically oriented efforts have helped at a slower pace than the spread of these diseases. Therefore, an effective educational tool to improve knowledge, attitudes and practices related to local people's living conditions that maintain high levels of American Cutaneous Leishmaniasis' transmission is challenging and timely, especially for the locals, who suffer the burden of such Climate Change prone Neglected Tropical Diseases. Education was among the first applications of "serious games" and remains an important focus of Information Technology work in this area. This paper introduces a prototype game called Dr Ludens' LSG (Leishmaniases Serious Game), expected to be the first game of a Doctor Ludens' series. It focuses on American Cutaneous Leishmaniasis, and aims to involve lay citizens and primary health-care personnel in collective tasks around their local community and individual households, where they attempt to decrease vector density and to protect people and dogs against vector bitting. This game can be easily extended to Visceral Leishmaniasis, as well as to other vector-borne endemic diseases, such as Dengue Fever, Chikungunya and Malaria. The design process of the game architecture of the so-called Dr Ludens' LSG, developed by a multidisciplinary team of computer and epidemiological scientists, is described, as well as a recent evaluation by a group of Leishmaniases' experts. These researchers have identified several positive aspects of our prototype, as well as suggested a number of improvements to make its future deployment more effective and widespread. The implementation of these suggested improvements is intended to be done before

releasing Dr Ludens' LSG to selected local people at the study region A longitudinal study of its use and potential educational benefits towards the Knowledge, Attitudes and Practices of these selected users, in regards to their diseases' preventative measures, is also envisaged. With the rapid spread of internet connectivity to otherwise remote regions, there is vast potential for application of the new generation of highly connected interactive games to disease prevention and control, by means of education and information campaigns conducted through gaming. When people see, clearly, interconnections between Climate Change and their own lives, including their increasing risk of contracting infectious diseases, they become more likely to adopt a low carbon way of life.

P-3321-03

Impact of Climate Change on Influenza Mortality in US: A Generalized Additive Model Analysis

S. Dasgupta (1) ; I. Wing, (2)
(1) Fondazione Eni Enrico Mattei (FEEM), Venezia, Italy; (2) Boston University, Dept. of earth & environment, Boston, United States of America

Each year approximately 5-20 percent of US residents suffer from influenza and more than 200,000 are hospitalized (CDC, 2014). The effect of annual influenza on the health care system is rather substantial, 3.1 million hospitalized days and 31.4 million outpatient visits with direct medical costs estimated at over $10 billion (Molinari, 2007). The influence of weather and climate on influenza transmission and mortality has been studied in a variety of ways and with varying levels of complexity, especially in epidemiology, however, there is little robust empirical evidence. Exposure to extreme temperatures and/or extreme humidity levels increases the risk of mortality mainly through impacts on our cardiovascular and respiratory systems. Epidemiological studies (Barecca and Shimshack, 2012; Deschenes and Moretti, 2007; Lowens, 2007; and Martens, 1998) state that colder temperatures have greater influence on mortality than warmer temperatures but hot temperatures are more likely to affect the inter-temporal distribution of mortality by expediting the time-to-death of those individuals already nearing death. Humidity can also affect human health through a variety of mechanisms. Low humidity levels can lead to dehydration and increase the spread of influenza (Lowen et al., 2007; Shaman and Kohn, 2009; and Xie et al., 2007), while high humidity levels exacerbate the effects of heat stress because humidity impairs the body's ability to sweat and cool itself (Ahrens, 2009). Low humidity conditions, which are often accompanied by low temperatures, enhance survival times of viral aerosols (Loosli, 1943; Harper, 1961; and Schaffer, 1976). This paper utilizes generalized additive models (GAM) which includes a link function g(.) relating the mean μ to the linear predictor Xβ. The general form is; $g(\mu) = X\beta$

Essentially, GAM is a nonparametric extension of generalized linear models (GLM), used often for the case when there is no a priori reason for choosing a particular response function and the response functions needs to be generated from the data itself. GAMs (Hastie and Tibshirani 1986, 1990) are semi-parametric extensions of GLMs; the only underlying assumption made is that the functions are additive and that the components are smooth. A GAM, similar to a GLM, uses a link function to establish a relationship between the mean of the response variable and a smoothed function of the explanatory variable(s). The idea behind using smooth functions is to removes the small variations while maintaining the major trend of each variable with a view to increase the efficiency in estimating the model. The non-parametric of GAM means that it does not assume a rigid form for the dependence of the response variable on the predictors. Another strength of GAMs is their ability to deal with highly non-linear and non-monotonic relationships between the response and a set of explanatory variables.

Our results provide robust evidence of non-linear impact of both temperature and humidity on influenza mortality rates. The risk of influenza mortality is highest between minimum temperatures of −30°C□ and −10°C and declines as the minimum temperature goes above 8°C. In the case of maximum temperature, the risk of influenza mortality is highest in the range of −15°C and 5°C, while the effect of minimum specific humidity is highest between 5 g/kg and 20 g/kg. The medical and epidemiological literature suggests that dry conditions result in moisture losses and lead to dehydration and increases spread of influenza by increased viral shedding (Salah et al., 1988; Loosli, 1943; Harper, 1961; and Schaffer, 1976). Results also suggest that influenza mortality is insensitive to high temperature levels. When considering the mean temperature and mean specification our results indicate that the highest risk of influenza mortality is between −20°C and −10°C and for mean specific humidity, the risk is highest between 7.5 g/kg and 15 g/kg. This range is particularly significant as Lowen et al. (2007) reports that the infection and transmission of influenza virus is highly efficient at relative humidity (RH) of 65 percent – equivalent to specific humidity of 11.3 g/kg, is within this range. Thus, our findings provide empirical evidence to epidemiological experiments. These results provide comprehensive empirical evidence influential epidemiological works under laboratory condition by Cannell et al. (2008), Lofgren et al.(2007) and Lowen et al. (2007).

P-3321-04

Modelling adaptation in climate change impact assessments of heat-related mortality

S. Gosling (1) ; D. Hondula (2)
(1) International Society of Biometeorology (ISB), Nottingham, Nottinghamshire, United Kingdom; (2) Arizona State University, Center for policy informatics, school of public affairs, Phoenix, United States of America

The potential for populations to respond to warmer temperatures under climate change scenarios by adaptation means that non-stationary heat-related mortality models should be applied in climate change impact assessments. However, there remains a long-standing debate as to how the adaptation response, which includes physiological acclimatisation as well as a range of behavioural adaptations, should be modeled in these assessments. The relatively limited state of knowledge on how populations may adapt to a warmer world, as well as limited knowledge on the extent to which populations may adapt, means that some climate change impacts assessments do not account for adaptation response at all. Such an approach is unrealistic and zero adaptation is improbable. Nevertheless, numerous studies have adopted this simplistic approach because there is no uniformly accepted method for modelling adaptation. Other studies have attempted to consider adaptation response by employing statistical methods, of varying complexity, including regression techniques that control for historical adaptation, interpolation of present vulnerabilities to the future, and the application of "analogue" cities whose present climate best approximates the estimated climate of a target city as expressed by climate model projections. Even considering the existence of these disparate approaches, there has to date been no comprehensive comparison of them. In turn this has precluded the development of a standard and commonly applied technique for modeling adaptation in heat-related mortality climate change impact assessments. We outline an ongoing study that aims to compare a number of approaches for modelling adaptation by using a consistent set of input data and temperature-mortality models for several cities, with a means to understanding the relative merits of the different approaches. An ambitious goal of our research project is to recommend a standard method that may be adopted by future climate change impact assessments of heat-related mortality and to this end address an important gap in knowledge and techniques on health responses to climate change.

P-3321-05

Whether Changing Environmental Conditions of Living negate the impact of Socio-economic Development on Health Outcomes of Urban Poor?

R. Goyal (1)
(1) Ramana Group, -, Dehradun, Uttarakhand, India

In recent years, climate change has almost becomes synonyms with development of environmental hazards affecting all living being. The adverse affects are particularly large on those segments of populations where current burden of climate-sensitive disease is high. One

such category is urban poor which is characterized by cramp living spaces, lack of sanitation and safe drinking water, poor and unhygienic environmental conditions, poor socio-economic status etc. As a consequence, their major health and morbidity indicators (due to communicable and non-communicable diseases) and mortality rates are higher than other sections of population viz, rural and urban non-poor. It has also been observed that unlike the rural areas, programs to address socio-economic development and healthcare needs in urban poor localities have limited impact on health outcomes. Why? Is it because living environment is quite degraded (inputs are rendered ineffective) or the interventions are not penetrating or accessed by all people to realize any measurable outcome?

This paper examines this phenomenon by taking India as a case. It compares the health outcomes for urban poor and non-poor in contemporary Indian communities against the socio-economic and healthcare developments, over a period of one decade. It also seeks to answer why development interventions are relatively less effective in case of urban poor, whereas it should have been other way around because urban poor have more intense poverty conditions and even small inputs would have made a difference.

The analysis is based on data are drawn from two large nationwide surveys (NFHS II and III) carried out in 1998-99 and 2005-06 segregated for urban poor (and non-poor) using wealth index (a composite index reflecting on quality of life and possession of household goods).

The findings are likely to provide more insight in to the development programming for urban poor against the backdrop of climate changes.

P-3321-06

The Effectiveness of Heat Early Warning System in South Korea

J. Ha (1)
(1) Korea Environment Institute, Korea adaptation center for climate change, Seoul, Republic of Korea

Heat early warning system is a first heat-wave measure to cope with the heat wave. And this system has been operating in many countries today. Evaluation of the effectiveness of heat early warning system may be utilized to present a further improvement. And, these days, it has been reported that the operation of heat early warning system brings to a decrease in number of emergency services or deaths related to stroke. The aim of this study is to quantitatively examine the associations between the operation of heat early warning system and the reduction of mortality in South Korea.

In South Korea from 2008 to 2012, heat-waves occurred for a total of 8 times, 26 days. I completed cardiovascular-related death counts in four periods. The four periods were defined as the days in heat-wave and above the threshold, the days in heat-wave and below the threshold, the days in non heat-wave and above the threshold, and the days in non heat-wave and below the threshold. And, the threshold was defined as the temperature at which the risk of mortality begins to increase with increasing temperature.

The daily average of CVD-related death counts were 19.83 and 20.44 for 18 days in heat-wave and above the threshold and 16 days in heat-wave and below the threshold, respectively. In case of 1-day lagged effect, the daily average of CVD-related death counts were 18.28 and 21.13 for 18 days in heat-wave and above the threshold and 16 days in heat-wave and below the threshold, respectively. In summary, the operation of Korea's heat early warning system has a positive effect on bringing a reduction of deaths caused by heat-wave.

P-3321-07

Assessing Health Vulnerability to Climate Change in Morocco: Governance and Adaptation Options

K. Kahime (1) ; B. Mohamed (2)
(1) Faculty of Sciences Semlalia, Cadi Ayyad University of Marrakesh, Laboratory of ecology & environment, Marrakesh , Morocco; (2) Head, Research Laboratory on Territorial Governance, Human Security and Sustainability (LAGOS), Public law department, faculty of law, economics and social sciences of agadir, Agadir, Morocco

The climate factor plays an important role in most systems critical to life. Its considerable effect on many physical and biological systems has the potential to increase humans' vulnerability to climate change. Among these vulnerabilities, human health is highly considered. Actually, and in addition to the health risks of extreme climate events, many infectious diseases are expected to change their geographical or seasonal patterns and incidence due to climate change and variability. More specifically, climate change will likely affect the distribution, prevalence and lifecycle of several vector-borne diseases – such as Malaria and Leishmaniasis – and water-borne diseases – such as Schistosomiasis. These disregarded diseases still ravage lives covertly in many parts of the Global South and are likely to be a major human health burden in the coming years due to climate change and other factors. However, and despite this alarming fact, there is still limited specific scientific evidence in this area that can serve as a relevant reference for policy-making processes in many countries.

In Morocco, infectious diseases are still a public health problem. Despite the adoption of a related domestic policy and the consideration of these diseases as reportable, the number of reported cases – both indigenous and imported – is constantly increasing. Given the knowledge gap in this area, the aim of this research is twofold: 1) Undertaking a vulnerability analysis of possible climate change impacts on infectious diseases in Morocco from an eco-epidemiological and socio-economical approach; 2) Assessment of Morocco's adaptive capacity and identification of existing gaps which may affect the health security of population in the future with regard to infectious diseases and their interactions with climate change. Throughout the analysis, the policy options needed to effectively monitoring and managing climate change impacts on human health – with a focus on adaptation options specific to Moroccan context – will be highlighted.

P-3321-08

Different heat wave definitions and their association with emergency department visits in seven major cities of South Korea

H. Kim (1) ; HL. Soo (1)
(1) Seoul National University, School of Public Health, SEOUL, Republic of Korea

BACKGROUND:
On-going climate change is accompanied by an increase in the frequency, duration, and intensity of climate-related extremes, such as heat waves, droughts, floods, cyclones, and wildfires, impacting on human health directly and indirectly.

OBJECTIVES:
We examined the association between heat waves and emergency department (ED) visits and estimated the impact of heat waves on emergency department visits in seven major cities of South Korea to understand the health effect of climate change quantitatively. In Korea, heat-wave warning is issued by the weather office if the daily maximum temperatures is expected to be higher or equal to 33℃ for 2 consecutive days. This definition is the same for all cities in Korea. We also would like to evaluate the effect of different definition of heat-wave using city-wise relative temperature rather than absolute temperature.

METHODS:
Different heat waves were defined as having at least 2 consecutive days with daily mean temperatures at or above the 98th percentile for warm season in each city and with daily maximum temperatures at or above 33℃ for all cities. We estimated the relative risks (RRs) of ED visits for heat-related, cardiovascular, and respiratory diseases on heat-wave days compared with non-heat-wave days using city-specific Poisson generalized linear models adjusted for daily mean temperature, relative humidity, day of the week, and time trends. In addition, we used time-stratified case-crossover with 28-day stratum to estimate the increase risk of ED visits associated with heat-wave, then and compared the estimates from time-series analysis with those from time-stratified case-crossover analysis. We also estimated the association between ED and duration of heat-wave with two different definitions using time-series

and time-stratified case-crossover analyses

RESULTS:
Heat waves defined as having at least 2 consecutive days with daily maximum temperatures at or above 33℃ for all cities were associated with RRs of 2.79 (95% CI: 1.84, 4.23), 2.19 (95% CI: 1.39, 3.46), and 1.5 (95% CI: 1.07, 2.11) for heat-related ED visits in Seoul, Gwangju, and overall across all cities respectively, and heat waves defined as at least 2 consecutive days with daily mean temperatures above the 98th percentile for warm season in each city were associated with 2.44 (95% CI: 1.47, 4.06), 2.29 (95% CI: 1.66, 3.16), 1.74 (95% CI: 1.07, 2.82), and 1.80 (95% CI: 1.44, 2.25) for heat-related ED visits in Daegu, Seoul, Gwangju, and overall across all cities respectively. These estimates indicated the significant increases in the number of ED visits on heat-wave days compared with non-heat-wave days with both definitions. Most of estimates suggested positive associations between heat waves and heat-related ED visits and varied among the cities. Most estimates of heat wave risk for cardiovascular and respiratory ED visits were very weaker than those for heat-related ED visits although these findings were not statistically significant. However, the estimates of heat waves risk for cardiovascular ED visits were 1.34 (95% CI: 1.10, 1.63) under 33℃absolute temperature and 1.39 (95% CI: 1.09, 1.77) under 98th percentile temperature in 65+ year age group. The time-stratified case-crossover analysis produced results similar to those found in the time series analysis for the associations between heat waves and ED visits. The estimated risk for heat-related ED visits for every 1-day increase in heat wave duration was the highest in Seoul with RR of 1.49 (95% CI: 1.29, 1.72), and the estimates of 1.48 (95% CI: 1.17, 1.88), 1.28 (95% CI: 1.04, 1.58), and 1.20 (95% CI: 1.10, 1.31) significantly indicated the positive associations between heat wave duration and heat-related ED visits in Daegu, Gwangju, and overall across all cities respectively.

CONCLUSIONS:
Our findings using different definitions and character for heat waves and ED visits data from NEDIS provide supportive evidences of the health effect of heat waves for further study and policy makers to reduce the health risk of heat waves varying among areas in South Korea.

P-3321-09

Northern populations in a changing climate

T. Klimova (1) ; V. Fedorova (1)
(1) North-Eastern Federal University, Research Institute of Health, Yakutsk, Russia

The Republic of Sakha (Yakutia) located in the north-eastern part of the Asian continent. On an area of 3083.523 sq. km is home to about one million people. The indigenous population of the region (Yakuts, Evens, Evenks) is about 53% of the total population. Territory of Republic belongs to the zone with the uncomfortable conditions for living of the population. The main environmental factors are cold exposure, temperature, violation of photoperiodic, geomagnetic, gravitational perturbations and deficiency of trace elements. According to a research, the indigenous population of the northern territories in the process of adaptation to extreme environmental conditions to formulate and institute specific features of the constitution and metabolism to ensure efficient functioning of all body systems. These features of the northern populations of researchers attribute the high density of the body, a relatively strong development of osteo-muscular component of the body, increased fat metabolism, high reserve capabilities of the antioxidant system, increasing the basal metabolic et al. At present, the processes of industrialization and urbanization, accompanied by psycho-emotional stress, changes in diet and lifestyle, lead to the failure of established mechanisms of evolutionary adaptation to extreme factors and lead to the development of pathological conditions. About stress adaptation reserves of the organism under the influence of complex environmental factors and suggest low life expectancy, high rates of morbidity and mortality among the population of northern regions. That is, these populations carry the double burden of the adverse effects of both natural and socio-economic factors affecting health. In terms of the future of climate change, these groups are among the most vulnerable. Climate warming is expected to change in the spectrum of diseases, increase the proportion of infectious diseases, the number of cardiovascular events, of stressing factors, the changing of nutrition. Therefore it is necessary to forecast possible trends in health and consider possible measures to maintain the health and life of humans.

P-3321-10

Integrating climate information into decision support tools for public health

R. Lowe (1) ; X. Rodó (1)
(1) Institut Català de Ciències del Clima (IC3), Climate dynamics and impacts unit, Barcelona, Spain

More frequent and severe extreme climatic events have been accompanied by the accelerated emergence of new infectious diseases worldwide. Infectious disease epidemics directly impact the health of local populations, strain healthcare systems, and cause substantial economic loss. Given climate change, globalisation, increased air travel and connectivity with endemic areas, there is a need to strengthen local resilience to infectious disease threats via innovative decision support systems. Seasonal climate forecasts provide an opportunity to incorporate precursory climate information into decision support systems for climate-sensitive diseases. This aids epidemic planning months in advance, for diseases such as dengue fever, cholera and malaria.

Here, we present a versatile Bayesian hierarchical statistical mixed model framework, designed to quantify the extent to which climate indicators can explain variations in disease risk, while at the same time taking into account their interplay with observed confounding factors and also intrinsic features of disease dynamics. Using forecasts of climate, timely spatio-temporal probabilistic predictions of disease risk can be obtained, to guide prevention and control activities. The framework can be adapted to model any climate-sensitive disease at different spatial/temporal scales and geographical settings. We provide case studies, quantifying the impact of climate on dengue fever in South America and South East Asia. We also illustrate how model results could be translated into actionable warnings for public health decision makers.

P-3321-11

Community-Based Heat-Stress Vulnerability Assessment with Monitoring, Social Survey, and Crowd-sourcing Technology for Health Adaptation

SC. Lung (1) ; DW. Wang, (2) ; SH. Tu (3) ; PS. Liao (3) ; MC. Chen, (2) ; SW. Chen (2) ; LJ. Chen (2) ; CY. Lin (1) ; WC. Wang, (1) ; FM. Huang, (2)
(1) Academia Sinica, Research Center for Environmental Changes, Taipei, Taiwan; (2) Academia Sinica, Institute of information science, Taipei, Taiwan; (3) Academia Sinica, Research center for humanities and social sciences, Taipei, Taiwan

Increased mortality was observed on heatwave days worldwide in recent years. According to the projected mortality changes in high income Asian countries such as Taiwan in 2030 and 2050 by World Health Organization, the increase in heat-related mortality is the highest compared to mortality change of all other potential causes due to climate change. A proactive heat-stress vulnerability assessment was conducted in support of reducing health risks and formulating health adaptation strategies in Taiwan, with emphasis on community-based heat-stress exposure assessment and response-capacity evaluation using social survey and crowd-sourcing surveys. This presentation showcases scientific findings from this trans-disciplinary research framework using Taiwan, a sub-tropical island, as an example. A novel two-tier heat-stress vulnerability assessment was conducted with multiple innovative facets. First, physical (heat), chemical (air pollution), and social (behavior and response capacity) aspects of vulnerability were assessed with crowdsourcing technology as well as mature methodologies in atmospheric chemistry monitoring/modeling and survey research. Secondly, both direct (heat) and indirect (air pollution) exposure pathways due to temperature were assessed. Thirdly, taking advantages of the bottom-up and top-down approaches, a two-tier framework is adopted to examine important factors and associated physical, chemical, and social mechanisms at the community level as well as to identify the spatial distribution of vulnerable groups and areas at the national

level. Fourthly, the controllable factors of exposure to heat-stress and air pollutants and those of individual and community response capacities were targeted so that the health risks can be minimized by either interrupting the exposure pathway or enhancing the response capacity of the stressed population. Lastly, the vulnerability factors studied correspond directly to the respective policy options in social and health promotion programs and heat-warning system establishment so as to facilitate the science-policy dialogue. Recommendations for health adaptation strategy were made accordingly to enhance resilience of individuals and communities facing the challenges of more frequent heat waves in the future.

P-3321-12

Climate Change, Episodic Drought, and Valley Fever Epidemic in California

M. Matlock (1)
(1) University of California Irvine, Public Health, Irvine, CA, United States of America

Valley Fever (Coccidioidomycosis) is a reemerging infectious disease that is endemic to the southwest United States (California, Arizona, Utah, Texas, Nevada, and New Mexico), Mexico, Central America, and South America. The disease results from inhalation of spores from soil fungi Coccidioides immitis or Coccidioides posadasii, which typically occur in separate regions but manifest the disease similarly. Environmental factors associated with low elevations, sandy soil, and less than 20 inches of rain per year favor the persistence of the fungi and risk of infection. The recent increase in incidence of Coccidioidomycosis in several California counties has been attributed to large amounts of dust due to several years of drought followed by rainy seasons. However, no research has been conducted to unpack the complex linkages between climate change, soil fungal diversity, and social conditions that lead to human vulnerability Coccidioidomycosis. We are investigating communities in the deserts of the Southwest United States, such as Borrego Springs, California, as part of the "front line" of global climate change and regional drought mitigation. Borrego Springs faces an impending water crisis, with some studies suggesting the town will run out of economically viable water within 30 years. With El Nino Southern Oscillation (ENSO) conditions expected to bring rain to the region after a prolonged drought, we hypothesized significant increase in the incidence of Coccidioidomycosis. The unknown risk of Coccidioidomycosis, the longevity of infection, and the lack of proper diagnosis are expected to contribute to increasing burden of this disease in the region. This study further explores local and regional health responses, and the challenges associated with linking Coccidioidomycosis climate change impacts and adaptation in California. The study tests hypotheses linking Coccidioidomycosis incidence to soil moisture and seasonality for California communities. The study addresses barriers, benefits, risks, and trade-offs of these local health responses and we discuss the integration of climate mitigation and adaption options to reduce the negative impact of climate change on Coccidioidomycosis prevalence in a vulnerable community.

The international negotiations under the United Nations Framework Convention on Climate Change: Insertion of the Health Sector and Implications for Foreing Policy

R. Milhomem (1)
(1) Fiocruz, Brasília, Federal District, Brazil

The scenarios outlined by the Intergovernmental Panel on Climate Change and research centers around the world reaffirm the intrinsic relationship between Climate Change and Human Health. Nevertheless, the international negotiations taking place under the United Nations Convention does not fully reflect the concerns, prevention, promotion and recovery of global health. The detachment between the scientific world and the reallity embraces a serious systemic risk that threatens human and planetary survival.

The time is ripe for concrete insertion of Health concerns in climate negotiations. With the creation of the Durban Platform, a new climate protocol is being negotiated, able to determine all future developments in the fight against Climate Change.

In this sense, the interrelationships between domestic and international politics conform to the formation of the international position of a country. Thus, the health sector has the potential to offer successful solutions to the climate negotiations, bringing new complexity able to change the whole structure of the negotiation and its outcome favorably.To this end, this work offers, in addition to these discussions, a number of policy recommendations to be used directly into the climate negotiations, as in the format and language of international treaties.

This is the historical and timing of insertion of Health concerns in discussions on Climate Change, as they determine the success of the agreement and cooperation between countries.

P-3321-14

Impact of Climate Change on Child

Z. Mina (1)
(1) National University of Sciences and Technology, School of Social Sciences and Humanities (S3H), Islamabad, France

Climatic shocks have adverse economic consequences for both developed and developing nations. However, the economic costs are far greater in developing nations which face greater risks and vulnerabilities due to climate change (UNDP, 2007; World Bank, 2010). Given a rise in the incidence of such shocks, recent development literature has attached increasing importance to studying their impacts. For children, climatic shocks exacerbate vulnerability and place them at increasing risk. Specifically, some of the risks include separation from families, deprivation in terms of schooling, adverse impacts on children's nutrition and learning outcomes, and increased susceptibility to abuse and exploitation. Therefore, studying the impact of such shocks on child welfare is imperative. Children are not only most at risk but early intervention is the most effective means in fostering long-term change.

The particular focus of this study is to analyze the impact of two different climatic shocks: floods and drought, on child human capital across Ethiopia, India, Peru and Vietnam – countries with diverse socio-economic backgrounds. Human capital, in this context, subsumes both child learning and health outcomes. The discussion of the impact of climate shocks on human capital is made in the context of both income and substitution effects and the possibility of a positive climatic shock impact is explored. If the income effect dominates we can expect a negative impact on our outcome variables, while the converse is true if the substitution effect dominates. Additionally, the study aims to elaborate the role of child, parental, household and community characteristics as well as institutional help in buffering these climatic shocks.

The data source is the Young Lives Project* and cross-sectional household data is utilized for the year 2009. The study examines the data on the older cohort of children, whose lives were documented from ages 14 – 15, and covers both urban and rural areas. The enrolment rate and three measures of cognitive ability: Peabody Picture Vocabulary Test (PPVT), CLOZE test and Mathematics test scores are used as proxies for child learning outcomes. The health outcome variables being studied are the WHO defined Body Mass Index (BMI) z-scores and Height for Age (HFA) z-scores.

* Young Lives is a 15-year survey investigating the changing nature of childhood poverty in Ethiopia, India (Andhra Pradesh), Peru and Vietnam (www.younglives.org.uk). Young Lives is funded by UK aid from the Department for International Development (DFID) with co-funding from 2010-2014 by the Netherlands Ministry of Foreign Affairs and from 2014-15 by Irish Aid.

University, Sydney, Canada; (4) University of Guelph, Guelph, Canada; (5) Trent University, Peterborough, Canada; (6) University of Winnipeg, Winnipeg, Canada; (7) University of the Sunshine Coast, Sippy Downs, Australia

The Inuit Traditional Knowledge for Adapting to the Health Effects of Climate Change (IK-ADAPT) project was launched in May 2012. Funded through the Canadian Institutes for Health Research (CIHR), IK-ADAPT combines scientific research and Inuit traditional knowledge to develop an evidentiary base to inform policy and programming needed to adapt to the health effects of climate change. Working with Canadian Inuit communities in the Inuvialuit Settlement Region, the Northwest Territories, Nunavut, and Nunatsiavut, as well as knowledge users at multiple levels, the project is examining ways to preserve, promote, and disseminate Inuit knowledge in order to prevent, prepare for, and manage the health impacts of climate change. Having just come to the end of its final phase, this presentation provides an overview of the project, shares results from projects conducted under IK-ADAPT, and identifies next steps for enhancing the resilience of communities and northern health systems in light of a rapidly changing climate.

P-3321-16

Arsenic Contamination in drinking water and Valuing Health Damages: A case study of Bihar

BK. Thakur (1)
(1) National Institute of Industrial Engineering (NITIE), Mumbai, General Management, Mumbai, Maharashtra, India

The present study attempts an empirical investigation on the health effects of Arsenicosis on individuals in the rural areas of Bihar. Systematic random sampling was used for the selection of households and 388 households were selected from Maner and Shahpur blocks of Bihar. We used a field test kit to test the arsenic contamination level of water samples which were collected from each household. The water test results reveal that Maner's drinking water is more contaminated (excess of iron and arsenic in drinking water) than Shahpur's. 82.22% of households in the study area are having poor water quality, while 72.42% of households are having excess of arsenic in their drinking water. The mean concentration of arsenic contamination for entire study area, Maner and Shahpur is found to be 89.31 ppb/l, 111.34 ppb/l and 61.93 ppb/l respectively. The study estimates incidence rate of Arsenicosis diseases for three categories of sample: for the entire sample surveyed; for male population; for female population; and found incidence rate as 92.24, 81.53, and 105.22, respectively. The incidence rate of Arsenicosis diseases among female is highest and lowest among male children. We predicted Bivariate (marginal) probability of success in the outcome, which is defined as the probability of observing the Arsenicosis diseases for surveyed household, is estimated and found to be 0.42. Arsenicosis disease is regressed with set of independent variables. Water source found to be significant and positively related to the Arsenicosis diseases. This indicates that the household which is using poor water sources is reporting more cases of illness. This also reveals those who used drinking water from hand tube wells are more vulnerable to the Arsenicosis diseases as most of the sample households draw water from hand tube wells. The study also reveals the awareness is significant and negatively related to the Arsenicosis diseases. It reveals that if household is aware about the water source there is decrease in Arsenicosis diseases. The study also finds doctor visit, work loss, and arsenic level all are significant and positively related to the Arsenicosis diseases. We find arsenic contamination level is significant and positively related to Arsenicosis diseases. This indicates the household drinking water is contaminated more and leads to more cases of Arsenicosis diseases. We also regress defensive activities i.e. water purification on set of explanatory variables. We find per capita income as significant and positively related to household defensive activities on water purification. This indicates that the higher income household installed more water purification devices. Adequate of sanitation is significant and positively related to water purification. This is also same with the per capita income and is an important finding. Depth of the hand tube well is significant and positively related to water purification strategy. This indicates that there are the lesser number of households have deep tube wells. One probable reason to this is that the more the depth of the hand tube well, better the water quality is. Water source and awareness are significant. The study estimates the cost of illness to the household due to contaminated drinking water that comprises treatment cost and wage loss. The study finds that the poor households are more affected than the well off. The annual wage loss cost of treatment and cost of illness for sample households are estimated as INR 2437.92, INR 5942.40 and INR 8380.32 respectively. The total annual cost of illness for both the block is estimated as INR 265979691.6. The defensive activities undertaken by higher income group household are taking water purification while the lower income group household could not undertake the water purification. The cost of illness may be taken as the willingness-to- accept by the affected household. Therefore, providing safe drinking water benefits both social and economic value. The results of the present study indicate that water source and awareness are the two most significant factors on both illness and defensive activities. Due to lack of alternative safe water sources, the households are left with no choice but to use the existing available source for drinking water. The government may use various channels to make the households aware that safe water is a fundamental right. Therefore, piped water may be an effective alternative water supply to all the households. The result of this study would provide policy inputs to the policy makers to make their strategies more effective in providing drinking water which may help to reduce the Arsenicosis in a cost-effective and sustainable manner.

In 2009, the UCL-Lancet Commission on Managing the Health Effects of Climate Change called climate change "the biggest global health threat of the 21st century". Five years on, a new multidisciplinary, international Commission has formed to to map out a comprehensive response to climate change, in order to ensure the highest attainable standards of health for populations worldwide.

The Commission represents a collaboration between over 80 European and Chinese climate scientists and geographers, social and environmental scientists, biodiversity experts, engineers and energy policy experts, economists, political scientists and public policy experts, and health professionals – all seeking a response to climate change which is designed to protect and promote human health.

The Commission's work is divided in to five inter-related chapters. It begins by conducting a review of the climate science and its subsequent impacts on human health since 2009, before assessing and presenting policy response options around four central themes: community resilience and adaptation in low-income countries; energy choices and technical solutions; economic tools and the finance; and political mechanisms. At every point, the Commission understands the policy solutions to the extent that they improve public health.

The Commission's work suggests that current greenhouse gas emissions projections and consequent climate change pose an unacceptably high and potentially catastrophic risk to human health. In response to this, the Commission then concludes and describes a path whereby tackling climate change could become the greatest global health opportunity of the 21st century.

It also notes the unique and crucial role of the health community in responding to climate change. This is described in terms of the importance of adequate health impact assessments to guide mitigation and adaptation policy; the role of health and health systems as a tool for building community resilience; and the power of the health professional as a messenger that can communicate the risks and opportunities of climate change as local, immediate, and personal.

The Commission's work has now been completed, and will be published in The Lancet in May 2015.

Unprecedented urbanization and challenges to model them in IAMs

S. Dhakal (1)
(1) Asian Institute of Technology, School of Environment, Resources and Development, Pathumthani, Thailand

World has witnessed unprecedented urbanization- with 2.8 billion urban residents added between 1950 to 2000 and more 2.8 billion more by 2050. Projections show that future population rise will mostly comprise of the urban population. Rapid urbanization leads into rapid rise in energy use and CO2 emission since such urbanization in taking place rapidly in economically growing regions of the developing world where per capita CO2 emission in urban areas are far higher than the national averages. Our analysis shows that urbanization is the key and irreversible global trend for now. Recent IPCC Mitigation report makes it explicitly clear that the next 2-3 decades are crucial for low carbon development and our ability to orient new urbanization to low carbon pathway will define our ability to tame global emissions trends. New urbanization calls for rapid deployment of infrastructure in small and medium scale cities and lock-on cities into particular carbon trajectory. For example, China has unveiled a new urbanization plan in March 2014 to boost urbanization to 60% by 2020 that aim to invest 7-8 trillion dollars in urban infrastructure by 2020. The implications of the choice of urban forms, urban design and infrastructure in new urbanization on global emission occurs though embodied emission in materials used in infrastructure, such as cement, steel, aluminum and others which are carbon intensive as well as through the direct emissions due to use of those infrastructure which also lock urban system into particular technological choice. Studies based on Integrated Assessment Models have shown our cumulative carbon budget for 2000-2050 to be about 1000 GtCO2 to stay under 2°C climate stabilization; some early studies are showing that over one third of that could come from infrastructure sector alone assuming residents in the developing countries catch up to the level of per capita infrastructure stock of the average developed country residents. However, given the enormous potential of urbanization to influence global carbon emission and its multi-faceted implications, our analysis suggests that the ability to model urbanization and its implications in the current Integrated Assessment Models and other large scale global models remains extremely poor. We argue that the next frontier in global and regional IAM models lie in addressing the full scale implications of the type and extent of urbanization in economic, infrastructural, social, geosphere and bio-spherical domains. This presentation will dwell on these issues and opens much needed dialogues and discussions on how to take-on this challenges in the modelling community to develop a new generation of Integrated Assessment Models.

Links between energy systems models and economic models: learning from the IEA ETSAP experience

B. O Gallachoir (1) ; J. Glynn (1)
(1) University College Cork, Environmental Research Institute, Cork, Ireland

In a climate constrained future, hybrid energy-economy model coupling gives additional insights into interregional competition, trade, industrial delocalisation and overall macroeconomic consequences of decarbonising the energy system. Decarbonising the energy system is critical in mitigating climate change. In this paper, we summarise modelling methodologies developed in the IEA ETSAP (Energy Technology Systems Analysis Programme) community to assess economic impacts of decarbonising energy systems at a global level and at a national level.

ETSAP is a unique network of energy modelling teams from approximately seventy countries involving 177 institutions over the world, well beyond the number of its contracting parties, who are the governments of eighteen countries and the European Commission. ETSAP was one of the multilateral technology initiatives (formally called Implementing Agreements) initiated in 1976 under the aegis of the IEA. ETSAP evolved from initially analysing existing tools to evaluate R&D strategies to the combination of the energy flow optimization approach with macroeconomic top-down modelling, technology learning and stochastic modelling.

This paper summarises a range of different methodological approaches to developing linkages between energy systems modelling and economic modelling, drawing on a significant and rich and body of analysis. The energy systems models discussed are bottom-up (BU) techno-economic linear optimisation engineering TIMES models. TIMES is a techno-economic model generator for local, national or multi-regional energy systems, which provides a technology rich basis for estimating energy dynamics over a long-term (20-50 years), multi-period time horizon. TIMES computes a time varying inter-temporal partial equilibrium on inter-regional markets. The objective function maximises total surplus. This is equivalent to minimising the discounted total energy system cost while respecting environmental, technical and scenario constraints. This system cost includes investment, operation and maintenance and fuel import costs, less export income, terminal technology values and salvage values. The top-down (TD) macroeconomic models range from single producer-consumer agent production function models, to multi-region structural computable general equilibrium (CGE) models. The paper compares soft-linking approaches (e.g. between TIMES and CGE models) and hard-linking (e.g. TIMES-MACRO).

The analysis demonstrates that the range of economic impacts of decarbonisation is regionally dependent upon the stage of economic development, the level of industrialisation, energy intensity of exports, and competition effects due to rates of relative decarbonisation. Developed nation's decarbonisation targets are estimated to result in a manageable GDP loss in the region of 2% by 2050. Energy intensive export driven developing countries such as China and India, and fossil fuel exporting nations can expect significantly higher GDP loss of up to 5% GDP per year by mid-century.

The national modelling studies outlined here show that

burden sharing rules and national revenue recycling schemes for carbon tax are critical for the long-term viability of economic growth and equitable engagement on combating climate change. Traditional computable general equilibrium models and energy systems models solved in isolation can misrepresent the long run carbon cost and underestimate the demand response caused by technological paradigm shifts in a decarbonised energy system. The approaches outlined here have guided the first evidence based decarbonisation legislation. They continue to provide additional insights as increased sectoral disaggregation in hybrid modelling approaches is achieved.

The paper concludes with a number of challenges that are necessary to address, including i) the uncertainty in exchanging price information from BU to TD models in soft-linking hybrid models and ii) the difficulty in capturing satisfactorily the changes in investment flows that arise due to large structural changes in the energy system.

Developing pathways for zero poverty and zero emissions

H. Winkler (1)
(1) University of Cape Town, Energy Research Centre, Rondebosch, South Africa

Poverty eradication has been a priority of developing countries for a long time, and this is reflected in the UNFCCC. Much more recently, framing a global goal on mitigation has been advanced, aiming at net zero emissions by 2050. In the post-2015 development agenda, the first Sustainable Development Goal is to "end poverty in all its forms everywhere". How to achieve zero poverty and zero emissions?

The problem is easy to state, any 'solutions' are hard to realise. It is easy to support Oxfam excellent slogan, to "make poverty history". And relatively easy to model zero emissions - though at what cost. Yet in developing countries, climate action needs to be in a way that reduces poverty and inequality.

Among South Africa's many development challenges, the National Development Plan identifies poverty and inequality as the foremost [1]. The same plan also refers to reducing emissions, and the climate policy of GHG emissions following a 'peak, plateau and decline' trajectory [2]. To achive both zero poverty and emissions in South Africa's energy economy is challenging [3].

Ongoing research seeks to model multiple development-climate objectives in SA's energy economy, aiming to provide information that is credible, analytically rigorous and is a story that enables interest to imagine themselves in a different future. This builds on a long-standing energy model development at the ERC, and more recently links with top-down economy-wide models, also with teams in other developing countries [4, 5].

Scenario of deep decarbonisation for South Africa - 14 Gt CO2-eq in SA's energy sector (scenario 14 Gt energy) from 2016 to 2050 [3] - and meeting the multiple development objectives is possible. The results of linked modeling of the 14 Gt energy scenario suggest it is technically plausible, but has negative welfare effects.

Earlier work has made the case instruments such as sustainable development policies and measures (SD-PAMs) would better frame action in developing countries [6-11]. But if zero poverty cannot be achieved, as recent results suggest, what is the implication for ambitious climate action? The ERC's research agenda will continue to analyse these wicked problems, and can only benefit from exchange of creative thinking with others grappling with this trilemma [12].

We do not think, however, that mathematical models alone will provide any 'solution space' (we tend to think of it more as a process). Through experience with long-term mitigation scenarios for South Africa [13, 14] and the Mitigation Action Plans and Scenarios (MAPS) programme in Brazil, Chile, Colombia and Peru, we think that the co-production of knowledge and its use of facilitated stakeholder process is powerful in helping a transition to zero poverty and zero emissions societies.

To realise zero poverty and zero emissions, a new social contract is needed [15]. What might the general idea of a social contract look like in a story of a different South Africa? SA has unemployment of 25% (40% by a broader definition), with even higher shares among youth. This emerged with past industrial policy focused on energy intensive sector growth. But if employment were reduced in mining, energy supply and beneficiation, where would it be created? One cannot simply assume unemployed are absorbed by an economy-wide model, without asking whether unskilled youth with no work experience would indeed find real jobs. Some SA economists believe employment-intensive sectors like agriculture and textiles are dead-ends. Others think more employment-intensive growth is possible, and may be helped by a small wage subsidy. We will continue to research, in various ways, the goals of zero poverty and zero emissions.

O-3322a-05

Tipping point policies for energy transformation - assessing their likely effect

M. Jaccard (1)
(1) Simon Fraser University, Resource and Environmental Management, Burnaby, British Columbia, France

A global climate agreement will not soon lead to a single global carbon price. But 10 years of efforts by individual and groups of jurisdictions have provided valuable lessons on the design of other types of market-oriented and regulatory policies that can foster tipping points in the costs (financial and psychological) of energy system transformation. Assessing the likely effect of such policies is a challenge for energy-economy-emissions modelers. This talk summarizes some of the challenges and possible solutions.

3322b - Development of pathways: their mix of endogenous and exogenous uncertainties and their future under a changing climate

Modelling Efficient and Equitable Scenarios for a Carbon Constrained World with TIAM-MACRO

S. Kypreos (1) ; J. Glynn (2) ; B. O Gallachoir (2) ; M. Gargiulo (3) ; A. Lehtila (4)
(1) Honorary Senior Scientist of Paul Scherrer Institut, LEA, Villigen, PSI, Switzerland; (2) UCC, Cork, Ireland; (3) E4SMA, Turin, Italy; (4) VTT, Espoo, Finland

We generate efficient climate change mitigation scenarios of low emission pathways for carbon dioxide and other greenhouse gases (GHGs) such that global warming remains below 2 °C with high probabilities. Then, we balance the cost of mitigation for different world regions based on equity principles and fairness. The study assumes early mitigation actions starting already in 2020 and quantifies the market penetration of carbon-free technologies, the emission pathways and the economic costs for an efficient reduction of GHGs emissions. The prerequisite is that the CO2 equivalent concentration will remain similar to the present levels while the temperature rise will stay below 2 °C of warming. The associated budget of Remaining Carbon Equivalent Emissions Quotas (RCEEQ) is 273 GtC for CO2 plus another 180 GtC-eq. for other GHGs, valid from the period 2020 onwards, and is imposed as constraint. This value of RCEEQ is in accordance with the

Summary Report for Policy Makers of the 5th Assessment report (5AR) of the UN Framework Convention on Climate Change.

Then, we evaluate interregional capital transfers originated from the industrialized world to support mitigation efforts of low income regions to ensure their participation to a binding agreement. Interregional equity transfers are established via a market of emission permits and are presented for different distribution rules concerning the initial endowments of permits. This refers to the effort-sharing or the resource-sharing regimes. Another option considered in the analysis is the introduction of interregional capital transfers in financing a huge joint implementation program covering fully the extra cost of a carbon-free energy system of developing countries up to a stage of full compensation of the economic losses for low income regions.

As all world regions profit from the reduction of damages under the RCEEQ constraint, it makes also sense to estimate the associated regional benefits and to compensate regions for their mitigation cost net of benefits. This capital transfers could take place with the help of burden sharing and emissions trade schemes or through join implementation projects. Therefore, the study undertakes a sensitivity analysis where a) different degrees of cumulative RCEEQ constraints are assumed to differentiate on the needed capital transfers that assure fairness and equity b) different allocation schemes apply while in the case of full compensation we consider the needed capital transfer net of damages and finally c) a scenario of late actions under the same RCEEQ constraints is introduced to investigate potential advantages and disadvantages in terms of regional GDP impacts and the timely restricted overshooting of temperature change. Finally we conclude on scenarios and compensation schemes that allow to define a well-balanced set of regional impacts.

This generation of efficient and equitable scenarios became possible using the Integrated Assessment Model TIAM-MACRO, a technology rich, hybrid general equilibrium model integrating a full scale bottom-up engineering model with macroeconomic top-down models that allows for international trade, developed for the IEA-ETSAP community (Energy Technology Systems Analysis Program www.iea-etsap.org). The model addresses the key concern for all parties of international climate negotiations which is the national economic effect of implementing climate mitigation targets and tries to define fairness in implementing early actions mitigating global warming. Coupling technology rich energy models, such as MARKAL/TIMES and economic models gives additional insight into interregional competition, trade, industrial delocalization and overall economic consequences of decarbonizing the energy system.

O-3322b-02

Bottom-up Economic Climate Change Impacts at the National Level: Known Trends, Unknown Tails, and Unknowables

K. Steininger (1) ; G. Wagner (2) ; P. Watkiss (3) ; M. Koenig (4)

(1) University of Graz, Graz, Austria; (2) Environmental Defense Fund, Boston, United States of America; (3) Paul Watkiss Associates, Oxford, United Kingdom; (4) Environment Agency Austria, Vienna, Austria

Economists attempting to evaluate the impacts of climate change are often caught between hard theory and exceedingly rocky empirics. Impact assessment models are necessarily based on highly aggregated - and sometimes highly simplified - damage functions. This study takes an alternative approach: a bottom-up, physical impact assessment and respective monetization, attempting to cover a much broader set of impact fields, feeding directly into a macroeconomic and welfare analysis at the national level. To ensure consistency, our approach applies impact assessment at the sectoral impact chain level using shared socioeconomic pathways, consistent climate scenarios, computable general equilibrium evaluation, and non-market impact evaluation. The approach is applied to assess a broad scope of climate impacts in Austria. Results indicate significant impacts around 'known knowns' (such as changes in agricultural yield from climatic shifts), with uncertainty increased by 'known unknowns' (e.g. changes in water availability for irrigation, changes in pest and diseases) but also raises the question of unknowns and unknowables, which may possibly dominate future impacts (such as exceedance of critical ecosystem function for supporting agriculture). Climate change, ultimately, is a risk management problem, where insurance thinking warrants significant mitigation (and adaptation) action today.

Analysis of the study result indicate that the current welfare damage of climate and weather induced extreme events in Austria is an annual average of € 1 billion (large events only). This has the potential to rise to € 4 to 5 billion by mid-century (annual average, known knowns of impact chains only), with an uncertainty range of € 4 to 9 billion. When extreme events and the tails of their distribution are included, even for a partial analysis focused on extremes, damages are seen to rise significantly, e.g. with an estimated increase to € 40 billion due to riverine flooding events alone by the end of the century. These highlight the need to consider the distribution of impacts, as well as the central values.

Economics of flood risk in Italy under current and future climate

L. Carrera (1) ; G. Standardi (2) ; E. Koks (3) ; L. Feyen, (4) ; J. Mysiak (2) ; J. Aerts (5) ; F. Bosello (6)

(1) FEEM – Fondazione Eni Enrico Mattei and Euro-Mediterranean Center on Climate Change, Venice, Italy; (2) FEEM – Fondazione ENI Enrico Mattei, Venice, Italy; (3) Institute for Environmental Studies, VU University Amsterdam, Amsterdam, Netherlands; (4) JRC, Ispra, Italy; (5) VU University Amsterdam, IVM, Amsterdam, Netherlands; (6) University of Milan, FEEM, and CMCC, Dep. of economics, Milan, Italy

We estimate current and future economic impacts of fluvial flood risk in Italy in view of climate change under a business-as-usual emissions scenario. The methodology combines a high resolution spatial flood hazard and exposure analysis for an ensemble of climate projections with a regionally-calibrated version of a global Computable General Equilibrium (CGE) model. The economic effects, output losses, are estimated per region in terms of Gross Regional Product change till 2100. Losses are estimated for two disaster risk management scenarios: with and without adaptation to changing flood conditions. Our results show that in Italy, because of climate change, current aggregated ensemble-average Expected Annual Output Losses increase fourfold without adaptation, exceeding 600 million Euro per year by the end of the century. With adaptation the increase is limited to 7 percent. The paper provides the distribution of adaptation benefits across regions, of which the cumulative value exceeds 23 billion Euro over the long term (2014-2100).

CIECIA: A New Climate Change Economic IAM and its Assessment of Global Cooperating Abatement Schemes

Z. Wang (1) ; J. Wu (1) ; G. Gu (2) ; C. Liu (1)

(1) Institute of Policy and Management, Chinese Academy of Sciences, Beijing, China; (2) East China Normal University, Shanghai, China

From the perspective of global economic general equilibrium, this study developed a new climate change IAM named CIECIA. The economic core of this IAM is a multi-country-sector general equilibrium model. The endogenous technology progress mode is introduced into CIECIA. Based on this IAM, three assessment principles of global cooperating abatement scheme, including effectiveness, feasibility, and fairness are presented. This study simulated and analyzed 6 kind of main global cooperating abatement schemes. The simulated results indicate that all the selected schemes can satisfy the climate protect target to 2100. Thus, they are all effective schemes. However, the schemes have quite different

feasibilities and fairness. The Stern Scheme benefits the developed countries, but is unfair to the developing countries. The Nordhaus Scheme promotes the economy of developing countries. However, it will have negative impact on the benefits of developed countries. The per Capita Emissions Cumulative Convergence and the per Capita Emissions Convergence Schemes benefit the development of middle and low developing countries most. However, these two kind of schemes will cause tremendous losses to main economic entities in the world including China. The Pareto Improvement Scheme which is developed from the Steady Economic Growth Scheme balances the fairness and feasibility in carbon abatement process and realize the Pareto improvement of economic utilities in all the participating countries. Thus, the Pareto Improvement Scheme is the most reasonable global cooperating abatement scheme.

Energy-economy-environment applied models: insights, developments and limitations

R. Bibas (1) ; J. Lefèvre (1)

(1) International Research Center on Environment and Development (CIRED), Paris, France

The IPCC Fifth Assessment Report shows the end of the controversy between top-down and bottom-up models that was the essence of the results from previous reports. State-of-the-art models have evolved towards more integration, thus becoming ever more complex.In this new era of integrated and hybrid models, models are classified according to criteria such as coverage, flexibility and sectoral details rather than the deep mechanisms themselves within the model.

The current approach to tackle the uncertainties is to create scenario ensembles to compare the reactions of models.Indeed, this top-down approach examines model results rather than starting with a description of model structures to characterize the outcome of model behavior.By contrast, we seek to complete this type of studies by developing a bottom-up approach to create a taxonomy based on the depicted representation and the implicit assumptions within the models.Therefore, we propose to examine the constitutive building blocks of the model to control the structural uncertainty inherent to the forward-looking analysis.Thus we posit that the full picture is needed to understand the forward looking potential of each model.Our goal is to understand the deep mechanisms driving the joint evolution of the energy, economy and environment systems.

This paper presents an updated an thorough taxonomy of the state-of-the-art models from the Fifth Assessment Report.This taxonomy builds on the existing taxonomy, in particular on the historical (and obsolete) opposition between top-down and bottom-up models to bring to light the building blocks of the models.Understanding the building blocks of the models gives an overview of their inner mechanisms as well as the explicit or implicit assumptions in the model.Furthermore, it presents all models in an unified manner in a summary table with a unified vocabulary.The comprehensive review of the models allows a relevant assessment of their potential to produce forward-looking scenarios to reveal insights about the decisions to be made for climate change mitigation.This paper then examines the forward-looking analysis potential of each approach and concludes on their respective uses.

This bottom-up approach is a complex endeavor, but the analysis of building blocks constitutive of the models sheds light on the diversity around key drivers.We identified several groups of deep mechanisms: demand drivers in relation with structural changes, the incorporation of technology, the representation of economic choices and the evolutionary factors of society.Therefore, we want to understand the drivers of the transition both in the short run and in the long run to discuss the global articulation between climate change mitigation and economic development.

Transparency in Integrated Assessment Modeling

R. Calel (1) ; DA. Stainforth (2)

(1) UC Berkeley, Berkeley, France; (2) London School of Economics, Grantham Research Institute, London, United Kingdom

The basis for concern over anthropogenic climate change is founded in the physical sciences but the rationale for action is rooted in the social sciences. Integrated assessment models (IAMs) are the main tools for combining physical and economic analyses to assess climate change policy. To a large extent, however, these models are black boxes to those outside the integrated modeling community. Economic assessments of climate change consequently risk misrepresenting physical understanding of the climate system, while physical science may fail to focus on the most salient issues for economic and policy assessments. Here we open the lid and resolve physical science differences between three of the most studied IAMs. We argue for greater cross-disciplinary transparency in this highly policy-influential field and for greater debate over the appropriate level of model complexity. Researchers, and research funders, should resist the temptation to increase complexity beyond the point where disagreements and uncertainty about modeling assumptions can be easily identified and debated openly with relevant experts. We suggest alternative ways to improve representativeness and extend the use of IAMs while maintaining and promoting transparency.

P-3322-03

Is there a reason for strong mitigation ? The role of time preference, inequality aversion and catastrophes

F. Dennig (1) ; M. Budolfson, (2) ; M. Fleurbaey (3) ; A. Siebert, (4) ; R. Socolow (5)

(1) Princeton University, Princeton, New Jersey, United States of America; (2) Princeton University, Uchv/wws, Princeton, New Jersey, United States of America; (3) Princeton University, Woodrow Wilson School, Princeton, United States of America; (4) Princeton University, Climate futures initiative, Princeton, New Jersey, United States of America; (5) Princeton University, Mechanical engineering, climate futures initiative, Princeton, New Jersey, United States of America

The debate about how strong and quick mitigation policy should be in the coming decades has mostly revolved around the discount rate, with the conclusion that only a discount rate much lower than ordinary market rates can justify drastic action toward abating emissions. There have been, however, some questions about what the relevant market rate is (the riskless market return is actually quite low), and some explorations of more pessimistic estimates of the extent of damages for temperatures rising more than 3°C above the pre-industrial temperatures.

In this paper, we develop a variant of RICE, called NICE (for Nesting Inequalities, Climate and Economy), which separates the ethical parameters of the social objective from the behavior of the economic agents and introduces empirical estimates of inequalities in living standards within the twelve regions of RICE.

The first feature (separating ethical parameters from

behavior) enables us to take the agents' saving behavior as given while we test the policy implications of various configurations of the key ethical parameters of the social objective: the pure rate of time preference and the degree of aversion to inequality across and within generations. The second feature (inequalities within regions) enables us to test whether the presence of huge inequalities in some regions matters for the design of optimal mitigation policy, depending on the distribution of the impacts of climate change and the distribution of abatement costs.

The first result we obtain is that the most aggressive mitigation policy would be warranted if the social objective was to maximize the total amount of consumption over all populations across space and time (no time preference, no inequality aversion). This is due to the importance of damages and the relatively modest abatement costs in the model.

The second result is that while the debate on the consumption discount rate has shown that this rate matters a lot for the pace of the optimal abatement policy, this discount rate is made of several components via the Ramsey formula:

discount rate = pure time preference + inequality aversion x growth rate,

and in this formula, a low inequality aversion does more for mitigation than a low rate of time preference, for the usual ranges of plausible values considered for these ethical parameters. This is due to the (relatively optimistic) assumptions in NICE (adopted from RICE) about the growth rate, which multiplies the former parameter in the Ramsey formula.

Our third result is that the role of these two ethical parameters is substantially muted when the damages are greater than in the standard damage functions of RICE, or when they affect the growth rate and not just the level of consumption. Such results echo earlier work by Dietz and Stern, Moore and Diaz.

Our last set of results is that the presence of inequalities within regions does not affect the optimal mitigation policy much when the damages and abatement costs are proportional to consumption. In contrast, if damages fall more than proportionally on the poor and less on the rich, the outlook of policy and of the role of ethical parameters changes dramatically. A strong mitigation policy may then be justified, and even more so with a strong inequality aversion, due to the implied value of protecting the future poor from strong damages. A progressive distribution of abatement costs also reinforces mitigation in the optimal path, and more so with strong inequality aversion.

The general conclusions of this paper are: 1) inequality aversion between and within generations is a crucial parameter in the design of the optimal mitigation policy (unless damages are much greater than usually assumed, in which case ethical parameters matter less); 2) the distribution of damages across income groups is equally important over the range of sensible assumptions; 3) in particular, distributions of damage that are less than proportional – poor bear larger burden than their share of income – will lead to stronger mitigation policy. The latter two points indicate that the distribution of damage with respect to income is an important field for future research.

P-3322-04

City Sustainability Risk under Climate Change: A Strategic Scan Methodology

K. Doust (1) ; J. Lam, (1) ; C. Wang (1) ; T. Doust (2)
(1) University of NSW, Research Centre for Integrated Transport Innovation (rCITI), Sydney, NSW, Australia; (2) Windana Research Pty Ltd, Research, Sydney, Australia

Revisiting the 2011 Climate Change and Cities First Assessment Report by UCCRN and the need to understand how climate risk relates to different cities and infrastructure sectors, the paper discusses transport system vulnerability in both car based and public transport based modes, bringing into play the vulnerability of different configurations of city transport networks and technologies when faced with climate change related hazards. Transport systems are designed to have an operational performance and are expected to contribute to a city's overall sustainability. However, under climate change related hazards, the transport system is at risk of being in a failed state, either below its expected operational performance level, or unavailable all together. The paper introduces the types of failed states for different modes and considers how the vulnerabilities can be better understood by first understanding the effect on reliability and availability of service. Climate change hazards can be viewed as an outcome of unsustainable practices in our built environment, infrastructure and use of resources. Sustainability itself is therefore a key contributor to mitigation of climate change hazards, but conversely climate change hazards put at risk the sustainability improvement we strive for in our cities. The paper explores measuring the vulnerability to climate change hazards, in terms of the change caused to sustainability performance when the transport system suffers loss in reliability or availability. A methodology which utilises accessibility as a useful measure in social and economic aspects of sustainability, generates visual sustainability metrics based on the concept of a sustainability goal in "environmental sustainability – accessibility space". A city's sustainability performance in relation to the goal is generated using plots of environmental sustainability & accessibility for each travel zone pair in the city. A collective plot of sustainability measures for individual zonal pairs creates a simple, but analytically rich visualisation, giving insight into the position, spread and internal distribution trends for a city's urban sustainability pillars of environmental stewardship, social equity and economic efficiency. For community and decision makers these visual differences give a simple snapshot of overall sustainability performance, for each scenario being considered. A feature of the methodology is its systems based drivers or levers. All visualisations have traceability back through the algorithms to the source inputs, allowing changes in system scenarios to be made. By including scenarios that include the transport system failed states, inclusive of the impacts of climate change hazards on travel time reliability and service availability, the paper explores the effect on the sustainability performance using the methodology. A particular strength is that the metrics are derived from data sets more likely to be found amongst transport and city planning departments. The paper presents Sydney case study visualisations to illustrate the type of high level outputs that can be built from this systems approach, to discern the merits of different resilience scenarios. With this methodology and the assistance of readily available GIS/T software, the sustainability metrics are able to be translated into spatial visualisations, to enable discernment of sustainability performance differences within the city. These metrics can also be applied in a way that expresses sustainability performance in terms of a sustainability risk ranking. High risk, where sustainability performance is poor, is indicated by low metric values. Low risk, where sustainability performance is satisfactory, is indicated by a higher metric value, above a community accepted minimum target. A grid concept likened to a risk matrix can be formulated allowing each zone pair to be assigned a sustainability risk rating. The sustainability risk boundaries are specific to each city, and influenced by the population's estimated resilience. The paper discusses this approach of sustainability risk rating, illustrating the technique of the translating this into a visual graphic in geographic space using geographic information system (GIS) thematic mapping. Visualisations of this type can be used to inform decision makers (community & government agencies) in the process of choosing climate change policies and programs for a city.The paper concludes with a discussion of next steps and need to further case study the work in conjunction with other researchers and with an initial selection of cities and their governments/agencies.

P-3322-05

A Research on the Multi-country-sector Economic Growth and Global Governance of Carbon Emissions under Global Carbon Taxes

G. Gu (1) ; Z. Wang (2)
(1) East China Normal University, Population Research Institute, Shanghai, China; (2) Institute of Policy and Management, Chinese Academy of Sciences, Beijing, China

This paper focuses on the national/sectoral levels, using a climate-economic integrated assessment model named CIECIA to have a research on changes of the multi-country-sector economic growth and carbon emissions under different global carbon tax rates and tax distribution schemes. The results indicate that carbon tax policies have obvious promoting effects on the carbon

abatements of the developing countries. The accumulative carbon emissions of China and India from year 2016 to 2100 can be reduced by 69.27GtC and 57.78GtC separately, whereas the carbon emission reductions of the developed countries are smaller under carbon tax policies because of their low abatement potentials caused by higher initial low-carbon technologies, lower economic growth rates, etc. In the simulations of four international carbon tax distribution schemes, the equality principle which is based on the population benefits China mostly, while the carbon emission per capita principle and the payment ability principle benefit countries with large populations and low economic developments e.g. middle & low developing countries mostly. Specially, the carbon emission per capita principle is harmful to China because the population of China will decrease after 2030, whereas its carbon emission demand will still increase for its rapid economic development. Investing carbon tax returns to the knowledge capital for improving process technology progress will increase the carbon abatements, especially in developing countries. While the investing rate of knowledge capital from carbon tax return reaches up to 50%, the accumulative carbon emissions of China and India from 2016 to 2100 will be reduced by 69.27GtC and 57.78GtC separately. However, the developing countries have relatively lower emission reductions because of their higher initial capital knowledge levels, lower carbon tax returns, etc.

A bottom-up approach to improve local-scale understanding and decision making in responding to climate change

A. Jakeman (1) ; S. Elsawah, (1) ; J. Guillaume, (2) ; T. Filatova, (3)

(1) Australian National University, iCAM, Fenner School of Environment and Society, Canberra, Australia; (2) Aalto University, Water and development research group, Espoo, Finland; (3) University of Twente, Centre for studies of technology and sustainable development, Enschede, Netherlands

Integrated assessment models of global change require improvements to better quantify climate change impacts and to represent the effects of adaptation decisions at local scales. This is especially relevant for understanding the consequences of local decision making on land use change processes, which varies significantly across cases. Assessment of realistic adaptation options to climate change at local scales also requires recognition of relevant governance and behavioural aspects in any modelling and analysis rather than making over-simplified assumptions such as relying solely on profit maximization. Methodologically, there is also a challenge of studying these processes through the continuum between collecting (often qualitative) data on local stakeholders' decisions and tracing the cumulative impacts of those local decisions in simulation models (often quite formal and quantitative). This presentation provides an overview of model-based ways to contribute to incorporating essential human elements in decision making processes for modelling of complex socio-ecological systems, and hence improve understanding and communication about decision making in complex socio-ecological systems. The presentation then specifically tackles the challenge of bridging the qualitative and quantitative by presenting a step-wise methodology for integrating perceptions of stakeholders (qualitative) into formal simulation models (quantitative). The methodology integrates cognitive mapping and agent based modelling. It cascades through a sequence of qualitative/soft and numerical methods comprising: (1) Interviews to elicit mental models; (2) Cognitive maps to represent and analyse individual and group mental models; (3) Time-sequence diagrams to chronologically structure the decision making process; (4) Building an all-encompassing conceptual model of decision making, and (5) a computational, in this case agent- based, model. We apply the proposed methodology (labelled ICTAM) in a case study of viticulture irrigation in South Australia, which faces the potential of aggravated water scarcity under a changing climate. In particular, we focus on local decision-making of winery holders – both at individual and community [TF1] levels – with respect to their understanding of risk of water shortage and chosen adaptation strategies. Finally, we use the strengths-weakness-opportunities-threats (SWOT) analysis to reflect on the methodology. Results show that the methodology leverages the use of cognitive mapping to capture the richness of decision making and mental models, and provides a combination of divergent and convergent analysis methods, deepening the understanding of decision making during the construction of an Agent Based Model.

Assessing future energy and climate pathways in an uncertain World: stochastic and parametric framework in TIMES models

A. Kanudia (1) ; M. Labriet (2)

(1) KanORS-EMR, NOIDA, UP, India; (2) Eneris Environment Energy Consultants, Madrid, Spain

Uncertainty introduces a new dimension in the decision making environment that simply cannot be captured by scenario analysis. Hedging strategy is not necessarily a combination of deterministic solutions; new options may emerge dominant with explicit treatment of uncertainty. For example, perfect foresight of no emission abatement may favor coal, and that of severe emission abatement may favor renewable sources, for near term power sector investments. However, under a stochastic cumulative emission bound, gas may become the most appealing solution for decision-makers, as it is relatively short-lived, cheap and not as polluting as coal. We see several examples of this dynamic in the runs that we propose to present.

Further, it is not easy for decision makers to assign probabilities to long-term uncertainties like abatement levels imposed in a future changing climate. Analyzing a wide range of probabilities of key uncertainties would provide more useful insights to policy makers.

To demonstrate, stochastic programming with the TIAM-World model is used for a parametric analysis of hedging strategies, varying the probabilities associated with each of two contrasted technology outlooks. The parametric analysis constitutes an original supplement to the computation of hedging strategies by identifying technologies that are robust under a broad range of probabilities of the two technology outlooks. Natural gas appears to be one of the most appealing robust options in an uncertain technological context, especially in China, given its relatively low emissions and the low capital cost of associated technologies. Natural gas and some other options are in fact considered as «super-hedging» actions, penetrating more in the hedging solution than in any of the deterministic scenarios. Nuclear power and CCS use are less robust: they depend much more on either the level of the climate target or the probabilities of the technology outlooks. The analysis also shows that technological uncertainty has a greater impact under milder climate targets than under more severe ones.

The combination of stochastic programming and parametric analysis proves to be powerful for policy formulation as it delivers useful insights with minimal assumptions from the policy maker.

2030 Climate Targets in Sweden: An Integrated BU and TD Approach

A. Krook-Riekkola (1) ; B. Charlotte (2) ; E. Ahlgren (3) ; P. Söderholm (4)

(1) Luleå University of Technology, Department of Engineering Sciences and Mathematics, Luleå, Sweden; (2) National Institute Of Economic Research, Environmental economics research division, Box 3116, 103 62 Stockholm, Sweden; (3) Chalmers University of Technology, Division of energy technology, dep. of energy and environment, SE-412 96 Gothenburg, Sweden; (4) Luleå University of Technology, Economics unit, Luleå, Sweden

The aim of this paper is to identify the role of biomass in meeting stringent Swedish climate targets in the year 2030. This is achieved by improving the existing soft-linking between TIMES-Sweden (national energy system model) and EMEC (national CGE model), with special emphasis on the representation of biomass in the two models. While the generation of electricity and heat is close to carbon-free, the Swedish industry sector and transportation has remained carbon-intensive. Biomass can play an important

role for CO2 reductions both in the industry sector (e.g. the iron and steel industry) and for transportation (e.g. biofuels). Some estimates indicate that the already high use of biomass for energy could double and still be ecologically sustainable (Börjesson et al., 2008), however, biomass will never be an unlimited resource.

The question is where, and to what extent, biomass can be used in an ecologically and economically sustainable way. The most cost-efficient allocation of this limited biomass can be assessed with a national energy system model covering the entire energy system, such as TIMES-Sweden. Moreover, the development of the industry sector (i.e. the demand for energy related goods and services) will both depend on future energy prices and on the remaining economy. Those are aspects that could be assessed by soft-linking TIMES with a national CGE model such as EMEC. A soft-link between the two models has been established (see Krook-Riekkola et al., 2013). A detailed soft-linking process, i.e. providing feed-back between the two models on a disaggregated level, was made possible by EMEC having a more detailed description of the energy use compared with many other CGE models. Nevertheless, CGE models are in general based on aggregated historical and current economic flows, which make it challenging to consider new fuels or technologies, such as different kinds of biofuels. In this present study, EMEC (the CGE model) have been modified to also capture the competition between conventional energy commodities and biofuels, which facilitate an improved feed-back between the two models and in the end an improved cost analysis of potential national Swedish climate targets. The soft-link now includes a disaggregated feed-back from TIMES-Sweden with different kinds of biomass use, including both energy intensities and cost figures, to the EMEC model. TIMES-Sweden has been improved accordingly. Preliminary results from when soft-linking the two models shows that biomass play an important role in meeting tough Swedish climate targets. Biomass, used efficiently, can reduce the cost of meeting a national climate target and still be within an ecologically sustainable level of biomass harvesting.

A household perspective on ecosystem services: a network approach

A. Tironi-Silva (1) ; LE. Delgado, (1) ; V. Marin, (2)
(1) Fundación CTF, Santiago, RM, Chile; (2) Universidad de Chile, Departamento de ciencias ecológicas, facultad de ciencias, Santiago, Chile

Addressing global climate change (GCC) is one of the major social, political and economic challenges of humanity for the next decades. Scientific evidence suggests that this process already started a few years ago and will last for hundred and even thousands of years, with a scientific consensus on the changes this global phenomenon will imply in climate, ecosystems and human societies. However, there still is uncertainty about the magnitude of their impacts, especially in terms of ecosystem services and social welfare, as these depend ultimately on our social response at local-global scales. In Latin America and the Caribbean, millions of people depend, to one degree or another, on ecosystem services because much of their well-being and production system relate to live in diverse and healthy ecosystems. Therefore, it is important to understand the relationships between natural and social systems to be able to understand the eco-social impacts of global climate change. This project aims to map, using an approximation of complex networks, natural and social capital in rural populations. These eco-social networks will be built at the household level using trans-disciplinary tools such as application and analysis of socio- ecological surveys & interviews, development of conceptual eco-social models and the development and application of network models and metrics (quantitative analysis). The project is been developed in two watersheds in shouthern Chile, as a case study. We already have more than 370 surveys of use of ecosystem services in rural households. Our approach tries to use complex network theory to construct a "map" of the use or demand of ecosystem services (natural capital).

Our current approach is to develop quantitative, star-shaped networks of surveyed services (wood & water usage, water treatment, hopefully recreation) with households as the center node. We'll also try to map the social interactions that constitute "bridge" social capital (committees, associations, subsidies, etc.) trying to find relationship within these two forms of capital. In our social capital networks, the household is also the center node of a star shaped network composed of social capital "bridge" relationships -water committees, unions, neighborhood councils, government subsidies.

Our results show different patterns of natural capital depending on the level of urbanization of each watershed. Those localities located on more natural landscapes showed a higher diversity and uniqueness of patterns of use of ecosystem services. Our method provides an inexpensive, flexible tool to assess ecosystem services demand at household level.

Further developments could include coupling of these networks of natural capital to biophysical models to include the offer of services from ecosystems, thus modeling the whole dynamics of ecosystem services, from offer to demand. We need to improve our knowledge of the dependencies of our wellbeing with natural ecosystems to build resilient neighborhoods and prepare our societies to adapt for an increasingly 'uncomfortable' planet.

P-3322-10

The regional macroeconomic effects of delayed action in meeting a global 2 degree climate target

M. Winning (1) ; C. Mcglade (1) ; J. Glynn (2)
(1) University College London, Energy Institute, London, United Kingdom; (2) UCC, Cork, Ireland

The UN Framework Convention on Climate Change (UNFCCC) negotiations have previously sought to reach a global agreement on how to limit climate change to 2°C. Despite progress over the past decades, and whilst nearly all countries have signed up to this 2°C threshold, no such comprehensive framework has yet been agreed. Whilst there is renewed focus for the COP21 negotiations to be held in Paris in 2015, the possibility still remains that there will be further delays on how to limit climate change to 2°C will result in increased costs for different nations.

Part of the reason for these successive failures, and a key concern for each party at the international climate negotiations in 2015, is the anticipated national economic effects of implementing ambitious climate mitigation targets that are consistent with the pledged agreement to limit climate change to 2°C. However, further delays will tend to only exacerbate these issues. The aim of this work is to use hybrid modelling techniques to determine the economic effects on regional economies of limiting global warming to 2°C. We also aim to explore the macroeconomic implications of the delays that have already occurred in reaching and implementing a global agreement, and how these will be amplified if there is further delay.

We use the TIAM-UCL energy systems model developed at University College London which is a global bottom-up technology-rich cost optimisation model. The model is based upon the ETSAP-TIAM model (Loulou and Labriet, 2007) but with several significant additions in terms of a climate module, a separate UK region and significant regional resource data improvements. The model has recently been applied to explore distributional effects of unused fossil fuels in meeting a 2°C target (McGlade and Ekins, 2015). Here, we expand upon the model by considering the general equilibrium effects and potential regional GDP loss of limiting climate change to the agreed 2°C threshold.

We have added a simplified general equilibrium macroeconomic growth module developed by Kypreos and Lehtila (2013). Macro Stand-Alone (MSA) is a single agent; single sector, multi-regional, general equilibrium optimal growth model which maximises discounted utility of a single consumer-producer agent. GDP is comprised of consumption, investment and energy system costs. Total

economic production is determined by a combination of energy, capital and labour where energy substitutes with a capital-labour composite via an elasticity of substitution parameter. Quadratic cost functions and demand decoupling factors are estimated from the calibration routine are fed from TIAM-UCL to MSA. MSA is then solved and the new energy demands are given back into TIAM-UCL which is then solved again. The iteration continues until the model converges, defined by the change in energy service demand variation between interactions slowing to within a specified tolerance.

Initial results for the TIAM-UCL-MSA model show that the macroeconomic effects across the 16 regions of meeting the 2°C target differ significantly. The range of GDP loss in 2050 compared against a 'no emissions target' baseline scenario for European countries and the United States is between 1% and 2%. This suggests that the losses that would be incurred while achieving the ambitious emissions reductions required to limit global warming to 2°C are relatively modest in these regions. Losses are, however, much higher in the Middle East and Former Soviet Union regions, reaching up to 5.5% lower compared with growth in the baseline scenario. This results from the reduction in markets and prices for these regions' fossil fuel exports that can be expected under such a 'no emissions target' scenario.

If action is delayed beyond 2030 then it is highly unlikely that reaching a 2°C world is feasible at all, however further set of scenarios which delay action to 2025 and 2030, and which thus make the emissions reduction more difficult to achieve, will be examined in this work. By examining the additional losses in GDP that will result from delayed action on mitigating climate change, these results will have profound consequences for the climate negotiations to be in 2015.

P-3322-11

Forecast on China's Energy Consumption and Carbon Emissions Driven by Micro Innovation:an Agent-based Simulation

J. Wu (1) ; Z. Wang (1) ; Q. Zhu (2)
(1) Institute of Policy and Management, Chinese Academy of Sciences, Beijing, China; (2) China university of petroleum, Beijing, China

To forecast the energy consumtion and carbon emissions in China, this paper established an input-output model with 17 sectors on the macroeconomy level, and an agent-based model on the microeconomy level simulating firms' innovations in each sector. Results show that due to the uncertainty of innovation, the peak years of energy and emission are also uncertain. The energy peak year will subject to a normal distribution from 2025 to 2036; while the distribution of emission peak year is also identified as a normal distribution from 2024 to 2033. The year with the maximum probability for energy peak will be 2031 with the probability of 23.57%; and 2029 will be the year with the maximum probality 33.51% for emission peak. Taking the average of 50 simulations, it is indicated that the energy peak will be 5146Mtce in 2029 with a decline by 2050 to 4086Mtce, and the emission peak will be 2.7GtC in 2029 with a decline by 2050 to 2.05GtC.

P-3322-12

The Simulation of China Regional Climate Trends

Q. Yue (1) ; J. Zhang (1) ; C. Yue (1) ; F. Xu (1)
(1) East China Normal University, Shanghai, China

In order to simulate the climate change in China, we adopt the regional climate model RegCM4, which is jointly researched and developed by NCAR/PSU (The National Center for Atmospheric Research/ the University of Pennsylvania). The model is widely used in the research of large range regional climate. Considering the CO2 emission strategy in the future process of climate change, A1B scenario simulation data produced by global circulation model EH5OM is chosen and used as the driver of regional climate model initial field and the lateral boundary conditions. Its change rate of annual average temperature is closed to observed value and the performance of the seasonal and interannual variability of precipitation is reasonable. Simulation period begins on 15 October 2040 and ends to 31 December 2060 and the period before 31 December 2040 is seen as simulation initialization phase. Sea surface temperature boundary field comes from SST_A1B data on RegCM4 website, interpolated on the grid simulation area.

The contemporary climate simulation results in 1981-2000 are subtracted form the A1B scenario simulation prediction results in 2041-2060 respectively. In this way, we reduce the uncertainty in climate predictions brought by the simulation error, and improve the reliability of prediction. Then we get the possible future climate change trend of China in the middle 21st century, under the A1B scenario. As results show, the multiyear average temperature increases more in the north region than it in the south, more in the east then it in the west. The increasement ranges from 1.5℃ in the southeast to 2.4℃ in the northwest, even reaches to 3℃ in some area. Different from mean temperature, the variation trend of multiyear averaged annual precipitation dose not shows an increasing trend in all reigons. The annual precipitation may have a decrease trend in the south of the Yangtze River, including the yangtze-huaihe region, which generally reduces about 100 mm. The average annual precipitation decrease rate is sharper in the southeast china and it decreases over 200 mm in some area. The precipitation may be lower in Guizhou and east Yunnan, as well as the east and north region of Taiwan. However, a increasing of annual average precipitation can be seen in the north region of China, especially in east Inner Mongolia and local area of Heilongjiang. In addition, there is a sharp increase in south Tibetan Plateau, which may exceed 200mm.

A lot of researches on climate change simulation are reported, and the simulation of RegCM4 under A1B scenario is accepted by most scholars now. While some details of this simulation results differ from others results, the error is acceptable.

P-3322-13

Modeling and Computation of Transboundary Industrial Pollution with Emission Permits Trading by Stochastic Differential Game

S. Zhang (1)
(1) Tianjin University of Finance and Economics, Tianjin, China

The topic on how to deal with the transboundary industrial pollution is becoming more and more popular, and it requires international actions to control its formation and effects. In this paper, we present a stochastic differential game to model the transboundary industrial pollution problems with emission permits trading. More generally, the process of emission permits price is assumed to be stochastic and to follow a geometric Brownian motion (GBM). We make use of stochastic optimal control theory to derive the system of Hamilton-Jacobi-Bellman (HJB) equations satisfied by the value functions for the cooperative and noncooperative games, respectively, and then propose a so-called fitted finite volume method to solve it. The efficiency and usefulness of this method are illustrated by the numerical experiments. The two regions' cooperative and noncooperative optimal emission paths, which maximize the regions' discounted stream of net revenue, together with the value functions, are obtained. Additionally, we can also obtain the threshold conditions for the two regions to decide whether they cooperate or not in different cases. The effects of parameters on the results have been also examined. All the results demonstrate that the stochastic emission permits prices can motivate the players to make more flexible strategic decisions in the games.

Human Dignity & the Future of International Environmental Governance in the light of ICJ Jurisprudence: A Normative Analysis

K. Bansal (1)
(1) International Policy Analysis Network (IPAN), Karnal, Haryana, France

More than being an attempt to suggest a direction for the further policy discourse, this paper presents a normative perspective which espouses and analyses Human Dignity as a School of Law with regards to International Environmental Governance.

The paper begins with an introduction of Human Dignity as the foundation of modern public international law and explains it further in the light of Elementary Consideration of Humanity doctrine as developed by the International Court of Justice (ICJ). This part explains the irreversible connection between the contemporary principles of international environmental governance and human dignity by relying upon various legal authorities and opinions.

The second part of the paper brings out the deficits of international environment law. It is argued that in the light of the conceptual trinity of sources of international law as enshrined in Article 38 (1)(c) of the ICJ Statute, one may observe that the deficit of international environment law is trilateral: treaty law, customary rules and the general principles of international law.

In the third part, this paper comprehensively analyses international environmental jurisprudence as developed by the International Court of Justice in order to address the deficits in the law as pointed out in the second part of the paper. It is argued that the ICJ's environmental jurisprudence reflects that progress in the international environment law can well be secured by the application of general principles of international law. Here, relying upon the ICJ jurisprudence, four such core principles are also identified which provide the basis for an environment specific legal application.

The objective of this paper is two-fold: firstly, to take forward the discourse on the future of global governance norms in the light of human dignity as the core principle, especially with regards to environmental governance; secondly, to propose the fundamental principles through a normative analysis which should form the cornerstones of the broader discussion taking place during the conference.

Justice and equity in REDD+

A. Wardell (1)
(1) CIFOR, Montpellier, France

The UNFCCC adopted Reducing Emissions from Deforestation and Degradation, enhancement of carbon stocks, conservation, and sustainable management of forests in developing countries (REDD+) as a climate mitigation mechanism given the scale of CO2 emissions resulting from the conversion and degradation of tropical forests (ca. 12-15% of global anthropogenic greenhouse gas emissions (GHG)), and the early belief that avoiding deforestation would be a 'quick, cheap and easy' mitigation option. REDD+ was originally conceived as a system of Payment for Environmental Services which aimed to link sellers and buyers via voluntary, conditional agreements over a well-defined environmental service – or a land use presumed to produce that service. The majority of funding, it was anticipated, would come from carbon markets.

Despite the significant technical, methodological and policy challenges that still need to be met, it is likely that REDD+ will be a component of a new climate change agreement given the Copenhagen Accord, the outcomes of the work on REDD+ safeguards of the AWG-LCA in Cancun, the Warsaw REDD+ Framework, the ADP's continuing efforts to address Non-Carbon Benefits, non-market based approaches and joint mitigation and adaptation, and the emergence of a plethora of project-based and jurisdictional REDD+ standards. This despite the effective collapse of (forest) carbon markets, and an overall negative performance at a global scale (GHG emissions in 2012 were at 58% higher levels than they were in 1990 cf. Article 2 of the Convention). REDD+ activities are now financed predominantly as part of Official Development Assistance programmes. The added incentives promised by REDD+ are likely to heighten the existing struggles for access to, and control over land and forest resources. As new values are assigned to forests, contestation between statutory and customary systems of individual and communal property regimes are likely to be exacerbated.

This paper adopts a 'rights, responsibilities, revenues and relationships' framework to highlight the (relatively) limited attention accorded, to date, to develop appropriate legal frameworks for REDD+ often in contexts distinguished by legal pluralism and multiple framings and dimensions (procedural, distributive and contextual) of 'justice' and 'equity' at different scales of governance. It raises questions (again) about the limits of 'blueprint development' that often privileges external actors (and their knowledge systems) over local communities. Complex legal issues such as those related to land tenure, benefit sharing, constitutional compliance, conflict resolution and liabilities have not been adequately addressed to provide enabling legal frameworks for REDD+ implementation. The paper draws on collaborative research conducted by CIFOR and IDLO in Tanzania, Mozambique and Zambia.

O-3323-03

Law and Governance Instruments for Sustainable Landscapes in the Low-Carbon Economy

MC. Cordonier Segger (1) ; A. Wardell (2) ; G. Markus (3)
(1) CISDL – Centre for International Sustainable Development Law (CISDL), c/o LCIL, University of Cambridge, Cambridge, United Kingdom; (2) CIFOR, Research capacity and partnership development, Montpellier, France; (3) LCIL, Faculty of Law, University of Cambridge , Cambridge, United Kingdom

Sustainable development of landscapes requires multi-sectoral and multi-level interventions, in order to deliver on the potential opportunities of the low-carbon green economy. What international law and governance instruments can assist land-use decision-makers, particularly in forest, agriculture, extractives and other sectors, to promote more sustainable trade and investments? New governance research and legal analysis is focusing on the innovative international economic instruments that global treaty processes, such as the UN Framework Convention on Climate Change, offer to provide incentives towards more sustainable landscapes. At the same time, while the Doha Development Agenda remains stalled in the WTO, emerging regional trade and investment treaty measures are seeking to encourage sustainable development of renewable energy, forests and other resources. These international regimes, and the financial flows that they govern, might serve to frustrate more sustainable development, requiring robust application of social and environmental safeguards. Or, if implemented in an effective and integrated manner, they may hold the potential to foster more sustainable development on the ground and across transnational value chains, provides levers for countries to ensure better governance of scarce natural resources in a way that supports global efforts to respond to climate change mitigation, resilience and financing challenges. Based on recent books and multi-country climate law and governance studies, this paper explores the key international, national and local policy and regulatory innovations, world-wide, and considers how can recent emerging treaty-based regimes and instruments contribute to sustainable landscapes governance.

O-3323-04

Migration, environment and climate change: legal frameworks and challenges

D. Mokhnacheva (1), A. Sironi (1)
(1) International Organization for Migration, DMM/MECC, Paris, France

The issue of a legal framework to address environmental migration is a widely debated topic. There is no internationally accepted legal definition or specific status for people on the move due to environmental factors, and no legal instrument dedicated specifically to this issue. As a result, ensuring the protection of affected individuals seems challenging in the absence of one instrument that identifies the applicable rights and corresponding States obligations tailored to the specificity of environmental migration. This has led to strong calls for international efforts to create a specific legal status for environmental migrants.

This presentation will provide an overview of the particular challenges environmental migrants may face in terms of human rights and justice; existing legal instruments, their applicability in the context of environmental migration, as well as their limitations; and discuss the prospects and challenges for creating a protection framework for those displaced or migrating in the context of climate change. As the leading migration agency, IOM will share its practical experience and emphasize the importance of a rights-based approach to the management of environmental migration.

O-3323-05

Hybrid Legal Approaches towards Climate Change: Concepts, Mechanisms and Implementation

C. Corendea (1)
(1) United Nations University Institute for Environmnet and Human Security (UNU-EHS), Environment, Migration, Social Vulnerability and Adaptation (EMSVA), Bonn, NRW, Germany

In the light of better understanding global risks, this paper will explore environmental risks from a climate change legal-related perspective, in particular human rights and migration, focusing on the core of the problem and not essentially on the form, drawing on and using regional level experiences, such as Pacific Islands. The paper will address climate change triggers, such as sea-level rise impact on national and regional law upscaling to international law, for considering a potential legal approach, not just in terms of mitigation, but also in terms of adaptation, risk reduction, transfer of technologies, climate finance and capacity building.

Hybrid approach is based on the (International) Hybrid Law, a legal research tool which concurrently, indivisibly and interrelated analyse a climate change case study from three perspectives: environmental law, human rights and refugee (migration) law. Hence, the research is simplified, using a single lens as a replacement for a three way analyse.

It was noted that having the main cause in breaching international environmental law, e.g. violation of the principles of international environmental law, the main legal effects are mostly to be found in the human rights law, due to its unavoidable first impact upon the targeted society. Secondary, as a subsidiary effect, there is refugee (migration) law, because of the same strong impact, regardless of the type of response: immediate, intermediate or long-term.

There are two methodologies the research will make use of in regards to address the issues mentioned above:

- Rights-based approach which will emphasise the bottom-up standpoint as imperative in the post-2015 climate agreement (human oriented analyses, loss and damage, etc.)

And

- The progressive interpretation of law methodology which will underline the need of hybrid approaches in addressing climate change from a legal perspective in particular in relation to human rights (direct effect) and migration (as subsidiary effect).

The paper applies international hybrid law methodology in its innovative endeavor to address the challenging questions of the existing legal gaps in international law, environmental (legal) risks and human security in an unprecedented global circumstance, when States, for the first time in the history of the humankind, are projected to disappear from the world map without war.

The expected outcomes of the paper are as follows:

- How rights and hybrid approaches apply to climate risks and lead to migration, as subsidiary effect at local, national and international level;

- How to use hybrid legal tools in climate change and migration related cases;

To address the questions of legitimacy and sovereignty under international law, of a State without a territory lost due to climate change triggers and provide preemptive legal solutions to potential risks associated with this unparalleled state of affairs.

O-3323-06

Exporting Harm

J. Moss (1)
(1) Practical Justice Institute, Social Sciences, Sydney, Australia

In this paper I will discuss an aspect of the problem of how to divide the World's remaining 'carbon budget' – the amount of CO2-e that can be emitted if we are to avoid dangerous climate change. I will argue that there is a prima facie case for allocating responsibility for the harms caused by exported emissions such as those produced by coal, as well as those that are produced within a country's borders. This is not a complete determination of the carbon budget problem by any means, but a step towards its development.

My paper sets out some of the factors that determine a country's carbon budget and argues that the current methods for allocating emissions and responsibilities for their harms are inadequate and more complex than they appear.

The paper will consider several dimensions of the harm caused by unrestricted fossil fuel exports. First, what kind of harm is caused by such exports? Second, whether analogies exist between other harmful exports ¬ medical waste, tobacco, unsafe jobs, uranium ¬ and fossil fuels to examine how the kind of harm caused by global warming is different from standard cases of harm where only two parties are involved. Third, whether unrestricted export of fossil fuel exports satisfy a 'fair shares' criterion. Finally, what allocating responsibility for harms means in practice.

Environment Tribunals and Justice: The Indian Experience

R. Brara (1)
(1) University of Delhi, India, Department of Sociology, Delhi, India

I inquire into practices and experiences with adjudication that emerge from a study of the cases filed before the newly formed National Green Tribunal in India and interviews with selected lawyers and appellants that focus on governance and justice. My endeavour is to show how the affected public's vulnerability to environmental and climate change intersects with the discourse and practice of governance, ethics and justice as well as resilience, mitigation and adaptation.

Taking a bird's eye-view, collective experiences of vulnerability have given rise to the organization of multiple environmental publics in India. Analyzing the cases filed before the National Green Tribunal by these publics enables me to demonstrate that by litigating the environmental public interest, the experience of vulnerabilities is often

transformed into events marked by resilience though not necessarily by success.

From a local perspective, issues of climate change and the environment cannot be easily disentangled since climate change hits the environment as base. It is a local climate-cum environmental violation that comes to threaten the life of an individual or household and is articulated as worthy of further action by gathering a public and acquiring a strategic local scale. The next step begins with the search for an environmental lawyer (and funds) for adjudication before the Tribunal. This step is the event's translation into the language of law and the state, which produces and views the violation from an altered scale and perspective. The transformation is experienced as a rupture that marks the distance from a local public to a public mediated by the environmental laws of the state.

New interactions then occur across scales such that the environmental/climate cause lawyer assumes a critical role – with one face turned to the local, as it were, and the other to the law as its representative interpreter. The environmental lawyer addresses the mismatches between the scale of law and the local apprehension of the problem and scale as he sifts the facts and frames them for presentation in a legal case. What comes into being at the local level, then, is a heightened awareness, friction and even a revelation, of the limits of legal processes (spatially, temporally and including their possibilities for justice). Simultaneously, therefore parallel channels of communication are activated and engaged to reach out to politicians and government officials at multiple sites in the quest for justice.

The Legal Bench of the Tribunal embodies the statutory perspective even more completely than the lawyer. Here the facts of the case are readily rendered as background and the legal order of argumentation and knowledge, into which the case must fit, takes precedence. From this perspective, the judge or Bench often reads the environmental violation as an issue that stems from the inadequacy of the executive which has failed to do its jobs and let the problem fester. As the legal judgment, in its corrective mode, travels back to the local, it is inevitably filtered through the visions of the executive, such that the local enforcement of a judgment on the ground is rendered uncertain and risky. The implementation of a sound legal judgment is contingent on the local bureaucracy and the local public attempts to adapt to this maladapted reality.

The global of environmental law and governance also emerges as a producer of new scales and perspectives from a different situated context. The transnational environmental climate sphere's scales and processes, too, journey downwards to nation-states where these are both ratified and refracted. The judge who embodies the statutory order of the nation state also appears as the arbiter of national difference from promulgated global principles of environmental-cum-climate regulation. International treaties are thus unable to trump national sovereignty in the present.

What you have, then, is an insubordination of scales, compelling us to move up, down and sideways to understand and address the legitimacies/ illegitimacies of governance and justice and the frictions of local and national difference in the context of environmental climate change.

P-3323-02

Governance of Local Disaster Management Committees in line with SOD in Bangladesh

SA. Siddiquee (1)
(1) WAVE Foundation, Monitoring and Evaluation, Dhaka, Bangladesh

Due to its geographical location Bangladesh has always been prone to natural disasters such as tropical cyclones, floods, droughts, tidal surges, tornadoes, river-bank erosion and many more. Bangladesh has shown significant improvement in disaster management which is proven by its possession of Standing Orders on Disaster (SOD), Disaster Management Act, National Disaster Management Plan, Disaster Management Policy, Disaster Management Committees at the District, Upazila and Union levels. However, despite the government's commitment and effort given by many actors the room for improvement prevails in the disaster management system. A total of 51 DMCs in five districts that were vulnerable to flood, river-bank erosion, drought and cyclone were taken as sample to analyse the current situation of these committees. The study was conducted using both qualitative and quantitative methods. Both open-ended and close-ended questions were asked. Questionnaire and KII tools were used to collect information from respondents in both the government organizations and NGOs. The study has observed poor coordination between GO and NGOs at the sub-national and local level. Surprisingly, the study has found that only 38.9% DMC members are informed about Disaster Management Act and 36.76% are aware about their roles and responsibilities in the Standing Orders on Disaster (SOD). Although the selected districts are extremely prone to disasters, surprisingly it has been observed that 70% of DDMCs and 30% of UzDMCs are holding regular meetings and only 16.22% of UDMCs are holding regular meetings as per the SOD. The scenario mentioned above clearly states that the DMCs are not active as they should have been according to the SOD. Only 43.80% of DMCs have Risk Reduction Action Plan (RRAP) but perform very few activities according to the RRAP. It was found that only 23.3% of DMCs have developed volunteer groups and only 26% of DMCs have arranged community awareness building programmes. The study has also found that only 34% of Union Parishads have incorporated DRR into their Annual Development Plan. It is alarming that even though Bangladesh is one of the prime victims of climate change, encountering severe and frequent disasters like Sidr, Aila and Mahasen, 66% of the sample Union Parishads did not have DRR integrated into their ADPs. Based on the gaps recognized in the study, it can be concluded that the functionality of the DMCs needs to be improved through capacity building, training, and materials such as a guidebook to simplify the SOD etc. in order to levitate the current Disaster Management System. Empowering the DMC members by increasing their level of understanding in Information Technology and by linking them to the national level will ultimately lead to more and improved governance system of Disaster Management Committees.

Risk Culture: Implications for Risk Governance

O. Renn (1) ; E. Boyd (2)
(1) University of Stuttgart, The economic and social sciences, Stuttgart, Germany; (2) University of Reading / Stockholm Resilience Centre, Department of Geography and Environmental Science, Reading, United Kingdom

Deciding about the location of hazardous facilities, setting standards for chemicals, making decisions about clean-ups of contaminated land, regulating food and drugs, as well as designing and enforcing safety limits all have one element in common: these activities are collective endeavours to understand, assess and handle risks to human health and the environment. These attempts are based on two requirements. On the one hand, risk managers need sufficient knowledge about the potential impacts of the risk sources under investigation and the likely consequences of the different decision options to control these risks. On the other hand, they need criteria to judge the desirability or undesirability of these consequences for the people affected and the public at large. This second part is an integral aspect of risk culture, understood as the systems of norms, vales and visions that an organization shares among its members Within the portfolio of organizational culture, criteria on desirability are reflections of social values such as good health, equity,

or efficient use of scarce resources. Both components – knowledge and values – are necessary for any decision-making process independent of the issue and the problem context.

Anticipating consequences of human actions or events (knowledge) and evaluating the desirability and moral quality of these consequences (values) pose particular problems if the consequences are complex and uncertain and the values contested and controversial. Dealing with complex, uncertain and ambiguous outcomes often leads to the emergence of social conflict. This is particularly the case for emerging technologies where the risks are not yet known. Although everyone may agree on the overall goal of safety and environmental quality, precisely what that goal entails (how safe is safe enough?) and precisely how that goal will be obtained may evoke substantial disagreement. Major issues in this context are: what are the most suitable criteria for judging risks? Hoe can an organizational culture cope with uncertain outcomes and how can it develop an effective monitoring system. How should an organization manage risks that benefit one party at the expense of potential harm to another?

These crucial questions of how to deal with complex, uncertain and controversial risks demand procedures of decision-making that go beyond the conventional risk management routines. Numerous strategies to cope with this challenge have evolved over time. They include technocratic decision-making through the explicit involvement of technical experts, institutional arrangements for foresight and monitoring, direct stakeholder involvement, and external reviews. The main argument of the paper is that public and private institutions that assess and manage risks are in urgent need of revising their institutional routines and of designing procedures that enable them to integrate professional assessments (systematic knowledge), adequate institutional process (organizational culture), responsible handling of public resources (efficiency) and stakeholder knowledge and perceptions (reflection on public values and preferences). These various inputs require the inclusion of multiple procedures and the involvement of several actors in the risk assessment and risk management process. The structures that evolve from the cooperation of various actors in all phases of the risk handling process are subsumed under the term risk governance . Governing choices in modern societies is seen as interplay between governmental institutions, economic forces and civil society actors, such as non-governmental organizations (NGOs). 'Risk governance' involves the 'translation' of the substance and core principles of governance to the context of risk and risk-related decision-making. It includes, but also extends beyond, the three conventionally recognized elements of risk analysis (risk assessment, risk management, and risk communication). It requires consideration of the legal, institutional, social and economic contexts in which a risk is evaluated, and involvement of the actors and stakeholders who represent them. Risk governance looks at the complex web rules, conventions, processes, and mechanisms concerned with how relevant risk information is collected, analysed and communicated, and how management decisions are taken. Such an approach links risk governance with risk culture.

Disasters and Green Growth: An Exercise in Complexity

C. Jaeger (1)
(1) Global Climate Forum, Berlin, Germany

It is by now common knowledge that air pollution is a huge disaster in Beijing as in other megacities of the present. It is less known that a century ago air pollution was at least as disastrous in Chicago and other large cities of those times. While efforts to reduce those historical pollution disasters started already in the 19th century, they became really successful only when economic growth had made far-reaching pollution control affordable. This option of "pollute first, clean-up later" is not open to countries like contemporary China. They need to switch to a path of green growth. This goal cannot be reached by simple top-down strategies. Rather, an approach fostering synergies between problem solving strategies by a myriad of actors is needed. Such an approach can be developed, but it requires a new view of the complex relations between economic growth and disaster management.

O-3324-03

World Regionalization of Climate Change [1961–2010]

Q. Ye (1) ; P. Shi (2)
(1) Integrated Risk Governance Project, Beijing Normal University, Beijing, China; (2) Beijing Normal University, State key lab for earth surface processes and resource ecology, Beijing, China

Existing climate regionalization aims to characterize the regional differences in climate based on years of the mean value of different climate indexes. However, with the accelerating climate change nowadays, existing climate regionalization cannot represent the regional difference of climate change, nor can it reflect the disasters and environmental risks incurred from climate changes. This paper utilizes the tendency value and fluctuation value of temperature and precipitation from 1961 to 2010 to identify the climate change quantitatively, and completes world regionalization of climate change (1961–2010) with state (province) administrative regionalization as the unit in combination with world's terrain feature. Level-I regionalization divides world's climate change (1961–2010) into thirteen tendency zones based on the tendency of temperature and precipitation; level-II regionalization refers to twenty-nine fluctuation regions based on level-I regionalization according to the fluctuation of temperature and precipitation.

O-3324-04

Everyday disasters, adaptation governance & resilience frameworks

A. Ghosh (1) ; E. Boyd (2)
(1) University of Heidelberg, South asia institute, Heidelberg, Germany; (2) University of Reading / Stockholm Resilience Centre, Department of Geography and Environmental Science, Reading, United Kingdom

This paper introduces the concept and consequences of 'everyday disasters' – when regular oceanic processes such as tidal bores and high tides become more intense and catastrophic, destroying lives of those who live in low-lying coastal areas with striking regularity under the influence of climate change, sea level rise, coastline erosion and land subsidence. In the Indian Sundarbans, world's largest mangrove ecosystem situated at the mouth Bay of Bengal and a part of world's largest delta, these 'daily' weather hazards are egregiously affecting the socio-ecological system, leading to human crises of unprecedented proportions. Not classified and defined as 'disasters' and thus unattended by local, national and international disaster management authorities, these events engender a socioeconomic challenge to structured adaptive governance which is yet to be studied formally or understood.

Majority of the indicators of global warming are already higher than global averages in Sundarbans. Eventual outcomes in terms of actual environmental shifts as a product of complex interactions between anthropogenic and climate changes in this socio-ecological system are making the challenge of climate change adaptation further complex, along with increased intensity and frequency of cyclones, typhoons, flash floods, which have, however, received considerable attention from disaster risk reduction scholars.

On July 12, 13 and 14, 2014, a regular oceanic phenomenon of a tidal bore devastated island villages across Indian Sundarbans, destroyed human settlements, infrastructure, dwellings and displaced about 100,000 people, forcing them into near starvation for over three months. It also destroyed prospects of agriculture and aquaculture for an indefinite future. Using snowball sampling, extensive qualitative interviews, photographic and audio-visual evidence were collected from five of the affected villages between July and September 2014. The findings reveal narrow and limited framing of disasters and a disparate adaptation discourse that have failed to internalise these events. Through grounded narratives and evidences, this paper elaborate how threats from environment (climate change) domain were extending to social ones, exacerbating the existing crisis in the socio-ecological systems; underscoring specific needs for governance processes and systems to target newly

emerging socio-environment risks. The analysis also underscores epistemological weaknesses of existing resilience frameworks that are unable to address changing nature of vulnerabilities to livelihoods and human security. Also, imprint of the event on the adjoining areas, especially towns and cities in the region because of large human migration, argues for reconfiguring development paradigms in wake of altering environmental realities.

Thus, this work addresses two of the biggest gaps in resilience geography about how smaller, daily disasters were aggravating environment shifts and how they were jeopardising livelihoods, threatening human security and posing an unforeseen challenge to development in the South.

For richer or for poorer? Examining science-governance relations from a global perspective

L. Van Kerkhoff (1) ; H. Berry (2)
(1) The Australian National University, Fenner School of Environment and Society, Canberra, ACT, Australia; (2) The Australian National University, Climate Change Institute, Canberra, ACT, Australia

The application of research-based knowledge to national-scale action on important public issues such as climate change is necessarily shaped by each nation's socio-political stance toward the value and role of science in governance and decision-making (Jasanoff, 2010). Similarly, it is shaped by their capacities to enact those values by governing effectively for the public good. Yet although there has been considerable study and scholarship regarding the challenges of linking knowledge to action for science and research and associated institutional innovations, there has been relatively little that has sought to investigate the national-scale relationships between research and the public functions of governance. Examining these relationships helps us to understand the socio-political substrate from which other knowledge to action innovations must grow. There is extensive analysis showing that greater investment in R&D is related to higher economic growth, but none that has specifically sought to describe whether governance and R&D are related independent of national income via better public management, and how this might vary globally. To contribute to this understanding we sought to answer the questions of: whether there are quantitatively discernible relationships between science and governance at the macro (global) scale; how these relations might differ across countries; and how this diversity can be understood. This latter question is particularly important from the perspective of governing global environmental processes such as climate change.

To address these questions we investigated two hypotheses: first, that governance performance and research and development (R&D) are related independent of national income levels. Second, that these relations differ across high-income countries and lower-income countries, both quantitatively and qualitatively. We drew on publicly available country-level statistical data from the World Bank and UNESCO to investigate how national governance capacities are related to research and development investment (RDI). Using a sample of 209 countries we show that, while national income is an important factor, governance performance is independently related to RDI. Importantly, different domains of governance are relevant for high-income and lower-income countries. In terms of governance, in high-income countries, 'governance effectiveness' is the sole predictor of RDI while, in lower-income countries, it is predicted by greater 'rule of law' but less 'control of corruption'. These results show that the relationships between governance and R&D in lower-income countries are complex and substantially different from high-income countries. More detailed analysis is warranted if we are to understand how to address the diversity of science-governance relations and the challenges andopportunities they pose for linking knowledge with action on global issues.

Addressing migration in the context of global environmental change: an institutional perspective

M. Traore Chazalnoel (1)
(1) International Organization for Migration, DMM/MECC, Geneva, France

As the leading migration agency, the International Organization for Migration has been working on migration, environment and climate change for more than twenty years, promoting research, awareness and knowledge of the subject, contributing to mainstreaming migration and environment into policies, promoting migration as an adaptation strategy in the context of climate change, building the capacity of key stakeholders, and assisting migrants in need, by combining bottom-up and top-down approaches to the management of environmental migration.

Building on the Organization's global research, operational, and policy experience, this session will reflect on the pathway from knowledge to action in the area of climate-related migration governance. The presentation will explore the opportunities migration offers in the context of climate change, and discuss the challenges around addressing environmental and climate-related migration, including the difficulty of measuring and framing environmental migration and producing evidence to inform decision makers; the challenge of bridging the gap between empirical knowledge and political action, and of putting policies into practice; the difficulties behind attracting funding to enable action; legal challenges; operational and coordination challenges.

The session will also present some recommendations and possible avenues for improved action and governance of environmental migration, as a contribution to the preparatory work ahead of the COP21.

O-3325a-03

The smallholder farmers' adoption challenges on conservation agriculture practices in the southern highlands of Tanzania

B. Gwambene (1)
(1) Institute of Resource Assessment, University of Dar es Salaam, Dar es Salaam, Tanzania, United Republic of

Conservation Agriculture (CA) used as a mitigation and adaptation options to address impacts of climate variability and an alternative practice for increasing food production while maintaining the soil resource base. It is promoted to address the problems of soil degradation resulting from the impacts of climate change and agricultural practices that deplete the organic matter and nutrient content of the soil. However, adoption of CA among smallholder farmers has been limited and features many challenges in the southern highlands of Tanzania. This paper assesses the challenges of adopting conservation agriculture practices in smallholder and subsistence farming in this region. It used the survey methods that include participatory rural appraisal (PRA), questionnaire survey, key informant interview and field observation to collect both qualitative and quantitative information. The qualitative methods established the knowledge and experience with livelihood activities, adoption of CA, spatial and temporal changes in agricultural production and response strategies while the quantitative method provided the percentages and statistical information. The qualitative data were processed and analyzed by using trend and content analysis while quantitative data were analyzed by using Microsoft Excel and SPSS software. The results indicate that about 95% of smallholder farmers tend to only adopt certain components, such as mulching, crop rotation and water management techniques. Factors such as the knowledge-intensive nature of implementing CA practices, long term crop yield benefits from CA, strong trade-offs posed adoption challenges. Poor functioning and access to the recommended inputs, markets and credit facilities and shortage of extension services increased adoption challenges at a local level. It was further revealed that climate variability, land exhaustion/ shortage, unreliable markets, and lack of product knowledge were reported to increase challenge in crop production. An enabling environment for farmers through appropriate policy, strategies and implementation plans at all levels provide an opportunity to increase adoption of CA and improve their livelihoods and productivity. This will need a policy and strategies that focus more on technical approaches to increase adoption rates with the consideration of social aspects such as perceptions that are equally important in conservation agriculture. Understanding what motivates farmers to try or reject specific CA practices is imperative in adoption of technology. In practice, farmers are able, or willing, to implement or partly adopt based on their perception of what is feasible in their particular circumstances. Issues such as the nature of the technology, affordability, time and resource invested, accessibility to appropriate tools and equipment, and competition for crop residue have influenced rate and extent of adoption among smallholder farmers.

Graduated response from the stakeholders to the climate change impacts on water using a vulnerability index combining the uncertainties

T. Pelte (1)
(1) Rhone Mediterranean Corsica water agency, lyon, France

The Rhone Mediterranean Corsica water agency and the Regional Direction in charge of the environment - the DREAL - have been engaged since 2012 in a common project for climate change adaptation.

The work has developed a method to assure a solid "interface" between water policy makers and the scientific and technical fields conducting research on the impacts of climate change. Key information are provided to planners, water managers and policy makers, on the scientific knowledge that will have an impact on short- and long-term decision making for regional adaptation.

The work is organized in three interacting processes :

1. the production and gathering of scientific knowledge in order to identify climate change - related phenomena that will impact water management strategies.
2. the building of maps of the Rhone-Mediterranean basin showing regional vulnerabilities to climate change from five points of view : water resources, soil water balance, biodiversity, trophic level of rivers and snow. Each map presents a vulnerability index built for a large scale approach in order to deliver the key information to stakeholders.
3. a short-list of adaptation measures is presented face to each vulnerability map. The measures are graduated according to the level of uncertainties of the vulnerability index.

The exercise combines the exposition level to climate change with the sensitivity of the basin. The exposition level is delivered by climate projection results from 7 regionalization methods and 2 hydrological models. The sensitive index is built with technical characteristics of the basin linked to the issue.

This exercise is an original approach which combines the bottom-up and top-down approaches that are ordinarily used to build climate change adaptation strategies. The vulnerability index is inspired by the top-down approach and the graduated response by issue is the result of a bottom-up approach connected to the stakeholders. This will allow the project to result in stronger, more efficient messages.

This work has been lead under the authority of the Basin Committee, a governance structure that includes all stakeholder groups involved in water policies (State and local governments, urban, industrial and agricultural water users ...).

Sharing local and scientific knowledge for climate change modeling. A case study from an Andalusian olive-growing region (Spain)

M. Cohen (1) ; J. Ronchail (2) ; M. Alonso-Roldán (3) ; S. Angles (4) ; E. Araque-Jimenez (5) ; D. Labat (6) ; H. Garcin (7) ; C. Morcel (7) ; B. Sultan (8)

(1) Université Paris Sorbonne, UMR ENeC, Paris, France; (2) LOCEAN and Université Paris Diderot, Paris, France; (3) Associacion Pasos, Participación y Sostenibilidad. , Órgiva , Spain; (4) Université Paris-Diderot, Sorbonne Paris Cité, Umr ladyss, Paris, France; (5) Universidad de Jaén, Facultad de geografía, Jaén, Spain; (6) Université de Toulouse, Géosciences environnement toulouse, Toulouse, France; (7) Université Paris-Diderot, Sorbonne Paris Cité, Ufr ghss, Paris, France; (8) IRD, LOCEAN, Paris, France

Under a research program focused on the adaptability of olive growing systems to climate change in the Sierra Mágina region of Andalusia and under the demand of a local action group, we combined an interdisciplinary approach, collaboration among climatologists, geographers and sociologists, and the participation of local farmers and stakeholders, all contributing their own knowledge. Sierra Mágina is a highly specialized Mediterranean agrarian territory: olive groves represent 85% of cultivated land (in 2006), half of them being irrigated. Our collaboration with stakeholders and farmers developed to the extent that we incorporated the "local knowledge system" in our scientific and modeling process. This incorporation had two objectives: on one hand, we expected that it would promote the buy-in of our projections by local stakeholders and farmers; on the other hand, we expected that local knowledge should help us understand the relationships between olive-growing, climate variability and climate change. This process is suitable for research incorporating complex issues and significant level of uncertainty, which is the case of olive growing adaptability to climate change.

Firstly, we analyzed projections of climate in Sierra Mágina, focusing on the parameters that 9 stakeholders considered as limiting olive growth. We assessed the evolution of rainfall and maximum temperature during the 21st century at the local scale using 17 regional climate models (RCMs) simulations. 15 to 30% rainfall reduction is expected in the fall combined with an 8% annual average reduction by 2030-2050 (verified for 16 and 14 models out of 17, respectively). The projections of the other parameters were more uncertain. Secondly, we observed during interviews with 15 farmers, that they expressed doubt about climate change since they are used to deal with inter-annual climate variability. Consequently, we verified and mapped which parameters of climate and water resources had changed over the last decades and to what extent. Indeed, rainfall decreased by 18% during the period 1955-2009, a more dramatic decrease than the one simulated for the 2030-2050 period (8%). Water resource availability has declined two or three times more than rainfall, in part because of the expansion of irrigation, which ameliorated the effects of droughts and increased profitability. Those farmers interviewed appeared to be less aware than stakeholders about the decline of water resources.

Thirdly, when we presented the results of the climatic study to local stakeholders, they asked us to determine the impacts of climate change specifically on olive production. These show that the cumulative rainfall of the two years preceding the harvest explains 41% of the variability of irrigated olive-tree yields and 46% of rain-fed yields. This result was unexpected for irrigated yields according to the literature, but some farmers have always known about the dependence of irrigated groves on rainfall. Contrary to local knowledge, biennial (and not seasonal) rainfall is the best yield predictor, due to the biennial fruit bearing of olive-tree. Fourthly, our model, although statistically significant, showed some discrepancies between observed and simulated yield values. We performed other 7 inquiries with olive-growing professionals and farmers to assess the validity of the model with local knowledge. Once verified the extent of the validity of our model, both statistically and using local knowledge, we projected yields for the future: they are expected to decrease by 7% and 3.5% by 2030-2050 for rain fed and irrigated olive groves. Although this moderate loss should be exacerbated by the expected shortage in water resources, it should allow sufficient time to elaborate a local strategy, particularly for irrigated olive-groves. Unfortunately, most stakeholders think that rainfed trees will better cope with future water shortage than irrigated trees.

The last step of this process consists in sharing our results in a seminar and in an engaging workshop, bringing together scientists, farmers and stakeholders, in order to elaborate jointly climate change adaptation strategies taking into consideration socio-economic challenges. These discussions also aim to build a mitigation strategy, by the recovery of pruning waste (currently burnt), in order to promote the transition to a low carbon territory (ongoing program Olizero).

Since the food riots in 2008 and 2009 at the international level, some strategies are in place to tackle the problem of food security. As soils are the main support of agricultural activities, it is necessary to preserve them because of their non-renewable status at the scale of a generation, agricultural activities and forest sensu lato.

On the other hand, African agriculture has to face both climates changes which can be a source of many threats and demographic pressure which goes increasingly. Therefore, to feed people, it will be necessary to adopt agricultural practices which preserve soils and the ecosystem services they provide, such as food production and biomass, regulation and filtering of waters, the mitigation and adaptation to climate change, the conservation of biodiversity. Soil organic carbon is recognized as an indicator of fertility and productivity, two essential qualities for the autonomy and the food security of many African countries.

To meet these challenges, the implementation of agriculture that promotes alternative agricultural practices focused on optimal management of organic matter and thus the soil carbon are proposed and considered as an «agriculture that sustainably increases productivity, resilience (adaptation), reduces/removes greenhouse gases (mitigation), and enhances achievement of national food security and development goals» according to the FAO.

Many of these practices are already implemented in Sub-

Saharan Africa (SSA) such as agroforestry, zai practices, and conservation agriculture. However, their extent and their efficiency to increase productivity, to be resilient and to mitigate GES need to be documented.

The "Soil Carbon Network for sustainable agriculture in Africa" or CaSA network was created in SSA in order to regroup the African soil scientists working on sustainable agriculture in link with soil organic carbon sequestration at SSA level. This network aimed to:

(1) replace the soil as the central support of production systems;

(2) show that the simple maintenance of soil carbon is essential, especially in arid and semi-arid areas;

(3) quantify the impact of the management practices on carbon sequestration in the soil for the different pedoclimatic African situations;

(4) promote research in connection with civil society and development agencies;

(5) facilitate access of the results of research to policy makers; improve the dissemination to civil society and farmers;

(6) strengthen the capacity of the teams and training expertise.

CasA network regroup more than 15 African and European research institutions distributed among 10 African countries (Benin, Burkina Faso, Cameroon, Ivory Coast, Mali, Senegal, Chad, Tunisia, Morocco and Madagascar) and 1 European country (France). An end-product of CaSA will be a book on combined research results of soil organic carbon storage/sequestration in sustainable agriculture at SSA level; it will be presented at the COP21 in Paris.

Local beliefs and strategies of adaptation to climate change in Korhogo (Côte d'Ivoire)

N. Boko (1)
(1) UNIVERSITE FELIX HOUPHOUET-BOIGNY, SOCIOLOGIE, ABIDJAN, Ivory Coast

The precedent decades, the area of Korhogo, Côte d'Ivoire, has experienced climate variability which disturbs populations' agricultural activities. This survey has been conducted from March 2009 to February 2012 in order to identify the perceptible causes of change; be they climatic or environmental to the populations, and their endogenous strategies of adaptation. A qualitative approach based on semi-structured interviews, life stories and focus groups has been used for data collection. The historical and comprehensive method enabled to establish a relationship between populations' perceptions and beliefs and, the indicators of climate variability and environment changes but also, their endogenous strategies of adaptation. As indicators, the populations notice an extension of the dry season at the expenses of the rain season, advanced deterioration of vegetation, draining of sources of water supply (rivers, backwaters and wells) and disappearance of some animals like elephant and hyena and, some floristic species used by sculptors and traditional healers.

The survey also shows that the causes of the phenomenon are not only related to human activities but are mystical or metaphysical (non-compliance with customary practices, fetishes, totems (make love in the bush, commit blood crimes) and prohibitions related to nature; the multiplicity of religions, degradation of traditional values and the upheaval of society's rules (non-compliance of the elderly, liberalization of land working). Thus, the coping strategies of the populations based on two fundamental pillars: social capital of actors (contributions of NGOs and technicians, media and social networks) and occult practices related to beliefs. The study noted three types of strategies. The first is the survival strategy that is neither planned nor based on any knowledge of the phenomenon but obey of an instinct and the need of the population survival («climatic» migration and exodus rural, reconversion of populations and the development of certain sectors of activity).

The second type of strategy is the suggested coping strategies that are based on a scientific understanding of the causes and consequences of the phenomenon and developed and / or proposed by scientists (researchers), technicians and professionals (agriculture officers, NGOs). These strategies are related to the abandonment of long-cycle crops to new and more adapted varieties (integration cassava), the practice of crop against season, the use of improved planting materials, the reconversion of the population to income generating activities and the development of vegetable gardening.

The third strategy developed by the population is related to local knowledge, guided by the Traditional Environmental Knowledge (TEK) and beliefs guided by the metaphysical causes attributed to the phenomenon. Here, people are consulting «Fodonons» or rainmakers and also request the help of marabouts or charlatans for sacrifices in the direction of ancestors and gods' protectors, prayers are organized in mosques and churches asking God's mercy and return of the rains. Eventually, the survey shows that populations' adaptation strategies are mainly based on local traditional beliefs and knowledge which are at the same time a barrier and an opportunity for the adaptation to climate variability. This article shows in the same time the importance of taking into account local knowledge in order to develop efficient adaptation strategies.

(1) Institut de Recherche pour le Développement (IRD), UMR Eco&Sols, Antananarivo, Madagascar; (2) Laboratoire des RadioIsotopes-Université d'Antananarivo, RadioAgronomie, Antananarivo, Madagascar; (3) University of Antananarivo, Laboratoire des RadioIsotopes, Antananarivo, Madagascar; (4) University of Antananarivo, Laboratoire des Radio Isotopes, Antananarivo, Madagascar; (5) Institut de Recherche pour le Développement, UMR Eco&Sols, Montpellier, France; (6) Institut de Recherche pour le Développement (IRD), Umr eco&sols, Antananarivo, France

Madagascar in a tropical country, hotspot of biodiversity, where people welfare greatly depends on natural resources, i.e., soil, water, forests, biodiversity. As a rural country, the need of agriculture and forest product is important inducing pressures on lands which have negative feedbacks on population such as soil erosion, loss of fertility, loss of biodiversity, vulnerability to climate change, deforestation, etc. Population livelihood and resource preservation together are therefore integrated in national development policies. These issues are also closely related with international objectives designed by three major conventions of the United Nations: Convention on Climate Change UNFCCC, Convention on Biological Biodiversity UNCBD, Convention to combat Desertification UNCCD. In this context, there is a great need and urgency to undertake research and capacity building. For 10 years, the Laboratoire des RadioIsotopes (LRI, University of Antananarivo) and IRD (French Institute of Research for Development, Research Unit Eco&Sols - Functional Ecology and Biogeochemistry of soils and agroecosystems) developed integrated research and educational activities on the understanding of soil ecosystem services and their responses to global change for a better decision-making on ecosystem and agrosystem management to improve livelihood and contribute to national development. LRI and IRD together undertook jointly research on Malagasy soil properties and cartography, soil and biomass carbon sequestration, greenhouse gas GHG emissions from eco- and agrosystems, nutrient recycling and crop production, and the role of soil biodiversity in these processes. Part of these studies is related to international frameworks such as REDD+ (Reducing Emissions from Deforestation and forest Degradation), REALU (Reducing Emissions from All Land Uses)and/or is shared with other African countries such as in the case of the CaSA framework (Soil Carbon for a sustainable agriculture in Africa, funded by the French Ministry of Foreign Affairs). Studies were undertaken at different levels: from plots to local and national levels. Different agroecosystems were also studied in order to cover the variety of existing systems and depending on

the ecosystem services measured. Carbon storage in vegetation and soil pools were measured or assessed using modern methodologies and technologies such as Medium InfraRed Spectroscopy MIRS, digital mapping/RS. Modelling (Ex-Act, Ex Ante Carbon-balance-Tool, FAO) was also used for upscaling and mapping for decision making on a sustainable development.

Some results showed that natural forests and agroecological systems were the agroecosystems which allow soil carbon sequestration and there could be as much as carbon in soil pool as in biomass pool, or even more (particularly in natural forests). Actually, they could store up to 100 Mg C.ha-1 in the first 30 cm depth, and more than 270 Mg C.ha-1 in 100 m depth[F2] , particularity in forest ecosystems.

Soil biodiversity has especially been studied in cropped fields from a functional point of view. The aim of theses studies is to understand which and how soil organisms are involved in different ecological functions, i.e., nutrient cycling, carbon dynamics and maintenance of soil structure. These studies are planned to be extended to forest systems.

The municipal solid waste (MSW) management studies showed that MSW composting reduced the amount of deposits in landfill (65% of initial mass of windrow) and creating product at relatively low-cost that is suitable for agricultural purposes. And after six years of organic fertilization the stock of SOM has increased by 48%, and the content of Olsen P and resin P, has increased respectively by 85% and 35%.

From a teaching point of view these issues are now integrated in different university courses such as the master of Agroecology (Higher School of Agriculture), the recent international master ABC (Agroecology, Biodiversity, Climate-Change, University of Antananarivo), the Doctoral School A2E (Agriculture, breeding, environment). The research conducted on soil ecosystem services for poverty alleviation and population development permitted the training of more than 15 PhDs. Efforts are also made by the team to train environment and agriculture stakeholders.

P-3325-03

The influence of stand-level attributes on wind damage probability of industrial tree plantation areas in Mindanao, Philippines

A. Codilan (1) ; N. Shiraishi (2)

(1) Institute of Renewable Natural Resources, College of forestry and natural resources university of the philippines los baños, Los Baños Laguna, Philippines; (2) Laboratory of Forest Management, Department of forest science university of tokyo, Tokyo, Japan

In the past decade, the increased frequency and intensity of tropical typhoons brought by the changing climate had clearly brought severe damages to industrial tree plantations (ITP) in the Philippines. These damages resulted in loss of high-value timber and increased economic costs. The risk of wind damage from strong storms and typhoons should be an important component of plantation management plans. The problem, however, is that risks that were not conceived before may have become relevant in the present. Such is the case of an ITP in Mindanao, Philippines where the unprecedented increase in the frequency of storms and typhoons is now causing serious wind damages to plantations. In this consideration, the site's probability of risk to wind damage was estimated empirically using logistic regression analysis. Specifically, the influence of stand-level attributes such as average stand height, elevation and topographic exposure on damage probability were assessed. For the analysis, post-storm inventory data from 2012 Typhoon Bopha, in combination with previous stand inventory data, were used.□Results show that all three stand-level variables are influential and that damage probability has a direct relationship with the variables. By considering constant terrain conditions, the effect of average stand height was determined. Results indicate that there are critical average stand height levels which put each site at high risk of being damaged. Critical stand heights of 25 m, 20 m and 10-15 m were identified for low, medium and high-risk level sites. This information, when combined with site productivity, could be used as a basis for determining risk-sensitive rotation ages at which certain species can be grown while reducing wind damage to plantation. Moreover, topographic stand variables used were derived from DEM thereby addressing the high-cost issue associated with developing damage probability models. Amidst the issue of climate change and the projected increase in weather disturbances, these results can improve management plans and make them more relevant and responsive to changing times.

P-3325-04

We don't want that offer «development»! The reinvention of the territories in the semi-arid region of Brazil and Argentina: the case of the peasant community radios

G. Lopes (1)

(1) University of Nairobi, Buenos Aires, Argentina

We speak from a epistemic place, from a locus of enunciation. In modernity, the actors and institutions of rational European thinking relate and proclaim themselves as if they were located in a higher stage of human knowledge (developed) and as such, they award themselves the right to invalidate, discard, (des)authorize, ticketing as lower all the other modes of knowledge. From a decolonizing epistemic turn, we seek visibilize and put in dialog two experiences of reinvention of the territories, carried forward by rural communities in arid regions of Latin America (Sergipe, Brazil and Santiago del Estero, Argentina), through its community radios. To propose and disseminate via radio the proposal of coexistence with the semi-arid and drought, the peasantry is proposing-living an alternative to development. In this way, resisting/re-exist in the public policies of rural development, who proclaim the 'fight to the drought', the peasantry reinvents its territories face/slowing the advance of the hegemonic model of rural development (agro-exporting mining extractive), collecting/spreading ancestral knowledge and technologies for collection and distribution of water from rain, which allows them to reduce the impacts of climate change. Look at that process demands geopolitics of knowledge, therefore the translation inter-cultural is the methodological tool necessary to achieve thinking with and together with the other.

P-3325-05

Exploring the links of artisanal fishery to climate change for developing a resilient livelihood for coastal communities in Ghana

O. Pabi (1)

(1) University of Ghana, Institute for Environment and Sanitation Studies, Accra, France

By nature, artisanal fishery operates on minimal investments and basic technology, and is therefore considered less adaptable and highly vulnerable. The paper argues that, though productive, it depends largely on natural marine productivity, which is closely linked to climatic elements. Studies conducted in the West African sub-region have not adequately demonstrated clearly the links between artisanal fishery and climate, due to the use of annual rather than intra-annual data and analyses. This impedes information generation suitable for informing fishery operational decisions, adaptive policy development and climate-resilient livelihood options. This study analyzed records of rainfall, atmospheric temperature, sea surface temperature (SST) and fish catch of three species with different sensitivities to temperature, on different time scales using time series techniques. Upwelling was derived from SST using the Bakun Model. It examines the interactions between the variables at different time scales to determine exposures and sensitivities. It also sought verifications from fisher perspectives, based on experiences and knowledge in respect of climate change dynamics and real impacts on fishery. The results depicted clear association in trends of sea surface and atmospheric temperatures; seasonality of rainfall and upwelling; fish catch and SST intensities, with round sardinella and anchovy showing clear sensitivities to temperature changes. Whereas the upwelling season period is typically three (3) months, in some cases it contributes some 60% of the total annual catch. Based on the evidence of high exposure and sensitivity of artisanal fishery to climate change, and overdependence of fishers on the artisanal fishery, the study proposes options of adaptive strategies for a climate change-resilient coastal fisher community livelihood.

P-3325-06

How can knowledge about health consequences promote acceptance of climate action?

R. Sauerborn (1) ; A. Flahault (2) ; D. Ganten, (3)
(1) Heidelberg University, Institute of public health, Heidelberg, Germany; (2) Université Paris 8 Descartes, Paris, France; (3) Charité University Hospital, Centre de santé publique virchow villermé, Berlin, Germany

Health is currently not prominent in climate policy. It is regarded as one of many climate sensitive sectors. However, arguments deriving from health and physiology, if properly communicated to climate decision makers, could play a strong role as a driving force to motivate them (and citizens) to accept new policies and new behaviors for the transformation towards a low carbon society. This is based on three sets of arguments, which have recently been corroborated by new evidence (since IPCC AR5), which we present, and which highlight further the need to communicate the strong influence health arguments should have at the COP21 negotiations. These sets of arguments are as follows:

(i) There are huge health benefits from climate friendly policies and behaviors. Although the concept is not new, but new evidence points to the large scope of known health benefits accruing from physical activity from walking and biking, insulated housing, low meat diets. Two recently identified co-benefits generate considerable additional health gains:

1. Large health gains from reducing local pollutants, particularly in low and middle income countries. Fine particles and black carbon have recently been recognized as "climate active pollutants". Black carbon are of particular interest for climate policy, as reducing its emissions leads to a fast reduction of stocks in the atmosphere.

2. Recent population projections till 2100 significantly exceed previous UN estimates. Gerland et al. publishing their modeling results in Science 2014[1] project a 2100 population size of between 9.3 to 12.6 billions. This urgently call for even greater efforts for voluntary family planning, hence reaping even larger the linked health benefits accruing to mothers and their fewer children.

(ii) There are clear limits to society's capacity to adapt to the projected health impact of climate change. This holds to some extent in a 2°C world, but definitely in a 4°C warmer world. This holds even given maximal resource allocation to the task (e.g. 2).

(iii) Heat stress lead to reduced in work productivity in a warmer world, particularly in a 4° climate (e.g. 3). This concerns mainly the large populations in (sub-) tropical and arid areas and applies both to outdoor work, such as farming and construction and to indoor industrial production in non-air conditioned factories. Hence the physiological impossibility to work and generate further body heat is a health argument of significant bearing on economic output.

The above evidence-based health arguments provide a unique combination of positive news -reaping health gains from climate policy- and the reference to the ultimate driving force behind any climate policy and citizens behavior change: protecting our children's health form the adverse health impacts of climate change.

3326 - The Mediterranean Basin in a warmer and drier world : challenges and opportunities

ORAL PRESENTATIONS

K-3326-01

Increased frequency of major heatwaves and droughts in the Mediterranean

R. Trigo (1)
(1) Instituto Dom Luiz - Universidade de Lisboa, Lisbon, Portugal

The last IPCC Assessment Reports (IPCC, 2007, 2013) identify the Mediterranean region as a climate change and biodiversity "hot spot" with an increasing likelihood of suffering in the future drought episodes and severe heat waves. In fact, most studies using global and regional climate model results suggest that the Mediterranean will experience a general trend towards drier conditions during the 21st century. Thus, the overall tendency towards a drier Mediterranean climate is not independent of the simultaneous increase of the heawaves frequency and magnitude in southern and central Europe. In fact, despite some contradictory results with state-of-the-art models, these combined tendencies towards a drier and more extreme Mediterranean climate fits particularly well into the expected changes predicted by most models for this climate change «hot spot» region (IPCC, 2007, 2013).

Summer heat waves are controlled by intense anticyclonic circulation, often associated with upper tropospheric blocking high. Heat waves have been shown to be responsible for excessive mortality, such as the 2003 heat wave in Western Europe that was associated with an excessive +50,000 fatalities (García-Herrera et al., 2010). Equally, heatwave events can be the main drivers of large wildfires occurrence, such as those that occurred in Portugal in 2003 with more than 430,000 ha burnt area (Trigo et al., 2006). Interestingly, this major heatweave was preceded by very dry conditions (winter and spring) in most of Western Europe, a factor that has been shown to play a crucial role in amplifying the heatwave magnitude (García-Herrera et al., 2010).

The summer of 2010 was exceptionally warm in Eastern Europe and large parts of Russia. In fact the anomalous 2010 warmth that caused adverse impacts exceeded the amplitude and spatial extent of the previous hottest summer of 2003 (Barriopedro et al., 2010). 'Mega-heatwaves' such as the 2003 and 2010 events displayed exceptional seasonal temperatures in a 500-yr long context over approximately 50% of Europe. According to regional multi-model experiments, the probability of a summer experiencing 'mega-heatwaves' will increase by a factor of 5 to 10 within the next 40 years. The results also indicate that the temperature maxima observed during these heatwave episodes were associated with the simultaneous occurrence of outstanding anticyclonic blocking patterns and were preceded by relatively dry soils resulting from the lack of precipitation in winter and spring and an earlier retreat of snow cover.

The western Mediterranean is recurrently affected by drought episodes and therefore by the adverse effects associated that range from severe water shortages to economic losses and related social impacts. During the hydrological years of 2004/2005 and 2011/2012, Iberia was hit by two of the worst drought episodes ever recording in this semi-arid region (Trigo et al., 2013). These two drought episodes were extreme in both its magnitude and spatial extent and appear to fit the tendency towards an increase in the frequency of drought events in the Mediterranean basin (Sousa et al., 2011) partially driven by anthropogenic greenhouse gases emissions (Hoerling et al., 2012; Trigo et al., 2013).

K-3326-02

The Medieval Climate Anomaly and Byzantium. A review of the evidence on economic performance, societal change and climatic fluctuations

E. Xoplaki (1) ; D. Fleitmann (2) ; A. Izdebski (3) ; J. Luterbacher (1) ; E. Zorita (4) ; S. Wagner (4) ; I. Telelis (5)
(1) Justus-Liebig-University Giessen, Geography: Climatology, Climate Dynamics and Climate Change, Giessen, Germany; (2) University of Reading, Department of archaeology: school of human and environmental sciences, Reading, United Kingdom; (3) Jagiellonian University, Institute of history: byzantine history department, Krakow, Poland; (4) Helmholtz-Zentrum Geesthacht, Institute for coastal research, Geesthacht, Germany; (5) Academy of Athens, Research center for greek and latin literature, Athens, Greece

The study of the unusual climate patterns and their impact on ecosystems and societies during medieval times is of considerable interest for scholars of various disciplines such as past, current and future climate researchers, climate impacts scientists, historians, archaeologists, anthropologists, among others. The global, hemispheric and continental climate variability, the associated forcing factors and potential dynamic origin of the Medieval Climate Anomaly (in this work ca. 850 -1300 AD) have been the focus of many studies. Although the wealth of paleoclimate information for the last two millennia available in the Mediterranean basin and to a lesser extent in the Eastern Mediterranean, the character of paleoclimate records in combination with the inhomogeneous proxy records density and distribution during medieval times still restricts scientists from critically assessing the manifestation of the MCA on a regional scale and further to a high temporally and spatially resolved characterization of the climate patterns and associated societal and environmental impacts for specific areas as the Eastern Mediterranean.

During the Medieval Climate Anomaly, Byzantium, a medieval empire encompassing the northern part of the Eastern Mediterranean, had formed an expanding society with a thriving economy and complex political as well as cultural institutions. Byzantium as a medieval society left a considerable body of written evidence, enabling the use of detailed information to investigate potential connections between the societal impact of climate change in the period that spans from the moment when the Byzantine state and economy began to recover after the crisis of the so-called Dark Age, and until the period that followed the fall of Constantinople in AD 1204.

This study aims at assessing the manifestation of the MCA in the Eastern Mediterranean, and linking the existing knowledge about the character and extent of the climatic variability during medieval times in the Eastern Mediterranean, both historical (textual), palaeoenvironmental, and model-based, with what is known about the socio-economic processes taking place in the Byzantine Empire at that time.

Rising concerns about ocean acidification and warming in the Mediterranean Sea

P. Ziveri (1)
(1) Institute of Environmental Science and Technology (ICTA), Universitat Autònoma de Barcelona, Bellaterra (Barcelona), Spain

The Mediterranean Sea is facing large biogeochemical changes driven by both climatic and non-climatic drivers. Unprecedented emission rates of CO2 into the atmosphere are responsible for two important drivers such as ocean acidification and warming that are rapidly altering the physico-chemical seawater properties with consequences for the marine ecosystems and ecosystem services.

There are rising concerns since this is one of the regions warming fastest under climate change and acidifying with a similar rate as subtropical regions. This marginal sea have a relatively short residence times and deep waters are likely to lag changes in surface waters by a few decades at most.

I will review here the state of knowledge on the combined effects of ocean acidification and ocean warming in the Mediterranean. Recent results demonstrated that some key organisms that are endemic to the Mediterranean, major contributors to habitat building, and/or ecological function, or species of economic value in the region, are largely affected by the rapid change in pH and/or increase in seawater temperature. The regional vulnerabilities alter the capacity of coastal and marine systems to provide ecosystem services and consequently affect economic activities.

O-3326-01

Climate Change Distress and Subjective Well Being in Urban coastal cities of India and French Mediterranean region

R. Mudaliar (1) ; AS. Lindenmannm (1)
(1) Aix-Marseille Université-CNRS, UMR ESPACE 7300, Aix-en-Provence, France

Human-induced global climate change and associated sea level rise (SLR) can have major adverse consequences for coastal ecosystems and societies (Hinkel & Klein, 2003). The IPCC in its various reports has established a clear link among global warming, climate change, SLR and coastal livelihood security. There is growing concern in France of climate change and sea-level rise. There is enough information to identify coastal areas that may be affected. Lambeck and Bard (2000) examined the evidence for relative sea-level change along the French Mediterranean coast. Considerable evidence has been presented in the past two decades for the sea-level change along the French Mediterranean coast. Poumadère et al. (2008) have found that in spite of the stance taken by political figures, general attitudes in France regarding climatic hazards appear to lag behind scientific warnings. The established fact that anthropogenic factors account for one of the major contributors to climate change makes it necessary to probe into behavioral facets as in spite of the best possible efforts around the globe to combat climate change, it is felt that people are still not as seriously aware/ alarmed of the expected future risk as they should be. In view of this, the present study aims at gaining insight into issues of human-climate interaction through a comparative study between coastal cities of India and France. The study is intended at exploring how the coastal population of Indian and French metropolitan cities perceive climate change, how much aware and concerned they are, what guides their opinions, judgments, behaviours, and actions , how efficient they find themselves in adapting with the situation, what adaptive measures would be feasible for them, how competent do they find themselves in terms of coping strategies in relation to the current phenomenon of changing climate. The study enables comparison of data collected from 400 respondents of coastal population of metropolitan areas of Marseille (1,7 million inhabitants), Nice (a little less than 1 million inhabitants) with the researcher's existing data for Indian metropolitan coastal cities of Mumbai and Chennai (400 respondents), both highly vulnerable to climate change related accelerated sea level rise. A specially designed questionnaire called Climate Change Perception Inventory (CCPI) by Rishi et al. (2009) would be used to collect data from French population. The tool is based on Likert type format comprising of 48 items (in its original version) pertaining to perceptual and attitudinal components of climate change.A correlational research study design would be used to study the relation between different study variables which would be subject to regression analysis for making predictions in regard to climate change.

This study will provide an understanding of mindset of people in urban settlements on climate change. Not only this, it will also help to find out about the level of climate change distress of people with regard to climate change and also what are their actions and reactions in the changing climate scenario. Through Assessment of perceptions and attitudes of people in regard to Cognitive, Conative and Affective dimensions of Human-Climate Interface, one would better be able to determine the level of sharing responsibility regarding changing climate. By studying the pattern of behavioral adaptation to climate change, it would be possible to identify and compare what coping strategies people in coastal cities of India and France are using/ are required to deal with the phenomenon of climate change. The present study is directly in line with Article 6 of New Delhi Work Programme of UNFCCC (2007) in which special effort to foster psychological/behavioral change has been

stressed through public awareness. Hence, it fulfills a very strong requirement to conduct behavioral study in the area of climate change.

Current and future Mediterranean Sea ecosystem functioning in relation with global change: The MERMEX/MISTRALS project

R. Sempéré (1) ; X. Durrieu De Madron (2) ; C. Guieu (3) ; I. Pairaud (4)

(1) CNRS, Mediterranean Institute of Oceanography (MIO), Marseille, France; (2) CEFREM, Cnrs-université de perpignan, Perpignan, France; (3) CNRS-UPMC, Villefranche sur mer, France; (4) IFREMER, Lerpac, La Seyne/mer, France

The semi-enclosed nature of the Mediterranean Sea, together with its smaller inertia due to the relative short residence time of its water masses, make it highly reactive to external forcing, in particular variations of water, energy and matter fluxes at the interfaces. This region, which has been identified as a ''hotspot'' for climate change, is therefore expected to experience environmental impacts that are considerably greater than those in many other places around the world. These natural pressures interact with the increasing demographic and economic developments occurring heterogeneously in the coastal zone, making the Mediterranean even more sensitive. The current knowledge on and expected changes due to single forcing (hydrodynamics, solar radiation, temperature and acidification, chemical contaminants) and combined forcing (nutrient sources and stoichiometry, extreme events) affecting the biogeochemical fluxes and ecosystem functioning are explored within the project MERMEX in the framework of MISTRALS program. MERMEX project based on MERMEX group white book (*) is dedicated to the response of Mediterranean ecosystems and biodiversity to climate changes and anthropogenic pressure. MERMEX aims to deepen the current understanding of the Mediterranean marine ecosystems to better anticipate their upcoming evolution. It is focusing on the response of ecosystems to modifications of physico-chemical forcing at various scales, both in time and space, linked to changing environmental conditions and increasing human pressure. Four years MERMEX results clearly showed that several processes including winter dense surface water convection, surface water stratification, river water discharge and episodic desert dust inputs play a major role on marine productivity as well as on organism community structure. Slight modifications of such processes that will be very likely affected by global change in 21th century can induce significant changes in Mediterranean Sea ecosystems.

Climate Change Impact on Mediterranean Forest Functioning

V. Baldy (1) ; C. Fernandez (1) ; IM. Reiter (2) ; E. Ormeno (3) ; JP. Orts (3) ; M. Santonja (1) ; AC. Génard (1) ; A. Bousquet-Mélou (1) ; C. Boissard (4) ; G. Castagnoli (5) ; A. Rotereau (2) ; T. Gauquelin (1)

(1) Aix-Marseille University, IMBE, Marseille, France; (2) CNRS, Eccorev, Aix-en-provence, France; (3) CNRS, Imbe, Marseille, France; (4) Universite Paris Diderot, Lsce, Paris, France; (5) CNRS, Ohp-osu pytheas, Saint Michel l'Observatoire , France

The combination of significant past and current anthropogenic pressure and high level of biodiversity makes the Mediterranean one of the world's most threatened regions by current change, warranting its classification as a biome "in crisis". Mediterranean forests play major ecological, social and economic roles by providing goods and services and thereby represent a great asset and opportunity for the future of the Mediterranean. The functioning of Mediterranean forests is contingent on the existence of the dry summer period. Intensified and prolonged drought periods related to climate change are then of special concern in these ecosystems. Currently, our understanding of the response, in terms of biodiversity and functioning of Mediterranean forests to extreme drought conditions is limited. A wide variety of methodological approaches have been put into practice to examine the mechanisms by which climate change could alter the functioning of terrestrial ecosystems, such as the study of altitudinal climatic gradients, latitudinal transects, and the experimental modification of precipitation or warming. Controlled field experiments are however costly and difficult to operate on a large scale without introducing environmental modifications. Further, the investigations of ecosystem functioning in relation to climate change are very demanding, as they require multi-scale and interdisciplinary research maintained over long time-spans. We set up an experimental facility with a rain exclusion system and a network of various sensors at different levels of the forest situated in a French Mediterranean natural old-growth oak forest, the Oak Observatory at the OHP (O3HP).

This observatory allows investigating functional components of the ecosystem such as phenology, growth, litter decomposition and emission of biogenic volatile organic compounds by trees. Moreover, functional changes in biodiversity-related traits in the context of a drier climate are monitored, particularly the role of soil biodiversity in the biogeochemical cycle.

The first results show a significant effect of the experimental increase of the summer-drought period. For example, prolonged drought slows down litter decomposition and consequently nutrient availability, and initially increased to eventually decrease the emission rates of volatile organic compounds by trees in the course of the drought period. These results point-out the importance of addressing climate change on future management practices for the sustainable development of Mediterranean forest ecosystems.

Lessons from the Past: Modeling past human adaptation to climatic change in the Mediterranean Basin

A. Kirman (1) ; A. Bondeau (2) ; D. Contreras, (3) ; J. Guiot (4) ; N. Hanaki (1) ; S. Thoron (5)

(1) Aix Marseille University, GREQAM, Aix en Provence, France; (2) Institut Méditerranéen de Biodiversité et d'Ecologie Marine et Continentale, Aix-en-Provence, France; (3) Aix Marseille University, Ot-med, Aix en Provence, France; (4) CNRS, CEREGE, Aix-en-Provence, France; (5) Universite Paris Est Creteil, Liphar, Paris, France

The Mediterranean Basin has a well-documented history of climatic fluctuations throughout the span of its human occupation. Detailing past climatic changes and predicting those in the future is thought of as the task for sophisticated climate modeling, while investigating the human consequences of climate change remains a challenge for the social sciences. The AMENOPHYS Project combines the two and explores the limits of cultural adaptability to climatic shifts in the Mediterranean through a modeling approach, combining paleoclimatic data, GIS-based landscape evolution modeling, agroecosystem modeling, and agent-based modeling to ask how past climate change in the Mediterranean directly affected the lives of the region's inhabitants, and which factors were most salient in rendering climatic changes more or less survivable.

There is an abundance of literature – archaeological, historical, paleoclimatic, and paleoenvironmental – born out of the reasonable premise that past climatic shifts were of magnitudes that must have had cultural consequences. Such work, however, has struggled to move beyond correlation; we aim to articulate these links between paleoenvironmental and cultural change and to thereby tackle what has been a persistent challenge. This will improve our understanding of cultural trajectories, of human ecological footprints, and provide a strategy for untangling human and environmental histories in the long term. It will make past human experience directly relevant to current global realities and challenges.

Our models aim to provide explicit, well-formulated mechanisms linking humans and environments, thereby enabling the articulation of testable hypotheses that can be compared to empirical evidence. Questions of scale and resolution are fundamental. Environmental parameters are generally the purview of environmental modeling and paleoclimate studies – where spatial scales are regional and temporal scales are centennial, if not millennial. In

contrast, social scientific explanation relies fundamentally on anthropological models of behavior – i.e., human decision-making at local and annual or decadal scales.

Agent based modeling can contribute significantly to reducing this important interpretative gap. We model the human consequences of climatic change, with a view to exploring their variability across different geographies, production regimes (i.e., subsistence practice and technology, and available resources), demographic, sociopolitical and economic contexts, and environmental inheritances. This will provide a means of articulating linking mechanisms where they cannot be directly observed.

Using landscape evolution and agroecosystem models in a feedback system with agent-based models of small Mediterranean communities, and starting from a specific example of Provençal geography,this project explores the effects of climatic shifts, legacies of human activity, available subsistence options and technologies, and community size and organization on vulnerability and resilience.

Modelling blooms of comb jellyfish -Mnemiopsis leidyi -population under Mediterranean climate change

E. Alekseenko (1) ; M. Baklouti (1) ; F. Carlotti (1)
(1) Mediterranean Institute of Oceanography, Marseille, France

The massive outburst of gelatinous plankton has important socio-economic impacts particularly affecting tourism, fishing, fish farming, and also impact on the structure of the pelagic ecosystem. Some species are opportunistic invaders that can cause permanent damage to the native fauna. This is particularly the case of comb jellyfish Mnemiopsis leidyi, a kind of gelatinous plankton that can form dense patches and, as a predator of fish larvae and other zooplankton, can have disastrous consequences on fish stocks and other aquatic resources. The potential for outbreaks of this species is based on its growth capacity and high tolerance to environmental conditions particularly considering salinity and temperature, allowing M. leidyi establishment in highly contrasting ecosystems (CIESM, 2014). High numbers of M. leidyi along the Mediterranean coastlines of Israel, Italy, and Spain and other Mediterranean countries (CIESM, 2014) were recorded during the last years. This fact strongly suggests that M. leidyi population is established in the Mediterranean coasts. However the specific causes and mechanisms of M. leidyi development are not well identified, and the lack of data makes any further investigation difficult (Boero, 2013).

Modelling can provide an additional understanding of mechanisms through the definition of the environmental characteristics that could support and/or favor M. leidyi and the description of the associated changes in the planktonic community structure. The aim of the present study is to understand the potential direct (temperature, salinity, nutrient enrichment) and indirect (through food chain changes) impacts of climate changes on M. leidyi blooms in the Gulf of Lions (NW Mediterranean Sea) using the biogeochemical model Eco3M-MED (Baklouti et al., 2006a,b, Alekseenko et al., 2014) coupled with the hydrodynamical model MARS3D (Lazure&Dumas, 2008). A M. leidyi compartment has been introduced in the Eco3M-MED model, in such a way that some of the physiological and demographic traits of this species are represented. A study on M. leidyi physiology and eating behavior has first been conducted with the biogeochemical model. Then, different scenarios have been simulated in order to analyze the role of several environmental parameters, namely, temperature, salinity and nutrient inputs of the Rhone River, on the seasonal variability of M. leidyi and the structure of the trophic web. The study is focused on the period 2009-2011 since the outputs of the model during this period have already been partially validated (Alekseenko et al., 2014).

Surface runoff evaluation watershed Tunisian-Algerian border modeling with software WEAP

M. Ben Abdelmalek (1) ; I. Nouiri, (1)
(1) l'Institut National Agronomique de Tunisie, génie rural eaux et forets, city El mahrajéne,El manzah 1 , Tunis , Tunisia

Tunisia is considered among the countries least endowed with water resources in the Mediterranean basin. The most significant changes in rainfall and making the periods of drought longer are the factors aggravating the imbalance between supply and demand water.

The main objective of this work is the hydrological study of the major trans-boundary watersheds Tunisian-Algerian. It is referred trans-boundary runoff modeling and assessment of surface water inflows to Tunisia of Algerian border regions.

The methodology used was based on the creation of a daily database (1 September 2009 – 31 August 2013) of rainfall in 43 stations, statistical analysis and spatial measurements. It also used for modeling the physical system of trans-boundary basins the software WEAP. The assessment of daily surface resources, demands and runoff were used to develop a daily dynamic management model.

The modeling results showed that Algeria's surface flows to Tunisia are mainly presented through the Oued Medjerda, Mellegue and El Kbir. The average annual intake is around 8204 million m3 which 22.41% are insured by the river of Medjerda , 63.51% from Mellegue and 14.08% from El Kbir one. The largest flows are carried by the Mellegue river which is valued at 2505 m3/s. The Medjerda and El Kbir river have recorded peak flows 806 and 732 m3/s, respectively, during the period of the study.

The simulation of climate scenarios and investment, showed that the change in the water flow follows the variation of rainfall. It is shown by simulation that if rainfall increases by 200% (very humid scenario), runoff can increase up to 265%. On the contrary, if rainfall decreases from 80% (very dry scenario), surface runoff would be reduced by about 85%.The first version of transboundary river basin management model developed Tunisian-Algerian proved useful for modeling of surface water resources for large hydrological catchments.

P-3326-03

Statistical and experimental approaches for demonstrating the effect of climate changes on the flowering dates as a road map for tree adaptations in the Mediterranean region

A. El Yaacoubi (1) ; A. Oukabli (2) ; M. Hafidi (1) ; JM. Legave (3)

(1) Moulay Ismail university, Meknes, Morocco; (2) INRA, Meknes, Morocco; (3) INRA, Montpellier, France

In this study two approaches were used to highlight the effect of climate on the tree behavior. The statistical approach was carried out in three geographically contrasting countries of the Mediterranean region. It aims to understand the impact of climate change, particularly the temperature increases, on phonological stage of three taxonomically different species (early and late-spring-flowering species). Three species, namely olive, apple and almond were investigated to highlight the phenological behavior of one species at different locations (mild and cold regions) and different species at one location. Climate and phenological data were collected from Morocco, France and Italy over the last 40 years. The experimental approach was done in mild (Morocco) and temperate (France) areas in the Mediterranean in order to interpret the effect of the climate changes on the dormancy process of trees. In this goal, three cultivars of apple and almond were investigated. In each location, two experimental approaches were used during two successive seasons: one-single cutting test to assess the dormancy in vegetative buds and Tabuenca test for floral buds. The target of combining these approaches is to interpret the wholly tree dormancy behavior in vegetative and floral buds of one species in different regions and different species in the same site. Analysis of data on temperature showed a strong warming in the northern locations (coldest areas), particularly in Nîmes, compared to the southern ones (warmer locations) during the period October to May. The marked spring warming in all locations since the end of 1980s in France (the beginning of 1990s in Italy and Morocco) resulted in blooming earliness, with regional patterns in terms of impact. The late-spring-flowering species (olive and apple) showed a remarkable sensitivity to continuous warming in different areas. No flowering earliness was observed in early-spring-flowering species (almond), due to the stability of mean temperature during February. Thus, a strong control of mean temperature during the forcing period on flowering earliness of apple was found in all areas. Physiological processes (dormancy and dormancy release) of trees during the dormant and growth period explain, in part, the regional differences observed in flowering dates among sites and species. In terms of tree dormancy dynamics, deeper apple dormancy was evinced in the temperate area compared to the mild one, showing a strong correlation with winter temperature. In Morocco, the almond and low-chill apple cultivars seemed to behave similarly, showing low Mean Time of Budburst and permanently high Rate of Budburst. The dates of breaking dormancy approached by fresh and dry masses of floral buds showed the same time of dormancy release on almond cultivars in Morocco. However in apple, the significant increase of masses was earlier in fresh bud mass, while it was later in dry bud masses in both sites. The transition from the endodormant to the ecodormant phase of apple flower buds was distinct in both locations. Mechanisms of solutes importation and utilization by floral buds were different in almond and apple. Overall, the pronounced warming in the southern France reflects a relative trend toward aridity of climate at this site, and consequently some vulnerability of fruit trees. As result, the process of dormancy and flowering in a high latitude locations (northern areas) in the future can be represented by that in a low latitude locations at present (southern areas), particularly for apple. The agronomic consequences caused by global warming are already expressed in the southern areas (floral abortion, heterogeneity and delayed flowering time ...) where the apple cropping is limited only in the upland location (high altitude). In France, ominously, production irregularities related to climate change were frequent during the 2000s. This requires immediate intervention to find some ways of adaptation or improvement as part of a regional strategy to fight against this scourge in context of food security. Creation of new varieties with low chill requirement is a way of improvement and plant breeding while the change of vulnerable crop by others (such as almond well adapted in mild climate areas) is a way of adaptation.

P-3326-04

Modelling how climate change will impact growth and productivity of evergreen Mediterranean forests using a process-based model and multiproxy data

G. Gea Izquierdo (1) ; F. Guibal, (2) ; R. Joffre, (3) ; JM. Ourcival, (3) ; G. Simioni, (4) ; J. Guiot (5)

(1) CEREGE-CNRS, Aix-en_Provence, France; (2) IMBE, Aix-en-Provnce, France; (3) CEFE, Montpellier, France; (4) INRA, Avignon, France; (5) CNRS, CEREGE, Aix-en-Provence, France

Different physiological processes determine gross primary productivity (GPP) and carbon allocation in relation to environmental forcing. Climatic variability limits these two processes differently and this needs to be properly addressed in process-based forest models. Generally, empirical models have been preferentially used in dendrochronological studies. However, it is necessary to better address the interaction between climate and other factors such as CO2 to properly assess the instability in the climate-growth response expressed by trees and increase the accuracy of the modelled relationships both in forward and inverse models. In this study we developed an existing mechanistic model originally implemented with dendrochronological data. The model was calibrated to fit a combination of eddy covariance CO2 flux data, dendrochronological time series of secondary growth and forest inventory data at two Mediterranean evergreen forests. Among other differences with the original formulation, the model was modified to be climate explicit in the key processes addressing acclimation of photosynthesis and allocation. It succeeded to fit both the high- and the low-frequency response of stand GPP and carbon allocation to the stem as calculated from tree-rings. Simulations suggest a decrease in mean stomatal conductance in response to environmental changes and an increase in mean annual intrinsic water use efficiency in both species during the last 50 years. However, this was not translated on a parallel increase in simulated ecosystem water use efficiency. A long-term decrease in annual GPP matched the local trend in precipitation since the 1970s observed in one site. In contrast, GPP did not show a negative trend and the trees buffered the climatic variability observed at the site where long-term precipitation remained stable. Long-term trends in GPP did not match those in growth, in agreement with the C-sink hypothesis. There is a great potential to use the model with abundant dendrochronological data to analyse future forest performance under climate change and in dendroclimatic reconstructions. This would help to understand how different interfering factors produce divergence in the climatic signal expressed in tree-rings.

P-3326-05

Climate variability, ecosystem response and socio-environmental changes in the northern Aegean (Greece) during the last 1500 years

A. Gogou (1) ; M. Triantaphyllou (2) ; E. Xoplaki (3) ; J. Luterbacher (3) ; C. Parinos (1) ; M. Dimiza (2) ; I. Bouloubassi (4) ; G. Rousakis (1) ; K. Kouli (2) ; D. Fleitmann (5) ; B. Martrat (6) ; A. Izdebski (7) ; H. Kaberi (1) ; M. Athanasiou (2) ; V. Lykousis (1)

(1) Hellenic Centre for Marine Research, Institute of Oceanography, Anavyssos, Greece; (2) University of Athens, Faculty of geology and geoenvironment, Athens, Greece; (3) Justus-Liebig-University Giessen, Geography: Climatology, Climate Dynamics and Climate Change, Giessen, Germany; (4) LOCEAN, Université pierre et marie curie,, Paris, France; (5) University of Reading, Department of archaeology: school of human and environmental sciences, Reading, United Kingdom; (6) IDAEA-CSIC, Barcelona, Spain; (7) Jagiellonian University, Institute of history: byzantine history department, Krakow, Poland

The first high resolution paleoceanographic study of the last 1.5 Ka BP at the northeastern Mediterranean, using organic geochemical, micropaleontological and palynological proxy indices, allowed the recognition of recent climatic changes and ecosystem response during the Dark Ages (DA; 500-900 AD), Medieval Climate Anomaly (MCA; 900-1250 AD), Little Ice Age (LIA; 1250-1850 AD) and Instrumental Period (IP; 1850-2010 AD). Multicore M2, retrieved in 2011 from the north Aegean Sea

(40°05.15'N, 24°32.68'E, 1018m depth), was sectioned at 0.5 cm intervals, and analyzed for lipid biomarkers (Gogou et al., 2007), coccolithophores (Triantaphyllou et al., 2009), and pollen assemblages (Triantaphyllou et al., 2009; Kouli et al., 2012). Stratigraphic framework was based on 210Pb and radiocarbon dating. Past SSTs (mean annual) were reconstructed using the alkenone unsaturation index Uk'37 ((U= C37:2/(C37:2 + C37:3) and the global calibration by Conte et al. (2006). For the estimation of the net primary production (NPP), the equation of Incarbona et al. (2008), NPP = 885.864 + (−138.963 x ln (F. profunda %)), has been used. In addition, the use of the ratio between F. profunda (F) and E. huxleyi (E) abundances: S = F/F+E, is applied as stratification S-index (Triantaphyllou et al., 2009; Triantaphyllou, 2014). The ratio H=AP/St (AP: Arboreal taxa excluding Pinus; St: Artemisia, Chenopodiaceae, Asteraceae and Poaceae), has been used as a humidity index (H-index; Kouli et al., 2012).

The SST-record reveals significant variability with marked cool/warm intervals. SSTs increase from 650-1375 AD and then decrease till the late 1600s, except for a warm episode in early 1600s (LIA) with values as high as ~20°C. After a sharp decrease ending at ~1700 AD, SSTs rise at approximately 0.6°C/100 yrs till the present day. Towards the end of DA period, a drop in SST and decrement of terrestrial inputs suggest a tendency towards more arid conditions. The onset of MCA is characterized by an increase in SSTs and elevated terrestrial inputs along with high values for S index between ~1000-1200 AD, characteristic of humid climate conditions, that positively impact the photic zone productivity, due to enhanced nutrients supply from riverine inputs and continental runoffs. The onset of the LIA is marked by an increase in water column stratification between ~1350-1650 AD, and a transition from arid conditions between ~1250-1400 AD to humid conditions after ~1400 AD. Finally, the IP is characterized by a significant rise in SSTs along with enhanced terrestrial inputs and algal productivity in the euphotic zone.

Atmospheric modes of variability play an important role on surface water heat fluxes that in turn have consequences on the Mediterranean thermohaline circulation, in particular during winter when cold winds cause important heat loss and stratification breakdown. Because of the tight coupling with the atmospheric forcing, the sampling area has proven ideally situated to investigate the coupling of paleooceanographic conditions with major atmospheric circulation patterns. Finally, a historical approach has been applied, in order to explore the complex interactions between climate, environment and human activity in the north Aegean region.

P-3326-06

New forms of governance and collective action for agricultural irrigation canal management in southern France: what opportunities in the context of climate change?

M. Jacqué (1) ; C. Aspe (1)
(1) Aix Marseille Université, Lped, labexmed, Marseille, France

One of the socio-cultural specificities found on both the north and south shores of the Mediterranean is the ingenuity of local societies for managing water shortages and/or the unequal distribution of water in different areas. In European Mediterranean countries two main types of techniques have developed over the past centuries: either rainwater harvesting via terrace systems or gravity-fed canals supplied by springs and watercourses more broadly. The infrastructure designed and created by Arab societies-which is still used today, particularly in oases-is based for the most part on subsurface irrigation systems for recovering infiltration water; these systems are called quanat, foggara or khettara, depending on the country. Approaches to management in the North and South have created knowledge and know-how and forged what could be called a "culture of water" that can be useful in times of crisis, like that posed by the threat of climate change.

Farmers in the south of France-and in Provence more specifically-have created organisations (ASAs) since the late 19th century that manage issues related to the supply of water and its division; these have also allowed local agriculture to become extremely competitive on international markets, particularly for fruits and vegetables. At the scale of France's PACA region, there are over 600 ASAs that manage canals and their irrigated perimeter still extends over a very large part of the region's territory. These organisations are experienced in water resource management and their know-how has allowed them to adapt and evolve with changes in Mediterranean irrigation systems (e.g., gravity-fed, overhead and drip irrigation).

This presentation will analyse how maintaining canal-based hydraulic infrastructure is of central importance for perpetuating sustainable farming at the regional scale. For this to occur, ASAs must now accept that the canals they manage also have other uses; their management needs to take into account the multi-functionality of the canals and embrace new challenges which are both environmental and social (replenishing the water table, flood management, promoting the heritage value of the canals, etc.). We will take an historical approach to show how agricultural actors created types of organisations that were both unique and solidarity-based which allowed them to manage droughts and flooding (particularly in the Durance basin). Other forms of multi-actor governance are emerging today: e.g., canal contracts, the signing of bi- or multi-lateral partnership agreements and "Agora" assemblies for the operational governance of water. Such projects are proof of the dynamic thrust of the agricultural profession, but they also raise questions about the funding of such initiatives and therefore their long-term viability.

Climate change impacts on water and local adaptation strategies in the Mediterranean: security versus sustainability

I. La Jeunesse (1) ; R. Ludwig (2) ; P. Quevauviller (3) ; C. Cirelli (4)
(1) University François Rabelais of Tours, CNRS 7324 Citeres, Geography, Tours, France; (2) Ludwig-Maximilians-University Munich (LMU), Institute of geography, Munich, Germany; (3) Vrije Universiteit Brussel (VUB), Hydrology and hydrological engineering, Brussels, Belgium; (4) University François Rabelais of Tours, CNRS 7324 Citeres, Cost, Tours, France

Introduction
Climate change is predicted to lead to raising temperatures in the Mediterranean region and reduced rainfall, with possible worsening of water resource shortages that Mediterranean basin is already experiencing. Climate change is thus probably likely to generate tense situations among users. A conservative approach is to believe that changes correspond to situations that have already occurred in the past and that, with a successful management of these conflicts through appropriate integrated water management with local actors, there would be no new challenge in facing these situations. However, in the present state of knowledge on the impact of climate changes, it is now recognized that the chains of causes and effects will lead to different situations. Thus, tools and procedures previously developed, might become obsolete if they are not updated continuously with advances in knowledge about criteria explaining the chain of causes and effects between climate changes, water availability and water uses.

In this context, models undeniably represent an educational support for the dissemination of scientific results in the science-policy interface to develop. But this support needs to rely on the validity of databases, on the moderation of dissemination by experts as close as possible to local stakeholders and last but not least, for Europe, on the common implementation strategy of the water framework directive in coherence with the European and national adaptation strategies and plans.

Methods and Materials
The EU FP7 research program CLIMB, embedded in a cluster of three EU projects (the CLIWASEC cluster) about climate change-water-security, aimed to decrease uncertainties of hydrological modelling in the context of climate changes in the Mediterranean region. For this purpose, CLIMB defined an ensemble of 4 GCM-RCM-combinations to generate climate data to be used by a set of hydrological models implemented at catchment scale for 7 case studies. Two periods have been considered: 1971-1990 as the reference period, and 2041-2070 as the future period. To support the local dissemination of

scientific results of CLIMB, interactions with stakeholders have been engaged in the context of a study of water uses and water rivalries.

Results and Discussion
Impacts of climate change on temperatures, precipitations and flows have been described. They essentially affect the availability of water. According to interviewed stakeholders, it is notable that, for the Mediterranean region represented by CLIMB case studies, the main pressure on water resource during the last 20 years has been linked to the population growth and urbanization. The results have also underlined that the terms « climate change » have not been cited by stakeholders during both interviews and open questions in the questionnaires related to threat on water resource. In other words, and considering that climate change is not considered as an issue for the stakeholders, the evolution of rainfalls quantity over the next 20 years is overlooked by them. This confirms the need to continue efforts on disseminating facts and figures about climate change to local water managers.

Conclusion
In the Mediterranean region represented by 7 case studies within the CLIMB project, the main answer to the increase of water demand, without considering climate change as a driving force, has been a progressive transfer of water. It seems that there is no spatial limit to this transfer with respect to national borders.

It has also been spotlighted that all analyzed water management plans mention desalination as an option, both for European case studies and non-European ones. It seems that this represents the next step of water supplying in the Mediterranean region. While these adaptation provide water security, it is not coherent with climate change mitigation or adaptation strategies.

P-3326-08

Adaptive action pathways in rural and urban systems facing the challenges of Mediterranean changing climates: Comparative views of efforts and propositions for Europe and South America

E. Martinez (1) ; L. Bascuñán (2) ; K. Ruiz-Carrasco (3) ; A. Berríos (4)
(1) UCN-CEAZA, Ciencias del Mar, Coquimbo, Chile; (2) CEAZA, Plant physiology, La Serena, Chile; (3) Fac. De Ciencias Agronómicas, Producción agrícola, laboratorio de bioinformática y genòmica funcional, universidad de chile, Santiago, Chile; (4) Laboratoire d'Apprentissage, Didactique, Evaluation et Formation, Sciences de l'education, espe, université d'aix-marseille, Aix-en-Provence, France

Four millions is the car fleet recently recorded in Chile, a South American country inhabited by only 17 million people. This ratio of 23 cars for every 100 persons is causing great circulation problems in Santiago, where one third of the population live but also in smaller towns. Big cities or European agglomerations suffer from similar problems. Concomitantly, our evaluations of social representation among car drivers about individual contribution to Green House Gases (GHG) indicate deep lack of basic knowledge on quantities emitted and on the ways to do effective compensation. This is probably due to our low human sensitive and visual appreciation of GHG and our lesser common knowledge of the effective modes of possible compensations.

In our study we show that in countries with high economic growth, like Chile during the last four decades, social representation of sustainable development in education systems is more associated to economic development than to social or environmental effects. Besides, critical visions on the development models are still much less present, although climate change towards desertification in countries like Chile is equal than that of south Sahel regions.

Finally we argue that connecting GHG compensation strategies to zero carbon agricultural practices could give impressing benefits to new urban and rural development strategies. More conscientiousness of climatic changes will result from strong government decisions, but our authorities must be well informed. The rural-urban connections could be based on existing taxation laws (like car circulation permits in Chile) and incentives to short-distance agro ecological production-consumption agreements (like AMAPSs in France). However further growth of such initiatives would need still stronger governance positions to limit growth of big cities, and to tax all carbon emitting production/consumption chains towards the promotion of changes of our ongoing agricultural and transportation paradigms. Conversely, the constraints to these changes could be counterbalanced by lower costs associated to improvement of poor public health-related parameters, another facet of modern globalization patterns. This statement is supported by the high nutritional value of some crops, like Andean quinoa, that respond well to agro ecological practices and can be cultivated worldwide under extreme climates. Our propositions could be implemented in all Mediterranean regions of the world, for which European and South American ones are good examples. These regions share strong urbanization, loss of biodiversity and migratory patterns among neighbouring countries so that education to have critical positions on these challenges should also be promoted.

Our hope with our vision is to contribute to:

1. More knowledge to take decisions on actions to reduce and to compensate GHG emissions, particularly those concerning agricultural practices and transport (that added are 25% of world emitted GHG).

2. To make this knowledge understandable to the most wide public

3. To link our propositions to sustainable health-care and food chains

4. To give examples of ongoing practices in the mentioned fields, from two distant Mediterranean regions (France and Chile) that are socially sustainable

5. To give education/formation to all publics a central role for making the changes a real possibility

6. To link urban and rural zones to give them hope of new opportunities for sustainable developpment

7. To make all public, from individuals to highest authorities, more sensible to accept the needed changes

We are the first generation (and the last one) that can make the changes. We cannot lose this opportunity. It is everybody's task and everybody's responsibility. We have all communication facilities for making COP21 a source of world's hope not only for future climate based visions but also for building new human societies, where interconnections can be much more acknowledged.

P-3326-09

Predicted climate change effects in a Mediterranean reservoir under different climate scenarios and management options

J. Prats Rodríguez (1) ; PA. Danis (1)
(1) Pôle Irstea - Onema Plans d'Eau, Aix-en-Provence, France

In the Mediterranean area, water is a scarce resource, especially in the summer season. Good management of the resource is thus essential, not only regarding quantitative aspects, but also regarding ecological and water quality. Climate change in the region is expected to result in an increase in air temperature that will affect water temperatures.

Water temperature is an important variable in freshwater ecosystems. It can affect the biology of freshwater organisms in many ways; it can modify vital cycles, physiology, distribution areas, behaviour, etc. In addition, the vertical distribution of heat in a lake or reservoir determines its hydrodynamic behaviour and by extension water quality. The thermal and hydrodynamic behaviour of a reservoir depends on external driving factors (hydrology, meteorology) and internal characteristics of the water body (depth of the inlets and outlets, morphometry, reservoir management). Process-based hydrodynamic models allow investigating the effect of the alteration of these characteristics and are interesting tools to address the effects of climate change in Mediterranean reservoirs and testing possible adaptation actions. In this work, we used the model EOLE to simulate the hydrodynamic and thermal behaviour of the reservoir of Bimont (Provence region, France). To account for the hydrodynamic model uncertainty, we used two different calibrations: one based

on expert judgement, and the other based on the method of Generalized Likelihood Uncertainty Estimation.

To consider the effect of climate change on the reservoir we simulated the hydrodynamic behaviour of Bimont under the projections obtained during the project CORDEX of three different regional climate models (RCMs) for each of the two emission scenarios RCP4.5 and RCP8.5. The projections used were those issued by the models HIRHAM5 and RACMO22, applied to the output of the GCM ICHEC-EC-EARTH; and by the model RCA4, applied to the output of the GCMs ICHEC-EC-EARTH, CNRM-CERFACS-CNRM-CM5 and MOHC-HadGEM2-ES. We considered two time horizons: medium term (2036-2065) and long term (2066-2095).

We also considered different management options to see which the potentialities of adaptation to climate change are by varying water level, the temporal distribution and quantity of flow through the reservoir, and the outlet depth.

Water temperatures in the reservoir of Bimont are expected to increase during the present century, both in the epilimnion and the hypolimnion. The stratification period will likely become longer. The elevation of the water level results in similar surface water temperatures, and slightly lower hypolimnion temperatures. Some modifications of the reservoir management have potential effects that can be more important than those of climate change.

P-3326-10

Accounting for ecological processes changes niche modeling predictions: adaptation of Mediterranean forests to climate change as a model

E. Rigolot (1) ; S. Oddou-Muratorio (1) ; F. Courbet (1) ; B. Fady (1) ; F. Lefèvre (1) ; N. Martin (1)
(1) INRA, Research Group: Ecology of Mediterranean Forest (URFM – UR 0629)), Avignon cedex 9, France

Bioclimatic niche models predict drastic changes in the geographical distribution of forest species habitats by the end of the 21st century. However, and despite recent advances, they are limited in their ability to account for ecological and demographic processes involved in forest dynamics. In this talk, based on recent interdisciplinary research results in Mediterranean Pinus halepensis – Quercus ilex and Abies alba – Fagus sylvatica mixed forests, we will show how taking into consideration these processes changes local forest structure and composition as compared to non process-based models. The key processes to be integrated are: migration (dispersal and recruitment), genetic adaptation and phenotypic plasticity. Migration, because it is constrained, limits the ability of species to track their optimal habitat. Phenotypic plasticity and genetic adaptation, on the other hand, facilitate local persistence when habitats become sub-optimal. However, in the Mediterranean, disturbances such as forest fire and insect outbreaks are expected to rise to more frequent and severe levels. These new disturbance regimes may result in demographic, evolutionary and functional tipping points where mortality becomes too massive and reproduction too limited for tree populations to adapt and survive.

P-3326-11

Impact of climate change on marine and coastal biodiversity: the case of Algeria

O. Rouane Hacene (1)
(1) University of Oran 1, Laboratoire Réseau de Surveillance Environnementale (LRSE), Department of Biology, Oran, Algeria

Known for its arid and semi-arid climate, Algeria is highly prone to climate change. The last 50 years, an increase of events due to extreme weather was observed. Among the phenomena recorded in Climate Studies of the National Meteorology that reflect this change, we observe an increase in the frequency of torrential rains, especially in the highlands, which led to flooding for the first time. Other extreme events that have occurred: cyclogenesis, drought, heat wave and sand storms. Scientists have estimated that rainfall will decrease by about 20 percent in the coming years. They predict a shortening of the rainy season and higher temperatures of about 1° to 1.5° in 2020, which would have fatal consequences for 30 percent of animal species. They also feel that temperatures will rise by 3 ° C by 2050 more due to global warming.

The flora and fauna (terrestrial and marine) have been greatly affected by this increase: the changing environmental conditions are favorable and/or unfavorable to certain environmental factors compared to others, which causes a change of environments and species of flora and fauna that constitute them.

Thus, the coastal areas were severely affected by the climate change. Today, it is permissible, in the light of scientific data to associate with threats to marine biodiversity three important parameters and determinants of climate change: (i) the warming waters, (ii) the elevation the sea level, (iii) water acidification. These changes will surely have consequences in medium and long-term on living marine communities in various ways. Especially that the Algeria includes a rich faunistic and floristic diversity.

According to the fourth national report on the implementation of the Convention on national biodiversity of March 2009, the known marine biodiversity amounts to 3183 species of which 3080 were confirmed after 1980. The marine flora is estimated at 713 species grouped in 71 genera and 38 families. If we add the coastal and island vegetation, marine and coastal bird life, the known total biodiversity of the Algerian coastal marine ecosystem is 4150 species, of which 4014 are confirmed for a total of 950 genera and 761 families. But it should be noted that these numbers do not reflect actual biodiversity but rather the known.

Through this contribution we will present aspects of the consequences of global warming on marine ecosystems and particularly on marine and coastal biodiversity and actions taken by Algeria to remedy this situation.

P-3326-12

An epidemiological assessment of stomatal ozone fluxes-based Critical Levels for Southern European forests

P. Sicard (1) ; A. De Marco (2) ; L. Dalstein-Richier (3) ; E. Paoletti (4)
(1) ACRI-HE, Environment, Sophia-Antipolis cedex, France; (2) Italian National Agency for New Technologies, Energy and Sustainable Economic Development, Rome, Italy; (3) GIEFS, Nice, France; (4) Consiglio Nazionale delle Ricerche, Istituto per la protezione sostenibile delle piante, Florence, Italy

The Mediterranean Basin is expected to be more strongly affected by ongoing climate change than most other regions of the earth. The Southeastern France and Northwestern Italy can be considered as case study for assessing global change impacts on forests. Southern forests are at the highest O3 risk in Europe where ground-level O3 is a pressing sanitary problem for ecosystem health. Exposure-based standards for protecting vegetation are not representative of actual field conditions. A biologically-sound stomatal flux-based standard has been proposed, although critical levels for protection still need to be validated. This innovative epidemiological assessment of forest responses to O3 was carried out in 54 plots in Southeastern France and Northwestern Italy in 2012 and 2013. Three O3 indices, namely the accumulated exposure AOT40, and the accumulated stomatal flux with and without an hourly threshold of uptake (POD1 and POD0) were compared. Stomatal O3 fluxes were modelled (DO3SE) and correlated to measured forest-response indicators, i.e. crown defoliation, crown discoloration and visible foliar O3 injury. Soil water content, a key variable affecting the severity of visible foliar O3 injury, was included in DO3SE. Based on flux-effect relationships, we derived species-specific exposure-based (CLec) and flux-based critical levels (CLef) for forest protection, by joining data from all plots and years. As AOT40 was better correlated with defoliation than with discoloration and visible injury, we selected defoliation as effect parameter for defining AOT40-based CLec values. As a tree with defoliation above 25% is commonly rated as damaged, CLec was calculated on the basis of a threshold of 25% average stand defoliation. As POD0 was better correlated with visible foliar O3 injury than with defoliation and discoloration, we selected visible foliar O3 injury as effect parameter and POD0 as O3 metric for defining PODY-based CLef values. Unfortunately, a definition of damaged tree/stand based on visible foliar O3 injury is missing in

the literature. We thus based the selection of a visible foliar O3 injury threshold on a comparison of gas exchange of leaves with a range of visible O3 injury that was carried out in a 3-year-old O3-sensitive poplar plantation. CLef was derived from flux-effect functions for 15% of visible foliar O3 injury (stand level). We obtained CLec of 11.7 ppm.h AOT40 for P. cembra (high O3 sensitivity) and 24 ppm.h for P. halepensis (moderate O3 sensitivity). For broadleaved species, the average CLec was higher than for conifers (23.6 ppm.h AOT40) and similar in the two species with significant correlation between crown defoliation and AOT40, i.e. Fagus sylvatica (moderate O3 sensitivity) and Fraxinus excelsior (high O3 sensitivity). For conifers, CLef of 19 mmol.m-2 for P. cembra and 24 mmol.m-2 for P. halepensis were calculated. For broadleaved species, we obtained a CLef of 21 mmol.m-2 for Fagus sylvatica and of 19 mmol.m-2 for Fraxinus excelsior. To avoid an underestimation of the real O3 uptake, we recommend the use of POD0 calculated for hours with a non-null global radiation over the 24-h O3 accumulation window. We showed that an assessment based on PODY and on real plant symptoms is more appropriated than the concentration-based method. Indeed, POD0 was better correlated with visible foliar O3 injury than AOT40, whereas AOT40 was better correlated with crown discoloration and defoliation (aspecific indicators).

In the current climate change context, a deterioration of the crown conditions was observed likely due to a drier and warmer climate. Clearly, if such climatic and ecological changes are now being detected when the climate, in Southeastern France, has warmed in the last 20 years (+ 0.46-1.08°C), it can be expected that many more impacts on tree species will occur in response to predicted temperature changes by 2100 (+ 1.95-4.59°C). Climate change will create additional challenges for forest management.

P-3326-13

Sea-level changes in the western Mediterranean during the last 12,000 years: a tool to better constrain the future projection of sea-level rise

M. Vacchi (1) ; N. Marriner (2) ; C. Morhange (3) ; G. Spada (4) ; A. Fontana (5) ; A. Rovere (6)
(1) Aix-Marseille Université, CEREGE CNRS-IRD UMR 34, Aix-en-Provence, France; (2) CNRS,Laboratoire Chrono-Environnement UMR6249,Université de Franche-Comté,, Besancon, France; (3) Aix-Marseille Université, CEREGE CNRS-IRD UMR 34, Cerege,, Aix-en-Provence, France; (4) Urbino University, Department of mathematics, physics and informatics, Urbino, Italy; (5) Università di Padova, Dipartimento di scienze della terra, Padova, Italy; (6) MARUM, ZMT, University of Bremen, Bremen, Germany

Global sea-level rise is the result of an increase in the ocean volume, which evolves from changes in ocean mass due to melting of continental glaciers and ice sheets, and the expansion of ocean water as it warms. The elevation of the ocean surface relative to the ocean floor is defined as a relative sea level (RSL), and any shift in height of either of these two surfaces produces a RSL change. Present-day sea level variations in the Mediterranean depend on various factors, including recent climatic forcing, tectonic activity, anthropogenic effects, and glacio-isostatic adjustment. Our understanding of current rates of sea-level rise from tide gauge and satellite data, requires correction for glacial isostatic adjustment (GIA) effects that are both calibrated to, and independently tested by, observations of former sea levels. With this purpose, we created a database of Holocene (last 12.0 ka) geological and geo-archeological sea-level data across the Western Mediterranean. We reconsidered ~600 published and unpublished sea-level data along the western Mediterranean Sea and we proposed a standardized approach for the production of index and limiting points following the protocol described by the International Geoscience Programme (IGCP) projects 61, 200, 495 and 588. We then reconstructed the RSL histories in 21 regions located in Spain, France, Italy, Malta, Tunisia, Slovenia and Croatia. At the basin scale, RSL rose rapidly from 12.0 to 6.0 ka BP. Younger data showed a significant decrease in the rising rates in the last 6.0 ka. During the late Holocene (last 4.0 ka BP) GIA, sediment compaction and local neotectonic activity played a major role in controlling sea-level variability between regions. Data showed that sea-level was higher than today only in Tunisia.

Preliminary comparison with long-term tidal gauge data (>50 years) indicates an increase in rates of sea-level rise during the last 100 years.

Results of this study are relevant for understanding how GIA operates in the far field of late-Pleistocene ice sheets and to assess sea level rise hazards, which are particularly magnified in low-lying or subsiding coastal areas.

EU-PolarNet - Connecting Science with Society

N. Biebow (1) ; K. Lochte (2)
(1) Alfred-Wegener-Institut, Helmholtz-Zentrum fuer Polar- und Meeresforschung, International Cooperation, Bremerhaven, Germany; (2) Alfred Wegener Institute, Helmholtz Zentrum fuer Polar und Meeresforschung, Directorate, Bremerhaven, Germany

The rapid changes occurring in the Polar Regions are significantly influencing global climate with consequences for global society. European polar research has contributed critical knowledge to identifying the processes behind these rapid changes but, in contrast to lower latitudes, datasets from the Polar Regions are still insufficient to fully understand and more effectively predict the effects of change on our climate and society. This situation can only be improved by a more holistic integrated scientific approach, a higher degree of coordination of polar research and closer cooperation with all relevant actors on an international level.

The objectives of EU-PolarNet are to establish an ongoing dialogue between policymakers, business and industry leaders, local communities and scientists to increase mutual understanding and identify new ways of working that will deliver economic and societal benefits. The results of this dialogue will be brought together in a plan for an Integrated European Research Programme that will be co-designed with all relevant stakeholders and coordinated with the activities of many other polar research nations beyond Europe, including Canada and the United States, with which consortium partners already have productive links.

The adaptation challenge in the Arctic

J. Ford (1) ; T. Pearce, (2) ; G. Mcdowell, (1)
(1) McGill University, Geography, Montreal, Canada; (2) University of the Sunshine Coast, Sippy Downs, Australia

We reviewed published research on climate change adaptation, vulnerability, and resilience, to identify and characterize the nature and magnitude of the adaptation challenge facing the Arctic. Framing the results using Adger and Barnett's (2009) 'reasons for concern about adaptation,' we demonstrate that: (i) even in the context of >3C warming already documented across the Arctic in the last 30 years, it is not the speed or magnitude of climate change per se that poses a challenge to adaptation, but how climate change interacts with non-climatic factors; (ii) significant barriers are likely to constrain adaptation in absence of concerted action on

broader human development deficits in northern regions. These barriers span multiple scales and are linked to long-term trajectories of disempowerment, colonization, and globalization; (iii) the potential for maladaptation is being increased by a weakening of key sources of adaptive capacity, compounded by limited anticipatory actions across scales to prepare for future impacts; and (vi) communities and Indigenous organizations have played leading roles in adaptation decision-making in the North American Arctic and to a lesser extent in the Nordic countries, but in Russia the very nature of climate change as a potential risk is not agreed upon. The challenge of adaptation in the Arctic is thus formidable, yet the review suggests that drivers of vulnerability can be overcome, avoided, or reduced by individual and collective efforts across scales.

APECS France, a network of French early-career polar researchers involved in education and outreach activities

P. Bourgain (1) ; AM. Thierry, (1) ; G. Lamarque, (1) ; C. Clément-Chastel, (1) ; M. Lacarra, (1) ; Z. Koenig, (1) ; F. Amélineau, (1) ; S. Serre, (1) ; X. Meyer, (1) ; Y. Drocourt, (1) ; M. Gesta, (1) ; LPAC. Bilan (1)

(1) APECS France, Grenoble, France

APECS-France (www.apecs-france.org), the French national committee of the Association of Polar Early Career Scientists (APECS), is a young organization of volunteers created in 2013. Its objectives are to promote early-career polar scientists and to improve the dissemination of polar sciences towards the general public and school children in particular. APECS-France has developed several activities, projects and partnerships to better educate French students about the polar regions, better explaining their importance in the context of global climate change. For instance, the French polar week is organized twice a year, and thousands of pupils can exchange with polar scientists about their research and their life as young scientists. Every December 1st, APECS-France collaborates with OurSpaces, British foundation for the good governance of international spaces, to celebrate Antarctica Day, connecting young students to the French research polar station Dumont d'Urville in Antarctica. Schools are also involved to follow scientific expeditions: such long-term education and outreach projects imply resources for teachers, a blog, visits in classrooms, and/or oceanographic data analysis. APECS-France is now planning to edit a children's book using students' drawings as well as photographs taken during the Pax Arctica - On the Shoulders of Shackleton Expedition. More recently, APECS-France has developed a partnership with Wild-Touch (French non-profit organization created by Luc Jacquet, director of March of the Penguins) and CRI (the Centre for Research and Interdisciplinarity) to help students and teachers develop a scientific project about polar regions. In the frame of COP21, APECS-France aims at organizing a physical event in Paris to allow students from 15 to 18 to exchange with young polar researchers and representatives of the indigenous population from the Arctic about the impacts of climate change in the Arctic.

The global economic implications of the melting of the Greenland ice sheet

MJ. Alvarez (1) ; D. Yumashev (1) ; G. Whiteman, (1) ; J. Wilkinson (2) ; P. Wadhams (3) ; C. Hope (4)

(1) Erasmus University Rotterdam, Rotterdam, Netherlands; (2) British Antarctic Survey, Cambridge, United Kingdom; (3) University of Cambridge, Cambridge, United Kingdom; (4) University of Cambridge,, Judge business school, Cambridge, United Kingdom

The Arctic has been changing at unprecedented rates over the past two decades, with the average rate of warming in the region roughly twice as high as the global average (IPCC, 2014). According to WGI of the 5th Assessment Report by IPCC (2013), there is growing evidence that Arctic change may have far-reaching consequences across the globe. Yet the potential global economic impacts from specific physical changes in the Arctic region are largely unstudied (Whiteman et al., 2013). This paper contributes to this emerging research agenda by assessing potential economic impacts from the Greenland ice sheet (GIS) using the PAGE integrated assessment model. PAGE is one of the top three IAMs used for climate change policy analysis and estimation of economic impacts related to climate change. While integrated assessment models (IAMs) have been previously used to estimate the net present value of economic impacts of climate change (Stern, 2007; Nordhaus, 2008; Hope, 2011; Hope, 2013), explicitly considering the potential economic impacts of Arctic change has thus far only been applied to potential methane release in the East Siberian Sea (Whiteman et al., 2013).

IAMs are simplified representations of key relevant systems such as "emissions and their socioeconomic determinants, the atmosphere-ocean-climate system, ecosystems, socioeconomic impacts, and policy and responses" (Parson and Fisher-Vanden, 1997). However, to date, IAMs (including PAGE), do not directly incorporate physical change into model configurations, but rather rely upon temperature estimates. Thus, large irreversibilities such as sea level rise from increased melt of the Greenland Ice Sheet (GIS) do not directly feed into the IAM structures. Current and future changes in GIS carry significant implications for the environment and for the global economy. To address this gap (and as part of the ICE- ARC project[1]), we adopt a transdisciplinary approach to adapt PAGE in order to evaluate the economic impact of different scenarios of GIS change.

More specifically, in this paper we (i) propose model modifications to integrate the physical changes in the GIS explicitly into the PAGE IAM, and ii) identify how best to assess economic impacts (costs and benefits) resulting from it. This includes looking into the potential drivers of the GIS melt - such as overall Arctic warming and black carbon pollution from the increasing wildfires (Benning et al., 2014; Doherty et al., 2013) as well as the main mechanisms by which the GIS melting will cause economic impacts globally. These include: sea level rise (which highlights the need to de-couple the GIS and Antarctic ice sheets in the PAGE sea level rise module), changing atmospheric and ocean circulations and its effect on weather patterns in Europe, North America and further afield. In order to achieve this, we develop distinct scenarios for the GIS melt under a given RCP (global emissions scenario) and work out the relevant economic costs globally using PAGE-ICE.References:Benning,L.G.A.M.Anesio,S.Lutz&M.Tranter(2014),Biological impact onGreenland's albedo,Nature Geoscience 7,691/Doherty,S.J.,T.C.Grenfell,S.Forsström,D.L. Why is socially-just climate change adaptation in sub-Saharan Africa so challenging? A review of barriers identified from empirical cases

S. Shackleton (1) ; G. Ziervogel (2)
(1) Rhodes University, Environmental Science, Grahamstown, South Africa; (2) University of Cape Town, Department of environmental and geographical sciences, Cape Town, South Africa

To enhance understanding of the process of climate change adaptation and to facilitate the planning and implementation of sustainable adaptation strategies, deeper consideration of the factors that impede adaptation is required. Barriers to climate change adaptation are, consequently, being increasingly reported. But, despite this progress, knowledge of barriers that hamper adaptation in developing countries remains limited, especially in relation to underlying causes of vulnerability and low adaptive capacity. To further improve understanding of barriers to adaptation and identify gaps in the state-of-the-art knowledge, this paper presents a synthesis of empirical literature from sub-Saharan Africa focusing on vulnerable, natural resource dependent communities and livelihoods. Our review illustrates that: 1) local level studies that reveal barriers to adaptation are diverse, although there is a propensity for studies on small-holder farmers; 2) many of the studies identify several barriers to adaptation, but appreciation of their interactions and compounded impacts remains scarce; and 3) most of the barriers uncovered relate broadly to biophysical, knowledge and financial constraints on agricultural production and rural development. More hidden and under-acknowledged political, social and psychological barriers are rarely mentioned, unless captured in studies that specifically set out to investigate these. We argue that research on barriers needs to start asking why these barriers emerge, how they work together to shape adaptation processes, who they affect most, and what is needed to overcome them.

E. Madela-Mntla (1)
(1) ICSU Regional Office for Africa, Pretoria, South Africa

Background: Africa occupies a unique position when it comes to Climate Change challenges. It is one of the most vulnerable continents yet has very limited capacity for adaptation and recovery. Some of its challenges owe to its poor economic and social developmental states. A brief illustration of this:

According to the UN Office of The High Representative For The Least Developed Countries, Landlocked Developing Countries And Small Island Developing States (UN-OHRLLS), of the 48 Least Developed countries (LDCs), 34 are in Africa; of the 31 Landlocked developing countries (LLDCs), 15 are in Africa; and of the 39 Small Island Developing States (SIDS), 8 are in Africa. Africa

Climate Change challenges that accompany this situation include those associated with sea-level rise and changes in coastal and marine resources, which have very serious consequences particularly for SIDS; biodiversity and ecosystems changes, which have a negative impact on tourism, food security and other socio-ecosystems services; frequent and severe natural disasters like mudslides, floods, droughts and veld fires; poor infrastructure, leading to high transportation and communication costs.

The ultimate result of these challenges is a ripple effect on health and human well-being, availability of land and water resources, management of waste, renewable energy options, infrastructure choices as well as national finances. Resilience declines, mortality rates go up, life expectancies decline and ultimately sustainable socio-economic development is retarded. Needless to say, some countries in Africa have a fair level of development, but they are not immune to some of these regional impacts of climate change. The cost of adaptation rises by the day in a region already facing many challenges like poverty. The IPCC 2007 Report estimates that the cost of adaptation to climate change in Africa could amount to at least 5 to 10% of Gross Domestic Product (GDP), and other projected impacts like increased water stress, reduction in yields from rain-fed agriculture, as well as an increase in arid and semi-arid land could worsen in the next few years (Report. Summary for Policy Makers, IPCC, 2007). Considering the scale of poverty for most African populations, adaptation is costly, it's about survival.

Call for Concerted Action: Africa is generally reported as one of the least environmental polluters because of its low industrial development. However, it stands to suffer dire consequences from the effects of climate change. Information available points to evidence that all sectors will be generally affected. Why then, you may ask, is there no or poor concerted response to mitigate the impacts. We take a closer look at the key role players on the continent and how their collaborative efforts could positively impact Africa's climate change mitigation and adaptation attempts.

African Climate Change Challenges : Innovative Climate Adaptation Practices in Ghana

A. Yeboah Obeng (1)
(1) Foresight Generation Group, Environment and Ecosystems Division, Cantonments - Accra, Ghana

INTRODUCTION
Recent studies by IFPRI suggest crop yields across sub-Saharan Africa may decline 5-22% by 2050, pushing large numbers of people deeper into in hunger and poverty as both of Africa's staple crops, maize and sorghum, are expected to be badly hit by increasing severe weather.

Climate Change and its adverse impacts is been felt across many regions of Ghana and also in the majority of ACP states, this project has been under implementation since 2012 particularly as a solution to the visible effects and impacts of erratic climatic patterns affecting crop and animal production in catchment communities in Ghana whiles encouraging environmentally friendly practices by farmers, also this project seeks to promote innovative ICT Climate driven agricultural practices and policies which has successfully increased agricultural productivity and profits in catchment communities and have proved to be very resilient to climate change on agriculture for the targeted farming communities thereby improving food security in the project's catchment towns in Ghana and replication prospects in other African countries.

DESCRIPTION
ITU data suggest that mobile penetration reached 84.8 per cent in 2011, compared with fixed line penetration of 1.14 per cent, although the number of individual subscribers may be lower than that in practice, also mobile network coverage is not uniform across Ghana as areas that lack coverage are typically those with small population centers, which cannot economically support the installation of a base station. Ghana's mobile networks were in the past was predominantly second generation (2G) GSM technology which did not provide data connectivity however there has been major upgrade to faster third generation (3G) Technology which is enabling many citizens and businesses to enjoy the enormous benefits of faster mobile telephone and data services across Ghana.

BEST CLIMATE CHANGE ADAPTIONS PRACTICES INAGRICULURE
Setting up virtual online farmer association meetings - To enable farmers from different farming towns and communities to communicate and shear challenges and the problems they have been facing in their villages, access to financing, new agricultural practices and new innovative

systems and practices including market information and latest prices for agriculture produce and farm crops. Remote col-laboration and applications of ICT's for virtual interactions will significantly reduce greenhouse gas emissions caused by travel. 0.5 billion tonnes CO2e can be saved without any major investments .

Agriculture e-commerce - we have successfully assisted farmers to sell their farm produce through selected Messaging Applications on mobile devices of farmers and that of our project field teams assisted farmers to be in touch with buyers of their farm produce without the need for the farmers to travel long distances to sell their foods at nearby marketing centers , by this online transaction fuel usage and emission by vehicles have been saved and time and money have been saved for the farmers using this service depending on uptake, these solutions can avoid more than a billion tonnes of CO2e.

Scaling up adaptation in Africa - barriers and enablers

P. Urquhart (1)
(1) Independent researcher, Cape Town, South Africa

A critical question as the adaptation discourse and practice matures in Africa relates to how to scale up adaptation in a way that is sustainable, and promotes social justice goals. A relevant point concerns the types of transformations that are needed in structures and processes to support and scale up sustainable adaptation. There is no doubt that governance institutions at different levels have a decisive role to play in these transformations. Currently, we have incomplete, under-resourced and fragmented institutional frameworks and overall low levels of adaptive capacity, especially competency at local government level, to manage complex socio-ecological change. Structural poverty and inequity are common found many countries. Despite these commonalities, the local context for adaptation differs not only between countries, but between sub-national regions and indeed within localities, for different groupings of people. So how do we begin to identify the kind of steps needed on the transformation pathway? The IPCC 5th Assessment Report identified a number of key principles for building adaptive capacity and climate resilience, based on extensive assessment of the academic and grey literature, on adaptation in Africa. The principles point to necessary changes in policy and practice, and to the role of adaptive management and social and institutional learning in scaling up adaptation. This presentation will examine the potential of these principles to play a role in overcoming key barriers towards scaling up sustainable adaptation in Africa, and raise questions for discussion on the social and process dimensions of enabling scaling up.

Welfare impacts of climate shocks: evidence from Tanzania and Uganda

A. Arslan (1) ; S. Asfaw, (1) ; F. Belotti, (2) ; A. Piano-Mortari, (2) ; P. Karfakis (1) ; L. Lipper, (1)
(1) FAO of the UN, Agricultural Development Economics Division, Rome, Italy; (2) University of Tor Vergata, Ceis, Rome, Italy

Sub-Saharan Africa (SSA) remains the world's most food-insecure region characterized by high levels of child mortality and poverty and low levels of human&physical capital (FAO, 2009). SSA countries, including Tanzania and Uganda, heavily depend on a smallholder-based agricultural sector, which in turn makes them particularly vulnerable to climate change. An estimated 90% of the population depends on rain-fed crop production and pastoralism to meet its basic food needs (Patt and Winkler, 2007). Rising temperatures and changes in rainfall patterns have direct effects on crop yields, as well as indirect effects through changes in irrigation water availability, thus exacerbating the impacts of droughts, soil degradation and decline in biodiversity. The combination of these effects makes agriculture the most vulnerable sector affected by climate change.

There is an emerging economic literature on weather variations and their implications for a wide set of economic outcomes ranging from economic growth, to migration and agriculture (Dell et al., 2013). Most of this literature is concerned with establishing linkages between these outcomes of interest and weather using data at aggregated levels including cross-country studies. These studies establish a negative relationship between economic growth/income and hot climates in general, and a positive one between income and rainfall in SSA (Miguel et al., 2004; Barrios et al., 2010; Hsiang, 2010; Brueckner and Ciccone, 2011; Dell et al., 2012).

In countries where agricultural sector is largely based on small-holders and dominates the economy, the main linkages between weather and incomes go through agriculture, and when the latter is based on rain-fed subsistence agriculture, this link also has substantial implications for food security and welfare. Since climate/weather fluctuations translate into income shocks especially faced by small-holders, not only are the average incomes low but also they are highly volatile. In addition to the important policy implications that can be derived from the investigation of these issues, we focus on weather-related risk for two reasons. First, the growing availability of high-quality geo-referenced data on weather makes this important and exogenous component of environmental risk measurable along with the related households' response. Second, although it is not the only exogenous factor affecting income and consumption of rural households, it is spatially covariant. As pointed out by Binswanger (1993), this feature makes it an important determinant of income variability that is most likely to influence welfare.

The goal of this study is, therefore, to provide a comprehensive analysis of the impact of weather risk on rural households' welfare in two countries in SSA. We use nationally representative household data together with a set of novel weather variation indicators based on interpolated gridded and re-analysis weather data that capture the peculiar features of short term and long term variations in rainfall and temperature. In particular, we estimate the impact of weather shocks on a rich set of welfare indicators (including total income, total expenditure, food expenditure and its share in total expenditure and calorie intake) and investigate whether and how they vary by different definitions of shocks. Moreover, we also analyze the interactions of these climate risk-welfare relationships with a number of policy relevant variables such as access to extension information, access to credit and the use of sustainable land management (SLM) practices, which may help farmers to cope with risk and smooth income (Morduch, 1995).

Our results show that both rainfall and maximum temperature variability (defined for the last 25, 10, 5 and 3 years) exert a negative impact on welfare, even if results vary according to the reference period with respect to which the indicators are computed. Our estimates also show a significant income-smoothing for households that have adopted SLM practices, highlighting the role of SLM as a potential ex-ante risk coping strategy. We also find that the most vulnerable rural households are much more negatively affected by a rainfall deficit compared to the households in the top income quantile. We compare and contrast the results from Tanzania and Uganda to draw site-specific and evidence-based policy implications to improve welfare outcomes under increasingly unpredictable weather conditions in these countries.

The African Safe Water Supply Challenges: Moringa Technology as an Alternative Approach

A. Bashir Yusuf (1)
(1) AHMADU BELLO UNIVERSITY, ZARIA, BIOLOGICAL SCIENCES, ZARIA, KADUNA, Nigeria, Federal Republic of

Water is one of the most important indicator of climate change today. This is seen in the two extremes of water supply, either being short through erratic rain spills affecting consumption and agriculture or excessive supply through flooding. In traditional African rural settlement, water for human consumption during the rainy season in particular is highly turbid with the consequence of water-borne diseases. "In the developing world, more than 1 billion people cannot get clean drinking water... The United Nations says that dirty water causes 80 percent

of diseases in the developing world, and kills 10 million people annually." While similar water supply during same season in urban centres is difficult to treat by water works departments since they depend on the clarification by importing aluminium sulphate. However, the existence of a natural coagulant from Moringa seed holds promise as a substitute to the chemical coagulant of alum. The practice of using Moringa seed in water treatment has been scientifically proven both at small household and large community pilot scale. Local varieties of Moringa from Nigeria has been shown to contain 18–20% cationic protein (MOCP) that is active on coagulation and against common microbes in untreated water. MOCP act on microbe by fusing their inner and outer membranes affecting exchange within and outside their cellular component. This paper highlights role of the Moringa seed technology in water treatment as a substitute to aluminium sulphate with the aim of portable safe drinking provision in Africa and other developing nations.

Harnessing the multidimensional climate and non-climate signals to livelihood vulnerability and adaptive capacity in Kaffrine, Sénégal

A. Diouf (1) ; C. Mbow (1)
(1) Institut des Science de l'Environnement, Faculté des Sciences et Techniques, Dakar–Senegal, Senegal

The Increase of rainfall variability has since the beginning of the 1970s, one of the common threats of semi-arid countries with rapid and strong anomalies and extreme events. Kaffrine is one of those areas facing these rapidly dynamic climate challenges that affect both productive systems and populations income. The history of this site exhibits a long lasting domination of groundnut production for cash and high dependence to forest resources for income and mostly as a livelihood asset. Both groundnut cultivation as a rain fed crop and forest resources are impacted severely by climate variability, but the magnitude of the climate drivers has not been fully accounted systematically in assessing vulnerability and subsequently developing adaption strategies that are context specific.

With the increasing local empowerment through devolution of natural resources management, many policy decisions are undertaken for sustainable development and socio-economic resilience at community level. Accounting for the real weight of climatic factor on livelihood dynamics can help better understand the essential variables or derivatives of vulnerability to co-design proper options for improved resilience in Kaffrine. The research question is how to set a series of criteria and climate indicators that help understand the real climate impact and how population are responding to those. The central hypothesis is that climate may be important but not sufficient information to understand communities' vulnerability in poverty condition.

We combined data collection through the AMMA WP 3.2 (questionnaire and interview guide applied at 14 villages across Kaffrine), statistical national data and cartographic tool, we try 1) to show how rainfall variability in Kaffrine affect livelihood dynamics, 2) to assess adaptive capacities of Kaffrine communities.

This results show important indicators of climate variability that are affect ecosystems and society. The study did not allow us to conclude that climate variability was the only driving force of livelihood and land degradation in Kaffrine. We conclude that scenarios on adaptation should consider both climate and non-climate factors such as basic land management systems. Options, potentials and constraints of adaptive capacity, must be based on integrated assessment of local stressors.

P-3328-04

Demographic and Socioeconomic Determinants of Vulnerability and Adaptation to Climate Change in the Nigerian Savannah

P. Elias (1)
(1) University of Lagos, Geography, Lagos, Nigeria, Federal Republic of

The paper examines the demographic and socioeconomic characteristics of rural farming communities as determinants of vulnerability and adaptation to climate change in the Nigerian Savannah. The Nigerian savannah has been seriously affected by human activities which have reduced its capacity to support the teaming rural farming communities and livelihood systems. The fact that livelihood systems in the region are closely tied to terrestrial ecosystems and changes in global climate further exacerbates the conditions of the rural farmers. The demographic and socioeconomic characteristics of selected agricultural communities in the Nigerian Savanna were examined with the view to assessing their vulnerability and adaption to climate change. The methodology for the study was based on multistage random sampling technique and Rural Rapid Appraisal (RPP) of 11 communities across 10 Local Government Areas (LGAs) in two states of the southwest and north central Nigeria. Site visits, Key Informant Interview of traditional rulers and Government officials were carried out while an intensive Focused Group Discussion among all the actors was done. The role of education, income from farm and other sources, ability to diversify, willingness to adapt, proportion of savings, and local adaptation mechanisms were identified and used to examine the relationship between indicators of vulnerability and adaptation of local farmers and communities to climate change in the region. By matching indicators of vulnerability and factors of local adaptation it help the understanding of local actions, barriers to adaption, present and future capacities.

The gender, age, marital status and size of households of the respondents reveal typical rural farming communities with large family sizes, low education and incomes from predominantly farming activities (65.8%). These conditions could perpetuate poverty and predispose rural farmers and their households to vulnerability to climate change impacts which could also limit adaptation. However, the paper analyse the opportunities to make money from other sources which shows that they could be protected from unexpected shocks from climate change and increase their resilience through the diversification of livelihoods. The poor culture of savings in these communities which cannot be divorced from their poor incomes from farm-based activities could limit adaptation. The results shows that the farming communities are facing the realities of climate change with 30% of the sampled population involved in adaptation while 21.9% are not. Some of the adaptation methods include use of fertilizer to boost production, shifting cultivation and irrigation while 17.2% do not know what to do. The farming communities deploy irrigation and organic farming, irrigation and rain harvesting and hiring of more labour as means of improving farming activities. The paper suggests that there should be a rural development policy to increase opportunities and prospects of non-farm activities and promote the culture of savings in these communities. The identified strategies for ameliorating climate change and improving farm activities must be developed sustainably to reduce vulnerability and ensure rural adaptation. This should engage the interest of policy makers if poverty eradication or at worst reduction is a sincere aspiration for the region.

P-3328-05

Climate Change Adaptation and Mitigation through Agro forestry systems in Wolaita Zone, Southern Highland of Ethiopia, East Africa

W. Hailesilassie (1)
(1) National Meteorological Agency, Numerical Weather Prediction, Addis Ababa, Ethiopia

Climate change is one of the most serious threats the world faces. It will affect all of us, but will have disproportionate impacts on millions of poor rural people in Ethiopia. For development work to be effective, we must not only help poor rural people emerge from poverty, we must also enable them to cope with and mitigate the impact of climate change. Agriculture is the human enterprise that is most vulnerable to climate change, because of the subsistence nature of the farming practices, and because communities have little resources to adapt to the impacts of climate change. Farmer's adaptive capacity is constrained by a lack of economic and technical resources, and they are vulnerable due to a heavy dependence on rain-fed crops. While agro forestry may play a significant role in mitigating the atmospheric accumulation of greenhouse gases (GHG), it also has a role to play in helping smallholder farmers

adapt to climate change. This paper presents data that examine the mitigation and adaptation potential of different agro forestry systems. Hence, the research questions those need to be answered concerning the role of agro forestry in both mitigation and adaptation to climate change. It is recommended that in low-income and food-deficit regions livelihoods including food security and climate change cannot be tackled in isolation.

P-3328-06

Responding to the Scares Skills Needs in the Renewable Energy Domain in South Africa

Y. Hamam (1) ; L. Makhubela (2) ; AM. Kurien (3)
(1) Tshwane University of Technology, Department of Electrical Engineering, Pretoria, South Africa; (2) Tshwane University of Technology, Post graduate studies research and innovation, Pretoria, South Africa; (3) Tshwane University of Technology, F'sati, Pretoria, South Africa

According to the South African department of Energy, almost 90% of South Africa's electricity is generated in coal-fired power stations. One nuclear station near Cape Town produces about 5 % of the total capacity. The remaining 5% is provided by hydroelectric and pumped storage schemes, the sites available for this power being limited. The Tshwane University of Technology (TUT) in Pretoria, South Africa is responding to these needs in collaboration with French and European Institutions.

This is done through institutions within the Faculty of Engineering and the Built Environment:

- The French South-African Institute of Technology (F'SAT)
- The Centre for Energy and Electric Power (CEEP)

These institutions collaborate within the graduate programme of the Department of Electrical Engineering to provide courses and research in the energy domain and specifically in the renewable energy specialisation.

F'SATI is a National asset contributing to the creation of knowledge and the transfer of technology in South Africa through the establishment of collaboration between various higher education and research institutes, as well as industry. F'SATI's mission is to improve the quality and the quantity of the output at postgraduate level. This proposition is enhanced through the collaboration with other French partners. In the last four years F'SATI has highly increased its output at both postgraduate students and publication levels. The present stakeholders of this venture are the French Ministry of Foreign Affairs, the French Ministry of Education and Research, The Chamber of Commerce an Industry of the Parisian Region, the South African Department of Science and Industry and National Research Foundation.

The European partners of the CEEP include the Hogeschool Utrecht University of Applied Sciences, the University of Utrecht, the ECOFYS, the RWTH-Aachen University and the French ESIEE-Amiens.

The partners of the above programmes include companies such as ESKOM the main power company, Local Municipalities, the Council for Scientific and Industrial Research (CSIR) and other South African Universities.

The above programmes have contributed to the training and education at both the Masters and Doctorate levels. These programmes cover the following domains: smart networks, photovoltaic applications, wind energy production as well as hydropower. This collaborative effort has resulted in the training of postgraduate students as well as the production of many scientific publications in the domain of renewable energy.

The graduates of these programmes contribute to the development of renewable energy in South Africa. This adventure gives an example of a collaboration between European countries and an African country. It shows that such a venture may respond to scarce skills that are highly needed in Africa.

The authors will give more details of these activities in the full document and the oral presentation.

The Nexus of Climate Downscaling Using RegCM4 and Hydrology dynamics in Ghana

R. Kasei (1)
(1) University for Development Studies, Climate Change and Food Security, Tamale, Ghana

Climate Downscaling is a term adopted in climate science in recent years to describe a set of techniques that relate local to regional-scale climate variables in relation to the larger scale atmospheric forcing. Theoretically, the techniques are advancements of the known traditional techniques in synoptic climatology. Climate downscaling specifically addresses the detailed temporal and spatial information from Global Climate Models (GCMs) required by precise researches of today. The Regional Climate Model version 4 (RegCM4), with horizontal resolution of 55 km, was used to downscale the ECHAM5 simulations forced with observed SSTs over southern Ghana. For each of the ECHAM5 AGCM integrations a nested integration with the REGCM was done for the period January-June 1961-2000. Six-hour wind, temperature, humidity, and surface pressure data from ECHAM45 AGCM outputs were linearly interpolated in time and in space onto REGCM grids as base fields. The results of the comparison for the Densu catchment station showed a good correlation between the observed REGCM-simulated monthly rainfalls with significant statistics. Although no coherent trends were found in the basin, interannual rainfall variability was more pronounced as revealed by the REGCM 4 simulations. The northern part of the basin is most vulnerable to these variations because it has a monomodal rainfall pattern compared to the south which has relatively higher rainfall amounts due to its bi-modal rainfall pattern. The SPI analysis conducted on projected precipitation based on REGCM using IPCC's A1B and B1 scenarios against the base period of 1961-2000 showed both scenarios agreeing to a general drying trend for the future. Results show that precipitation will decrease by up to 70% in some areas and the duration of the rainy season will narrow, which may have extensive implications for agriculture and city water supply. In lieu of this, adaptation will be central to sustaining development and four response measures are discussed as being cardinal to this process. These include mainstreaming adaptation into policy planning processes at varied levels, enhancing water conservation for agriculture, promoting the cultivation of drought resistant and early maturing crop varieties, and promoting access to food through technical and economic infrastructure and services that facilitate food exchange. Climate Downscaling is a term adopted in climate science in recent years to describe a set of techniques that relate local to regional-scale climate variables in relation to the larger scale atmospheric forcing. Theoretically, the techniques are advancements of the known traditional techniques in synoptic climatology. Risques Hydrométéorologiques dans les Villes Africaines RHYVA/PARRAF

A. Konaré (1)
(1) University Felix Houphouet Boigny, Laboratoire de physique de l'atmosphere et de mecanique des fluides, Abidjan, Ivory Coast

RHYVA Network: Risques Hydro-météorologiques dans le Villes Africaines

In synergy with the ECOWAS vision , the objective of RHYVA network is to develop a basic understanding of the risks in urban environments and to provide expertise to strengthen the resilience of African cities Capacities for hydrometeorological disasters.Specifically, RHYVA aims to:promote dialogue between the different actors that contribute to reducing the harmful effects of hydrometeorological disasters (scientists, emergency services and risk management, policy makers, NGOs, communities at risk) to share knowledge (results of the research, experience feedback, good governance practices, evaluation, coordination, communication and appropriate conduct).Make a plea and conduct training and awareness activities on reducing urban disaster risk to parliamentarians and local authorities, journalists and the target communities. ;to support research activities on risk Hydrometeorological in African cities and support the development and networking of national platforms in charge of disaster risk reduction at the subregional level

P-3328-09

The role of indigenous knowledge systems in climate change, prediction, adaptation and mitigation in sub Saharan Africa

PL. Mafongoya (1) ; N. Chanza (2) ; C. Mubaya (3)
(1) University of KwaZulu Natal, Agriculture, Earth and Environmental Science, Pietermaritzburg, South Africa; (2) Nelson Mandela Metropolitan University, Department of geosciences, Port Elizabeth, South Africa; (3) Chinhoyi University of Technology, Resource mobilisation, Chinhoyi, Zimbabwe

The recognition of the significance of indigenous knowledge systems (IKS) has only begun to emerge at the international level in the last few years. Understanding the nature and relevance of IKS for climate change adaptation and mitigation is a new and expanding area of collaborating research involving indigenous people, local communities and scientist. IKS is the basis of community based observations of climate impact and traditional practices and mechanisms that provide a robust basis for climate change response. IKS can be defined as ecological knowledge or accumulative board of knowledge, practice and belief, evolving by adaptive processes and handed down through generations by cultural transmission about relationships of people with one another and their environment. For communities to adapt to climate change it is critical for them to perceive how climate is changing. Farmers have the following perception on climate change, shorting of growing season, changes in rainfall characteristics, increase in temperature, changes in wind characteristics and extreme events such as droughts, floods, dry spells, cyclones and increased incidence of pests and diseases. Farmers in Africa use indigenous knowledge systems for weather forecasting and prediction of season quality. They use a combination of tree phenology, animal behavior such as insects and birds and atmospheric phenomena such as the shape of the moon, type of clouds and wind direction. In most cases seasonal quality forecast and scientific forecast are identical. Scientific forecast may able to compliment indigenous forecast so as to mitigate the loss of traditional weather and climate indicators. Farmers use indigenous practices to adapt to climate change and mitigation.

Responding to Sustainability Challenges in Irrigation Sector: Community-based Integrated ICT Solutions for Sub-Saharan Africa

H. Mongi (1) ; A. Mvuma, (1) ; A. Sife, (2)
(1) The University of Dodoma, Information Systems, Dodoma, Tanzania, United Republic of; (2) Sokoine University of Agriculture, Sokoine national agricultural library, Morogoro, Tanzania, United Republic of

Irrigation is the most water intensive sector, consuming nearly three quarters of global fresh water resources. Significant number of countries in Sub-Saharan Africa (SSA) are emphasizing on expansion of land under irrigation to offset food insecurity brought about by climate change and other factors. This is happening amid increasing evidences on declining fresh water resources in the same region, therefore triggering options to their sustainable management. This contribution highlights some technologies to enhance decision making, coordination and control in the community level as part of concerted responses to address sustainability challenges in the water sector. The solutions were developed involving stakeholders in three SSA countries: Tanzania, Uganda and Rwanda. Testing focused on small scale but sensitive irrigation schemes around Trans-boundary Lake Victoria Basin in Tanzania's part. Among priority adaptation options for climate change is to develop, pilot implement and scale-up information systems. The paper describes integrated Information and Communication Technologies (ICTs) solutions that have been developed with and for communities to support coordination for sustainable water resources in the SSA. They provide tools and techniques that can create a common platform for sharing information at the bottom level. They provide many options through which community can engage in giving and receiving information regarding water resources. These solutions are believed to improve coordination, decision making and control on water resources for irrigation thereby contributing to sustainable water for agriculture, livestock and domestic uses.

P-3328-11

Impacts of climate change on water resources and relevant adaptation strategies in upper catchment of Pangani basin in Tanzania

S. Mwakalila (1)
(1) University of Dar es Salaam, Geography, Dar es Salaam, Tanzania, United Republic of

The climate change impact on water resources is the major challenge across the Pangani basin in Tanzania. In some areas, too little water leads to droughts and desertification, whereas in others too much water leads to increased flooding. The Tanzania Agriculture Policy advocates for improved water use efficiency as an adaptation strategy, which can help the nation to achieve in improvement of food security; increasing farmer's productivity and income. Following local peoples' perception, the major climate change impact is drought (78%) with high frequency of occurrence. Irrigated agriculture which depends on water resources is by far the largest water use sector in Tanzania, is affected by changes in water availability that is caused by climate change. Climate change also alters irrigation water demand. Higher temperatures and more variable rainfall tend to increase water demand per unit of irrigated area. The adverse effects of climate change is felt by poor communities because of their low adaptive capacity associated with limited financial resources, poor infrastructure, low level of education, dependence on natural resources and lesser access to technology. Traditional irrigated agriculture is the most common adaptation strategy for crop production and account for more than 79% of the total irrigation schemes in the study area. Traditional irrigated agriculture which is the most common adaptation measure for crop production is usually associated with significant water losses and low crop productivity. Traditional schemes are usually initiated and operated by farmers themselves, with no external intervention or support. They include schemes based on traditional furrows for production of paddy, maize and vegetables. Traditional schemes are usually characterized by locally improvised infrastructure which is poorly constructed and temporary in nature. They are often associated with low productivity due to poor farming and water management practices. Intake structures are made from locally available materials like stones, grass, earth, wooden poles and straw. Intake structures are usually built across the river, partially or wholly blocking the channel, and are thus prone to damage during high river flows. The majority of intakes do not have control gates to regulate the amount of water entering the furrow.

Conveyance canals are usually hand dug and not lined to minimize seepage. Because the canals are unlined, they quickly get clogged by vegetation growth which reduces their efficiency. The canals typically lack flow control devices for effective conveyance and distribution. This implies that, traditional irrigation has low efficiency due to wastage of water sources from the source to the field level. Promotion of efficient irrigation water use and adoption of good farming practices is, therefore, critical to ensuring sustainable use and management of the water resources for sustaining local peoples' livelihoods in Tanzania. Since water demands have intensified with the increase of economic activities such as irrigated agriculture, hydropower generation, livestock keeping, fisheries and wildlife activities, this paper recommends effective implementation of integrated water resources management as adaptation measure to be enhanced and implemented, to ensuring sustainable use and management of water resources for sustainable development.

Complementing Local Indigenous Knowledge and Practices and scientific knowledge for better policy planning on climate change adaptation: the Case of Cameroon

E. Ngang (1)
(1) Information and Communication University (ICT-U), Management, Yaounde, Centre, France

Climate change is a defining issue of our era, with its impacts reaching regional and global scales. The current magnitude and variability have critical implications for agriculture, fisheries, forestry, life histories, community compositions, and essential ecosystem functions. Warming, combined with the higher risk of extreme floods and droughts, shrinking water resources will lead to the rapidly lengthening list of potentially damaging impacts, from soaring food prices to famine and mass migration of species including humans and increase in conflicts over diminishing natural resources. Countries of the African continent are among the most vulnerable to climate variability and extremes, given that only 5% of their cultivated land is irrigated and food production is dependent mainly on rain-fed agriculture. How serious the repercussions will be, depends on how fast measures and strategies are adopted to facilitate coping with the extreme and inevitable conditions posed by climate change especially for grass root communities. Unfortunately, some of these agriculture-dependent areas that are most vulnerable to negative effects of climate change are quite remote with improper coverage by scientific forecasting stations. The farmers in these areas have been modifying their farm practices to adapt to inevitable changes in climate. Through on-farm management and post-harvest conservation practices, they have used their wealth of Local Indigenous Knowledge and Practices (LIKPs) in the food production chain to enhance their food security. It has been observed that although LIKPs have been recognised as a resource, they have however been given a tokenistic consideration through the addition of a small portion of traditional ecological knowledge in decision making processes related to climate change while business is still done as usual. These traditional practices and strategies that have been linked to changes in climate and long-term extreme weather conditions, transferred orally and through mutual and collective on-farm learning on-farm learning and practices, from one decade to another and from generation to generation, have been grossly neglected. This poster presentation shall highlight the conflict between traditional (indigenous) knowledge, which is contextual, localised and the western-scientific and bureaucratic (often top-down) method of management that finds it difficult to reconcile national planning with local action (bottom-up) within the framework of climate change adaptation. Focus shall be on Cameroon, one of main breadbaskets of the Central African Sub region. Over many decades, 70% of the 30 million inhabitants' livelihood is hinged on agriculture and these communities have learned to use their LIKPs to cushion themselves inevitable climate risks. Although acceptable levels of adaptation and resilience to climate change have not been defined across the board, this paper emphasises that reconciliations between LIKPs and 'western' science is essential for policy formulation and implementation processes. This places local communities as co-creators of knowledge and practices that cushions them against climate risks, ensuring ownership and sustainability of policies and implementattion strategies. Some examples of successful local indigenous knowledge practices gathered through evidence-based research and engagement with local agriculture dependent communities in Cameroon shall be highlighted to contribute to steer reflections on the subject.

P-3328-13

Influence of Madden-Julian Oscillation (MJO) on Rainfall Variability over West Africa at Intraseasonal Timescale

C. Niang (1)
(1) Laboratoire de Physique de l'Atmosphere et de l'Ocean, Ecole Superieur Polytechnique (ESP), Dakar, France

Intraseasonal variability of rainfall over West Africa plays a significant role in the economy of the region and is highly linked to agriculture and water resources. This research study aims to investigate the relationship between Madden Julian Oscillation (MJO) and rainfall over West Africa during the boreal summer in the the state-of-the-art Atmospheric Model Intercomparison Project (AMIP) type simulations performed by Atmosphere General Circulation Models (GCMs) forced with prescribed Sea Surface Temperature (SST). It aims to determine the impact of MJO on rainfall and convection over West Africa and identify the dynamical processes which are involved. The simulations show in general good skills in capturing its main characteristics as well as its influence on rainfall over West Africa. On the global scale, most models simulated an eastward spatio-temporal propagation of enhanced and suppressed convection similar to the observed. However, over West Africa the MJO signal is weak in few of the models although there is a good coherence in the eastward propagation. In addition, the ensemble average of models give better performance in reproducing those features. The influence on rainfall is well captured in both Sahel and Guinea regions thereby adequately producing the transition between positive and negative rainfall anomalies through the different phases as seen in the observation. Few models overestimate the composite intensity in phases with strong MJO signal over the Sahel while the opposite is simulated over Guinea coast. Futhermore, the results show that strong active convective phase is clearly associated with the African Easterly Jet (AEJ) but the weak convective phase is associated with a much weaker AEJ particularly over coastal Ghana. In assessing the mechanisms which are involved in the above impacts the convectively equatorial coupled waves (CCEW) are analysed separately. The analysis of the longitudinal propagation of zonal wind at 850hPa and outgoing longwave radiation (OLR) shows that the CCEW are very weak and their extention are very limited beyong West African region. It was found that the westward coupled equatorial Rossby waves are needed to bring out the MJO-convection link over the region and this relationship is well reproduced by all the models. However, Kelvin waves do not account for the overall impact of MJO signal on convection over West Africa. Results also confirmed that it may be possible to predict the anomalous convection over West Africa with a time lead of 15-20 day with regard to Indian Ocean and AMIP simulations performed well in this regard.

P-3328-14

Adaptation and response to climate change, an opportunity for local development in Central Africa: case study of Cameroon western highlands

DJ. Nkue Nouwezem (1)
(1) University of Dschang, Geography, Dschang, Cameroon

Climate change offers opportunities for African countries to emerge. It calls the attention to a sustainable development in a century where African countries aspire to development, emergence and economic stability. According to observations made in different localities on the continents, African local communities are trying to assess and mitigate the impact of climatic change with their own means. This will help them to address particular issues concerning them. Indeed, general measures proposed by stakeholders and policy makers based on them are not always the best to resolve problems arising. Besides, some are living in remote or rural areas and

hence not aware of these mitigation measures and policies adopted. In Cameroon and especially in its western part, to ensure their productivity, farmers have ameliorated their production capacities by developing and mastering new production and commercialization tools. When talking about production we refer to the understanding of the new climatic patterns, the improvement of tilling and irrigation systems. Concerning commercialization, models have changed. Furthermore we see buyers going directly to purchase goods from farms while some years ago it was the producers who were going toward the buyers. Moreover, things have improved at the national level. Contrary to what was done during the last ten years, the publication of meteorological data through national televisions programs and newspapers shows a great progress in the African sub region. This meteorological data have a great impact on the daily lives of populations in the area. Also, state institutions such as ministries of environment and their respective departments, which control industrial production models and sanction those who pollute the environment helps in encouraging sustainable development. This paper shows how local communities in central African countries in general and in the western highlands of Cameroon in particular have adapted to climate change, showing how they respond to it in order to ensure their agricultural production in climatic variability circumstances and how this adaptation contributes to their development. The data presented in this paper are the result of a qualitative research based on in situ observations, interviews and literature review. These data reflect globally what is happening in most of central African countries.

P-3328-15

Biomass Economy in the Era of Politicization and Economization of Nature in Africa: A Case for Clean Energy Transition

AIS. Okoh (1)
(1) Benue state university, political science, Makurdi, Nigeria, Federal Republic of

Over the next 25 years, 600 million people to over 700 million will rely on biomass energy in Africa. According to International Energy Agency 61.2% of the population of sub-Saharan Africa will depend on biomass and waste for total primary energy demand when you exclude South Africa, it is 81.2%. Yet, biomass economy as a vital sector of the economy is not integrated into the national development plan of most states. Traditional biomass is mostly unplanned heightening depletion of resources. Africa will witness increases in biomass consumption in 2035 whereas in other regions will witness decreases. With business as usual scenario Africa consumption will rise with exponential population explosion leading to between 51% - 57% higher demands for biomass in 2035. With greenhouse gases reaching 400ppm, man-made climate change will be a barrier to attainment of Sustainable Development Goals (SDGs) of this generation putting an end to poverty in 2030. However, ending global poverty is inextricably linked to energy consumption and production which will also exacerbate climate change. Resolving this complexity is critical in the years to come in that they are mutually reinforcing in Africa. In recognition, many countries made remarkable progress towards resolving this challenge by integrating renewable energy into the energy supply mix in the transition to zero society. However, carbon emission play vital role in clean economy as net zero emission and green growth are not just coterminous but axiomatic necessities. Yet, such necessity is also inter-related with our biospheric limits. Carbon-based growth for low income countries of Africa will ensure transition to middle income economy but such growth is based on resources depletion. For Africa, natural capital is still the large bowl for the transition to middle income country. I argue that though clean energy transition is the future to low carbon civilization. But for many countries in Africa biomass still holds more potential for improving economic wellbeing of the poor. Despite this beneficial attribute, biomass extraction will not only magnify existing inequalities within the continent but will result in reversal of growth. It is my contention there are still many gray areas in clean economy as unsustainable extraction and consumption will continue into the future reinforcing climate-related extreme events. This will require dramatic low carbon trajectory which aims at eco-efficient utilization of green infrastructure. And as such, it is a paradox of cohabiting extremes in the politicization and economization of nature in Africa.

In this paper, the above dilemma is closely examined in the light of its impediment to the food system and meeting SDGs. Finding an enduring energy policy solution to food insecurity will require an ecologically responsible food system that is not undermined by land grabs for biofuel production. This then prompts us to ask: Can Africa's biomass economy made eco-efficient? In what ways has Africa's energy policy mix changed with the politicization and economization of nature? Has Africa's clean energy complex imbibed principle of allocative justice? Can policy reforms rebalance growth towards net zero trajectories? The answers to these questions shall be uncovered through secondary data sources which will point us towards proffering adjustments for policy changes. We conclude by advocating a policy mix of materialization and dematerialization as solution to agro-ecological deteriorations. This will require dramatic changes in production or consumption critical in biomass economy as different phases of the economic process may cancel each other out when it comes to overall energy consumption. To achieve efficient use of energy will require a new roadmap called food sovereignty economy. This model advocates some form of dematerialization if we will not lock present generation into a fossil fuel dependent future. It combines eco-friendly policies of food sovereignty and sufficiency economy to set a pathway to net negative emissions in the attainment of SDGs.

P-3328-16

Ensemble Modeling using General Circulation Models from Global Producing Centres for Rainfall Forecasting over the Greater Horn of Africa

G. Otieno (1)
(1) university of nairobi, meteorolgy, nairobi, Kenya

Climate extremes like flood and drought have threatened the social-economic sustainability over the Greater Horn of Africa (GHA). Lack of accurate and reliable forecasts systems with correct time leads results to devastating impacts. Under the auspice of Global Framework for Climate Services (GFCS), World Meteorological Organization (WMO) in effort to address the challenges due to climate extremes designated global producing centres Models (GPCs) to provide accurate and timely climate services and information.

This study evaluated the skill of forecasting seasonal rainfall over the GHA using the GPCs models. The datasets used included; monthly rainfall model hindcasts, Climate Research Unit (CRU) blended with observed rainfall stations between 1983-2001. The methods employed in the study included Spearman Rank correlation, Composite Analysis, Weighted averages, Continuous Ranked Probability Skill Scores(CRPSS) and Taylor Diagrams.

The skill of the ensemble model was higher than that of the individual models in capturing the rainfall peaks during the ENSO phenomena. Correlation analysis showed higher values for ensemble model output than for the individual models mostly over the Equatorial region. The skill of the models was relatively higher during the onset of the ENSO event and became low towards the decaying phase of ENSO period.

It is clear from the study that ensemble seasonal forecasting significantly adds skill to the forecasts over the region. Blending dynamical ensemble forecasts with statistical forecast currently being produced during Regional Climate Outlook Forums (RCOFs) would add value to seasonal forecasts. This significantly reduces the impacts and damages associated with climate extremes over the region.

P-3328-17

Food security in African drylands: Learning from socio-ecological patterns of smallholder agriculture

D. Sietz (1) ; J. Ordoñez, (2) ; M. Kok (3) ; P. Janssen, (3) ; H. Hilderink, (3) ; DH. Van (1)
(1) Wageningen University, Wageningen, Netherlands; (2) ICRAF, Turrialba, Costa Rica; (3) PBL Netherlands Environmental Assessment Agency, Bilthoven, Netherlands

Food production is key to achieving food security in

African drylands. Agricultural productivity is however significantly constrained due to climate variability, low water supply, limited soil fertility and farmers' remoteness from decision-making centres. In addition, future climate change is projected to further undermine agricultural productivity. Vulnerability is employed as a concept to capture the relation between farming systems and climate stresses impacting upon these systems. To promote learning for a food secure future, we present a quantitative and spatially-explicit typology of smallholders' vulnerability in the drylands of Sub-Sahara Africa. This typology explicitly incorporates malnutrition as cause and consequence of vulnerability. We indicated the most relevant socio-ecological properties of dryland farming systems at a sub-national resolution including child malnutrition, water availability, soil erosion sensitivity, agropotential, income, population density, urban population share, distance to markets and governance. Cluster analysis revealed nine typical patterns of vulnerability showing distinct indicator combinations. For example, one pattern depicts high levels of child malnutrition, a poor resource base and poor governance and is indicated in the hyper-arid to semi-arid areas of eastern Africa. This typology enables the evaluation of key inter-linkages between smallholders' climate vulnerability and food security. Their evaluation facilitates the transfer of successful strategies for resilience building based on similarities among the farming systems and supports the identification of entry points for managing transitions towards a food secure future. The manageable number of socio-ecological patterns enable new insights into the prioritisation of interventions to improve and monitor food security.

P-3328-18

Barriers and enablers to climate change adaptation in four South African municipalities, and implications for Community Based Adaptation

M. Spires (1) ; S. Shackleton (2)
(1) Rhodes University and ICLEI Africa, Grahamstown and Cape Town, South Africa; (2) Rhodes University, Environmental Science, Grahamstown, South Africa

Despite the fact that municipalities have a vital role to play in planning and implementing climate change adaptation, numerous barriers are encountered when they do so, especially at the community level. A study was conducted to analyse these barriers and enablers, both via literature review and case study analysis of four South African municipalities. Comparison of barriers and enablers across the case studies revealed a number of key themes. Municipalities struggle to implement climate change adaptation and community based adaptation within contexts of significant social, economic and ecological challenges. These contextual barriers, when combined with certain cognitive barriers, lead to reactive responses. Existing municipal systems and structures make it difficult to enable climate change adaptation, which is inherently cross-sectoral and messy, and especially community based adaptation that is bottom-up and participatory. Lack of locally applicable knowledge, funding and human resources were found to be significant resource barriers, and were often underlain by social barriers relating to perceptions, norms, discourses and governance challenges. Enablers of engaged officials, operating within enabling organisational environments and drawing on partnerships and networks, were able to overcome or circumvent these barriers. When these enablers coincided with windows of opportunity that increased the prioritisation of climate change within the municipality, projects with ancillary benefits were often implemented.

Predicting future climate for adaptation in northern Côte d'Ivoire: contribution of statistical downscaling model

K. Yao Etienne (1) ; K. Brama (2) ; C. Guéladio (3) ; S. Issiaka (4) ; A. Konare (5)
(1) Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Abidjan, Ivory Coast; (2) Université Péléforo Gon Coulibaly of Korhogo, Abidjan, Ivory Coast; (3) University of Basel, Bâle, Swaziland; (4) Université Nangui Abrogoua, Abidjan, Ivory Coast; (5) Université Félix Houphouët Boigny of Abidjan, Abidjan, Ivory Coast

In the region of Korhogo in northern Côte d'Ivoire, recent climate variations are marked by a superposition of droughts and floods. These events contribute to weakening the wellbeing of populations, particularly the most vulnerable. To enhance the actual and future resilience and adaptation capacity of these people, it is necessary to have more information on present climatic parameters and their future evolution.

Temperature and rainfall of the white Bandama basin in the region of Korhogo from 1971 to 2000 were collected at the Société d'Exploitation et de Développement Aéroportuaire, Aéronautique et Météorologie (SODEXAM) and processed. Statistical downscaling method was used to project theses data at three horizons: 2020 (2011-2040), 2050 (2041-2070) and 2080 (2071-2099) base on IPCC A2 and B2 scenarios. Model calibration was done by multiple linear regression between four predictor variables derived from the general circulation model HadCM3 and local observation variables (temperatures and rainfall).

The results generally show that the model simulates well enough both temperatures and rainfall. Of the three horizons, the model predicts an average temperature increase of 0.43°C; 0.97°C and 1.63°C. In general, the A2 scenario provides greater increases than B2. Indeed according to A2 scenario, the current minimum temperature (20.87°C) could increase by 0.48°C, 1.16°C and 2.02°C respectively at the horizons 2020, 2050 and 2080. For current average temperatures (26.8°C), the increase could be 0.44°C, 1.13°C and 1.96°C, respectively for the three horizons. When actual maximum temperature (32.27) could increase by 0.31°C, 1.36°C and 1.17°C also for the same horizons. According to B2 scenario, minimum temperature could increase by 0.43°C, 0.82°C and 1.39°C for the three horizons. Current average temperatures could increase by 0.43°C, 1.13°C and 1.33°C according to B2 scenario. And for maximum temperature, increase could be 0.78°C, 1.11°C and 1.14°C. The months of september and october record the higher values of maximum temperatures.

For precipitation, A2 and B2 scenarios presented the same average annual increase of 34% at the 2020 horizon with a margin of error between 10% and 9% respectively. By 2050, the annual increase could be valued at 29% and 33% for A2 and B2. This increase could be 12% and 28% respectively for A2 and B2 by 2080 with lower margins of error of 4% (A2) and 7% (B2). The months of May and June could see the largest increases (149 mm and 109 mm respectively), which is twice the observed quantities. Such information's are useful for the planning and implementation of programs and plans for adaptation to reduce the potential risks associated with these climatic variations.

3329 - How Might East African Landscapes Respond to Future Climate Change?

ORAL PRESENTATIONS

0-3329-01

Understanding the past to develop a sustainable future: the value of the East African palaeoecological record

R. Marchant (1)
(1) University of York, Environment department, York, United Kingdom

Ecosystems are the primary resource for human well-being and provide key functions essential to the sustainable economic development, especially for African nations whose economies are heavily dependent on agriculture, rangeland pastoralism, forestry management and wildlife tourism. Planning for the long-term sustainable use of

Africa's ecosystem natural resource requires a longer-term historical perspective on human-ecosystem-environment interactions than is currently available. A synthetic overview of the palaeoecological records from East Africa will be presented and used to chart the interactions between people and their use of ecosystem resources during the transition into agriculture. The time period will draw on the palaeoecological record of the last 6000 years with a focus on the historical past. Zooming in on the past 500 years we will present how this has been used to build a foundation to construct informed climatic and socio-economic scenarios for the future. The presentation will focus on unpicking the temporal, spatial and complexity of interactions and interdependencies in the social-ecological systems in Eastern Africa to understand the interactions between people, their environment, wildlife, livelihoods, and provide a better potential future for the sustainable use of Africa's ecosystem. The presentation will unpick how societies, landscapes, ecosystems and Protected Areas have responded to climate change, so as to better understand how they may respond to future climate change and societal use.

0-3329-02

Landscape Resilience and Vulnerability in eastern Africa: an archaeological prospectus for the future

P. Lane (1)
(1) Archaeology & Ancient History, Uppsala, Sweden

The need to create and sustain resilient societies capable of facing the burgeoning challenges posed by accelerating global climate change has become a dominant mantra of our age. Both sustainability and resilience are inherently temporal concepts, but in planning for the future it is often difficult to identify which practices and systems are likely to enhance resilience and which may make communities and even whole societies more vulnerable to the detrimental effects of climate change. For this reason, examples from 'the past', and specifically tangible evidence for long-lasting socially and ecologically enabling practices are increasingly used as a source of information for planning the future. Using archaeological examples from East Africa spanning the last ca. 1000 years, this paper outlines some concrete instances of past strategies aimed at enhancing socio-ecological resilience during periods of extreme climatic pressures and critically discusses whether these can be used as models for the future.

"Growing water" in Northern Kenya: Resilience of the Gabbra ecology and technology to adverse climate change

B. Hazard (1)
(1) Institut Interdisciplinaire d'anthropologie du contemporain, Institut National des Sciences Humaines et Sociales – CNRS, Paris, France

Northern Kenya is frequently described as one of six areas directly impacted by the global climate change as well as a region having a low resilience to climate change. Yet the temporal and spatial dynamics of northern Kenyan socio-ecological systems have been relatively stable within a longer-term variability during the Holocene period. Driven by the Lower Omo Basin and the Lake Turkana basin, ecological conditions have only changed with the prolonged period of severe drought of the late-18th century and earliest 19th century and therefore started to challenge local incentives of pastoralist societies. The presentation discuss how severe climate variability and recent socio-ecological change is altering or modifying existing traditional resource governance, adaptation strategies and coping mechanisms in Northern Kenya by focusing on how Disaster Risk Reduction programs implemented to adverse effects of the climate change interact with the Gabbra ecology of the Chalbi desert. For long the local concept of "finn" was used to describe human-landscape interaction and to predict climate events and their relation to ecological conditions and adaptation mechanisms for pastures and water. Based on a complex predictive model, including memory of past climate events, moon calendar and local indicator of ecological condition, this traditional early warning system has probably collapsed with increasing "aid addiction" and the implementation of technological innovation to "grow water" in the desert. From an ethnographic survey done in 2011, the presentation will explore how the lost of local knowledge regarding climate, land and water resource reshape resilient capacities of socio-ecological system. From this situation of environmental acculturation, we expect to discuss how predictive model of climate and more widely the African Union "Policy framework for pastoralism in Africa" may help to build common responses to future climate change.

Adopting landscape approach in enhancing resource governance, adaptation and resilience in arid and semi-arid lands of Kenya

Y. Salah (1)
(1) IUCN, People and landscape programme, Nairobi, Kenya

Efficient and balanced utilization of natural resources dispersed in spatial and temporal basis in vast landscapes of arid and semi-arid lands is the main survival strategy for pastoralist communities in Northern Kenya and horn of Africa for generations. Natural resource planning and management in pastoral communities is anchored on traditional regulations and institutions that facilitates mobility one of the cornerstone strategies that allows balanced use of the resource and survive harsh climatic conditions and stresses including drought. The traditional institutions plan and manage their resources in integrated manner at landscape level. External factors including formal government institutions and approaches have weakened these institutions and disrupted sustainable resource management hence making pastoral communities vulnerable to climate change.

Reviving and strengthening the landscape level approaches in resource management and governance that involve all the relevant stakeholders in participatory manner is paramount in facilitating resilience building and adaptation in pastoral areas of northern Kenya and horn of Africa. Towards entrenching and enhancing landscape level resource management and governance IUCN in collaboration with diverse stakeholders initiated natural resource governance projects in northern Kenya. This paper highlights the outcomes of the initiatives, opportunities and challenges that exist in adopting landscape level natural resource management interventions under the devolved system of governance in Kenya to enhance resilience and adaptation to climate change.

Integrated natural resource management anchored on participatory planning and management hold enormous potential in overcoming drought and climate extremes in pastoral areas of northern Kenya. One of the key approaches implemented to facilitate integration is adapted sub-catchment management planning approach. The approach is based on integration of the rangeland management and sub-catchment management plans to best serve the need of the pastoral communities. Landscape level planning and management was enhanced through this approach by bridging the gap between the formal and traditional resource management institutions that derive legitimacy from the national policies and local level governance structures. The formation of hybrid institution tasked with multiple resource planning and management operations were strengthened through formulation of integrated natural resource management bylaws anchored on traditional systems of resource planning and management which is formalized by county government through the devolved functions hence creating ownership and local control over resources. The bylaws formulation is informed by participatory resource mapping exercise which jointly facilitates tenure rights for resources at landscape level. The devolution process also offers inter-county collaboration on resource use and coordination which is critical aspect in implementation of landscape level interventions.

The key challenges in effective implementation of landscape level interventions in the northern Kenya are mainly related to low understanding of the value of the landscape approach in resources management which is intertwined with less appreciation of the pastoral livelihood among some government official. Although there are some challenges there are policies and laws that promote landscape approach at national level and opportunity exists for formulation of the further policies and laws at the County level.

The Rusizi plain,an area proneto the challenges of climate change and subject to political contraints

A. Cazenave- Piarrot (1) ; C. Thibon (2) ; G. Joseph (3) ; G. Rwanyiziri (4) ; S. Ndayirukiye (5)
(1) Université de Pau et des pays de l'Adour, Géographie, Pau, France; (2) Université de Pau et pays de l'Adour, Histoire, Pau, France; (3) Kigali Institute of Education, Histoire, Kigali, Rwanda; (4) National University of Rwanda, Sciences-géographie, Butare, Rwanda; (5) UNIVERSITE DU BURUNDI, GEOGRAPHIE, BUJUMBURA, France

Statement of the problem: Is it possible to have a political ecology in a natural and human environment which is both subject to the global change and geopolitical tensions?

1. The starting point: The alarm was raised by the increase of natural physical challenges: frequent floods, erosion, fragile biodiversity, soil degradation, epidemics, etc. which reveal a serious ecological crisis which, nonetheless, is not the first one in the region.

- This crisis goes back into the past from the demographic pressure on the environment and its resources. It takes various aspects: settlement front in the plain, rapid urbanization, overpopulation, degradation of watersheds which undermine, beyond hill level, the upper slopes and the forests.

-This gap has been maintained by political instability over the last 30 years of civil wars accompanied by forced migrations, depopulation of one area and resettlement in another, the intensification of land disputes between herdsmen and farmers, which have been exacerbated by contrasting political styles of governance in different countries and, even more, by the effects of climate change (rainfalls, intensity of natural disasters-this needs to be better identified).

2. Short and mid-term projections :In the mid-term, the projections confirm this pattern and even exaggerate it: the Rusizi plain is a breathing space for the Great Lakes population, due to area development and agriculture projects. It is becoming an attractive economic frontier due to emerging economies, asymmetric national economies and their new sources of revenue (trade, tourism, etc.), an area for farming activities (rice- growing and processing project and cattle farms, etc.), an area with high demographic growth, both natural and due to migrations (refugee resettlement, long-term settlement in camps).

-Demographic policies, initiated in the three countries, although in an unequal manner, have had little or no effect in the short and mid-term, due to the inertia of the population movement.

-In addition to the above, you also have political, geopolitical, sub regional and bilateral challenges amid instability in some sub-regions of the Rusizi , conflicts between asymmetric political systems (strong/weak/failed state: Rwandan, Burundian and Congolese), fueled by outbreaks of rebellionin connection with the politicsin the three countries, and to which could be added territorial disputes. This situation does not help nascent public policies.

3. The way forward:In response to these challenges, sectoral approaches as well as technical-economic processes are possible, but they lack a comprehensive political framework. The best known are conservation policies for threatened areas (niches, protected areas, parks and nature reserves) ...., with local/ zonal public policies, with technical solutions for each type of soil (land use plan and landscape map). The aim is a sustainable agricultural and agro pastoral development, with a view to improving the population's living conditions. These require comprehensive policies that would lead to regional and international planning (diagram), with harmonized sectoralpolicies and investments (water, energy, town, mines agriculture, tourism).

- Everything will depend on the role of the states, the international and regional community, the provincial and municipal authorities and their cross-border cooperation, the national and international civil society, the means invested in such a scheme, focusing on the public good across the borders and in the region, with a view of creating 'peace lands'; hence, the relevance of a political ecology.

0-3329-06

Adapting to Climate- Bringing Back Traditional Grains to the Dinner table

J. Gatune (1) ; D. Cohen, (2)
(1) African Centre for Economic Transformation (ACET), Research, Accra, Ghana; (2) Pardee RAND Graduates School, Santa Monica, United States of America

Climate change will have significant impact on crops yields. Adaptation to climate change will necessarily call for shifts in diets. This will require diversifying diets to reduce the risk for failure of one crop and shifting diets towards more draught resistant crops. In the Eastern part of Africa huge reliance on maize already make the regional vulnerable to famine as maize is a sensitive to shortage of water at critical period of growth. This vulnerability is going to be significantly magnified in the wake of climate change that will see reduction in precipitation and also increase in uncertainty on the timing of the rains.

The region can thus benefit greatly from shift towards diets that use traditional grains of millet and sorghum that are more resistant to draught and more suited to the region's agro-ecological conditions and importantly more nutritious than maize rice and wheat (the other grains whose consumption is growing fast). However the traditional grains have over the years lost their place in the dinner table, first to maize following introduction by the Portugese and more recently to wheat and rice. The loss to maize can be explained largely by resistance of maize to quelea birds attack and the rise of wheat and rice (which are largely imported) can be largely explained by ease of cooking and convenience offered by these garins, qualities which are important in urban areas where time is limited. The consumption by the more affluent urban dwellers has also conferred to wheat and rice a positive image of food of the successful. Conversely growing and consumption of millet and sorghum has remained confined to the poor and marginal and therefore poor areas, where they are really the only grains that can grow due to their hardiness, and the consequence is that the grain are now seen as the food for the poor an image that has made them very uncompetitive. They have been neglected by research and also food systems and as a results yields remain very low and farming system largely subsistence. The value chains remain highly fragmented with very low level of product development a factors that has further disadvantaged them in emerging dynamic urban food markets that call for convenience, good packaging and product variety.

Bringing the traditional grains back to the dinner table will therefore be problematic as it will require the upgrading of the value chains to meet the demands of modern food system. RAND and ACET are conducting an intervention to increase consumption of traditional grains. The intervention includes a millet and sorghum cooking competition by top chef to demonstrate the many ways millet can be used to cook nutritious foods and develop a millet and sorghum recipes book as an output of the competition. We are also working with food manufacturers and together with a supermarket chain to use the recipes to develop high value health millet and sorghum products under the supermarket brand. This intervention aims to position traditional grains as healthy foods and catalyse the development of healthy branded premium sorghum and millet products target at the emerging middle class while at the same time building a strong supply chain that can link small holder farmers to markets to processors and to the emerging regional supermarket chains.

The short term objective is to improve the image of the traditional grain by targeting high income consumers whose consumption is an important signal in conferring a positive image. The intervention will also support processors and farmers to tackle the pressing challenges including the quelea bird and mechanization for farmers and the upgrading of equipment and knowhow on product development for SME food processors.

In the medium term the objective is to increase general demand by leverage the improved image and upgraded value chains to target the low income urban poor with low cost and nutritious ready-To-Eat (RTE) sorghum and millet products.

The overall impact will be greater resilience through increase diversity in diets and also increased consumption of draught resistant grains. Nutrition will also be improved due to increased consumption of more nutritious food products and poverty as millets and sorghum replace imported rice and wheat products.

Geothermal Development in Kenya, a Climate resilient strategy?

C. Adongo (1) ; B. Hazard (2)
(1) EHESS, Anthropology, Paris, France; (2) Institut Interdisciplinaire d'anthropologie du contemporain, Institut National des Sciences Humaines et Sociales - CNRS, Paris, France

Due to high vulnerability and lower adaptive capacity, Africa is predicted to contend with greater impacts resulting from climate change. This could potentially hamper past and future developments. 83% of Kenya, for example, consists of Arid and Semi Arid land inhabited by populations which are highly vulnerable. Moreover, there is indication that ASALs are increasing, one consequence of deforestation and climate change. According to the Stockholm Environment Institute (2009), major droughts occuring in 1998-2000, 2004/2005 and 2009 resulted in economic losses worth approximately $2.8 billion from water and energy deprivation. Declined water levels in dams for hydroelectric power production also caused widespread electric power rationing. In accordance with the Kyoto protocol, calling for countries to commit to decreasing green house gases, and the World Summit on sustainable Development (WSSD) specifically requiring countries to commit to producing 10% of their energy from renewables, the National climate Change Response strategy of 2010 aserts; that following a low carbon development path will result in significant economic and huge environmental and social benefits. The focus is to zero rate taxes on renewable energy technologies and promote alternative renewable energy such as solar, bio fuels, wind and geothermal. Currently, the government is focusing on electricity production from geothermal sources, most of which lie within the central rift valley. Here, geothermal development can be considered a climate change mitigation measure as well as an adaptation mechanism. Firstly, with completion of the targetted 5300MW by 2030, the geothermal power production is projected to save 906008 tones of CO2 /year and further reduce significantly, use of fossil fuels in electricity production. Secondly, Hydropower, on which Kenya depends for most of her electricity, is dependent upon climatic conditions and therefore highly vulnerable in the face of climate change. Thirdly, close to 80% or rural households and small businesses depend on biomass energy. Affordable electricity from alternative source - geothermal, seen as the most cost effective means of power production, could mean decreased dependence on biomass and subsequent deforestation. Fourthly, Non-annex 1 countries like Kenya; in undertaking mitigation projects can gain from 'carbon markets', which allows for trading in Certified emission Reduction (CER) credits. This contribution will explore the adoption and implementation of the geothermal industry in Kenya as a significant pathway to climate resilience.

P-3329-02

Nubians as Egyptian Indigenous people and Climate Change Mitigation

EHM. Ahmed (1)
(1) Lead Author, WG III, IPCC, climate change and sustainable development, Cairo, Egypt

Egypt and Sudan are the most populous countries in Africa and the Middle East. Nile River is considered as a very important artery that joins Sudan and Egypt. Nile was an important part of ancient Egyptian spiritual life.

Nubian peoples are an ethnic group; they considered as one of the most ancient people all over the world, their civilization started more than 8.000 years ago. Lake Nasser is the second largest man-made lake in the world; among the impacts that were anticipated were the resettlement of the Nubian population in the area inundated by the reservoir, saving of historic monuments, health impacts and coastal erosion.

The climate models all estimate a steady increase in temperatures for Egypt, with little intermeddle variance. Somewhat more warming is estimated for summer than for winter.

However, since Egypt is mainly a desert and relies primarily on irrigated agriculture, precipitation over the country itself matters very little. Much more important are precipitation changes at the water sources of the Nile, which affect the vulnerability of water resources.

The potential impacts of climate change on coastal resources are ranked as most serious. Climate change induced sea level rise only reinforces this trend. In addition to this high biophysical exposure to the risk of sea level rise, Egypt's social sensitivity to sea level rise is particularly high.

In general, although the models on average show an increase in precipitation, inter-model variation is so high that it is uncertain as to predict whether annual average precipitation will increase or decrease.

A meta-analysis of long-term land management effect on Soil Organic Carbon (SOC) in Ethiopia

AS. Dakka (1)
(1) University of Bern (UB) and USAID/Ethiopia, Science faculty (ub) asset and livelihood in transition office (usaid), Addis Ababa, Ethiopia

The role of Soil Organic Carbon (SOC) in mitigating climate change, indicating soil quality and ecosystem function has created research interested to know the nature of SOC at landscape level. The objective of this study was to examine variation and distribution of SOC in a long-term land management at a watershed and plot level.

This study was based on meta-analysis of three case studies and 128 surface SOC data from Ethiopia. Three sites (Gununo, Anjeni and Maybar) were compared after considering two land management categories (LMC) and three types of land uses (LUT) in quasi-experiment design.

Shapiro-Wilk tests showed non-normal distribution ($p=0.002$, $\alpha=0.05$) of the data. SOC median value showed the effect of long-term land management with values of 2.29 and 2.38 (g/kg) for less and better-managed watersheds respectively. SOC values were 1.7, 2.8 and 2.6 (g/kg) for Crop (CLU), Grass (GLU) and Forest Land Use (FLU) respectively. The rank order for SOC variability was FLU>GLU>CLU. Mann-Whitney U and Kruskal-Wallis test showed a significant difference in the medians and distribution of SOC among the LUT, between soil profiles ($p<0.05$, confidence interval 95%, $\alpha=0.05$) while it is not significant ($p>0.05$) for LMC. The mean and sum rank of Mann Whitney U and Kruskal Wallis test also showed the difference at watershed and plot level. Using SOC as a predictor, cross-validated correct classification with discriminant analysis showed 46% and 49% for LUT and LMC respectively. The study showed how to categorize landscapes using SOC with respect to land management for decision-makers.

Reconstructing 200 years of human-induced soil erosion in the Lake Baringo catchment (Kenya) based on sedimentology and geochemistry of lake sediments

A. Degefa (1) ; I. Bessems (1) ; R. Tjallingii (2) ; B. Cumming (3) ; D. Verschuren (1)
(1) Ghent University, Biology, Limnology Unit, Gent, Belgium; (2) German Research Centre for Geosciences (GFZ), Climate dynamics and landscape evolution, Potsdam, Germany; (3) Quen's University, Biology, Ontario, Canada

Summary. Land degradation due to loss of vegetation and fertile soils by strong erosion during the rainy season is one of the major environmental problems affecting the Lake Baringo catchment in Kenya's central Rift Valley. In this study we used magnetic susceptibility, X-ray fluorescence (XRF), and grain-size measurements on sediment cores from Lake Baringo to trace the variable influence of human activity on catchment soil erosion through time. The three studied sediment sequences, recovered from different offshore locations, display a similar stratigraphy of fine-grained and low-organic lacustrine clays deposited above stiff clays representing a desiccation horizon dated to the late 18th - early 19th century.

High-resolution magnetic susceptibility and XRF data reveal a cyclic pattern of peak values with apparently annual periodicity, particularly in sediments dated to the early to mid-20th century. It is interpreted as alternating seasonal spikes of sediment influx from rivers and direct run-off, linked to increased population and livestock pressure. Results of grain-size analysis indicate that the very fine-grained clay sediments dominating this particular zone are derived from old lacustrine sediments, originally deposited in offshore areas of the early Holocene 'mega-lake' Baringo, but which is now part of the gently-sloping Rift Valley plains surrounding the lake today. Sediment thickness above the desiccation horizon increases towards the southern end of the lake, due to high sediment influx from the Perkerra and Molo Rivers, which drain the largest catchment area. Lead-210 dating of these 200-year sequences shows that variation in the rate of sediment accumulation is strongly influenced by historical lake-level fluctuations, with accumulation maxima occurring during lowstands due to sediment being concentrated into smaller area of accumulation.

Understanding the Vulnerability to Climate Change Effects in East Africa. Case Study of Rice Farmers in Bugesera District, Rwanda

G. Rwanyiziri (1)
(1) University of Rwanda, Centre for geographical information systems and remote sensing (cgis), Huye, Rwanda

Located in the Eastern region of Africa, Rwanda has been faced with unusual irregularities in climate patterns including extreme temperatures, variability in rainfall frequencies and intensity over the last 30 years. In fact, the analysis of rainfall shows that, since 1992, Rwanda has been characterized by a declining trend with a remarkable variability in rainfall frequencies and intensity which resulted into serious floods in 1997-1998 and a prolonged drought in 1999-2000. This study has been conducted in Bugesera District to reveal the effects of climate change on rice farmers. According to the results, the rise in temperature and changes in the amount of rainfall and its distribution have altered the availability of water resources, consequently affecting the productivity of rice. The variability in the onset of the rainy season has led to variation in the start of the planting season which has negatively affected the production of rice. Assessment of people's perceptions on ongoing change on rainfall and temperature patterns, and their adaptation strategies has been made. The respondents accept that there is a change happening in their area and have already started to feel its impacts. The study revealed that yields of rice have been distorted by changes in precipitation, temperature, as well as soil moisture. Flooding in lower zones of altitude along river Akanyaru have been reported for many times in the study area as causing the submergence of rice fields thereby damaging the growth and reducing the productivity of rice. In adaptation to climatic change effects, rice farmers have started to take on some adaptation measures. These measures include constructing water reservoir to collect water for irrigation use in the dry season, switching to new varieties of rice that resist to drought and flooding, and application of pesticides to combat with pests.

Observatories, a Key Tool to Tackle Climate Changes in Tropical Regions

T. Lebel (1) ; C. Peugeot (2) ; M. Grippa (3) ; S. Galle (1)
(1) IRD, LTHE, 38041 Grenoble Cedex, France; (2) IRD, Hydrosciences montpellier (hsm), Montpellier, France; (3) Université de Toulouse, Get, Toulouse, France

For both physical and socio-economic reasons, tropical regions are highly sensitive to the impacts of climate change. At the same time, the model projections are more uncertain than for many other regions of the world, especially regarding the hydrologic cycle that is the key driver for water resources, agriculture and food security. The various components of the continental water balance display a strong variability over a large range of space and time scales that are not properly documented by the operational meteorological and hydrological networks. This natural variability of the water cycle challenges our ability to detect significant trends potentially linked to the global warming and/or other factors, such as land use changes or ecosystem evolutions. While detecting changes in the annual mean of precipitation, runoff or deep infiltration is not always self-evident, it is still much more challenging to assess significant changes in the extreme values, because the less frequent are the phenomena to observe, the longer should be the period of observations to detect a statistically significant non stationarity. This set of issues applies in much the same way to other key components of our environment, such as for instance, erosion, dust transportation, soil resources.

Adequate observing systems allowing the documentation of both the climate evolution at regional scale and its impacts on the air quality, radiative budgets, hydrology and vegetation are thus a key tool for a fine characterization of climate change and for providing decision makers with the appropriate knowledge to be used for implementing and following ambitious public policies in order to mitigate its socio-environmental consequences. In the long run, observing systems are also crucial for improving climate models, especially when it comes to the simulation of variables -such as rainfall, river flows, dust transportation - that display the largest interannual variability.

This will be illustrated through the history and achievements of the AMMA-CACTH and other observing systems (IDAF, PHOTONS, Dust-Transect, GPS) providing the ground to debate the need for consolidating a collaborative strategy for tropical climate change observations and to discuss how to reinforce the science/policy interfaces in this area.

Climate Change Projections in the Sahel. The what and the why

M. Biasutti (1)
(1) Columbia University, Lamont Doherty Earth Observatory, Palisades, NY, United States of America

This talk will review the projected 21st century changes in temperature and precipitation at seasonal and sub seasonal scale in Subsaharan Africa, with particular emphasis on the Sahel and the West African Monsoon region.

Greenhouse-gas induced temperature increases are large compared to interannual variability and such forced seasonal temperature anomalies are decoupled from the occurrence of drought or pluvials; this results in a robust projection of unprecedented seasonal temperatures by mid-century.

Precipitation anomalies remain more uncertain. In the Sahel, although outlier models remain, the ensemble anomalies indicate lesser precipitation totals in the west and greater in the east, and a change in seasonality that is manifest in a delay in the beginning, peak, or demise of the rainy season.

Additionally, we present the projected changes in the characteristics of rainfall and in the occurrence of extreme events and we evaluate the robustness of such anomalies with respect to model uncertainty, natural variability, and the use of statistical downscaling to debias daily rainfall and temperature.

Finally, we interpret seasonal rainfall anomalies in terms of thermodynamic and dynamic forcings and in terms of regional and global modes of change. We emphasize the role of the large-scale circulation and the forcing from both the tropical and the midlatitude sea surface temperature anomalies.

External forcing and Sahelian African climate anomalies - A study from the WAMME project

Y. Xue (1) ; W. Lau, (2) ; A. Boone, (3) ; SI. Seidou (4) ; W. Thiaw (5) ; L. Druyan, (6) ; D. Rowell (7)
(1) Professor, UCLA, Dept. of geography & dept. of atmospheric and oceanic sciences, Los Angeles, United States of America; (2) 2. University of Maryland, College Park, College Park, United States of America; (3) CNRM, Toulouse, France; (4) Centre Régional AGRHYMET/CILSS, Niamy, Niger, Republic of; (5) 5. National Centers for Environmental Prediction, NOAA, College Park, United States of America; (6) Goddard Institute for Space Studies/NASA and Columbia University, New York City, United States of America; (7) Met Office Hadley Centre, Exeter, United Kingdom

The Sub-Sahara Africa is a diverse climatic and economically fragile region and dramatic change over the Sahelian Africa from wet conditions in the 1950s to much drier conditions in the 1970s-1980s and then to partial recovery from the 1990s represents one of the strongest interdecadal climate variability and the longest drought on the planet in the twentieth century. A significant climate feature in the Sahelian Africa is the West African monsoon (WAM), which variability dominants the climate variability there. However, the CMIP5 coupled models underestimate the WAM decadal variability and the drought. Although encouraging progresses have been achieved, many systematic and robust biases of the coupled and atmospheric models have not improved from CMIP3 to CMIP5. It is necessary to have comprehensive understanding on the past Sub-Sahara decadal variability and predictability to provide reliable assessment of future climate change and adequate strategy for mitigation and adaptation under changing climate.

In past several decades, the West African climate community has recognized the importance of external forcings: oceans, land processes including land cover and land use change (LULCC), aerosols, and greenhouse gases, on WAM variability, especially their roles in the Sahel drought. However, most of these studies only focused on one external forcing with one single model. The West African Monsoon Modeling and Evaluation (WAMME) is a project comprised of both general circulation models (GCMs) and regional climate models (RCMs) with the objective to collectively provide best estimation of the relative importance of all those external forcing on WAM at seasonal to multi-decadal time scales. WAMME research activities are closely coordinated with those of AMMA, involving many African institutions. The observational and other relevant datasets acquired from AMMA provide important benchmark for assessing the role of external forcing in regional climate variability and anomalies.

In this paper, we mainly present the latest results from the WAMME-2, which is designed to test how seasonal and decadal variabilities of WAM precipitation are associated with external forcings, and assess their relative contributions in producing/amplifying the WAM seasonal and decadal climate variability. The sensitivity of the WAM variability to those external forcings is also examined. The WAMME-2 strategy is to apply observational data-based anomaly forcing of SST, land surface and aerosols, i.e., «idealized but realistic» forcing, in GCM and RCM simulations with the specific purpose of estimating the relative impacts of each forcing and feedback mechanisms.

In the SST experiment, in addition to the global SST effect, each ocean's role is also evaluated. The preliminary results from most GCMs consistently indicate that SST has a maximum impact on the WAM decadal variability compared with other forcings, and that the effect of the Pacific Ocean is most dominant. The models, however, differ in producing other oceans' contribution. Moreover, the models with specified maximum SST anomaly forcing are still unable to produce full Sahel drought (only slightly above 50% of the full drought). In the LULCC experiment, a newly available land use change map is applied. A consistent change in the vegetation maps is imposed for each modeling group. The simulated LULCC impact is also substantial, compatible to but less than the SST forcing (about 40% of the drought). In the dust experiment, the direct impact of dust on the radiation budget and its influence to the Sahel rainfall are evaluated using the GOCART dust data and its effect also contributes to the drought (less than 20% of the drought). In addition, some preliminary results for impact of the greenhouse and global warming on the Sub-Sahara climate decadal variability will also be presented.

WAMME is the first attempt to use multi-GCMs and RCMs to collectively explore the roles of multiple external forcing in WAM variability. WAMME2's achievement provide better understanding of relative importance of various forcing and possible feedback mechanisms, complementary to experiments under CMIP, which are focused more on impacts of emission scenarios, and CORDEX, which is focus on RCM downscaling ability. The results from WAMME should provide useful information to analyze and understand the CMIP results for future climate change and help design impacts scenarios and plan adaptation options.

O-3330a-01

Projected Climate Conditions over West Africa for the End of the 21st Century: Impact on Extreme Precipitation Events

MB. Sylla (1) ; D. Wisser (2) ; N. Elguindi (3) ; F. Giorgi (3)
(1) WASCAL Competence Center, Climate Modeling and Climate Change, Ouagadougou, Burkina Faso; (2) University of Bonn, Center for development research (zef), Bonn, Germany; (3) Abdus Salam International Centre for Theoretical Physics (ICTP), Earth system physics (esp) section, Trieste, Italy

Global warming resulting from increased anthropogenic greenhouse gas (GHG) forcing will substantially alter West African regional climate conditions. 21st century projections from both Global Climate Models (GCMs) and Regional Climate Models (RCMs) indicate lower warming along the Gulf of Guinea and orographic zones and greater warming in the Sahel and the Sahara desert. In addition, mean precipitation changes and trends exhibit more complex, seasonally varying spatial patterns from the Gulf of Guinea to the Sahel and from the orographic areas to the flatter regions.

Investigating how these combined temperature and precipitation changes will affect the climate of West Africa requires a multivariate approach. Climate classifications integrate the influence of energy and moisture in order to define the climate of a region, and are thus well-suited tools for this purpose. As climate is the major influence on biological life, such classification is critical for the region, particularly at the time during which the loss of major ecosystems and croplands is a fact. Information on projected climate types over West Africa can thus enable the impact community to develop mitigation strategies and adaptation measures for the most vulnerable areas.

In this context, recent studies identified also substantial increases of very high monthly precipitation and an amplification of daily precipitation extremes by the end of the 21st Century. These increases in extremes are considerably spatially variable over West Africa and mostly driven by an intensification of the local hydrological cycle. However, key sectors and activities in West Africa may be more vulnerable to the seasonal timing of the occurrence of extremes than its yearly average. Estimating and understanding such seasonal and sub-seasonal changes is important for the formulation of adaptation and mitigation strategies. For example if an increase in high intensity rainfall events is concurrent to the peak of the rainy season, this may result in widespread flooding requiring strong responses. As another example, in the case of pre-monsoon high intensity rainfall events, early deployment of flood control measures may be required.

In this study, the revised Thornthwaite climate classification is employed to investigate the shift of West African climatic zones in response to future anthropogenic climate change under two Representative Concentration Pathways (RCP4.5 and RCP8.5) from multiple data sources: ensembles of GCMs from CMIP5, RCM projections from CORDEX and higher-resolution RegCM4 simulations over West Africa. The use of multiple ensembles enables us to assess the robustness of the response, and in particular the extent to which the higher resolution experiments offer added regional details. In addition, the study also examines how such a shift impacts on the timing of extreme events. In particular, we focus on the response to increasing GHG concentrations of the annual cycle of high intensity precipitation events, specifically during the pre-monsoon (April-June), mature monsoon (July-September)

and post-monsoon (October-December) seasons. This task is carried out through the analysis of a series of standard indices of precipitation extremes applied to the daily precipitation projections.

The results reveal that West Africa evolves towards increasingly arid and semi-arid regimes with the recession of moist and wet zones, thus adding another element of vulnerability to future anthropogenic climate change for the ecosystems and agricultural lands in the regions.

In addition, analysis of the changes in the annual of high intensity precipitation events indicate that the pre-monsoon season experiences the largest changes in daily precipitation statistics. These changes are particularly towards an increased risk of drought associated to a decrease in mean precipitation and frequency of wet days, and increased risk of flood associated with very wet events. Both these features can produce significant stresses on important sectors such as agriculture and water resources at a time of the year (e.g. the monsoon onset period) where such stresses can have stronger impacts.

O-3330a-02

Trends in West African floods: A comparative analysis with physiographic indices

NN. Bernadette (1) ; H. Karambiri (2) ; O. Ludovic (3) ; P. Ribstein (4) ; JE. Paturel (5)
(1) International Institute of Water and Environment Engineering, Kadiogo, Ouagadougou, Burkina Faso; (2) 2IE, Ouagadougou, Burkina Faso; (3) UPMC, Metis, Paris, France; (4) Université Pierre et Marie Curie, Laboratoire sisyphe, Paris, France; (5) IRD, HydroSciences Montpellier, Abdijan, Ivory Coast

After the drought of the years 1970 In West Africa, the variability of rainfall and land use changes affected mostly flow, and recently, flooding is said to be an increasingly common occurrence throughout the whole of West Africa. These changes aroused many questions about the impact of climate change on the flood regimes in west african countries.

This paper investigates whether floods are becoming more frequent or more severe, and to what extend climate patterns have been responsible of these changes. We analyze the trends in floods of 14 catchments within the main climate zone of West Africa. The methodology includes two types of sampling flood events, namely the AM (Annual maximum) method and the POT (Peak over threshold), and two perspectives of analysis are presented, precisely long term analysis based on two long time series of flood, and regional perspective involving 14 catchments with shorter length of series.

Mann Kendall trend test and Pettitt break test are used to assess the stationarity of the time series. The trends detected in flood time series are compared to the trends of rainfall indices in one hand and vegetation indices in the second hand using contingency tables, in order to identify the main driver of change in flood magnitude and Flood frequency. The dependency between flood index and physiographic index is evaluated through a Success Criterion and the CramerV criterion calculated from the contengecy tables.

The results point out the existence of trends in flood magnitude and flood frequency time series with two main patterns. sahelian flood show increasing trends, and some sudanian catchments present decreasing trends. for the overall studied catchments, the maximum five consecutive days rainfall index (Rx5d) seems to follow the trend of floods, while NDVI indices do not show significant link between with the trends of floods, meaning that this index has no impact in the behaviour of flood in the region.

O-3330a-03

Evolution of surface temperature and heat waves over West Africa during the near and the far future

M. Camara (1) ; AB. Sarr (2) ; I. Diba (3) ; A. Diedhiou (4)
(1) Laboratoire d'océanographie, des sciences de l'environnement et du climat (LOSEC), Université de Ziguinchor, Ziguinchor, Senegal; (2) Laboratoire d'océanographie, des sciences de l'environnement et du climat (LOSEC), Université assane seck de ziguinchor, Ziguinchor, Senegal; (3) Laboratoire d'océanographie, des sciences de l'environnement et du climat (LOSEC), Uiversité de ziguinchor, Ziguinchor, Senegal; (4) Institute of Research for Development (IRD), LTHE - University Grenoble Alpes, Grenoble Cedex 9, France

The aim of this work is to study the spatio-temporal variability of the future evolution of surface temperature and heat waves over West Africa using regional climate models outputs engaged in COordinated Regional climate Downscaling EXperiment (CORDEX) project. CORDEX is an international project implemented by many research centers worldwide which aims to supply reliable climate change scenarios to the scientific community. These simulations are perfomed with the latest state of the art regional climate models over most emerged lands of the planet for environmental impact studies and also to characterize the associated uncertainties. The data analyzed within the framework of this work are the climate change projections performed with the latest greenhouse gaz emission scenarios: RCP4.5 and RCP8.5.

This work focuses on the near (2020-2050) and the far (2070-2100) future and analyzes the spatio-temporal variability of the surface temperature and heat waves episodes over West Africa; these heat waves remain under studied over this region despite their negative impacts on the populations and their socio-economic activities.

Assessing climate impacts and adaptation options for cereal systems in West Africa

D. Lobell (1) ; K. Guan (1) ; M. Biasutti (2) ; C. Baron (3) ; S. Benjamin (4)
(1) Stanford University, Department of environmental earth system science, Stanford, United States of America; (2) Columbia University , Lamont-doherty earth observatory, New York, United States of America; (3) CIRAD, Montpellier, France; (4) 40 rue Joseph Gaillard, Vincennes, France

Much has been learned in recent years about the nature of climate changes in the West African region, including robust projections of delayed monsoon onset and, in many locations, increased late-season rainfall. This talk will examine the implications of these changes for crop adaptation strategies. Two process-based crop models (APSIM and SARRAH-H) are used to explore climate change impacts under various management and cultivar scenarios for sorghum, the main crop in the region. Potential adaptation strategies we test include more conservative sowing rules (to reduce risks of early-season drought stress and crop failure), a switch to longer-season varieties (to avoid shortening of the growth period), increased fertilizer rates and planting density (to take advantage of increased late-season rainfall), switching from photo-sensitive to photo-insensitive varieties, and rainwater harvesting to provide supplemental irrigation. The results are analyzed in terms of effects on both average and variability of yields, with the goal being to identify strategies that will very likely reduce negative impacts of climate trends on average and/or variability of yields, while not sacrificing performance in the current climate. Such strategies could then be promoted as adaptation priorities in the region.

The challenge of water resource management in the Lake Victoria basin, East Africa

H. Houghton-Carr (1) ; M. Fry (2)
(1) Centre for Ecology & Hydrology (CEH), Water Resources, Wallingford, United Kingdom; (2) Centre for Ecology & Hydrology (CEH), Water information management, Wallingford, United Kingdom

The Lake Victoria basin, in the headwaters of the Nile in East Africa, is home to over 30M people. As the population continues to increase, demands for water for irrigation, hydropower, and domestic and industrial supply are growing rapidly. The significant drop in Lake Victoria water levels, beginning in 2000 and reaching the lowest recorded level since the 1940s six years later, inconvenienced those who depend on the lake for their livelihoods and generated not just a regional, but a global, debate. A number of conflicting narratives regarding the cause of the decline were advanced by the scientific community, the regional press and the citizens of the five riparian countries, namely Burundi, Kenya, Rwanda, Tanzania and Uganda.

Lake levels are a primarily a function of regional climate and resultant lake rainfall and evaporation; the impact of water releases for hydropower and other abstractions within the basin is still relatively minor. The Lake Victoria region is characterised by high intra- and inter-annual climatic variability, the consequence of which is significant uncertainty in future rainfall on, and inflows to, the lake. Long good quality hydrometeorological time series records have always been considered important for the assessment and management of water resources. However, many countries in sub-Saharan Africa, and elsewhere, have experienced a marked decline in hydrometeorological data collection and management in recent years.

An increasing need is emerging for long-term datasets to understand how national and basin-scale hydrological regimes are responding to climatic variations and anthropogenic influences. Predicting future water availability, for effective water resource planning under climate change and population growth, requires well-founded predictions of regional climate, hydrology and societal demands across the basin. Whilst climate and hydrological models can inform about expected impacts of change, validation of these models requires real data. In an interesting paradox which illustrates the current lack of capacity to predict the impacts of climate variability and change on water resources, the East African long rains are observed to be decreasing, whilst climate models predict an increase.

Initiatives to improve understanding of the climate and hydrology of the lake basin are welcomed e.g. GEWEX HyVic regional hydroclimate project, DFID-NERC FCFA (Future Climate for Africa) programme, and WMO data rescue activities which aim to identify and preserve records that capture natural variability.

K-3330b-03

Using climate information to build resilience agriculture for farmers in Kaffrine district in senegal

O. Ndiaye (1) ; M. Seck, (2) ; D. Ndiaye, (1) ; R. Zougmore (3)
(1) ANACIM, research and development, dakar, Senegal; (2) SDDR, Agriculture, Kaffrine, Senegal; (3) CCAFS, Bamako, Mali

Senegal, at the image of many sahelian countries, is one of the most affected area by climate variability. Climate is varying at decadal, inter-annual and sub-seasonal time scales. So population living in such environment are affected by climate shocks in their livelihood.

Funded by the CCAFS initiative there is a 5 years going on project with farmers demonstrating how to use climate information to help farmers in their decision making. This initiative is a pluri-disciplinary and multi-scale processes. In the course of this project many lessons were learnt and many good successful actions that lead to improve farmers decision system.

Downscaled climate and weather is produced for the district of Kaffrine. This information is then provided to a local pluri-disciplinary working group (GTP) which interpret it into actionable decision. In this GTP sit representative of farmer's organization, local decision makers, boundary organization and local department extensions working on agricultural related issues (agriculture, crop protection, forestry, water, seed producers, ...). Then the advices coming out of the GTP is broadcasted through rural radio, bulletin, text messaging as well as during social gathering (naming ceremony, funeral, ...). In this process indigenous knowledge is also used beside state of arts climate forecasting. During all the crop cycle, each ten days period, information is provided to farmers to help them to make the best decision. These decisions include choice of the planting dates, avoiding false start, applying fertilizer, removing the herb, harvesting and storage. In this project all initiatives are discussed with farmers representatives and evaluated after the cropping cycle.

A monitoring and evaluation study has shown that farmers in this project was able to cope with climate shock better than other farmers which lead to increase substantially their yields. Today this project in Kaffrine is owned by local government representative who calls and leads such meeting. Now the project is at its upscalling phase to other districts of Senegal using rural radio network. In the upscaling process community radio journalists are trained to understand climate information in order to disseminate such information at broader scale.

We will present lesson learnt and evidence in this project during these 5 years for a climate smart agriculture.

Yield Gap and the shares of climate and crop management in yield and yield variability of staple crops in West Africa

F. Affholder (1) ; B. Sultan (2) ; P. Kouakou (3) ; C. Poeydebat (4) ; B. Muller (5)
(1) CIRAD, UR AIDA, Montpellier, France; (2) IRD, Paris, France; (3) CIRAD, Bobo-Dioulasso, Burkina Faso; (4) CIRAD, Martinique, le Lamentin, France; (5) CIRAD, BIOS, Montpellier, France

« Yield gap » (Yg) is a key concept of agricultural science for identifying the room for improvement of yields through better management of the agroecosystem. In rainfed agriculture Yg is the difference between actual yield (Ya) and the theoretical water limited yield (Yw) that would be achieved if solar radiation, temperature and precipitations were the only factor limiting the crop's growth and yield. Changes in Yw over regions and years are due to climate-soil interactions that are not easily modified by crop management, whereas changes in Yg are due to limiting factors that are typically within the scope of crop management such as nutrient availability, weeds, and pests.

We provide an example of yield gap estimates in semi-arid Africa, using yield and other agronomic data collected in famers' fields of Senegal in 1990 and 1991 and from 2006 to 2012. It illustrates how contrarily to what most people would expect climate is not, on average, what most limits yields in that region: yet, actual yields are on average a quarter of water limited yield, and this is due to constraints whose reduction is technically possible albeit subject to the economic and environmental relevance of doing so.

Most studies dealing with the impact of climate change on agriculture in West Africa compare Yw under present and future climate as predicted by climate models. The magnitude of those predicted long term changes in Yw by 2050 is down to -20% in the worst scenario combining a +6°C change with a -20% rainfall change. Such changes in water limited yields are certainly concerning, but they are remarkably small compared to the potential +390% increase that would result from closing the current yield gap.

When considering yield variations observed across plots and years, and not anymore regional averages over a few years, what strikes is the stability of observed yields compared to variations of Yw. We used crop model simulations with historical series of 20 years of weather data to compare yield distributions over years of a crop grown using 3 contrasted levels of fertilisation and no incidence of weeds, pests or diseases. For each fertilisation level, the simulated yield reached a maximum value the 'best year' of the series. The three fertilisation levels were chosen so that the maximum simulated yield reached 0.25 Yw, 0.5 Yw, and 0.75 Yw respectively. The resulting simulated yield distributions show that even if management allows increasing the median yield, in many years the climate is the main limiting factor and fertilising has no or a slight impact only. In other words, the way the current climate limits crop production in this region is by making uncertain the output of investing for high yields. Buying fertilizers or working hard for manure collection, transport and distribution do not translate, a certain number of years, into more production. For farmers struggling for the daily subsistence of their family,

that kind of risk may not be justified while alternative use of family resources in cash and labour force provide less risky ways to produce subsistence means. Until recently, in many farming systems of West Africa, the growth in food needs due to population growth in rural areas was matched thanks to increases in cultivated or pasted areas rather than increases in crop yields or livestock pressure on land (i.e extension rather than intensification of crop or livestock activities). When rural families reached the limits of this strategy, migrations of many kinds of distance and duration became the adjustment variable to the gap between resources available from farming and population needs. This suggests that for many, it is less risky to leave home than to intensify cropping or livestock systems. Anyway, as job opportunities for migrants from the rural zones are currently low in West African cities and elsewhere, there are legitimate concerns about the way this strategy may soon reach its limit as well.

In terms of climate change, the worst scenario for farmers of that region would be if crop intensification became even more risky under future climate than at present. There is thus an urgent need for joint agronomic and climate research to go beyond the prediction of Yw or of yield under unchanged crop management and determine whether or not the future climate will increase the yield risks associated with crop intensification in that region. But this should not divert from designing and implementing policies incentive to such intensification under present climate, as this might be much easier now than later.

The re-greening Sahel: How green is green enough ?

C. Dardel (1) ; L. Kergoat (2) ; P. Hiernaux (2) ; M. Grippa (3) ; E. Mougin (2)

(1) LSCE/CESBIO, Toulouse, France; (2) GET, Umr cnrs 5563, Toulouse, France; (3) Université de Toulouse, Get, Toulouse, France

The Sahel region has long been the focus of a debate on its possible desertification, especially because of its sensitivity to climatic variations. This debate was fuelled following the extreme droughts that occurred and peaked in the mid 1970s and mid 1980s. Since the appearance of global and frequent satellite observations, a re-greening theory emerged in the 1990s, in total contradiction with a desertifying Sahel. This re-greening is simply defined as an increase in a vegetation index such as the Normalized Difference Vegetation Index (NDVI), widely used by the community as a proxy for aboveground Net Primary Production (ANPP).

The AVHRR instruments onboard the NOAA satellites provide daily NDVI data since 1981 at the global scale, and thus have been widely used for monitoring vegetation production over time. Their analysis regarding temporal trends over the Sahel since the 1980s clearly evidence the re-greening of the Sahelian belt. However, such data are subject to uncertainties, so that there is a real need for independent validation of this re-greening observed from space. However, this validation is very difficult to make since field measurements of vegetatio mass are scarce at a matching scale, especially in the Sahel, and especially over long time periods.

In the framework of an ILRI-ILCA project and afterwards thanks to the AMMA-CATCH observatory, we beneficiated from a long-term database of field measurements collected over the pastoral Gourma region in Mali (1984-2011) and over the agro-pastoral Fakara region in western Niger (1994-2011). These databases provide, among other variables, the aboveground herbaceous mass used at the end of the growing season as a proxy for ANPP. Data are available over a large number of sites covering the landscape heterogeneity.

The objective of this study was to evaluate the performance of NDVI products (especially the new GIMMS3g dataset) as compared with long-term field observations. Our analysis over the Gourma region showed that both datasets detected a strong re-greening over the 1984-2011 period, whereas a negative trend was found over the Fakara region in Niger. Moreover, we were able to show contrasted changes depending on the different soil types found in the Gourma: whereas the deep sandy soils show a clear recovery from the droughts, the trend is heterogeneous over the shallow soils with some sites showing a recovery and others not. The picture is also variable over the clayed soils usually located in small depressions. The negative trend found over the Fakara region could be attributed to changes in land use, since this region has experienced a large increase in agriculture since the 1950s. However, the landscape being fragmented and very dynamic, further studies have to be done to fully understand the changes observed in the vegetation cover.

In both cases, a very good agreement is found between remote sensing data and field observations, giving additional confidence to the satellite archive. The Sahelian re-greening observed over the past three decades therefore seems undisputable. However, this re-greening does not happen everywhere, and contrasted changes may have happened at a finer spatial scale, thus demanding caution in concluding about the resilience of the ecosystems. In any case, since the re-greening is mostly explained by a recovery in rainfall over the past decades, the future climatic conditions and especially the rainfall trend will have a tremendous impact on the evolution of the vegetation cover in the semi-arid Sahel. Of particular concern is the fate of areas already showing an absence of greening (eroded shallow soils, Fakara area for instance).

The probable impacts of climate change on malaria and Rift Valley fever in Africa

A. Morse (1) ; C. Caminade (1) ; A. Jones, (1) ; J. Leedale, (1) ; A. Tompkins, (2)

(1) University of Liverpool, Geography and Planning, Liverpool, United Kingdom; (2) ICTP, Trieste, Italy

Dynamical models of disease transmission between vectors and hosts and back to vectors have been developed for diseases including malaria and more recently Rift Valley fever. These models are driven by climatic and other environmental variables. This is a complex task, as the models require both accurate projections of the seasonally varying mean values of the climatic drivers and their correct variability across a range of time scales from days to multi-decades.

The relationship between finding parameter settings that represent the correct sensitivities to the climate drivers and the inherent spread of these drivers within an ensemble of climate models; develops the inherent uncertainties in the model outcomes. By using an ensemble of climate models then a signal to noise ratio can be used to display the outcomes of the model projections to decision makers.

Recent FP7 projects QWeCI in West and southern Africa and HEALTHY FUTURES in East Africa have run two dynamical malaria models, the Liverpool Malaria Model (LMM) and VECTRI (ICTP) across Africa with a range of bias corrected CMIP5 GCMs. Patterns of changes in malaria distribution in West Africa and East Africa have consistent signals seen into the future using climate model projections. The simulated malaria incidence is increasing over the tropical highlands and the uncertainties related to the disease models are generally larger than that from the climate models. The largest GCM related uncertainty is found at the arid fringes in areas, which have simulated epidemic malaria transmission. Generally the signal to noise ratios in the malaria outcomes improve with increasing projection time and also with higher RCPs.

Recently a new model the Liverpool Rift Valley fever model (LRVF) has been developed using the framework of the LMM but with much more complex structure. It has two dynamic vector models and a dynamic age stratified host model. One main task in its development was parameterising the two different behaviours of the two vectors correctly in the model whilst maintaining the correct sensitivity to the climate drivers.

For both diseases the main uncertainly lies with the future projections of seasonal rainfall patterns and the interannual and intraseasonal variations of this rainfall within the climate models. By using an ensemble of climate models to drive an ensemble of impact disease models, an improved assessment of the model-related uncertainty of the future projections of climate-driven health hazard can be obtained.

Wind erosion flux and dune front dynamic at the Sahara-Sahel border: case of Kilakina (SE Niger)

A. Abdourhamane Touré (1) ; AD. Tidjani (2) ; JL. Rajot (3) ; M. Mamadou Daboua (1) ; B. Marticorena (4) ; Z. Garba (1)
(1) JEAI ADE – Geology, Université abdou moumouni, Niamey, Niger, Republic of; (2) Université Abdou Moumouni Faculté D'agronomie , Sols, Niamey, Niger, Republic of; (3) IRD – iEES-Paris / LISA, lees-paris, Paris, France; (4) Laboratoire Interuniversitaire des Systèmes Atmosphériques (LISA), CNRS-UPEC-UPD-IPSL, 94010, France

Sahelian sandy soils are more sensitive to wind erosion. In the south-east Niger, the population are essentially rural and their activities are dominated by traditional breeding and agriculture developed on sandyhill soils. The region is characterized by a continuous degradation of soil structure by wind erosion. This erosion is emphasized by an important human pressure and recurrent draught witch reactivated dunes. The most productive soils lost more than a quarter of their surface in recent decades because of wind erosion witch transformed cultivated area to moving dunes. This work conducted at Kilakina (SE Niger) aimed to characterize wind erosion dynamic of moving dunes. Thus, measurements of wind erosion horizontal flux by using BSNE (Big Spring Number Eight) sand catcher and dunes front dynamics have been done more than 2 years. It's appeared that on moving dune, wind erosion had a temporal and spatial variability. Thus, the foot was eroded particularly between April and Jun while at the top of dune, wind erosion and dune movement can occur all the year. At this place, the intensity of wind erosion reached close to the double of the intensity measured at the dune foot. In another way, the monsoon wind is the most agents of dunes front moving which attained a mean annual displacement near to half-meter.

Precipitation and disturbance as main determinant of the spatial variability of carbon fluxes in 16 West African ecosystems

EE. Ago (1) ; EK. Agbossou (1) ; P. Ozer (2) ; M. Aubinet (3) ; EE. Ago (3)
(1) UNIVERSITY OF ABOMEY-CALAVI, Faculty of agronomic sciences, Abomey-Calavi, Benin; (2) UNIVERSITY OF LIEGE, Department of environmental sciences and management, Liege, Belgium; (3) UNIVERSITY OF LIEGE Gembloux Agro Bio Tech, Department biosystem engineering, Gembloux, Belgium

This study reports carbon fluxes between sixteen different ecosystems and atmosphere in the West Africa region. Data were averaged at annual scale, but obtained by eddy-covariance and other indirect methods. Ecosystem types include forests, savannahs, grasslands and croplands under sudano-sahelian and guinean climates. Carbon fluxes data were recorded in the annual mean rainfall ranged between 350 (Agoufou site, Mali) and 1850 mm (Ankasa site, Ghana). The total ecosystem respiration (TER) were found very highly ($R2 = 0.71$) and Gross primary productivity (GPP) highly ($R2 = 0.50$) correlated with the annual mean rainfall. Both TER and GPP appeared to be saturated for sites receiving annually a mean of rainfall above 1000 mm.

No clear relationship was found between these two carbon fluxes (GPP and TER) and annual means temperature. Moreover, GPP and TER values ranged from (3.3 and 3.0) in the Sahelian fallow savannah to (27.0 and 20.5 t C ha^{-1} yr^{-1}) in the sudanian Forest, respectively. Finally, the annual carbon sequestration varied spatially according to the degree of human disturbance and ecosystem management strategy.

Study of CLOUDSAT products in semi-arid region of Cameroon

A. Lenouo (1)
(1) University of Douala, Physics, Douala, Cameroon

Clouds play a major role in weather and climate processes. In this effect, a variety of satellites was put in orbit in the years 2002 to scrutinize them forming the «A-Train» providing raw data (digital data, images). This work aims to analyze and process these satellite images, preferably those in January and July 2009 in northern Cameroon from satellite data CLOUDSAT in order to explain why in this part of Cameroon, January was a very sunny month against July the raining month. From these data (base image), we applied algorithms (ECMWF-AUX, 2B-GEOPROF, FLXHR ...) to extract reflectivity coefficient and masks clouds that cover the region of the different types of clouds which appears and their water rates. We have found that the month of July is marked by a significant presence of clouds at low, middle and vertical development (clouds rushing) against January which is marked by a very light cloud cover at higher floor. Therefore, the results of the profile vertical clouds predict the weather and climate; which equate January to July in the dry season and the rainy season respectively. These results can affecting ecosystems and societal functioning, water resources, agro-pastoral and economic activities over the northern Cameroon.

P-3330-04

Impacts of climate variability on crop yield: how do local farmers adapt in Nigeria?

S. Ayanlade (1)
(1) Obafemi Awolowo University, Ile-Ife, Nigeria, Dept. of Geography,, Ile-Ife, Osun, France

The recent impacts of climate variability on crop yield raise the question as to whether there will be enough food in Nigeria in the next century. Various studies on the impacts of climate variability on crop yield have been carried out in different parts of the world and well established through decades of field experiments, statistical analyses of observed yields and monitoring of agricultural production by IPCC and other scholars. The majority of these studies assess inter-annual variability in the climate of West African countries, particularly the magnitude of rainfall variability impact on human activities, including crop production. Surprisingly, little systematic research has focused on the distribution patterns of the impacts of climate variability on crop production, in terms of mapping its spatiotemporal impact using the modern GIS techniques such as Kriging interpolation technique. Thus, the present study uses both Geographical Information techniques (GIS), social and demographic survey to assess the impacts and how local farmers (of different demographic characteristics) adapt to climate variability in Nigeria. The study aimed at using GIS Kriging interpolation technique together with questionnaires methods to examine and map the spatiotemporal impact of rainfall variability on crop yields in the Guinea Savanna Ecological Zone of Nigeria. Both parametric and non-parametric techniques are used for testing whether there have been significant impacts and how farmers adapt to climate change/variability. The result show that modelling with a GIS offers a better mechanism to integrate many scales of data developed for agricultural research. Also the results also show that the zonal variability of rainfall is observed to bring about not only the differences in the types of crops cultivated but also the rate of yield of such crops and deferent adaptation methods. The major finding is that climate change/variability has two major effects on crops. First, during the latter part of the growing season, insufficient soil moisture may restrict transpiration to well below the potential rate, with corresponding reduction in growth and yield. Second, after harvesting the crop, there will be a deep layer of soil which must be recharged to something approaching field capacity early in the following rains before satisfactory growth of the next crop can occur. The results from demographic survey using questionnaires show that local farmers have different adaptation strategies and that the variability climate implies that crop yield is exceedingly variable over space and time.

P-3330-05

Climate and climate variability: case study of the traditional lowland rice cultivation in the middle and upper Casamance Region

M. Bacci (1) ; M. Pasqui (2)
(1) Institute of Biometeorology, National Research Council, Florence, Italy; (2) Institute of Biometeorology, National research council, Rome, Italy

The Casamance Region is an enclave territory in southern Senegal that has suffered from the sociopolitical instability caused by the separatist movement for the independence of the region in the 1990s and 2000. This has led to a significant delay in infrastructure development to support the economy of the region. Nowadays, it has an unexploited potential due to a series of structural limits for the creation of an efficient supply chain for local agricultural production. The change in the security context of the region and the new Senegal rural development policies provide new opportunities for agricultural production in Casamance.

Among the various food crops, the traditional lowland rice cultivation by woman in the secondary valleys along the Casamance River is a peculiarity of the region. This crop is mainly grown to cover the food needs of the farmer's family, therefore within a strategy of food security. There are many limits to rice production in the region. The lack of mechanization, the absence of a regular distribution of improved cultivars, poor labor quality and quantity and conflicts with the livestock rearing in the valley make the system very fragile and strongly dependent on seasonal weather patterns. For these reasons, the traditional rice cultivation is becoming marginalized, with a gradual abandonment of the valleys.

In order to preserve lowland rice production and make it sustainable, an analysis of meteorological factors that most influence the crop yield aims to provide useful information for the identification of alternative cultivation strategies and implementation of direct and indirect mitigation practices on crops. The study therefore aims to assess recent climate change recorded in the region with particular attention to the parameters determining a bad or good rice crop.

Weather data from rain gauges are quite scarce in the region, often limited only to the registration of the total daily rainfall in the major towns. It was therefore chosen to use the CHIRPS daily rainfall estimate dataset that covers the period from 1981 to 2013 at 0.05° resolution. Attention has focused on assessing the fundamental parameters of the growing season such as total rainfall, number of rainy days, average daily rainfall, onset and the cessation of the growing season. In addition, we evaluated the incidence of dry periods and heavy rains during the germination and flowering period of rice, as these are the most vulnerable stages of the crop. The relationship of these parameters with large scale oceanic and atmospheric forcing was also evaluated.

The variability of these climatic parameters over time are a source of uncertainty for local farmers decision-making process and their ability to adapt to new climatic forcing. Describing the climate, identifying observed trends and overlapping the future predictions derived from atmospheric General Circulation Models has allowed us to define a set of future scenarios that should guide local farmers and policy makers in the orientation of agricultural development policies for the middle and upper Casamance Region.

P-3330-06

Using multi-agent simulation to assess the impact of adaptation scenario on agricultural land use change and household food availability in northern Ghana

B. Badmos (1) ; G. Villamor (2) ; S. Agodzo (1) ; S. Odai (1)
(1) Kwame Nkrumah University of Science and Technology, Kumasi, Ghana; (2) Centre for Development Research, University of Bonn, Bonn, Germany

The impact of climate change and variability on the growth and development of sub-Sahara Africa (SSA) is severe. Farmers are already changing their agricultural land-use to adapt to the impacts of changing climate. In Ghana, agriculture contributes to food availability and accessibility of some food commodities consumed annually. The capability of agriculture to ensure food availability has been affected by low production, and climate change also plays a significant impact. National policies and strategies to sustain food security at a high level have concentrated on increasing domestic production. Some of the policies aimed at improving farm household resilience to the impacts of climate change may have implication on land-use change. Hence, adequate understanding on the impact of these policies in a temporal manner is vital. This study therefore applied multi-agent simulation (MAS) model to assess the impact of adaptation scenario on agricultural land use change and farm household food availability in northern Ghana. MAS model is able to simulate the impact of human decision processes explicitly. Few studies applied MAS model to relate adaptation with changing climate in West Africa. Application of MAS model for land-use change studies is still at embryonic phase in Africa

We applied the Land Use Dynamic Simulator (LUDAS) as a MAS model to investigate the impact of farm credit as adaptation strategy to climate variability on agricultural land-use change and farm households' food availability in Vea catchment, Upper East Region of Ghana. The model was parameterised using 186 surveyed farm households. From these households, we identified the determinants of their crop choices grouped into household characteristics (e.g., age of head, household size, dependency ratio) and farm plots characteristics (e.g., soil type, wetness index, elevation, upslope area, plot size and proximity features). The crop choice sub-model is directly linked to an agricultural yield sub-model to determine the yields of selected crops. To adapt to climate variability in the study area, household choice of maize adoption with respect to maize cultivation credit (maize credit scenario) was integrated in the decision making and simulated for a 20-year period, and compare with the business-as-usual scenario.

Findings show that under maize credit scenario, maize adopters increased from about 20 % to about 50 % and the area allocated for maize cultivation significantly increased by about 266% at the expense of traditional crops. Average annual aggregated household crop yield was 6.3 % higher under the maize credit scenario as compared to business-as-usual scenario. In conclusion, this study shows that access to credit can significantly influence agricultural land-use change and food availability in the study area. However, food may be available as a result of access to farm credit, but sustaining it is a big question.

P-3330-07

Comparative study of five statistical methods of climate change analysis in the Niger River basin (West Africa)

DF. Badou (1) ; B. Diekkrüger, (2) ; A. Abel (1) ; K. Evison (3)
(1) Universite d'Abomey-Calavi, Graduate Research Program on Climate Change and Water resources, Abomey-Calavi, Benin; (2) University of Bonn, Gegraphy, Bonn, NRW, Germany; (3) Council for Scientific and Industrial Research, Natural resources and the environment, hydrosciences research group, Pretoria, South Africa

Climate change is characterized by a significant change in the mean values of climate variables. However, detection of trends in climate variables depends on the methods applied. In this study, 4 commonly used statistical methods, Pettitt's test, Lee and Heghinian's bayesian method, Hubert's segmentation and Mann-Kendall's test at 5% significance level are compared to the cross entropy method. The latter is a stochastic optimization technique initially developed for assessing the number and the position of breakpoints in continuous biological data. From a theoretical view point, the approaches of Pettitt as well as Lee and Heghinian provide only one breakpoint. The Hubert's segmentation gives multiple breakpoints but within a series even just one extreme value could result as a break. The Mann-Kendall's test detects trend in series for a given level of significance. As for the cross entropy method, it provides multiple breakpoints and offers the possibility for the user to choose the number of breakpoints desired. The five methods were applied to 17 rain gauges of the Beninese part of the Niger River basin whose data cover the periods 1981-2010

(5 gauges) and 1970-2010 (12 gauges). There was 16% of chance of obtaining a trend with the Mann-Kendall's test. The likelihood of detecting a breakpoint with the Pettitt's test, the Hubert's segmentation, the Lee and Heghinian's method and the cross entropy method was 16 %, 28%, 72% and 100% respectively. We also noticed that the cross entropy method was 100% and 89% of the times able to replicate a breakpoint detected by the Pettitt and Hubert's approaches and the Lee and Heghinian's method respectively. On the other hand, there was 60% of chance for the Lee and Heghinian's method to reproduce a breakpoint indicated by the cross entropy method. These results suggest that the cross entropy method outperforms the 4 others and should be considered in statistical climate change studies. However, further studies are necessary to confirm the performance of the novel method in comparison to the 4 others.

P-3330-08

Latitudinal ITCZ sensitivity to the width and depth of the convective activity in WAM

M. Baldi (1) ; G. Dalu (1)
(1) Institute of Biometeorology, National Research Council, Rome, Italy

The onset of the West Africa monsoon (WAM) occurs in 2nd half of June, with a week uncertainty on the date. The onset date is defined by the date of the suddenly migration of the intertropical convergence zone (ITCZ) from the Guinea Gulf to an inland position placed at about 10° North of the equator. Prior to this latitudinal jump the ITCZ stays in an almost stationary position at 5° North for two months; during this period, the convective activity widens and deepens. This increase of convective activity is observed by satellites as an ORL minimum and as a rainfall maximum over the Guinea Gulf. Towards the end of June, the convective activity weakens over the Guinea Gulf, to crop out few days 5° further inland.

The mechanisms which accompany the development of WAM are rather complex, thus a simple model for the ITCZ behavior is not yet available. One cause reported in the literature of this peculiar behavior of the ITCZ in WAM is the positive feedback between the deepening of Saharan low at the time of the onset and the confining action of the inland orography to the ITCZ inland penetration. An other confining action can exerted by the presence of inland critical lines for propagating easterly wave.

We propose a mechanism which can concur to this sudden latitudinal jump of the ITCZ. Following results found in the literature of a latitudinal ITCZ sensitivity to the shape of the forcing, using a Matsuno-Gill model, we show that a widening of convective activity is accompanied by a temporary weakening of the convergence 5° North, followed by a strengthening of convergence at 10° North, when the width of the convective activity exceeds one equatorial Rossby radius. When this width is exceeded, the ITCZ transition is rather rapid, this is when the convergence maximum settles at at one Rossby radius North of the equator. This mechanism the ITCZ migration is complementary to other mechanisms; the feedback between different mechanisms might be difficult to model in terms of simple theory.

P-3330-09

Climate change in a tropical region: the case of LAMTO reserve in Côte d'Ivoire

K. Benjamin (1) ; F. Yoroba (1) ; A. Diawara (2) ; Y. Kouadio (1)
(1) University Felix Houphouet Boigny – Cocody – Abidjan, Physic, Abidjan, Ivory Coast; (2) University Felix Houphouet Boigny – Cocody Abidjan, Physic, Abidjan, Ivory Coast

LAMTO reserve is located on the center of Côte d'Ivoire in West Africa. Climate variability of LAMTO reserve was studied over the period from 1962 to 2010 (49 years). This study uses climate data (precipitation and temperature) measured on LAMTO geophysical station. In general, rainfall decreased in the reserve. Compared to the average of the 49 years, the region recorded a rainfall deficit over thirty years (1971 to 2000). This deficit was more pronounced during the 90s. On the over side, during the period 2000 to 2010, the rainfall increased.

The region recorded an increase of the mean temperature (+1.4°C) compared to 1960s. This is a sign of global warming. In contrast, from 2001 to 2010, the average minimum temperature decreased (-2.43°C). In fact, this fall causes the decrease of the average mean temperature (-1.25°C) of this decade.

P-3330-10

Recent rainfall variability and vegetation activity in the experimental site of the Upper Ouémé basin (Benin)

S. Bigot (1) ; T. Do (1) ; B. Dieppois (2)
(1) Laboratoire d'étude des Transferts en Hydrologie et Environnement (LTHE), Université Grenoble Alpes, Grenoble, France; (2) Coventry University, Centre for agroecology, water and resilience, Coventry, United Kingdom

From the late 1990s, the Sudano-Sahelian zone is, a priori, wetter than during the two previous decades, which were marked by the development of persistent droughts. This recent evolution is likely to influence local to regional climate and, thus the vegetation cover, the biomass and seasonal phenology in the forest and savannah belt. Contrasted results in simulating the future regional climate trends, however, leaves the future of West African environments widely open and uncertain. Accurate in-situ monitoring is therefore needed to increase knowledge and understanding of West African regional climatic contrasts and, thus, and to exceed diagnostics, which are limited to the semi-continental scales. In this context, an instrumental period was launched in 1997 on the Upper Ouémé meso-scale site (Benin) under the AMMA-CATCH (African Monsoon Multidisciplinary Analysis – Coupling the Tropical Atmosphere and the Hydrological Cycle) observation initiative. This experimental catchment basin of approximately 14 366 km², which is influenced by a Sudanian climate, present different hydroclimatic conditions to those studied in the Sahelian regions. This catchment basin show a lower decrease in streamflow during dry periods, and unclear relationships between land degradation, vegetation cover, surface hydrological and climatic fluctuations. By comparing the satellite images during different time-periods, continuously deforestation and clearing land processes is identified since the 1970s, while anthropized fallow land and savannah are increasing by 24% and 22%, respectively.

This study thus aims to a better regional understanding of the recent rainfall variability and of vegetation phenology through the photosynthetic activity. We compare observed bioclimatic patterns among the four main defined as "non-climatic or climatic degradation" versus "climatic or non-climatic greening" by the current conceptual modelling studies. We focus on the 2001-2013 period using in-situ rain-gauges from AMMA-CATCH, 10-day rainfall estimates from satellite data (RFE; 8 × 8 km), and 5-day photosynthetic activity (NDVI EROS-MODIS; 0.5×0.5 km). Although monthly rainfall amounts are underestimed in the RFE data, the interpolated rainfall field from AMMA-CATCH and the RFE dataset are highly correlated (R = 0.93), which ensures a good reproduction of the year-to-year variability.

The recent period (2001-2013), which displays annual rainfall amounts of about 934 to 1302 mm in 2001 and 2003, respectively, is significantly wetter than during the earlier decades (1970s and 1980s) showing regional rainfall amounts rarely above 900 mm. The start of the growing season is significantly correlated with January-May rainfall amounts over the Upper Ouémé catchment and the length of this season is positively correlated with mid-May rainfall amounts. The length of the vegetation activity could therefore be especially sensitive to rainfall at the beginning of the growing phase. Meanwhile, the end of the growing season could be explained by late September to late December rainfall amounts. The end of the growing season is thus delayed by 10 days per decades, e.g., 68th pentad (early December) in 2002 to 70th pentad (late December) in 2010. This could indicate that bioclimatic conditions are more favourable and, thus, lead to a longer duration of photosynthetic activity. This could, however, indicates that green vegetation, which can originate from agricultural land and, thus almost independent from the regional rainfall variability, remain a bit longer in the year. A multivariate statistical analysis of the NDVI thus clearly shows regional contrasts and response specifics over certain areas and in different forms of vegetation in the Upper Ouémé Basin. The contrast between protected

native forest (forest reserves) areas and those undergoing a transformation into farmland (crop-growing and fallow land) is very clear. More accurate spatio-temporal analyses (at daily and 250m spatial resolution), such as multi-criteria regional analysis (e.g., dynamic factor analysis), could provide a better understanding of environmental processes involved and the contribution of associated agrosystems.

P-3330-11

HORIZONTAL VISIBILITY as witness of ENVIRONMENTAL DEGRADATIONS in CENTRAL SAHEL (NIGER) SINCE 1950

B. Hassane (1)
(1) University Abdou Moumouni, Science & Technics Faculty,, Niamey, France

Environmental degradation is one of the most important consequencesof persistent drought occurringin the Sahel between the late1960s and the 1980s. Although central Sahel experiences a partial rainfall recovery since the 1990s, environmental responses to the recent climate trends are still contrasted mainly due to increasing anthropogenic pressure. Analyses of long-term proxy of Sahelian land surface conditions, such as horizontal visibility, and their response to regional climatic variability, such as regional to local rainfall and wind dynamics, are therefore of major importance in understanding the relationship between climatic and environmental processes.

Time-evolution of the relationship between horizontal visibility (and associated weather types: blowing sand, sandy haze and dust haze) and regional rainfall and wind speed variability have been examined. Over a NE-SW transect from southern Sahara to central Sahel, 3-times daily measurements (i.e., 6am, 12pm and 6pm) of horizontal visibility and wind, and daily rainfall amounts from 4 weather stations have been selected (Bilma: 18.68N-12.92E; Nguigmi:14.25N-13.12E ; Maine-Soroa:13.23N-11.98E; Niamey: 13.48N-2.17E) and, then, analyzed between 1950 and 2009.

The horizontal visibilities and Sahel rainfall show similar seasonal cycles. Horizontal visibility is increasing during the rainy season (June to September), while horizontal visibility is decreasing during the dry season (October to April). While increasingsuspended dust in the atmosphere, e.g.,due to increasing soil erosion and particle transport, is likely to reduce horizontal visibility during the dry,the rainy season actsto reverse this trend by moistening the soil and by blocking dynamically a part of the dust transport. This is thus not true at the southern limit of the Sahara (i.e., in Bilma), where horizontal visibility is lowest between February and August.

At the interannual timescale, decreasing horizontal visibility over the Sahel is linked to increasing occurrence of specific weather types, such as blowingsand, sandy haze and dust haze. During the dry season, we note an increase in wind speedsbetween the wet period (1950-1969) and the dry period (1970-2009), which is associated with a decrease in horizontal visibility. The dry period (1970-2009) is also marked by an increase in daily occurrences of weather types associated to low visibilities (sandy haze). However horizontal visibility decreased in Bilma by sandy haze increase particularly since 1967.

One could think that the mechanisms of the climate change are earlier than what is generally admittedonrainfall evolution only. These mechanisms would first affect zones that are most sensitive to wind erosion. In Bilma, it is also observed that the increase of the blowing sand, originating particles in suspension is significant before the drought of 1973., Is it thus also possible that increasing dust in the Sahelian region was caused bythe particles mobilized in another source area, which could bemore fragile andlocated northward (e.g., central Sahara)?

Furthermore, it is observed that sandy haze increased in Niameysince the 2000s, even if this region experiences a partial rainfall recovery. That tried to the consequence of a supplement of the environment degradation in relation to the demographic explosion of this area and the overexploitation of the natural environments which was followed from there.

P-3330-12

Weather related income shocks and the child's health in Burkina Faso

S. Brunelin (1) ; C. Simonet (2) ; C. Araujo-Bonjean (3)
(1) The World Bank, Washington DC, United States of America; (2) ODI, London, United Kingdom; (3) CERDI, Clermont Ferrand, France

We combine health data originating from the 2008 national household survey with meteorological data to test the ability of rural households in Burkina Faso to smooth investment in child health over agricultural income fluctuations. An in-depth econometric analysis of shock transmission mechanisms shows that children are vulnerable to a rainfall shock occurring in the prenatal period or during the first months of life. Results also shed light on the risk-coping strategy set up by households. Households smooth part of positive weather shock but are unable to dampen large negative shocks. Livestock is an effective buffer asset only for a minority of large livestock owners whose children are spared. By contrast, children living in poorly endowed households are severely affected by a weather related income shock. The implementation of weather insurance mechanisms appears to be desirable to fight against moderate malnutrition but would be ineffective in reducing severe malnutrition which depends above all on the health and educational status of mothers.

Rainfall in the Sahel and global temperature: lessons from a 1500-year long paleoclimate record

M. Carré (1) ; M. Azzoug, (1) ; P. Zaharias, (1) ; A. Camara, (2) ; R. Cheddadi, (1) ; A. Gaye (3) ; S. Janicot (4) ; M. Khodri (5) ; J. Mignot (6) ; N. Mitma (1) ; N. Patris, (7) ; M. Wade, (3)
(1) Institut des Sciences de l'Evolution de Montpellier, Montpellier, France; (2) Institut Fondamental d'Afrique Noire, Dakar, Senegal; (3) Univ. Cheikh Anta Diop, Lpaosf, Dakar, Senegal; (4) IRD, Locean, Paris, France; (5) IPSL, LOCEAN, Paris, France; (6) Institut Pierre Simon Laplace, Locean, Paris, France; (7) Hydrosciences Montpellier, Montpellier, France

As climate model uncertainties remain very large for future Sahel rainfall, it is necessary to look for a long-term perspective in the past climate to better understand the relationship between global warming and the centennial trend of increasing aridity observed in the 20th century in the Sahel. We present here a new record of aridity conditions over the past 1500 years in Senegal, obtained from stable oxygen isotope analyses in archaeological shell middens in the Saloum Delta. Our dataset shows that the actual aridity in western Sahel is unprecedented in the past 1500 years. We observe significantly more humid conditions during the medieval warm period, a transition into the little ice age that was the most humid period in the past 1500 years, and a sharp increase of aridity in the past 200 years. While the recent aridity may be partly due to anthropogenic changes in the local vegetation feedback, a clear link between global temperature and Sahel aridity is revealed in the multi-centennial climate variability. Although this relationship may change in the future with increased greenhouse gases, the climate history supports the scenario of decreasing rainfall in the Sahel in response to future temperature rise.

P-3330-14

Assessing Impact of Climate Change on Vegetative Species Diversity Using the Normalised Difference Water Index: The Case of Mutirikwi Sub-catchment, Masvingo Zimbabwe

L. Chapungu (1)
(1) Great Zimbabwe University, Physics, Geography and Environmental Science, Masvingo, Zimbabwe

Vegetative species diversity is essential for human well-being because it provides services, such as food, medicines, clean water and soil stabilization within a catchment or sub-catchment. However, it is under threat from climate change which poses a challenge by exacerbating the impacts of other pressures. Climate change affects

different ecosystems in different ways, depending on the complexity and original characteristics of the system, geographical location and presence of factors that may regulate the extent of the changes. In southern Africa in general and Zimbabwe in particular, there is still paucity of scientific understanding of climate change's impact on vegetative species diversity specifically species richness and evenness. A plethora of studies have claimed that climate change affects biodiversity but without focusing on specific diversity indices. This poses challenges when designing adaptive and mitigative strategies that are ecosystem and species specific. This study assesses the effects of climate change on vegetative species diversity in Mutirikwi sub-catchment using the Normalised Difference Water Index (NDWI).

To achieve the research objective, the relationship between vegetative diversity indices (richness and evenness) and climatic variables (rainfall and temperature) was explored based on species data directly collected from the field over a 3 year period and climate data collected from three local stations (Makoholi, Masvingo airport and Buffalo range). Relationship between NDWI and species diversity indices was examined to confirm the utility of remote sensing in predicting vegetative diversity. NDWI was calculated using the formula:

NDWI=(□NIR-□SWIR)/(□NIR+□SWIR).

Where □NIR and □SWIR are the reflectances of the near-infrared (NIR, 0.78-0.89 m) and shortwave-infrared (SWIR, 1.58-1.75 m) regions, respectively.

The species diversity indices were calculated using the Shannon Weaver Index which usually combines aspects of richness and evenness. This index was calculated using the formula:

H = -Σ (Pi In (P) Where the summation is over all species and P1 is the relative abundance of species in the quadrat. This index measures the average degree of uncertainty in predicting to what species chosen at random from a collection of S species and N individuals will belong. Species evenness (E) was calculated using the formula:

E= H/In (S) Where H is the Shannon Weaver index and S is species richness observed within the quadrat.

The resultant predictive model was used to estimate changes in species diversity over a 40 year period (1974-2014). The species diversity data was then regressed with climatic data for the same period. These data were also modelled to project future changes in vegetative diversity in the face of climate change.

Preliminary findings reflect a significant ($P<0.05$) correlation between species diversity and climatic variables. The results also indicate that there is a significant ($P=0.003$; $\alpha=0.05$) relationship between species richness and NDWI. Species evenness was also significantly correlated ($P=0.04$, $\alpha=0.05$) with NDWI. This implies that we can use NDWI to assess changes in species diversity over time. The Mann Kendall test revealed a significant decrease in the rainfall received within the catchment over the 40 year period (1974-2014). The minimum and maximum temperatures over the period were significantly increasing. These changes in climatic variables were matched with a decrease in species richness and evenness. Some species tend to be succumbing to the environmental changes influenced by climate change resulting in their changes in phenology, abundance and distribution.

The study concludes that climate change in Mutirikwi sub-catchment is influencing species diversity through changing species phenological features, abundance and distribution. Besides being a good indicator of water content in leaves, NDWI has proved to be a useful indicator of species diversity. The study leads to the understanding of the relationship between vegetative species diversity and climate change and this provides a platform for nations to devise strategies to enhance the resilience of ecosystems to climatic changes through the adoption of species based adaptive and mitigative strategies.

P-3330-15

Responding to Climate Change Challenges in Sub Saharan Africa - A case for Water Supply

P. Chukwuma (1)

(1) Sustainable Water and Sanitation in Africa, Abakaliki, Ebonyi State, Nigeria, Federal Republic of

Change is a permanent phenomenom in all spheres of life. Many a time changes present both opportunities and threats on diffent facets. For sustainability, we need to constantly anticipate changes and their impact. Some changes come with heavy impact. Climate change is one of them. It has spiral effect on several frontiers of human existence. It is one phenomenom that derseves urgent attention. Based on risk assement, we need to take proactive steps to either eliminate adverse impacts or mitigate them or compensate for the perceived impacts. Sometimes changes present beneficial opportunities. In dealing with changes, time of reaction and availability resources are vital.

Sub Saharan Africa Countries are presently existing on fragile economy. Population is increasing while social infrastructures are dwindling. This presentation outlines the challenges of dealing with climate change in Sub Saharan Africa. It analysis the following issues as it relates to climate change

- Threats of climate change
- Opportunities occassioned by climate change
- Capacity to respond to climate changes
- Effect of climate change
- Consequence of climate changes in Sub Saharan Africa
- Strategy to coping with climate change challenges
- Risk identification
- Stakeholders communication strategy

The paper asserts that Sub-Saharan Africa remains the most vulnerable region in Africa due to inherent poverty and lack of clear policies on dealing with climate change. Climate change will have adverse impacts leading to decreased food production, displacement, increased poverty, conflicts and reduction in production capacity in the region. Although, some parts of Sub Saharan Africa will experience increased agricultural production as a result of increased rainfall but there exist little capacity to take maximum advantage of the opportunity or mitigate the adverse impact of excessive rainfall. Generally, climate change portends a bleak future for Sub Saharan Africa. The paper posits that Sub Saharan Africa countries need to take urgent actions towards tackling the threats of climate change and plan on take advantage of emerging opportunities.

The paper elicites that climate change challenges in Sub Saharan Africa will adversely affect other regions of the world in one way or the other.

The impact of global changes on agriculture: the case of Ivorian Basin of Comoe River

N. Dabissi (1) ; L. Bruno (2) ; M. Gil (3) ; B. Kamagate (1) ; S. ÉRic (3) ; BTA. Goula (1) ; S. Issiaka (1)

(1) Université Nangui-Abrogoua, Ufr sge, Abidjan, Ivory Coast; (2) 2CIRAD TA 60/02, G-Eau, UMR Cemagref, Montpellier Cedex 05, France, G-eau, umr cemagref, cirad montpellier, MONTPELLIER, France; (3) Université Montpellier 2, Hsm/ird, MONTPELLIER, France

Since some decades, the Ivorian Comoe river Basin faced environmental and climatic changes. As one of rainfed agriculture leading forces, climate conditions display (here) a major role in agriculture transformations. The simulation of water need requirements, coupled with farming systems, shows that actual global changes mainly benefit to annual crops such as corn (Zea mays), and allows the upgrading of the trees crop as cashew (Anacardium occidentale), rubber tree (Hevea brasiliensis), etc. However, the precariousness of the production systems, whose practices have not deeply changed, has to be linked with the combined effects of land saturation, agricultural policies and need of cash faced by farming communities. Therefore, the diversification and reconversion toward rubber plantation, are to be considered as farmers' strategies aiming at finding alternatives for old speculations such as coffee

(Coffea L.) and cocoa (Theobroma cacao L.). For instance, the countryside has been gripped by a frenzy of agricultural development of Chromolaena Odorata and wetlands, which were previously not cultivated. These changes go with intense competition for land that benefits some urban elite who, in example, seeks to cope with retirement by investing in rubber plantation (Hevea brasiliensis). We are witnessing social and spatial reconstructions that, in view of the uncertainty of present conditions, leave small room for environmental protection. The present survey analyzes the ongoing processes, speculates on their future development, and suggests some ways for sustainable agriculture.

P-3330-17

Impacts of climate variability and agricultural intensification on the origin of runoff: the case study of the watershed Kolondieba in the south of Mali

A. Dao (1) ; B. Kamagate (2)

(1) Université Nangui Abrogoua, Laboratoire de Géosciences etEnvironnement, Abidjan, Ivory Coast; (2) Université Nangui Abrogoua, Laboratoire de géosciences et environnement, Abidjan, Ivory Coast

As part of the international research program RIPIECSA (Interdisciplinary and Participatory Research on Interactions between Ecosystems, Climate and Society in Africa), watershed Kolondieba (under Sudanese climate) was selected to understand the mechanism of runoff process in order to improve hydrological model in a context of strong climate variability and agricultural intensification (cotton culture is the main economic activity in the basin). The method used is based on rainfall, hydrometric, geochemical and piezometric data monitoring over the period 2009-2011. The results showed that 2009 and 2010 were normal rainfall years (1300 mm, in average), compared to the average of chronic 1960-1969 (wet period), while 2011 has emerged as a dry year compared to the chronic 1970-1992 (dry period). During the last contrasted two years, the runoff coefficient has decreased by half from 2010 to 2011 occasioned groundwater discharge deficit estimated at 33%. Monitoring the mineralization of targeted water compartments: rainfall, surface water, and groundwater with the integrator chemical parameter (Electrical Conductivity), showed a very little mineralization of rainfall with an average of 16.99 ± 8.53 µScm-1. Mineralization of surface water is closer to the rainfall's, but it's far from the groundwater's consist of shallow aquifers and deep ones with respectively 120.58 ± 90.07µScm-1 and 133.57 ± 85.68 µScm-1 in average. This chemical relationship between water compartments showed that deep aquifers don't contribute enough to the runoff. This allowed to deduct a double origin of the runoff on the watershed consists of stormflow and subsurface flow. The separation of the hydrograph in a normal year (2010) gave a contribution of stormflow about 77%. This contribution has increased by 3% in dry year (2011). In these conditions runoff doesn't depend only on rainfall variability, it can be assigned to the land use because cotton culture area is increasing on the basin since 1960.

P-3330-18

Climate projections in West Africa: evidence and uncertainties?

A. Deme (1) ; AT. Gaye (2) ; F. Hourdin (3)

(1) Gaston Berger University of Senegal, Applied Sciences and Technologies, Saint-Louis, Senegal; (2) University Cheikh Anta Diop Dakar, Laboratory of atmospheric and ocean physics, Dakar, Senegal; (3) IPSL-LMD, Paris, France

The Subsaharan Africa response to global warming was uncertain in the models of the third phase of the Coupled Model Intercomparison Project (CMIP3) used for the Fourth Assessment Report (AR4) of the Intergovernmental Panel on Climate Change (IPCC), which even disagree on the sign of future rainfall anomalies over this region. This disagreement remains even among models that correctly simulate the twentieth-century West African climate. Our study investigates results from a new ensemble of state-of-the-art climate modelswhich participated of the fifth phase of CMIP (CMIP5) and raises several questions. Do the models agree more on Subsaharan Africa rainfall projections ? Do they well simulate the partial rainfall recovery observed over the last decades ? How well are models able to reproduce the main features of the West African Monsoon (WAM) ?

Preliminary results of twelve CMIP5 models have shown, in despite of great progress in the representation of MAO characteristics, little changement on their climate projections on West Africa compared to CMIP3. Robust tendancy to warming over the Sahel, larger by 15 to 50% compared to global warming is noticed. The spread of models projections remains very large for both temperature and precipitations. But the dispersion in surface air temperature is large over the Sahel and Sahara and seems to be linked to the radiative aerosols properties and surface albedo in this region. Most of CMIP5 models project increasing temperature with 1.8-4.2°C amplitude in a rcp4.5 scenario (3.5-8.5°C in a rcp8.5) in Western Sahel (15°W-5°W) ; these values being slightly higher in Eastern Sahel (10°E-35°E). The uncertainty temperature changes will have dramatic consequences as those associated with precipitation. An opposite response between the western and eastern Sahel for rainfall projections seems to be robust. However, some « outliers models » predict rainfall increase which cancels part of the Sahel warming during the summer monsoon. This finding on the western Sahel gathers more and more models as we advance into the 21st century: 40% for the period 2011-2040, 60% for the 2041-2070 period and more 80% in the last period. In contrast, the eastern Sahel, although the consensus model is relatively high, it decreases by 80% in the first period to 70% in the last period. The rcp4.5 scenario shows precipitation oscillations around a mean value (positive for the first zone/negative for the second) as well in the East and the West of Sahel, indicating a high interannual variability ; while rcp85 scenario gives a tendency net increase of abnormal rainfall in the eastern reaches 100 mm at the end of the 21st century. A particular domain (5°W-10°E), encompassing western Mali, Burkina Faso, northern Nigeria and eastern Niger, where consensus between the models is low on changing rainfall for two scenarios have been charachterized.

Finally, our study indicates that further investigations on the rainfall response mechanisms in these outliers models should help to assess their credibility and need to be explored.

P-3330-19

Why is the « Sahelian paradox » recently exacerbated?

L. Descroix (1) ; JP. Vandervaere (2) ; H. Dacosta, (3) ; M. Malam Abdou (4) ; A. Diongue Niang (5) ; A. Bodian, (6) ; T. Sané, (7) ; V. Tarchiani, (8) ; P. Vignaroli, (8)

(1) UMR PALOC, Lmi pateo, campus international de recherches ucad/ird de hann, Dakar-Hann, Senegal; (2) LTHE-UJF, Grenoble, France; (3) Université Cheikh Anta Diop, Dept of geography, Dakar, Senegal; (4) Université de Zinder, Dept of geography, Zinder, Niger, Republic of; (5) ANACIM, Dakar, Senegal; (6) Université Gaston Berger, Dept of geography, Saint Louis, Senegal; (7) Université Assane Seck, Dept of geography, Ziguinchor, Senegal; (8) CNR, Ibimet, Firenze, Italy

During the Great Drought that West Africa suffered at the end of the 20th century, hydrological observations highlighted an increase in runoff only in the Sahel, although this was the area where the rainfall deficit was the highest. From the small experimental plot to the major tributaries basins of the main rivers, runoff coefficients and discharges values increased significantly during the dry period. This was named the «Sahelian Hydrological Paradox». From the very end of the century, after 1995, rainfall generally increased again in the whole West Africa. Therefore, an increase in runoff afetr 1995 is easy to explain. However the increase in runoff and discharges valuesbegan in 1970, at the very beginning of the Great Drought; the hydrological behavior of Sahelian surfaces remains thus paradoxical at least from 1970 to 1995. Thus its recent exacerbation is not such paradoxical, yet needs to be explained.

The more commonly cited Sahelian paradox explanation is the widespread soil crusting through the Sahel. It is considered as a consequence of the extension of crops, leading to a quasi-disappearance of natural bushes. This trend was accompanied by a decrease in fallowing, the main fertility restoration practice used in the Sahel. After 3-4 years of cropping, a 8-10 years fallowing was traditionally practiced. The population increase and subsequent food needs progressively led to the

abandonment of this practice, and then to e decrease in crop yields and a general soil degradation (structure, water holding capacity, fertility, OM content, etc). This was for long way considered as the main cause of soil crusting. Soil crusting and its consequence the runoff coefficient rise was general, within in exorheic areas as well as within endorheic ones. In the latter, it caused an extension of ponds, which are the main groudwater recharge sites, and then it led to a rise in water table levels. The rise in local runoff due to soil crusting was sufficient to provoke the change of someendorheic areas into exorheic ones: the overflowing of some ponds effectively transformed closed valleys into tributaries of the Niger River. In the sole Niamey area, 1700 km² of supplementary catchments were added to the known previous basin; this is close to 50% of the direct catchment of the Niger River in this region (small basins directly supplying the Niger River, without considering the main tributaries). Locally, urbanisation should also explain an increase in runoff, because it leads to a decrease in soil permeability (buildings, roads, etc..). Otherwise gutters are not always maintained and in many cases they are blocked, their overflowing aggravating then the flood. Recent flooding of capital cities without rivers (Ouagadougou in 2009; Dakar in 2012 amogst others) proved that a purely urban cause of increasing runoff is possible.

A recent observation of an increase in frequency of extreme rainy events cannot be considered as a factor of increase in runoff coefficient and flooding. So far, neither the number of rainy events above certain high thresholds of daily amount, nor the amount of rain fallen during these events have (until 2014) exceeded those observed during the 1950s and 1960s decades, before the beginning of the observed increase in runoff coefficients. An intensification of rainfall is observed, however it is evidenced only by the increase in the proportion of rainfall amount observed during high daily rainfall amount events (commonly named extreme events).

The annual flood does not always provoke inundations; however, floods can evolve in inundation owing to at least two series of factors: the silting up of river beds led to the reduction of hydraulic sections, and thus overflow must occur for discharges values which did not cause overflowing in past years. Otherwise, urbanisation again is the cause of severe damages of flooding, because it applies in floodable areas occupied by spontaneous settlements (areas not flooded since the beginning of the Drought, more than 40 years ago), anciently secondary river beds of the main stream flows, or current floodplains.

Soil crusting and then land use changes seem to be the main explaining factors of increase in runoff. Therefore it is important for policy makers to be sensitized about the effects of consequent land use changes on the hydrological regimes of Sahelian rivers.

P-3330-20

Impact of climate changes in the last thirty years on the second generation of Cocoa in Ivory Coast

A. Diedhiou (1) ; E. Kassin Koffi (2) ; GF. Yao (2) ; LKA. Koko (3) ; AA. Assiri (3) ; B. Kouamé (2) ; A. Konaré (4) ; NK. Kouassi (5) ; GR. Yoro (2)

(1) Institute of Research for Development (IRD), LTHE – University Grenoble Alpes, Grenoble Cedex 9, France; (2) National Center of Agronomic Research (CNRA), Central laboratory of soil, water and plants, Bouaké, Ivory Coast; (3) National Center of Agronomic Research (CNRA), Cocoa program, Divo, Ivory Coast; (4) University Felix Houphouet Boigny, Laboratoire de physique de l'atmosphere et de mecanique des fluides, Abidjan, Ivory Coast; (5) National Center of Agronomic Research (CNRA), Central laboratory of biotechnology, Abidjan, Ivory Coast

The Ivorian cocoa sector is facing in the recent three decades with difficulties to plant a new generation of cocoa due to changes in the annual cumulative rainfall and the inadequacy of the current crop calendar in the present climatic context. This study, conducted in the center-west of Côte d'Ivoire aims to assess climate risks for cocoa and determine the suitable period to establish new cocoa farm and to ensure the survival of young trees during replanting. Agro-climatic data were collected at the agronomic research stations of Divo and Gagnoa. The comparison between climatic parameters and the water needs of cocoa shows that the favorable period of implementation of cocoa in the current climate context of the study area is between March and April and not between May to June as recommended since the 1960s, to enable young trees to take advantage of the long rainy season that occurs earlier. A strategy of implementation the second generation of cocoa taking into account the climate change observed over the region is proposed.

P-3330-21

Determination of malaria parameters using meteorological data sets of Senegal stations and reanalyses products

I. Diouf (1) ; AT. Gaye () ; A. Deme (2) ; JA. Ndione (3) ; B. R. F. (4)

(1) University UCAD, Lab. of atmosphere and oceanic physics, Dakar, Senegal; (2) Gaston Berger University of Senegal, Applied Sciences and Technologies, Saint-Louis, Senegal; (3) Centre de Suivi Ecologique, Dakar, Senegal; (4) Universidad Complutense de Madrid, Facultad de fisicas departamento de meteorologia, Madrid , Spain

Climate behavior is an important factor for malaria development, a vector-borne disease which is a really public health problem, particularly in Sub-Saharan part of Africa. High temperatures are favorable for the quick growth of mosquitoes and the shortening of the reproductive cycle of the pathogen known as plasmodium, while the proliferation of vectors in breeding sites is driven by precipitations. Due to difficult access of observations datasets, this study has a huge component of simulations of malaria parameters using the Liverpool Malaria Model (LMM) developed by Hoshen et al (2004). The inputs of the model are meteorological data of stations and different reanalyses products. The results of this study show that a two-month lag is often observed between the maximum of precipitations and the peak of malaria incidence in Senegal. Malaria occurrence period is centered on the September-October-November period corresponding to the end of the rainy season warm and humid. These findings are highlighted both with stations datasets and reanalyses.

Otherwise, this study attempts to assess the impact of past, present and future climate features on vector-borne diseases such as malaria. Our findings about malaria changes under climate change will be useful in order to prevent malaria outbreaks due to high probability of climate change.

These results taking account the main climate and environmental behaviors could be useful in the prevention of malaria in Senegal and elsewhere.

P-3330-22

Climate variability and its role in accessibility to and use of water: social and health issues in informal settlements in Ouagadougou (Burkina Faso)

S. Dos Santos (1) ; FDC. Ouédraogo (2) ; BA. Soura (3)

(1) IRD, LPED (AMU/IRD), Ouagadougou, Burkina Faso; (2) Université de Ouagadougou, Géographie, Ouagadougou, Burkina Faso; (3) Université de Ouagadougou, Institut supérieur des sciences de la population, Ouagadougou, Burkina Faso

Expected changes to the global environment have led to a burgeoning literature on climate change vulnerability and adaptation. A part of this literature focuses on developing higher-resolution climate models to better characterize uncertainty in the regional climate projections offered to decision-makers – the "top-down" methods. Another part of the literature addresses past and present climate variability and aims to reduce vulnerability, in a "bottom-up" approach. As social scientists, we want to contribute to this second part of the literature, as we agree with the geographer Richard Washington and his colleagues that coping with present climate variability is in itself enough of a challenge. In this communication, we wanted to document the diversity and the variability of access to water depending on the variability of the climate (across seasons) in an African capital-city characterized by both population and spatial expansions.

Indeed, better access to water is as much a factor conducive to development as its result. Improved water

access has many effects on human health. This effect is mediated by both the quality and the quantity of water available in a household. Greater quantities of water and a reduction in the risk of water contamination are two principal means of preventing the diseases transmitted through the faecal-oral route, such as diarrhea, which are a leading cause of death among children in sub-Saharan Africa. Nevertheless, in terms of water access, sub-Saharan African cities are some of the worst off in the world, with 20 % of their populations supplied by an unimproved water source. Urban growth of African cities is leading to the development of informal settlements that do not have access to basic services, including access to water. Changes in both water supply (because of climatic variability) and demand (because of the increase of urban populations and economic growth) have caused many African urban dwellers to experience difficulties in meeting daily water needs. In light of climate change and the continued growth of urban population, there is concern that the gap between the supply and demand for clean water will widen.

We use original data on access to water from a survey implemented in 2012 in the three informal neighborhoods of the Ouagadougou Health and Demographic Surveillance System. The aim was to monitor the diversity and the variability of access and use of water in households, across seasons. Four times per year, a questionnaire was administrated to the same representative sample of households (n=1496). It was composed by seven modules addressing issues as varied as the types of water supply, the conditions of collection and storage of water, and the cost of water, as well as various domestic water uses and a health section on water-related diseases for each child under the age of 10 living in the household. To complete the dataset, water samplings was analyzed to test the microbiological quality of the water consumed by these households.

Results show that population's adaptation to seasonal variability is high in terms of diversity and changes in the choice of water sources. This choice implies variability in the distance and in the price paid for water. To a certain extent, in some period of the year, people have not the possibility to choice between different sources: the scarcity lead to pay a high price and/or to travel long distances to a water fountain and, to limit the quantity for each domestic use or to alter the quality of water used. Results also highlight that a number of factors related to water access are associated with higher occurrence of childhood diarrhea, and specifically the use of rainwater. The use of hand pumps is as well interesting owing to its impact on higher childhood diarrhea due to microbiological quality issues.

From these results, we have a broad picture and we can make first hypothesis on the future adaptation to consequences on climate changes in those informal parts of the city, and more generally in African irregular settlements.

P-3330-23

Rainy extreme events and phenomenon of flood in the city of Cotonou (Benin): Measure of protection and adaptation of the population

CG. Etene (1)
(1) Université d'Abomey-Calavi, Géographie, Cotonou, France

More and more, because of the climate change, the populations have to resist frequent and extreme meteorological phenomena, greater climatic variability and changes of the climatic standards. In Benin and more exactly city of Cotonou, occurrence of the extreme rain events associated to a lack of adequate politics of the urban development contributed these last two decades to the degradation of the living environments of the urban population.

To appreciate the impacts of the extreme phenomena on the physical and socioeconomic environment of the population, the pluviometric and infrastructural data are used. The statistical analysis was used to determine the extreme rains. The socio-anthropological inquiries will allow to determine the perceptions of the population on their states of vulnerabilities to the phenomenon of floods and to see that they are the strategies of possible adaptation.

The results of this study show that the populations with average income, the socio-urban equipment's and houses are the most exposed to the phenomena of floods. This vulnerability is often understandable by the collapse of certain houses, the break of ways and bridges under the influence of the phenomenon of the érodibilité provoked by runoff water. Today, it is about develop or to make developments which are capable of adapting itself to the current climatic evolution of the context and future.

P-3330-24

Diffusion and scaling of Soil and Water Conservation measures to manage Climate Change in Nigeria

J. Ezeji (1)
(1) Rural Africa Water Development Project (RAWDP), Water Resources and Supplies, Owerri, Imo, Nigeria, Federal Republic of

Throughout Nigeria, small holder farmers are increasingly affected by extreme climate and environmental change events. Worsening droughts in particular is ruining the lives and livelihood of many small holder farmers as it continued to hamper farming activities. Their albatross includes water mismanagement, inappropriate land use, as well as poor knowledge of anti-drought measures and this has led to land degradation such as soil erosion and loss of the soil's productive capacity to produce food.

Also the limited potential for dry season farming through soil and water conservation, the non-employment of rain water harvesting technology, as well as conflicts over limited water resources have not helped the situation. Consequently, local livelihoods are being jeopardized while increasing poverty for thousands of these farmers expands.

The paper therefore reviews the adoption and scaling of the World Overview on Conservation Approaches and Technologies (WOCAT) technologies and measures based on the fact that it offers a basket full of Soil and Water Conservation measures that work under specific or under a range of conditions. Soil and Water Conservation (SWC) in this context include the prevention or reduction of soil erosion, compaction and salinity; conservation or drainage of soil water; maintenance or improvement of soil fertility, etc.

The paper also documents, evaluates, compares, monitors and analyses the performance of these WOCAT technologies and approaches such as agronomic, vegetative, and structural and management measures that have proven capable of controlling soil degradation and enhance productivity in the field under existing environmental and climatic variations.

It recognizes and acknowledges the challenge and importance of adapting to climate change. Thus, standardized documentation and evaluation of approved as well as innovative land management technologies and approaches, taking into consideration their adaptation potentials and tolerance towards possible scenarios of climate change, builds the basis to get prepared for the future.

Using the WOCAT methodology, this paper discusses how small holder farmers in eastern Nigeria; whose livelihoods are based on small-scale cropping and livestock agriculture sustainably harvest and use rain water through agronomic, vegetative, and structural measures. It underscores the sheer grit, courage and the determination this vulnerable group and many others bring to the endless challenge of survival. It further underscores that -individuals, households and communities are not passive in the face climate change, and even economic change.

Managing water and nitrogen fertilizers in maize production for smallholder farmers' resilience to climate change impacts

IR. Fandika (1)
(1) Department of Agricultural Research Services, Kasinthula Research Station, KASINTHULA RESEARCH STATION,

CHIKWAWA, Malawi

Water scarcity is one of the most limiting factor for maize production in Malawi, especially the areas that are vulnerable to climate change. Irrigation alone without proper soil nutrient management fails to enhance maize yield. Participatory embracement of efficient water and nutrient management strategies from on – station to on – farm would help farmers build resilience to the impacts of climate change. This paper discusses how development and dissemination of efficient water management strategies in maize can adapt smallholder farmers to climate change. Irrigation scheduling techniques combined with nitrogen rates and the use of maize varieties efficient in water use were participatory assessed from on-station to on-farm in comparison with farmers' practices. Alternate furrow irrigation technique was evaluated at on – station in a randomized complete block design experiment with four replicates with three irrigation scheduling treatments: (1) Alternate Furrow Irrigation (AFI); (2) Fixed Furrow Irrigation (FFI) and Convention Furrow Irrigation or farmer practice (CFI). Following on-station successful results, AFI was participatory evaluated at on – farm against, crop stage – based irrigation, daily water budget irrigation scheduling and farmers' practice combined with nitrogen rates using OFD mother – baby approach at five different irrigation schemes. It was RCBD Split – Plot Experiment with above four irrigation scheduling as main treatments. Three nitrogen rates of 100, 125 and 150 kgN ha-1 were mini-treatments. Maize was planted at 0.25m apart with one seed per station on a 37.5m2 plot. Results for both On-station and On-farm indicated that farmers' irrigation scheduling practice uses more water than the AFI. Alternate furrow irrigation reduced irrigation amount and labour by 38 – 45% compared to farmer practice. Water use efficiency (kg m-3) determined as total grain yield (kg ha-1) per crop water use (m3 ha-1) for each irrigation scheduling, differed with irrigation strategy ($P<0.0001$), location ($P<0.05$), nitrogen rates and maize varieties. Application of 125kgN ha-1 increased yield. Water use efficiency was highest in AFI and lowest in farmer's practice. Both the on-station and On-farm results suggested that AFI strategy and use of maize varieties efficient in water use can definitely adapt farmers to water scarcity by conserving water without affecting economic maize yield.

P-3330-26

Recurrent climate disasters in Cameroon: an indicator of inadequate adaptation to climate change

RA. Feumba (1) ; C. Boukar, (2) ; M. Tsalefac, (3)

(1) Higher Teacher Training College- University of Yaoundé I, Geography, Yaoundé, Cameroon; (2) GIZ/CBLT, Lake Chad Programme, N'Djamena, Chad; (3) Faculty of Arts and Social Sciences, University of Dschang, Geography, Dschang, Cameroon

Cameroon is a central african country with a variety of climates determined by its location on the Atlantic ocean, its extension in latitude from 02 ° to 13 ° N, and its varied landscape. As a young country with low-middle income, Cameroon is highly vulnerable to natural hazards, particularly to those related to climate variability and change (World Risk Report, 2014). This results in a variety of climatic disasters which unfortunately recur every years, usually at the same places and during the same periods of the year despite responses from the State and its partners. Therefore, the efficiency of strategies and adaptation approaches in place ought to be questioned. This paper aims at making a comprehensive assessment of the government's approach to adapt to recurring impacts of climate variability and change in Cameroon. At first, we list climate disasters recorded in the archives between 1960 and 2012 in Cameroon while highlighting recurrent events at specific locations and time of the year. Following this historical review, we analyse recurrent disasters for each decade and the rate of change of the occurrence of climate disasters between the first decade of the study period and the others. Finally, through content analysis, we review the types of responses implemented by the State to address these impacts and the consideration given to long-term solutions, or planned and anticipated adaptation in the country's key strategic planning documents since independence in 1960. As a result of our work, we have highlighted 450 climate disasters that occurred in Cameroon between 1960 and 2012. They are of various natures: floods, storms, droughts, landslides, hazes, wildfires, disruptions of seasons, sea level rise and others. All the 58 administrative divisions of the country experienced at least one climate disaster during the above period, which is enough to show that the scale of the problem is national. These unfortunate events occurred each year, with an average of 9 per year and a maximum of 55 in 2010. Similarly, a high increase of these events is noticeable over the years and decades, with a higher occurrence during the 2000s (30% of climate disasters of the period).The number of disasters increases by an average of 28 between two decades. This foreshadows an amplification of climate disasters for the current decade and those to come as projected by some recent publications (Mc Sweeney, C. et al, 2010; Climate Service Center, 2013;...). The ten-year rate of change is generally between 161.11% and 616.67%. Thus, compared to the first decade (1960-1969), weather-related disasters are multiplied by at least 2 during other decades and even more during the 2000s (by about 6 for all climate disasters and 7 for floods specifically). In some areas (large cities like Douala and Yaounde, the Sudano-Sahelian plains of the Logone and Benue), recurrent climate disasters were recorded at the same periods of the year with rising intensity and higher damages each time. The government is aware and concern is shown at the highest level. In August 1988 and August 2012, the president of Cameroon, Paul Biya, visited the same places hit by floods in the Sahelian part of the country. Relief type responses like evacuation of populations, accomodation in camps, comfort visits, donations in materials and money are the type of measures found in the literature after these disasters. Anticipated and planned adaptation strategies are rare (10% of observations). The government scheme for civil protection is still deficient. More so, an overview of the main strategic planning documents in the medium and long terms indicates low consideration for climate hazards by the government. Cameroon still lacks a National Adaptation Programme of Action (NAPA) and a National Adaptation Plan (NAP). A process to develop a NAP started in 2012 but is still not finalized because of the weaknesses of the legal and institutional frameworks as well as inappropriate methodology. Meanwhile, disasters and other climate change impacts are increasing and the government is taken unawares most of the time! The recurrence of climate disasters in Cameroon is thus a consequence of poor adaptation to climate change, the strategy in place being more oriented to measures after blows instead of anticipated or planned medium and long term strategies at national level.

P-3330-27

Trends of Heat Exposure in Northern Ghana

K. Frimpong (1)

(1) Edith Cowan University, Center for Ecosystem management, perth, Australia

Farmers are largely exposed to heat in the performance of their outdoor activities especially in developing countries. As global climate change is intesified, farmers occupational health and productivity need to be safequarded to ensure food security in the developing world where mechanized farming is at the bearst minimum This study present results of yearly trend of heat exposure in northerast Ghana where temperature could reach sa high as 45 degrees celcius with WBGT in the of 29 to 37 degrees celcius. Farmers work with minimal rest which can be injarious to their health, productivity and food security. The study uses Lascar El USB temperature and humidity sensor which can record temperature and humidity for longer period of time. The results are expressed in terms of heat stress to show the yearly pattern in the north east part of Ghana.

P-3330-28

Development and Assessment of Non-Linear and Non-Stationary Seasonal Rainfall Forecast Models for the Sirba Watershed, West Africa

A. Gado Djibo (1) ; H. Karambiri (2) ; O. Seidou (3) ; JE. Paturel (4)

(1) Institut International d'Ingénierie, de l'Eau et de l'Environnement (2iE), Ecole Doctorale, Ouagadougou, Burkina Faso; (2) 2IE, Ouagadougou, Burkina Faso; (3) University of Ottawa, Civil engineering, Ottawa, Canada; (4) IRD, HydroSciences Montpellier, Abdijan, Ivory Coast

Water Resources Management in the Sahel region, West Africa, is extremely difficult because of high inter-annual rainfall variability. Unexpected floods and droughts often compromise economic activities and sometime lead to severe humanitarian crises. This is exacerbated by endemic poverty, poor preparedness to disaster response, the inadequacy of climate information, and weak institutional capacity. All these factors worsen the vulnerability of sub-Saharan Africa countries to climate changes and make them to be the regions which are highly impacted worldwide. Seasonal rainfall forecasting is one possible way to increase resilience to climate change/variability by providing information in advance about the amount of rainfall expected in each upcoming rainy season. Rainfall forecasting models often arbitrarily assume that rainfall is linked to predictors by a multiple linear regression with parameters that are independent of time and of predictor magnitude. Two probabilistic methods based on change point detection that allow the relationship to change according to time or rainfall magnitude were developed in this paper using Normalized Bayes Factors. Each method uses one of the following predictors: Sea Level Pressure (SLP), Air Temperature (AirTemp) and Relative Humidity (RHUM). Method M1 allows for change in model parameters according to annual rainfall magnitude, while model M2 allows for changes in model parameters with time. M1 and M2 were compared to the classical linear model with constant parameters (M3) and to the climatology (M4). Results showed that model that allows a change in the predictor-predictand relationship according to rainfall amplitude (M1) and using AirTemp as predictor is the best model for seasonal rainfall forecasting in the study area.

The competitive impacts of global SST warming and CO2 increase on Sahelian rainfall: results from CMIP5 idealized simulations

M. Gaetani (1) ; C. Flamant (1) ; F. Hourdin (2) ; S. Bastin (1) ; P. Braconnot (3) ; S. Bony (2)

(1) IPSL-LATMOS, Paris, France; (2) IPSL-LMD, Paris, France; (3) IPSL-LSCE, Gif-sur-Yvette, France

The West African Monsoon (WAM) is affected by large climate variability at different timescales, from interannual to multidecadal, with strong environmental and socio-economic impacts associated to climate-related rainfall variability, especially in Sahelian countries. State-of-the-art coupled climate models still show poor ability in correctly simulating the WAM historical variability and also a large spread is observed in future climate projections.

In this work, climate simulations from a set of 10 CMIP5 atmospheric global climate models are used to study the July-to-September WAM variability in the period 1979-2008. The individual roles of global SST warming and CO2 concentration increase are investigated through idealized experiments simulating a 4K warmer SST and a 4x CO2 concentration, respectively.

Results show a dry response in Sahel to 4K SST warming, with dryer conditions over western Sahel. On the contrary, wet conditions are observed when CO2 is 4x increased, with the strongest response over central-eastern Sahel. The precipitation changes are associated to coherent modifications in the regional atmospheric circulation: dry (wet) conditions are associated with reduced (increased) convergence in the lower troposphere, a southward (northward) shift of the African Easterly Jet (AEJ), a weaker (stronger) Tropical Easterly Jet (TEJ). The analysis of the changes in the regional and global connections of WAM dynamics reveals that in the 4K experiment the observed relationships with the global SST and the regional dynamics patterns are weaker, while in the 4xCO2 simulation the connections are more robust. Specifically, a strong coupling between WAM precipitation and Equatorial Pacific and Atlantic SST is observed, along with a reinforcement of the regional connections with the Saharan heat low, the AEJ and the TEJ.

The above results suggest a competitive action of global SST warming and CO2 increase on the WAM climate variability, with opposite effects on precipitation. The global SST warming affects Sahelian precipitation by weakening the global Tropical convection, while the CO2 increase results in a strengthening of the regional dynamics features associated to wet conditions in the Sahel. It is argued that the large spread in CMIP5 future rainfall projections may be related to the weight given to SST warming and direct CO2 effect by individual models.

AMMA-CATCH a hydrological, meteorological and ecological long term observatory on West Africa

S. Galle (1) ; C. Peugeot (2) ; M. Grippa (3) ; I. Bouzou Moussa (4) ; B. Cappelaere (2) ; J. Demarty (2) ; E. Mougin (5) ; T. Lebel (6)

(1) IRD, LTHE, 30041 Grenoble Cedex, France; (2) IRD, Hydrosciences montpellier (hsm), Montpellier, France; (3) Université de Toulouse, Get, Toulouse, France; (4) Université Abdou Moumouni, Niamey, Niger, Republic of; (5) GET, Umr cnrs 5563, Toulouse, France; (6) IRD, LTHE, 38041 Grenoble Cedex, France

AMMA-CATCH is a multi-scale observation system dedicated to long-term monitoring of the water cycle, the vegetation dynamics and their interaction with climate and water resources in West Africa. In the context of the global change, long-term observations are required to i) gain understanding in eco-hydrological processes over this highly contrasted region, ii) help their representation in Earth System Models, and iii) detect trends and infer their impacts on water resources and living conditions.

It is made of three meso-scale sites (~ 1°x1°) in Mali, Niger and Benin, extending along the West African eco-climatic gradient. Within this regional window (5° by 9°), each of the three sites comprises a multi-scale set-up which helps documenting the components of the hydrologic budget and the evolutions of the surface conditions over a range of time scales: raingages, piezometers, river discharge stations, soil moisture and temperature profiles, turbulent fluxes measurements, LAI/biomass monitoring.

This observation system has been continuously generating coherent datasets for 10 to 25 years depending on the datasets. It is jointly operated by French and African (Mali, Niger and Benin) research institutions. The data-base is available to the community through the website (www.amma-catch.org). AMMA-CATH participates to several global or regional observation networks, such as FluxNet, CarboAfrica, International Soil Moisture Networks (ISMN) and to calibration/validation campaigns for satellite missions such as SMOS (Europe/France/Spain), MEGHA-TROPIQUES (France/India) or SWAP(NASA). AMMA-CATCH fills a gap over a region, West Africa, where environmental data are largely lacking, and thus, it can usefully contribute to the international networking effort for environmental monitoring and research.

P-3330-31

Preparing for El Nino: a starting point for climate change adaptation for malaria

A. Gemeda (1)

(1) Ethiopian Public Health Institute (EPHI), Bacterial, Parasitic & Zoonotic Diseases Research, Addis Ababa, Ethiopia

Background on impact of El Nino on malaria in Ethiopia

Malaria outbreaks in East Africa and Ethiopia overlapped with El Nino events, which has been documented since the beginning of the 1950s until 2003/2004.

Response of the malaria community based on 2014 early warning

An El Nino was predicted to develop late in 2014 and was expected to last through at least spring 2015. This translates to a period of heightened likelihood that extreme weather conditions can occur with associated malaria outbreaks in East Africa. The International Research Institute for Climate and Society (IRI) issued a Bulletin "Emerging El Nino conditions: Guidance for the East African Malaria Community following series of consultations.

Difficulties associated with uncertainty of forecast

Forecasting malaria risk remained a series challenge due to focal nature of malaria transmission in Ethiopia.

Analysis of historical events using Ethiopia ENACTS products

The National Meteorology Agency (NMA) and the IRI have been collaborating on improving climate service since 2008. The most prominent of these activities has been the implementation of the ENACTS (Enhancing National Climate Service) initiative, which was first started in Ethiopia. In order to accurately assess the influence of climate variables and malaria morbidity data at district level. In order to accurately assess the influence of climate variables and phenomenon on malaria data, charts and maps from Ethiopian climate series, epidemics at the district levels, and the IRI Data Library, NMA Ethiopian Map Room were used in this analysis. Thus, mean annual rainfall and temperature across Ethiopia displays a normal interannual decadal fluctuation but overall shows a slightly positive trend. The region has been receiving more rainfall and becoming 'wetter' but temperature has been warming and becoming 'hotter'.

An El Nino event in Ethiopia is typically associated with enhanced and increased probabilities of above normal rainfall during the secondary Belg rain season (March-May). However, El Nino rainfall during the primary Kiremt rain season (June-September/October) is more varied and subject to other climatological factors.

To determine whether an El Nino event, subsequent rainfall and temperatures were associated with the below malaria epidemics of the district "hotspots" we assessed these climatic factors in certain three month groups prior to and during the actual epidemic.

Temperatures and relative humidity within the districts were usually already at an acceptable level to encourage malaria transmission. From our prior research, we found that El Nino events in Ethiopia were typically associated with enhanced and increased probabilities of above average rainfall during the secondary Belg rain season. However, this was not substantial in our analysis. Probabilities of a wet El Nino (rainfall) or a hot El Nino (temperatures) deviated from the actual observations. Although the sections in these tools were very insightful in the study of climatic conditions that encourage the probability of malaria transmission, it fails to properly demonstrate the probability of transmission based on ENSO state without a high level of uncertainty. It also does not indicate the strength of the ENSO state, which could be helpful in the future analysis. Monitoring and use of climate information for public health decision requires strong collaboration and sustainable collaboration between the health sector and climate community. In the last decades, both MOH and NMA have moved towards preparing capacity building and strategic documents. The health sector should benefit better through the recent advancement of climate information services from NMA's ENACTS.

P-3330-32

Policies to favour crop intensification and farm income under climatic risk in West Africa

F. Gérard, (1) ; F. Affholder (2) ; A. Ricome, (3) ; C. Poeydebat (4) ; B. Muller (5) ; M. Sall, (6) ; P. Quirion (7)

(1) CIRAD, Nogent sur Marne, France; (2) CIRAD, UR AIDA, Montpellier, France; (3) CIRED, Nogent sur Marne, France; (4) CIRAD, Martinique, le Lamentin, France; (5) CIRAD, BIOS, Montpellier, France; (6) ISRA-BAME, Dakar, Senegal; (7) CNRS, Cired, Nogent sur Marne, France

In West African countries, agricultural production per capita has decreased over the past half century. With continued population growth and the diminishing availability of marginal arable land, pressure on land is rapidly increasing and there is now a common view that crop yield must be increased in this region, especially as there is a wide gap between actual and potential yields. Although there are several factors which may explain this yield gap, the fact that agricultural production takes place in resource-constrained farm households exposed to risk is widely recognized as being important. Indeed, risk discourages the adoption of high-risk, high-return agricultural technologies, which in turn impedes the improvement of yields.

In order to assess how climatic risk constrains intensification strategy in West Africa, we built and calibrated a bioeconomic farm simulation model predicting the choice to intensify crops or livestock as depending on the availability of key policies in the economic environment of farms, for typical cases in the groundnut basin of Senegal. These cases include two regions contrasted in terms of rainfall (Sine and Saloum) and in each region two typical farms, representing poor and less poor farmers. The model features uncertainty in weather (hence yields) and crop prices, farmer's risk aversion, nine cropping systems representing millet, maize and groundnut with various intensification levels, and the main interactions between crop and livestock: draught animal power, the feeding of animals with suitable crop products (groundnut haulms, cereal straw) and the production of farm manure. Farmers are constraint by land, labour, cash and credit availability. 180 households were surveyed to build the socio-demographic and economic dataset used by the model, and agronomic data were collected from 206 fields.

These key policies analysed are (i) weather index insurances against drought impact on crop yields, either subsidised or not, (ii) subsidies to short term credit for purchasing farm inputs, (iii) subsidies to fertilizer, and (iv) direct payments to farmers. In our simulations, under the current climate and prices of agricultural products and inputs, all these policies appear favourable to the increase of farmers' expected utility for typical farms representing the vast majority of farms in the groundnut basin. Apart for insurance, all of them appear also favourable to intensification of coupled crop and livestock activities for those typical farms. Insurance appears favourable to this intensification strategy only for farms located in the northern part of the region studied, where climatic risk is higher. Among the scenario tested, for most typical farms, combining unsubsidized insurance with subsidized credit appeared as the best use of a given amount of public funds in support of crop intensification: subsidized credit allows the farmers to buy costly inputs while insurance reduces the risk that a drought prevents them from reimbursing the credit. Direct payments also rank high in this respect, because they efficiently mitigate the cash constraint. The amount of subsidies required to obtain a given increase of the value of farm production varies across farm types and subzones in the region, but is relatively reasonable. These results suggest that crop intensification is currently relatively close to becoming a relevant option for farmers and that public policies may favour it by improving the economic environment of farms.

A study of flood intensification in Niamey based on satellite, gauge data and hydrological modeling

M. Gosset (1) ; C. Casse, (2) ; C. Peugeot (3) ; T. Vischel (4) ; B. Tanimoun, (5) ; A. Boone, (6) ; G. Quantin, (4) ; V. Pedinotti (6) ; L. Descroix (7)

(1) Institut de Recherche pour le Developpement, Geoscience Environnement Toulouse (GET), Toulouse, France; (2) GET, toulouse, France; (3) IRD, Hydrosciences montpellier (hsm), Montpellier, France; (4) Laboratoire d'étude des Transferts en Hydrologie et Environnement, Saint Martin d'Hères, France; (5) autorité Bassin Niger (ABN), Niamey, Niger, Republic of; (6) CNRM, Toulouse, France; (7) UMR PALOC, Lmi pateo, campus international de recherches ucad/ird de hann, Dakar-Hann, Senegal

One anticipated impact of climate change is a possible enhancement of the hydrological cycle and an intensification of extreme hydrological events, such as floods. Observing the present and past changes in hydro-systems is helpful to understand the causalities - and the respective roles of climate variability and land use changes, in the increase of floods. In many tropical basins, and notably in sub-saharian Africa there is a deficit of in situ observations. In these regions satellite data and modeling can help analyzing the hydrological behavior and the recent evolution.

Since the beginning of flows observations, in 1920's, Niamey (Niger) has suffered drastic hydrological changes. Several studies highlighted the hydrograph modification from one to two floods (around 1970's). This hydrological change has been attributed to increased runoff in the basins of the local tributaries (Gorouol, Dargol, Sirba), resulting from land clearing and soil crusting,;. In the last decade (2000's) a dramatic increase in the frequency and intensity of the first flood as been observed. Years 2010, 2012 and 2013 recorded the three highest water levels and peak discharge since the beginning of observations;

and lead to severe material losses and several casualties.

Recent studies have raised the issue of a possible increase in extreme rainfall in the Sahel, which may had an important role in the last extreme floods. This study explores the possible impact of this rainfall change in the Niger flood in Niamey. It focuses on the 125000km2 basin between Ansongo and Niamey, corresponding to the drainage area contributing to the first flood. Several long series of satellite and gauge based rainfall estimations, from 1950 to present, are analyzed and used as input to a hydrological model to analyze the possible role of rainfall in the observed evolution of the flood regime and compare with the effect of land use on the basin. These results should provide a basis to anticipate future changes.

P-3330-34

Towards innovative solutions for monitoring climate changes in observation poor regions : Rain Measurement based on cellular phone networks in Africa

M. Gosset (1) ; F. Cazenave, (2) ; F. Zougmore, (3) ; A. Doumounia, (3) ; M. Kacou, (1)

(1) Institut de Recherche pour le Developpement, Geoscience Environnement Toulouse (GET), Toulouse, France; (2) Laboratoire d'étude des Transferts en Hydrologie et Environnement, Saint Martin d'Hères, France; (3) LAME / Université Ouagadougou, Ouagadougou, Burkina Faso

The observed anthropogenic global warming over the last century is well documented but the effect on rainfall is less clear, particularly at small scales. Confidence in future precipitation scenarios is currently subject to large uncertainties and can only be assured if there is a comprehensive understanding of the processes controlling rainfall variability, made possible through reliable rainfall records. In many part of the Tropics the ground based gauge networks are sparse, often degrading and accessing this data for process studies, climatological analysis or for validating satellite products is sometime difficult.

Here a novel approach is presented. It is based on using commercial microwave links from cellular telephone networks to detect and quantify rainfall.

Rainfall monitoring based on commercial terrestrial microwave links has been tested for the first time in Burkina Faso, in Sahelian West-Africa. In collaboration with one national cellular phone operator, Telecel Faso, the attenuation on a 29 km long microwave link operating at 7 GHz was monitored at 1s time rate for the monsoon season 2012. The time series of attenuation is transformed into rain rates and compared with rain gauge data. The method is successful in quantifying rainfall: 95% of the rainy days are detected. The correlation with the daily raingauge series is 0.8 and the season bias is 5%. The correlation at the 5 min time step within each event is also high. These results demonstrate the potential interest of exploiting national and regional wireless telecommunication networks for monitoring rainfall in the Tropics, where operational rain gauge networks are degrading and the hydro-meteorological risk increasing.

P-3330-35

Less rain but more surface water: paradoxical evolution of ponds and runoff in pastoral Sahel

M. Grippa (1) ; L. Kergoat (2) ; L. Gal (2) ; P. Hiernaux (3) ; J. Ramarohetra (2) ; C. Dardel (4) ; E. Mougin (2) ; C. Peugeot (5)

(1) Université de Toulouse, Get, Toulouse, France; (2) GET, Umr cnrs 5563, Toulouse, France; (3) retired from CNRS GET, Caylus, France; (4) LSCE/CESBIO, Toulouse, France; (5) IRD, Hydrosciences montpellier (hsm), Montpellier, France

The Sahelian region has experienced a dramatic rainfall deficit over the second half of the last century with severe droughts in the early seventies and eighties which had dramatic consequences on the ecosystems and the population living in these areas. In parallel and paradoxically an increase in surface runoff has been observed over the same period of time in different areas of the Sahel, particularly in Niger where the increase in areas cleared for cropping was suggested as a possible explanation for this phenomenon.

This presentation focuses on the evolution of ponds and surface runoff in pastoral areas in central and northern Sahel, where agricultural activities are very limited. It addresses in particular the Gourma area, in Mali, over which in-situ data on vegetation, meteorological variables and pond water levels are available via the AMMA-CATCH observatory.

The analysis of different satellite data and aerial photographs revealed a spectacular increase in the surface of ponds in the Gourma region over the last 60 years (Gardelle et al. 2010) as well as over other similar zones in Mauritania and Niger. A water balance equation, which includes water volume changes derived by in-situ water level coupled to pond's surfaces, water input by rainfall and water losses by evaporation and infiltration, has been derived for the Agoufou pond. This allowed to quantify changes in the water amount supplying the pond over time, with annual runoff coefficient (estimated as the ratio of water supply over rainfall) going from 0.005 - 0.05 in the 60s-70s, 0.5-1 in the 90s and ranging from 3.5 to 10 in the last ten years.

These results prove that the Sahelian paradox is also taking place in non-cultivated areas. Analysis of land cover changes over the Agoufou and Tin Adjar watersheds indicates that vegetation degradation and soil erosion occurring over the shallow soils that generate most of the runoff ending up in ponds, play an important role on the evolution of the hydrological system in these areas.

A first analysis on the capability of general land surface models to represent runoff in this region has been carried out in the framework of the ALMIP2 project (AMMA Land Surface Model Intercomparison exercise, Boone et al. 2009). It was found that the representation of shallow soils has to be taken into better account to correctly represent surface hydrology and runoff in endoheric Sahel. More generally, better understanding and modeling the eco-hydrological mechanisms operating in this regions and particular the co-evolution of vegetation and runoff systems is necessary to correctly reproduce past changes and predict the future evolution of these ponds.

Temperature in the Sahel: mean climate and multidecadal warming in observations and climate simulations CMIP5

F. Guichard (1) ; J. Barbier (1) ; C. Leauthaud (2) ; L. Kergoat (3) ; D. Bouniol (1) ; F. Couvreux (1) ; B. Diallo (4) ; F. Hourdin (4) ; S. Janicot (5) ; R. Roehrig (1)

(1) CNRM-GAME (UMR 3589, CNRS and Meteo-France), Toulouse, France; (2) LSCE, CEA, Gif-sur-Yvette, France; (3) GET (UMR CNRS 5563), Toulouse, France; (4) LMD (IPSL, CNRS, UPMC), Paris, France; (5) LOCEAN (CNRS, IPSL, IRD, UPMC), Paris, France

In a companion study (Leauthaud et al.), we show with observations that the Sahel experienced a strong warming since 1950; it is stronger in Spring, which is already climatologically very hot, and more pronounced in nighttime than daytime temperature. This warming is more pronounced that further South in the tropical Soudanian region and increases with latitude from the Gulf of Guinea to the Sahara. Observations also indicate a decrease of the diurnal temperature range (DTR) which is more pronounced outside of the rainy monsoon season.

In this study, we address the ability of climate models to simulate these salient observed features. We use outputs from the CMIP5 archive, and in particular amip, control and historical simulations. We also use amip-type cfSites ouptuts, that allows a more in depth understanding of the physics underlying the simulation of temperature with high-frequency energy budgets (when available). Here, we evaluate the simulation of the annual and diurnal cycles, of the distribution of temperature, and their multi-decadal fluctuations and changes.

The observations used for evaluation include CRU, GHCN and BEST monthly-mean gridded datasets, but also results from several SYNOP stations located across the Sahel and providing daily minimum and maximum temperature, plus, for some of them, 3-h sampled data. The later are used to compare temperature distributions and distribution shifts in the last decades.

First, it appears that the simulation of the annual cycle of

temperature is very challenging, especially outside of the monsoon season (cf. also Roehrig et al. J. Climate 2013). Simulations often display phase shifts of several weeks to a few months in their extrema (Spring and Autumn maxima and Summer and Winter minima). Biases typically reach a few to several degrees in their monthly-mean values. In numerous models, compensating errors arising from sub-diurnal to seasonal scales are involved in the representation of the annual cycle. In general, differences among models are also found to dominate over differences among scenarios (amip, historical...).

High-frequency observations of the surface meteorology and radiative budget, available over the last decade, point to strong physical couplings between radiative fluxes and thermodynamics, for instance between longwave fluxes, DTR, water vapour, clouds and precipitation. Strong couplings are also found in simulations, but they are quantitatively distinct.

The causes and implications of these simulation biases for the study of the Sahelian climate and its future evolution are discussed.

Characterization of seasons with the wind profiles observed by VHF radar in West Africa

K. Hilaire (1) ; E. Houngninou (1)
(1) University of Abomey-Calavi, Faculty of Science and Technology, Cotonou, Benin

The variability of the West African monsoon had socio-economic and environmental impacts on populations. This variability is closely linked to atmospheric circulation, which also plays a dominant role in the organization of the monsoon. These experimental results provide information on the dynamics of winds through the features of the jets. Data are provided by a VHF wind profiler radar installed in North-Benin, precisely Nangatchori (9°6472N, 1°7411E) during the measurement campaign AMMA program (2006-2007). This study shows the presence of the African Easterly Jet (AEJ) in the middle troposphere (2-4km) . It shows also the presence of the Subtropical Jet (STJ) and the Tropical Easterly Jet (TEJ) in the upper troposphere (10 km) . The patterns obtained let distinguish two great seasons characterizing the Hydrometeorological Observatory of Oueme Upper Valley. The Hierarchical Agglomerative Clustering (HAC) applied to the wind mean velocity and frequency of direction at 10 km associated to the monthly rain confirms the two great seasons existence: one dry season (November to March) and wet season (April to October). The wet season is characterized by three phases: the pre-wet phase (April, May, June), the heart of the wet season (July, August, September) and the post-wet phase (October).

P-3330-38

Description of the agro-climatological characteristics of the rainy season in southwestern Burkina Faso for the 1970-2013 period

B. Ibrahim (1) ; W. Fonta (1) ; B. Barry (1) ; S. Sanfo (1) ; K. Greenough (1)
(1) West African Science Service Center on Climate Change and Adapted Land Use (WASCAL), Competence Center, Ouagadougou, Burkina Faso

The rain-fed agricultural system of West Africa is very vulnerable to climate variability. The different drought phases during the last four decades (1970-2010) revealed the weakness of the agriculture system with a high decrease in crop production, and a significant deficit in food availability. Many studies have identified the seasonal pattern of the rain events during the rainy season as a key driver of agricultural production failure during these drought phases. In this study, rainy season potentialities with regard to crop growth (maize, millet, and sorghum) are described for southwestern Burkina Faso through seven key climate characteristics: annual rainfall amount, rainy season onset and offset, dry spell duration, seasonal maximum rain event, maximum temperature, and wind speed. These characteristics are calculated from daily climate data recorded by a local network of 16 stations from 1970 to 2013. A computation of the intensity and occurrence of these characteristics during the rainy seasons help to draw a description of the drought phases. The rainy seasons during the drought phases are characterized by a low annual rainfall amount, a late rainy season onset, and a more frequent long dry spells (>7days). Unfortunately, the long dry spells mostly occurred during the most sensitive crop phases: leaf initiation, flowering and grain filling. Moreover, the dry spells are accompanied by high daytime temperature. The intensity and the probability of occurrence of the other extremes events (hot spell and strong wing) in the rainy season are very high in the study area mainly during the sowing and the harvest periods.

The adaptation strategies to these worst climate conditions in the region should include a selection of crop varieties with short cycle and the implementation of a supplementary irrigation system and an agricultural insurance scheme.

P-3330-39

Project ACASIS : A early warning system on Sahelian heat waves and their impacts on health

S. Janicot (1)
(1) IRD, Paris, France

While the heat wave impacts on public health have been widely addressed in developed countries especially after the intense event over West Europe during summer 2003, no effort has been made to detect them and evaluate their impacts in least developed countries, and especially Africa, where climate is warmer and adaptation capacities are low. Over West Africa preliminary interviews, climate and epidemiologic analyses show however that this problem is emerging and climate projections indicate that such events should increase in frequency and intensity in the coming decades. However these climate models display important temperature and radiative biases over this region, which must be reduced to provide robust information on the future evolution of heat waves.

Starting from this context, the main objective of ACASIS is to set-up a pre-operational heat wave warning system over West Africa tailored to health risks of the population living in this region. This is a demonstration project focused on Senegal and Burkina where national weather services have already started developing products dedicated to weather/climate and health relationships, and where several health and demographic observatories have been operating for up to several decades. Based on qualified meteorological, climate and demographic data bases, firstly, the dynamics of the heat wave events and their atmospheric patterns will be determined, as well as their evolution over the last decades. Their predictability at short and medium ranges will be evaluated on ensembles of multi-models forecasts outputs. On a longer time scale, control simulations and climate scenarios of the CMIP5/AR5 (5th phase of the Coupled Model Intercomparison Project the results of which are synthesised in the IPCC Assessment Report) database will be analysed and the simulated future evolution and associated uncertainty of these events will be evaluated. More precisely the processes at the origin of model radiative biases will be examined and reduced as much as possible. In parallel, epidemiologic studies associated with interviews will be conducted in the health and demographic sites in Senegal and Burkina in order to evaluate the physiologic and social vulnerability of the African population to high temperature extremes. It will allow to define tailored bio-meteorological indicators to be used in the warning system. From these outcomes and by implementing downscaling to link the synoptic scale of the heat waves to local bio-meteorological indicators, we will set-up a demonstration warning system on a "testbed" platform named MISVA, already implemented as the result of a prior collaboration between Meteo-France, OMP and ANACIM, the meteorological agency of Senegal. Based on the interviews, and with the setting of several workshops with stakeholders and public institutions, we will be able to provide specific recommendations associated to these warnings. An implementation in the Meteo-France operational system at the end of the project or after might be possible.

To carry on this project, a pluri-disciplinary consortium has been set-up gathering climatologists, physical processes specialists, meteorologists, biostatisticians, demographers, socio-economists, epidemiologists, geographers, and operational meteorological agencies. It

will work through a close collaboration between French and African teams where young African researchers will be highly involved.

P-3330-40

Estimation of the West African Monsoon variability through the analyses of the induced wave parameters

P. Kafando (1) ; F. Chane-Ming (2) ; M. Petitdidier (3)
(1) University of Ouagadougou, Department of Physics, Ouagadougou, Burkina Faso; (2) Université de la Réunion, Laboratoire de l'atmosphère et des cyclones, Saint- Denis, France; (3) Université Versailles St-Quentin; Sorbonne Universités, UPMC Univ. Paris 06 , Cnrs/insu, latmos-ipsl, Paris, France

Using local (rainfall data) and global satellite observations (atmospheric fields reanalysis, OLR data, satellite-observed brightness temperature data and cloud cluster data), the activity of convective equatorial waves revealed to be strongly coupled with the West African Monsoon (WAM) variability.

A previous study of wave activity in the West African area (Kafando et al., 2008), revealed that the signature of the monsoon is clearly observed on total energy density in the lower stratosphere (19-23km). The annual cycle and the climatology of wave total energy density showed that peaks of activity match the period of intense convection. In the present study, wave activity in relation with monsoon proxies (convection and precipitations) has been used to analyze the WAM interannual variability using nine years radiosonde observations, Tropical Rainfall Measuring Mission (TRMM) data and Outgoing Longwave Radiation (OLR) data over several West African meteorological stations located in the latitudinal belt 4°N-20°N.

P-3330-41

Impact of climate variability on the water balance of the anthropized Agneby watershed in the southeast of Côte d'Ivoire: application of nTopAmma hydrological model

B. Kamagate (1) ; N. Dabissi (2) ; A. Bamba (3) ; S. Issiaka (4)
(1) Université Nangui Abrogoua, Laboratoire de géosciences et environnement, Abidjan, Ivory Coast; (2) Université Nangui-Abrogoua Abidjan (Côte d'Ivoire), UFR Sciences et Gestion de l'Environnement (SGE), ABIDJAN, Ivory Coast; (3) Universite Nangui Abrogoua, SGE, Abidjan, Ivory Coast; (4) Université Nangui-Abrogoua, Ufr sge, Abidjan, Ivory Coast

Agneby Watershed (8490 km2) is located in the southeast of Côte d'Ivoire. It is subject to a monsoon (1500 mm annual rainfall) with four contrasted climatic seasons. This basin is also subject to strong human impact that contributes to a change in water balance due to intense agriculture (cocoa, coffee, rubber and food crops).

This work is part of a general framework for understanding the impact of climate variability and agricultural intensification on water resources in the watershed of the Agneby. The main objective of this study is to evaluate by modeling the different terms of the water balance and their evolution over the period 1970-2000. We use a modified version of nTopAmma model developed from observations in the upper basin of Ouémé (wet site AMMA-Catch observatory). The nTopAmma model favours the shallow groundwater efflux as the origin of the flow. The amended taking into account changes in land use and the seasonal cycle of vegetation in the calculation of evapotranspiration can address the impact on the water balance of the plant cover changes.

P-3330-42

Climate impact studies in the Sahel: A word of caution

L. Kergoat (1)
(1) GET, Umr cnrs 5563, Toulouse, France

One can easily understand why climate impact studies are increasingly solicited for regions such as Subsaharan Africa in general and the Sahel in particular. Past climate fluctuations like the multidecadal drought that started in the 70ies had a very strong impact on people, societies, natural resources, and ecosystems. The Sahel drought is the strongest multidecadal drought recorded so far, and this drought combined with a high vulnerability to result in dramatic consequences.

Therefore, it seems meaningful to address the consequences of future climate changes in the Sahel. However, I would argue that a number of limitations and misunderstandings considerably reduce the conclusions one can reach with climate impact studies.

Managers, resources planners, stakeholders, NGOs and scientists in non-climate domain like ecology, hydrology or health, often look for climate projections which have horizons of 20, 30 or 50 years, and in many cases, which are local or regional, from the size of a city to one or a couple of countries. Again, the logic behind these scales is rather straightforward: A couple of decades is seen as the proper timescale for many infrastructures planning (buildings, dams), and for public policies also (laws on resource use and preservation for instance) . The spatial scale, from local to regional, obey the same logics. Of course, there are also interests in larger spatial scales (global, continental) and longer time scale (century), but this is not the most common design of climate impact studies.

Based on a review of recent studies, I will argue that caution is needed for impact studies in the Sahel because of two rather simple facts of far-reaching consequences:

- 1) The Sahelian climate at these time-scale is dominated by multidecadal variability. A few climate parameters may escape this statement, like surface temperature just before and after the monsoon season (Guichard et al. this session, Léauthaud et al. this session), and more global parameters like sea level and CO2 atmospheric concentration. However, most parameters related to the monsoon season are dominated by the multidecadal variability: this notably includes rain, temperature during the rain season, and less immediate factors like dust emission in the dry season and ecosystem dynamics that also depend on rain. Of course, these parameters have huge impacts on many systems and activities. I will show examples of effect of climate variability on ecosystems and hydrosystems.

- 2) Present climate models do not have the skills to produce reliable projections of future multidecadal variability. This is true for global and regional climate models, coupled with oceans which multidecadal variability has still to be fully understood. This is a well known issue in the climate community, which is probably not that well recognized in the 'impact' community and by the funding agencies. To make things worse, even the longer term trend is prone to marked differences in climate scenarios for the Sahel.

For these reason, I would call for cautious in impact studies. Multidecadal variability has to be considered, and its understanding is, in my opinion, a prerequisite to most impact studies. Extensive dialog between communities is needed to clarify this issue as much as possible.

Improving the incomes of producers on family farms in the context of climate change in Burkina Faso

P. Kinda (1)
(1) Insitut d'Applications et de Vulgarisation en Sciences, Sciences et économie des changements climatiques, Ouagadougou, Burkina Faso

Climate change in the context of Burkina Faso results in recurrent pockets of droughts, heat waves, reduction in the number of rain days and a high variability of rainfall. The consequences of this claimate hazards on family farming are inter-alia, the drop of productions and yields. One of the major challenges of the agricultural sector is improving yields and incomes. Our research aims at presenting the initiatives developed in connection with the improvement of yields and incomes of the producers of family agriculture covering more than 90% of farmers in Burkina Faso. Climate information associated with proven practices and the market information system used could inspire other stakeholders of family farming in similar contexts.

P-3330-44

Impact of climate on groundwater recharge in the crystalline basement rocks aquifer of Northern Ghana

KV. Koffi (1)
(1) WASCAL/ University of Abomey-Calavi, Abomey-Calavi, Benin

Water is the cornerstone of human life and for all economic developments. West Africa and specifically Ghana are no exception to this reality.

Northern Ghana is characterized by a semi-arid climate, with prolonged dry season (7 months of very few rainfall) leading to the drying up of many rivers and streams. In addition, rainfall is highly variable in space and time. Therefore, surface water is unreliable and insufficient to meet the water demands for socio-economic development in this area. As a result, the area is heavily dependent on groundwater for domestic water supply as well as for dry season irrigation of vegetables (cash crops).

However, aquifers in northern Ghana are dominantly the hard rock type (Crystalline basement rock). This aquifer has no primary porosity and may not be able to sustain the increasing demand on the resource. Further, climate change may worsen the situation as recharge is dependent on rainfall in northern Ghana. Therefore, it is important to understand exactly how climate change will impact on recharge to the groundwater for sustainable development and management of the resource.

Previous groundwater studies in Northern Ghana barely analyzed the impact of Climate change on the recharge to the groundwater. This research is aimed at determining the current relationship between groundwater recharge and rainfall and to use the relationships to determine the impacts of changes in climate on the groundwater recharge. The results will inform plans and strategies for sustainably managing groundwater resources in Ghana and the Volta basin.

P-3330-45

From Artisans to Entrepreneurs: Understanding the role of small business for sustainable energy access

W. Kruger (1) ; R. Aitken, (2)
(1) University of Cape Town, Energy Research Centre, Cape Town, South Africa; (2) Restio Energy Pty Ltd, Somerset West, South Africa

The «Developing Energy Enterprises Project - East Africa» (DEEP EA), which ran from 2008 to 2013, was funded by the European Union (EU) and the Dutch Ministry of Foreign Affairs (DGIS). The Global Village Energy Partnership - International (GVEP-I) coordniated the partnership programme responsible for implementing the project. DEEP EA aimed to increase clean energy access among the rural and peri-urban poor in East Africa by assisting entrepreneurs to grow their businesses through enterprise training, mentorship and possible linkages to finance. The project was implemented in Kennya, Tanzania and Uganda, and included three principle technologies and services: improved cook stoves (ICS), briquettes and solar PV (solar lanterns, solar home systems, and PV-based mobile phone charging). During March 2013, Restio Energy conducted an independent terminal evaluation of DEEP EA. This presentation is aimed at capturing and articulating many of the lessons learned - with the purpose of strengthening majority market climate change mitigation enterprises in the future. DEEP EA provides a number of crucial lessons on the nature of support needed to stimulate private sector-led energy access initiatives in Africa. Ther project has discovered how to develop people from artisans to entrepreneurs; from someone merely involved in producing a piece of low-tech, low-carbon energy technology to someone who takes ownership of the entire business aspect. Throughout the project, there has been an effective non-technical shift in business performance, which (along with the technical abilities) has raised the performance of a significant number of these DEEP EA supported businesses. Overall, the project has developed a deeper and more textured undertanding of the challenges of entrepreneurship in East Africa. The small and micro-business model that emerges presents a blend between certain defining features of the formal economy and other features with a distinct «informal economy» nature. The outcome is a blend that is more in-tune with the socio-economic realities of not only the entrepreneurs themselves, but the market they service. This is where a great deal of support should be aimed if the private sector is to play its indispensable role in meeting the Sustainable Energy for All targets by 2030.

P-3330-46

Recent climatological trend of the Saharan Heat Low and its impact in West Africa

C. Lavaysse (1) ; C. Flamant (2) ; A. Evan (3)
(1) European Commission / Institute for Environment and Sustainability, Climate risk management unit, Ispra, Italy; (2) LATMOS, Paris, France; (3) Scripps Institution of Oceanography, La Jolla, CA, United States of America

The Saharan Heat Low (SHL) plays a crucial role in the West African Monsoon in spring and summer. The recent trend in SHL activity has been analysed using two sets of numerical weather prediction reanalysis. A local increase during the 90's has been found in the two sets of temperature. This increase is stronger within the heat low region than the surrounding areas. This change is accompanied by a modification of the large scale and slow increase of temperature, but we do not observe a change in the filtered signal under 25 days. Despite a large variability of the temporal trends between 15 climate models from the CMIP5 project, the trend is observed using the ensemble mean. Nevertheless, the spatial and temporal evolutions of the HL activities display a large difference between the reanalysis and climate models. The impacts and atmospheric variabilities have been compared in reanalysis and climate models and reveals different behaviours of the climate models to represent the west african monsoon interactions with HL pulsations.

P-3330-47

Changes in temperature and precipitation patterns in Benin Republic between 2000 and 2050

AE. Lawin (1) ; Pl. Akponikpè (2) ; A. Jalloh (3) ; CG. Nelson (4) ; TS. Thomas (4)
(1) Faculté des Sciences et Techniques, Laboratoire d'Hydrologie Appliquée, Cotonou, Benin; (2) Faculté d'Agronomie, Environmental soil physics and hydraulics unit. (pshe), Parakou, Benin; (3) West and Central African Council for Agricultural Research and Development, Dakar, Senegal; (4) International Food Policy Research Institute, Washington, United States of America

Climate change is considered as a worldwide concern. The consequences include changes in temperature and precipitation patterns, with more and more extreme weather events, and shifting seasons. It will disproportionately affect the poor who depend mainly on agriculture for their livelihoods and have a lower capacity to adapt. Benin republic's economy is based essentially on agriculture and its population is projected to at least double (to 18 million) or possibly more than triple (to 25 million) by 2050. Food security is therefore a great challenge for policy makers.

This work focused on analyzing climate changes in temperature and precipitation trends between 2000 and 2050 in Benin. Four downscaled climate models (i.e CNRM-CM3, ECHAM5, CSIRO-MK3 and MIROC3.2 GCMs) and 2 climate scenarios (A1B and B1) were used to assess changes.

We found that all four GCMs show an increase in the normal annual maximum temperature for the whole country, ranging from slight (1°-1.5°C for MIROC 3.2) to substantial (2.5°-3.0°C). The climate models show different outcomes for precipitation levels for the country in 2050. CNRM-CM3 and ECHAM 5 showed increased precipitation, while the two other models (CSIRO Mark 3 and MIROC 3.2) showed areas of precipitation decrease, mainly in the south. These changes in climate may affect in varying ways crop production and food security.

P-3330-48

Observed multidecadal changes in air temperature from 1950 to 2010 in the Sahel

C. Leauthaud (1) ; F. Guichard (2) ; L. Kergoat (3) ; J. Barbier (2)

(1) LSCE, CEA, Gif-sur-Yvette, France; (2) CNRM-GAME (UMR 3589, CNRS and Meteo-France), Toulouse, France; (3) GET, Umr cnrs 5563, Toulouse, France

The Sahel experienced in the last decades the strongest climatic signal ever recorded. Alongside the well documented changes in precipitation amount and frequency of extreme events, modifications of air temperature stronger than the global increase in mean annual temperature in the past 60 years is evidenced. However, little is known about the changes in the seasonal and diurnal cycles in temperature and the underlying processes. Furthermore, most studies addressing this subject rely on satellite products or gridded datasets and not directly on observational data, thus limiting their temporal depth and accuracy.

The objective of this study was to address this shortcoming by analyzing observational air temperature data obtained from the various synoptic and daily datasets available for the Sahel region (roughly defined here by the box 11-17°N ; 18°W-20°E) and its surroundings during the period 1950-2010. To do so, all available synoptic and daily temperature data were collected. Only stations retaining less than 20 % missing data were retained for analysis. This final database was constituted of over several tens of stations spread over the Sahel region. Analysis focused more specifically on (i) characterizong the seasonal and daily cycles of daily minimum and maximum temperatures, and (ii) comparing them with available gridded datasets for specific localities.

Preliminary results show that temperature characteristics have indeed evolved, with an increase of mean daily air temperature of over 1°C over all the Sahel. Increases are most important at the onset of the rainy season. The observed decrease in diurnal temperature ranges is mostly explained by strong increases in minimum air temperature. Finally, the evolution of temperature characteristics differed geographically, with stronger variations in the Northern part of the Sahel. It is now important to compare these observational data with meteorological reanalysis and with historical simulations of Global Climate Models. This is undertaken in a companion presentation by Guichard et al.. These modifications of daily temperature, diurnal temperature range and minimum and maximum air temperature can have serious consequences on agriculture, but also human health, even the more as increases have occurred in periods of the year during which temperatures are already critically high.

P-3330-49

Innovating low carbon waste management models in developing countries: a case of local community based artisanal entrepreneurship in Sub Saharan Africa countries

J. Li (1) ; L. Dayan, (2)

(1) Curtin University of Technology, Perth, Australia; (2) University of Paris 1 Panthéon-Sorbonne, APREIS, Paris, France

The prospect of global economic growth in the next decades will depend on the performance of emerging and developing economies given their rapid population growth and accelerated urbanisation and industrialisation. Growth in emerging markets will not sustain without the inseparable concern for ecological sustainability of their economies and the global environmental challenges such as climate change. The global sustainability targets can only be achieved when actions are taken at both global and local levels. It entails decoupling the global economy of pollution, shaping autonomous and endogenous local development, organizing productive social inclusion while enabling decentralized governance of a multipolar global economy at the local level, driven by local solidarity initiatives and culture-specific entrepreneurship in developing nations. This paper aims to shed light on how local entrepreneurship innovations may contribute to sustainable and inclusive growth, enhanced human capital and global equity in sub-Sahara Africa from the perspective of a specific sector—namely waste, in which multidimensional challenges of poverty reduction, cultural diversity conservation, community solidarity and climate change governance are intertwined. One key element of sustainable development and climate governance in SSA is the waste. Today waste is a thorny issue in many SSA countries and has resulted in significant resources loss, income deficiency and poverty concentration, greenhouse gases emissions, and disastrous environmental impacts including public health degradation. The widespread practice of dumping waste into water bodies and scattered dumps prompted by fast-growing urbanization contribute to aggravate the problem. In effect, investments from FDI and aid programmes led by international institutions such as UNEP, World Bank, European Commission have indeed brought capitals and technologies necessary for the socioeconomic development programmes in SSA countries. It is not yet clear how these parachuted aids and investments are accommodated locally and how they impact traditional artisanals in waste treatment from the perspective of poverty reduction and local governance for climate change mitigation and adaptation. It would be inappropriate to transplant directly the top-down waste management model developed in industrialised countries to SSA without adaptation to local community-based solidarity culture and inclusion of bottom-up entrepreneurship innovations, particularly in the domain of utilisation of agricultural residues for generating renewable energy. This study attempts to answer a key climate policy question: how can low-income SSA countries develop a climate friendly waste-based circular economic growth model incorporating bottom-up entrepreneurship innovations? The model takes into account traditional artisanal know-how and communal solidarity as well as sustainability ethics within an intercultural environment, which is pertaining to Africa in the context of growing urbanization and socioeconomic transition. Our study focuses on several low income countries in SSA: namely Cameroon, Ivory Coast, Burkina Faso, Guinea, Senegal, Niger and Ghana. To render our research results replicable to a broader development perspective, we draw lessons from the experiences in the projects implemented by APREIS in Burkina Faso and Cameroon over the past years, and also from some Latin American countries such as Brazil and Argentina in particular where waste management is characterised by bottom-up civil organisation model with limited state intervention. Community economy experiences learnt from our fieldwork suggest that pro-development policy encouraging 'inclusive innovations in climate friendly waste management entrepreneurship' has to incorporate four building blocks: economic, social, environmental and cultural dimensions within a coherent climate governance framework in SSA countries.

P-3330-50

Multi-Agent System for simulating the change pattern of agricultural land-use under changing climate in the semi-arid region of Ghana

A. M. Laouali (1) ; G. Villamor (2) ; MA. Emmanuel (3) ; KB. Nicholas (4)

(1) Kwame Nkrumah University of Science and Technology (KNUST), Civil Engineering, Kumasi, Ghana; (2) Centre for Development Research, Bonn, Germany; (3) University of Ghana, Legon, Department of geography and resource, Accra, Ghana; (4) Kwame Nkrumah University of Science and Technology (KNUST), Agricultural engineering, Kumasi, Ghana

One of the operationalised tools of human-environment system (HES) approach is Multi-Agent System (MAS) which has been used in a number of areas to study the dynamics and management of human and natural systems especially when facing unexpected disturbance. Therefore, increasing studies are interested in using MAS approach for the understanding of agricultural adaptation to environmental change. However, when it comes to the use of MAS for the operationalization of adaptation decision making in agricultural land-use based on the implications of climate variability, only very few studies empirically operationalise the concept in their simulations. In this research, Land Use Dynamic Simulator (SKY-LUDAS as referred to the communities where it was implemented: Sirigu-Sumbrungu-Kandiga-Yuwa) framework was applied by integrating the two step-decision making sub-models. Therefore, three scenarios have been designed and tested: baseline (Baseline), perception of climate change (PCC) and No perception of climate change (NO-PCC). Simulation results of SKY-LUDAS suggested that the

land-use behaviour in the study area reflects a tendency of subsistence farming. In terms of farm-households' livelihood strategy, especially the structure of the farm income, there was a growing contribution of rice and groundnuts. Accordingly, SKY-LUDAS has revealed a gradual shift among land-use types from traditional cereals farming to the cultivation of groundnuts and rice. As a result, this study has a merit of contributing to answer the critical question on whether certain adaptation decisions are stimulated by climate change. Therefore, farmers in the study area have adapted their land-use to climate change based on their income source and gradual change in the cultivated land-use in the purpose of being less dependent on the vulnerable farming systems.

P-3330-51

A Bayesian Trend analysis of annual maximum stream flows of the Oti River Basin (West Africa)

B. H. Maleki (1)
(1) WASCAL GRP - Climate Change and Water Resources, University of Abomey-Calavi, Benin, Benin

Non-stationary analysis of hydrological extremes is crucial for characterizing hydrologic phenomena, planning and management of hydraulic and water resources systems. Moreover, Bayesian analysis appears to be a consistent framework for deriving complex statistical models and implementing uncertainties into induction problems. For this study which is conducted in the Oti River Basin, West Africa (75,859 km²), a set of discharge data from two gauging stations in Benin (upstream at Porga) and Ghana (downstream at Saboba) were obtained from the national hydrological services. These records were quality checked and preprocessed in order to derive long term annual maximum stream flows (AMSF) time series between 1952 and 2008. The Generalized Extreme Value (GEV) distribution was fitted to AMSF under stationary and non-stationary conditions. The non-stationary condition tested here is the variation of AMSF over time. To this end a time covariate was introduced in the location parameter of GEV distribution using a Bayesian approach. The results showed better non-stationary fitting for the upstream site (Porga) which exhibits significant decreasing trend in AMSF. The reservoir between the two gauging stations strongly controls the flows at the downstream gauging station which in turn affected the detection of no significant trend in AMSF while annual maximum rainfall are changing over the basin. The estimated return levels under non-stationary conditions showed a decreasing trend over time. This study provides good baseline information for climate change and flood frequency research within the basin. However, further investigations are required to understand the impact of the reservoir on the downstream discharge in general, but also on extremes and the occurrence of floods.

Impact of deforestation on surface water and energy feedbacks in sudanian region of West Africa

O. Mamadou (1) ; S. Galle (2) ; JM. Cohard (3) ; C. Peugeot (4) ; J. Seghieri (5) ; B. Kounouhewa (6) ; O. Mamadou (7)
(1) Université d'Abomey-Calavi, Laboratoire de physique du rayonnement, Abomey-Calavi, Benin; (2) IRD, LTHE, 30041 Grenoble Cedex, France; (3) Université Grenoble Alpes, Lthe, Grenoble, France; (4) IRD, Hydrosciences montpellier (hsm), Montpellier, France; (5) I.R.D., DGDS-Département Environnement et Ressources, Montpellier cedex 5, France; (6) Université d'Abomey-Calavi , Laboratoire de physique du rayonnement, Abomey-Calavi, Benin; (7) Université de Liège Gembloux Agro-Bio-Tech, Exchanges ecosystems - atmosphere, Gembloux, Belgium

In West Africa, surface atmosphere exchanges have been found to impact both regional and local features of the Monsoon. At local scale the spatial patterns of evaporative fraction can drive the trajectories of mesoscale convective systems. Within Sudanian climate, ~80% of the precipitation returns to atmosphere through evapotranspiration. However, this amount and its seasonal dynamic may vary with the vegetation cover. Consequently, one might expect that any land use or climate changes could lead to the modification of the surface water and energy feedbacks, and, thus both the atmospheric and the regional water cycle. Finally, the sudanian region of West Africa is submitted to a 3% demographical increase per year, which induces a drastic expansion of crops areas. This study aims at quantifying the changes in evapotranspiration and sensible heat flux regimes caused by such a land use change under sudanian climate.

The AMMA-CATCH observatory documents evapotranspiration flux in West Africa since 2007. A pluri-annual energy budget term of a clear forest and a cropland area are analysed. It is shown that sudanian forest evapo-transpirated always more than crop areas because of agricultural practice, which cleaned to bare the crops areas with bush fires and water availability for trees. Thus, during the dry season, the cultivated areas remain bare. At the same time, more than 1mm per day of evapotranspiration rate is measured above the forest area despite the lack of precipitations. Deep rooting systems allow the clear forest to get access to water from deep soil layers for transpiration throughout the dry season. During the rainy season, low but significant differences in evaporative fraction are also observed. These differences will lead to a large deficit of the water vapour that returns to the atmosphere, and, thus, will change significantly the continental water cycle when forests will be replaced by crops. In the future, agroforestry that combines local crops (yam, manioc, millet, etc.) and sparse trees could mitigate surface feedbacks. Finally, the selected trees could provide extra agricultural products taking benefit from deep water availability, but also strengthen social equilibrium between men and women.

Impact of Climate, Agriculture and Vegetation in the Sahel in the recent past : the CAVIARS Projet

B. Marticorena (1) ; CT. The (2)
(1) LISA, CNRS-UPEC-UPD-IPSL, Créteil, France; (2) GET; CIRAD; CNRM-GAME; iESS-Paris; LTHE ; JEAI ADE, Toulouse, Montpellier, Bondy, Grenoble, Niamey, France

The semi-arid regions of the Earth are particularly vulnerable to wind erosion. The Sahelian region experienced contrasted climatic conditions during the last decades, with severe drought in the 70's and 80's and a relative re-greening in the recent years. Over the same period, changes in land use have occurred with an increase of the cultivated surfaces leading to a decrease of fallows and rangelands. As a result, a significant proportion of the land is bare or sparsely vegetated, and thus is not efficiently protected from the erosive action of wind. In this region, wind erosion tends to decrease the productive capacity of the soils whose fertility is already very low. In addition, the impact of wind erosion is expected to increase significantly in the near future (1) in relation with the expected changes in climate (in particular the modifications of precipitation and surface wind) and (2) in response to the increasing land use due to population increase and the related food needs.

The aims of the CAVIARS project (Climate, Agriculture and Vegetation: Impacts on Aeolian ERosion in the Sahel) are to develop an integrated modeling tool to describe the evolution of wind erosion in the Sahel in connection with climatic and land use changes, to validate this tool in the current period by making the best possible use of the numerous data sets acquired in recent years over West Africa, and to test its ability to reproduce specific events (such as the drought in the Sahel) of the recent past (about the last 50 years). This project is based on a modeling approach of this recent past (hindcasts) that is justified by the need to ensure the robustness of the simulations with different forcings prior to any simulation of future scenarios.

The proposed strategy is (1) to develop or optimize reliable modeling tools for quantifying the various terms (land use, changes in aridity...) responsible for changes in the intensity of wind erosion (2) to synthesize quality-checked observations, that can be used as direct or indirect indicators of wind erosion (precipitation time series, changes in vegetation cover, atmospheric dust load,...) (3) to implement a validation strategy based on the quantification of wind erosion both locally, measured on grazed and cultivated plots, and at the regional and continental scales.

P-3330-54

Using longterm rainfall and streamflow trends to inform local level agricultural water management in Benin

M. Masiyandima () ; C. Mufwaya, (1)
(1) AfricaRice, Sustainable productivity enhancement, Cotonou, Benin

Due to lack of irrigation and water storage facilities rice production is mostly practiced under rainfed conditions across most of Benin. Farmers use temporary water control structures to divert water from streams to rice fields in valley bottoms. This type of production system is dependent on rainfall and streamflow. It is vulnerable to natural variability of rainfall and streamflow. Analysis of rainfall and streamflow observed in the Ouémé River basin between 1951 and 2012 was carried out to understand rainfall and streamflow trends at local level to identify relevant climate indicators and data that best serve the needs of farmers for water management at local level as a way to improve water management and productivity under a changing climate. The Mann-Kendall test was used for the analysis. Significant rainfall trend was confirmed at 3 of the 19 rainfall stations in the basin. The 3 stations showed increasing rainfall at 95% confidence level. An increasing trend was evident at 13 stations but not significant at 95% confidence level while a decreasing trend was evident at 3 stations. Increasing streamflow trend (95% confidence) was confirmed at 3 of the 13 streamflow gauging stations in the basin. Further analysis of streamflow for the non-perennial rivers in the basin showed increasing number of days with zero flow at 2 of 8 streamflow gauging stations and decreasing number of days with zero flow at 1 station (95% confidence). Long term trend of monthly rainfall for June, July, August and September (the rice growing season) provided additional insight into variability at local level. This research highlights the relevance of considering indicators that may be relevant for local level water management in support of rainfed agricultural production in the Ouémé River basin in Benin.

P-3330-55

Assessment of climate change impact on water resources in the senegal river basin

ML. Mbaye (1) ; A. Haensler (2) ; S. Hagemann (3) ; AT. Gaye ()
(1) Universite Cheikh Anta Diop, Ecole Superieure Polytechnique, Fann-Dakar, Senegal; (2) Climate Service Center, Hamburg, Germany; (3) Max Planck Institute for Meteorology, Hamburg, Germany

In this study we assess the impact of climate change on water resources by using uncorrected and bias corrected data of the regional climate model REMO simulations over the Senegal River Basin (SRB). Both simulations were used as input of the Max Planck Institute for Meteorology - Hydrological Model (MPI-HM) over the Upper Senegal Basin (USB).

Applying the bias correction simulations of present day climate (1971-2000) substantially improved for both temporal and spatial variations of the analyzed climate parameters (precipitation, temperature) when compared to observations and independent station data. Additionally, the bias corrected input give better representation of the mean river flow regimes and the 10th (low) and 90th (high) flows at the outlet of the USB.

For the future, the regional climate model projections for precipitation show a general decrease by the end of 21st century (2071-2100) for both scenarios (RCP4.5 and RCP8.5 Representative Concentration Pathways) and datasets in the majority of the basin, except the Guinean highlands where slight increase is found. In case of the potential changes of the maximum number of dry days and wet days, the northern basin is likely to face the most pronounced increase of dry days and decrease of wet days, although slight increase of heavy rainfall is found with similar spatial patterns in both data. Higher decadal variability of the maximum 5-day precipitation with the uncorrected in RCP8.5 is projected, while uncorrected and bias corrected data depict similar temporal variability for extremely wet days. Furthermore, a general temperature increase is projected over the entire basin for both scenarios, but more pronounced under the RCP8.5 scenario. Warm night's percent is found to be higher than warm day's percent. As for the potential changes of the basin's hydrology, a general decrease of river discharge, runoff, actual evapotranspiration, soil moisture is found under RCP4.5 and RCP8.5 in all simulations. The decrease is higher under RCP8.5 with uncorrected data in the northern basin. However, there are some localized increases in some parts of the basin (e.g Guinean Highlands). Furthermore, the available water resources are projected to substantially decrease by more than -50% in the majority of the basin for all data, except the Guinean highlands where no change is projected.

The impact of the bias correction on the projected climate change signal, affects mainly the magnitude of the signal rather than its direction of change although some alteration may occur in particular months and localities.

P-3330-56

The main projections of the West African monsoon : mean climate, seasonal cycle, extreme rainfall events

PA. Monerie (1) ; E. Sanchez-Gomez (1) ; J. Boé (1)
(1) CERFACS, Toulouse, France

The main responses of the climate change effect on the West African Monsoon is evaluated in terms of mean climate and intense rainfall events with CMIP5 models under the rcp8.5 emission scenario. We examine the projections and how they are related to the mean biases of the historical model simulations. The projections range from an increase to a decrease of rainfall amounts, exhibiting a large spread. These differences are due to radiative forcing ranging from 4 to 6°C in the Saharan desert and to feeding (export) of moisture at low-level (mid-level). A majority of models exhibits a decrease (increase) of rainfall over the western (central) Sahel along with more subsidence (air ascent) and a southward location of the AEJ (more moisture flux convergence). The extreme indices change exhibit a more extreme Sahelian climate, but the results remain strongly model-dependant. This study draw up a catalogue of the model projections in order to allow a selection of models for impact studies.

P-3330-57

The impacts of environmental variability and model uncertainty in disease prediction

A. Morse (1) ; A. Jones, (1) ; C. Caminade (1) ; J. Leedale, (1) ; D. Macleod, (2)
(1) University of Liverpool, Geography and Planning, Liverpool, United Kingdom; (2) University of Oxford, Physics, Oxford, United Kingdom

Modelling vector-borne diseases using dynamical models driven by climate and environmental variables is a complex task. The models require both accurate predictions of the seasonally varying values of environmental drivers and their correct variability across a range of time scales from days to decades. Whereas, the model's internal structures and the parameter settings for key processes have to develop the correct sensitivities to the external driving variables. The relationship between these two areas develops the inherent uncertainties in the model outcomes especially when driven with an ensemble of outputs from climate models.

Most of these detailed diagnosis runs and investigations are undertaken within the initial development phases of the models. Detailed diagnoses are perhaps even more challenging than the initial model development and construction. Once the model becomes established, in its use, the pace and quantity of model runs required in large collaborative projects make it difficult to find time and resource to allow detailed in depth diagnosis. Development of partially automated diagnosis methods and visualisation needs to be supported with the ever increasing loading of climate model runs that are being undertaken by disease modelling groups.

This paper will discuss two models the established Liverpool Malaria Model (LMM) and the recently developed Liverpool Rift Valley fever model (LRVF). Using the LMM we explore the relationship between seasonal average climate and malaria risk, which remains largely unquantified.

We also investigate key uncertainties in the malaria model, by introducing variability in parts of the model formulation. Results are visualized as location specific impact surfaces: easily integrated with ensemble seasonal climate forecasts. Using the LRVF, which is based on but much more complex than LMM, having two dynamic vector models and a dynamic age stratified host model. One main task in its development was parameterising the two different behaviours of the two vectors correctly in the model. In that, Culex spp. mosquitoes are the amplifying vector that, in the model, and only show significant spikes in population dynamics and EIR following flooding and a sizable Culex spp. population. The Culex spp. were infected from a substantial number of infectious hosts in the model simulation. These host infections came from Aedes spp. mosquitoes whose relationship with rainfall is more complex and gain infection through vertical transmission.

P-3330-58

How farmers permanently adapt to climate evolution by testing new options and caring for food security: case of long-cycle sanyo millet comeback in Serer area in Senegal

B. Muller (1) ; L. Richard (2) ; P. Kouakou (3) ; S. Arame (4)
(1) CIRAD, Bios umr agap, Montpellier, France; (2) IRD, Umr 151 urd/amu, Marseilles, France; (3) ISRA-CERAAS, Thiès, Senegal; (4) UCAD, Département de géographie, Dakar, Senegal

During the last decade, Serer farmers of the Sine region in the central and western part of Senegal have started to grow again the sanyo millet (Pennisetum glaucum), a long-cycle (110-140 days) and photoperiodic traditional variety that had disappeared for 30 years from this region due to the rainfall decrease which has affected the Sahelian and Sudano-Sahelian zones starting from 1970, leaving only the short-cycle (90 days) souna millet in the fields. We made the assumption that the reintroduction of the sanyo millet could be an agronomic "marker" of the increase in rainfall observed in Senegal since the mid-1990s (Salack and al., 2011) attesting to the capacity of farmers to adapt to the evolution of their environment. We wanted to check, however, whether this necessary climatic opportunity was sufficient to explain farmers choices.

We investigated how important was the sanyo comeback in local farming systems, its geographical diffusion, and its biophysical, economic, social and cultural drivers. We carried out (a) simulations of souna and sanyo annual development during the 1950-2013 period using the SarraH©Cirad model; (b) several Focus Group Discussions with farmers; (c) a large survey by questionnaire on farming systems among 1,061 farms in the 30 villages of the IRD human and health observatory zone of Niakhar (monitored since 50 years); and (d) a rapid survey in 240 villages of the region located between Bambey and Diourbel in the North and Fatick in the South (about 1000 km2) on whether the sanyo millet was grown and its date of reintroduction. The SarraH©Cirad crop model was parametered according to previous works. Survey data were carefully analysed using relevant statistics to assess the factors underlying sanyo reintroduction.

Crop model simulations confirmed that sanyo reappearance is due to the recent rainfall improvement which now allows getting again grains with this variety whereas since 1970 grains production was only possible with souna. But simulations also show that sanyo yields remain very risky due to the rainfall interannual variability whereas souna yields are higher and surer. They also show that sanyo provides important biomass (stalks and straw). Farmers comments and surveys data analysis complement and confirm the results of the simulations. First, peasants report that they prefer the taste of sanyo and above all the quality of its stems rather than those of souna. In addition, adopting sanyo does not require any specific know-how or investment as it is grown like souna. Its qualities explain why it has quickly spread throughout the area. Sanyo was present in 61% of the sites surveyed in 2013 compared with 23% in 2000. But farmers stress that it is a risky cultivation and that they will not endanger their food security by substituting souna with sanyo. Souna and groundnuts still remain their main staple and cash crops, respectively. They also deplore that sanyo (similarly to souna) cannot provide cash, unlike groundnuts or watermelon that has also expanded in recent years. Statistical analyses highlight some social and family influences since farmers belonging to the "warrior caste" and those whose fathers formerly cultivated sanyo are more likely to cultivate it. But "land resources" appear to be the key factor. Yet, farmers explain they would plant fields dedicated to sanyo only if they were sure to produce enough souna. This is why sanyo is mainly cropped in association with souna, in an average proportion of 1 line of sanyo for 4-5 lines of souna. Moreover farmers point out that they would easily stop sanyo if they had other opportunities, particularly if they provide cash. Thus, despite its spectacular diffusion, sanyo cover very little surfaces: in the zone of Niakhar it was present in 2013 on 2.8% of the cropped areas and on 7.3% of millet areas.

Sanyo reappearance and its important and rapid diffusion is clearly an agronomic "marker" of the recent climate evolution (rainfall increase) observed in Senegal. It attests to the adaptive capacity of farmers to quickly and autonomously adapt to the evolution of their environment by permanently looking and trying new options, but underlines how cautious they are to not endanger their food security, and confirms that a climatic opportunity is not sufficient to account for farmers' choices. Comparisons can be made with recent watermelon emergence in the same area and developments of maize and rainfed rice areas in the southern areas of Senegal, which have been enabled by the rainfall evolution but benefit of solid economical drivers.

P-3330-59

Economic futures of African family farms in the face of climate change: addressing three big questions through integrated assessment with a Tanzanian case

K. Mutabazi (1)
(1) Sokoine University of Agriculture, Agricultural Economics and Agribusiness, Morogoro, Tanzania, United Republic of

Family farms have sustained the livelihood and development of most Sub-Saharan African countries and will continue to do so for a foreseeable future. Much of the development literature has widely addressed the economic futures of African family farms in the perspective of regional and global economic trends and trajectories -with limited attempts of scoping these futures in the context of climate change. Where such attempts have been made, the assessments overly fall short of an integrated approach that utilizes recent advances of interfaced biophysical and economic modeling. Based on a sample of 168 family farms in the semi-arid and sub-humid farming systems of Wami-Ruvu Basin in Tanzania, the paper applies an integrated climate change assessment to address the following three big questions: How the African family farms will be impacted by climate change if they continue with business as usual? What will be the impacts with foreseen development pathways without adaptation? What will be the impacts with foreseen development pathways with adaptation?

P-3330-60

Trends in daily extreme precipitation and temperature indices over Ghana from 1980 to 2011

F. Nkrumah (1) ; NAB. Klutse (2)
(1) University of Cape Coast, Physics, Cape Coast, Ghana; (2) Ghana Space Science and Technology Institute, Remote Sensing, GIS, Climate, Accra, Ghana

In this study, the spatial and temporal patterns of the variabilities in the indices of precipitation extremes, on the basis of daily data and it association with climate change at twenty synoptic stations in Ghana over the period 1980-2011 were analyzed. Daily temperature (maximum and minimum) and precipitation data over the period of 1980 to 2011 were used. Data were quality controlled, and processed into indices of climate extremes, and the indices were calculated using RClimDex which is based on R software and is developed and maintained by the Climate Research Branch of Meteorological Service of Canada. From 1980 to 2011 hot days and nights have increased, leading to a decrease in cold days and nights. Except simple daily intensity (SDII) index station, other precipitation indices

do not illustrate statistically significant trends across the whole region. The precipitation indices show a general increasing trend in annual rainfall (PRCPTOT), heavy precipitation days (R10mm) and very heavy precipitation days (R20mm) with an increasing trend also in the simple daily intensity observed. However, the results of other precipitation indices indicate an unstable trend in the intensity of rainfall. In spite of the results of the precipitation indices it is noticed that more intense rainfall is observed over short periods although the temperature trends increase sharply and dramatically. Therewith, the climate of the region is becoming warmer.

P-3330-61

Revivifying a 13th Century Craft to Enhance Community-based Adaptation through Ecosystems and Farm-lands Resilience enhancement in Uganda

D. Nkwanga (1)
(1) Nature Palace Foundation, Programs, Kampala, Uganda

Bark-cloth making is a 13th Century craftsmanship steeped in ancient culture and tradition where it played significant cultural, financial, social and conservation roles. Uganda's bark-cloth, a unique fabric proclaimed by UNESCO as 'a masterpiece of the world's intangible heritage' and indigenous textile production craft, is produced from Ficus natalensis. The F. natalensis trees are cultivated on the farm in an agro-forestry system intercropped with other crops. The bark of the tree is harvested, without harming the tree, to make an environmentally-friendly, renewable material. Where the trees have been cultivated it has been found that crops like coffee, bananas and others are able to withstand dry spells better than where it is not cultivated. Beyond this F. natalensis branches are harvested to provide a sustainable supply of firewood making households energy-secure and reducing on deforestation - cooking energy being one of the major causes of deforestation and environmental degradation; leaves of the trees provide fodder for domestic animals; and, the sale of bark-cloth provides a passive income that is always accessed by households even if the weather conditions are not favorable for seasonal crops. The presentation discusses the potential of bark-cloth making as a stimulus to long-term community-based adaptation.

P-3330-62

Climate change and surface water resource mobilization for agricultural purposes in the okpara basin (west africa)

R. Ogouwale (1)
(1) Université d'Abomey-Calavi, Laboratoire Pierre PAGNEY, ABOMEY-CALAVI, France

This research aims at evaluating the ongoing impacts of climate change on water resources availability in the Okpara basin. It seeks to identify water resources vulnerability in the basin in regard to the ongoing climate changes. These changes are characterized by variability in climate indicators.

To identify current climate change impacts, climate data of the normal (1941-1970) and (1971-2000) are assessed and compared. The rainfall averages have been used to determine differences (gaps) between the two above-mentioned normal. The data generated at different levels have been translated into relative values. As for temperatures, warming indicators are identified on the basis of calculation of the differences (° C) between the said normal (1941-1970 and 1971-2000). Besides, considering the evolution of climate parameters on the target period, 1971-2000, their future trend has been estimated.

Comparative analysis of the rainfall data between normal 1971-2000 and 1941-1970, shows overall that rainfall has decreased by 16 and 28 % in the Okpara basin. During this very period of time, temperatures have increased overall by +1° C in the basin.

This has led to a degradation of water resources in the basin, which has resulted in the Okpara River's flows downfall. In fact, analysis of the hydrological flow rate over the period 1965-2000 shows an overall downward trend of about 20-25 % during July, August, September and October, which consequently reduces water resources availability in the basin.

On the basis of projections and events considering the period 1971-2000, temperatures will be rising between 1.5 and 2° C in the basin by 2050. The fall in rainfall would be between 11 and 30 %. As for river flow, during the same period, the decline will increase up to 30% by 2025 and beyond 40 % by 2050. If this trend is not reversed, we will be experiencing a decrease of water availability in the basin.

In this increasingly climate dryness context, potential reduction of surface water resources disrupts the performance of ecological and socioeconomic systems. Facing this situation, efforts to mobilize surface water for agricultural purposes are the main measures for adapting to climate impact hazards in the basin. These efforts should be continued and backed up for a sustainable economic production.

P-3330-63

Challenges of climate change in Southeastern, Nigeria: Sustainable containment measures

E. Okoyeh (Okoro) (1)
(1) Nnamdi Azikiwe University Awka, Nigeria, Dept. of Geological Sciences, Awka, Anambra, Nigeria, Federal Republic of

Climate change, a global phenomenon has recorded great significant in sub-Sahara Africa and Nigeria in particular. The total environment of land, water and air are under the severe threat of climate change challenges (CCC). The ecological hazards of gully erosion and landslide ravaging Southeastern, Nigeria though geogenic/anthropogenic in origin have been exacerbated by increasing impacts of climate change. The well established variation in the onset and cessation of rainfall attributed to climate change has significant implication on water availability, water quality, ecological hazards, vegetation cover, food security and public health. The torrential rainfall with attendant huge runoff results in flooding. The impacts of climate change induced flooding is significant in rural, semi urban and urban areas of southeastern, Nigeria. Loss of farmland and water supply sources with impact on food and water security respectively has been recorded. Standard of living and sustainable socioeconomic developments are hindered due to climate change challenges (CCC) in Southeastern, Nigeria. Outbreak of water borne diseases especially in the river rein areas is a recurrent trend affecting poverty alleviation and capacity building. Siltation of rivers, lakes and streams is commonplace exacerbating water scarcity and sustainable development. Heavy rainfall that initiates the development of new gully erosion and landslide sites and widening of existing ones is a consequence of climate change challenge (CCC) in the area. Over 750 active gully erosion and landslide sites have been recorded in Southeastern, Nigeria with depth ranging from 2 m to > 300 m and length from 25 m to 2.9 km. Removal of sediments from gully and landslide sites and deposition of same in surface water sources has resulted in the siltation of most rivers and lakes in the area. This is complimented by the excessive heat and temperature of above 400C during the dry season to cause total loss of some surface water bodies. The impact of desert encroachment also abounds with the rate of southwards advancement of desert increasing seasonally. The degradation of the rainforest vegetation to savanna grassland with remnant of rainforest vegetation only around water courses has generated serious concern to all stakeholders in recent time. The rainforest vegetation of southeastern, Nigeria has been severely degraded exposing the arable lands to the scourging effects of climate change. These climate change challenges (CCC) disproportionally affect women and children in the developing economies such as Southeastern, Nigeria. There is need for the creation of awareness on the adverse effects of climate change on the environment in terms of water scarcity, gully development, vegetation degradation and food security. Tree planting campaign of planting two trees at the removal of one should be promoted and given the wide publicity it deserves. Laws prohibiting illegal tree cutting and building along flood plains should be constituted with the political will to punish defaulters. Establishment of research centers for researches on climate change related issues is also recommended.

P-3330-64

Use of the CORDEX simulations to with ORCHIDEE crop to assess the impact of +2/4 K climate change on crop yields in Subsaharan Africa

B. Parkes (1) ; B. Sultan (2) ; P. Ciais (3)
(1) UPMC, LOCEAN, Paris, France; (2) IRD, LOCEAN, Paris, France; (3) IPSL, Lsce, Gif sur Yvette, France

The population of Subsaharan Africa is projected to increase during the 21st century. This population increase needs to be matched with an increase in the amount of food available.

The IPCC AR5 used the CMIP5 models to assess future climate impacts on a regional and global scales. Alongside the development of AR5 recent publications have changed approach to a «not if, but when» approach to passing certain climate thresholds. The +2/4/6 K global temperature changes are examples of these thresholds. The Representative Concentration Pathways (RCPs) used in AR5 were simulated using different inputs and models and therefore reach temperature thresholds at different times. Here we present the projected change in crop yields in Subsaharan Africa for global average temperature changes of +2/4 K.

In tropical regions the ability of Global Climate Models (GCMs) to reproduce realistic weather patterns is known to be poor, this is largely due to the low resolution of climate models being unable to simulate the weather conditions accurately. To counteract the low resolution issues, the Coordinated Regional Climate Downscaling Experiment (CORDEX) used several Regional Climate Models (RCMs) to focus on specific geographical regions, including Africa, South East Asia and Europe. The higher resolution RCMs are better at simulating accurate weather and can be bias corrected to remove any large inconsistencies. Models which represent the range of the CORDEX simulations have been used to drive the ORCHIDEE-Crop model. The ORCHIDEE-Crop model is the crop specific version of the ORCHIDEE land surface model. The crop specific version has been tuned to produce accurate yields with various crops including maize, wheat and rice.

In this work we investigate how maize yields will change in Subsaharan Africa at +2/4 K using data from the CORDEX experiments. The changes in yields and the responses to different stresses will be used to assess how the future climate will affect the populations in Subsaharan Africa.

West Africa has experienced a long lasting, severe drought as from 1970, which seems to be attenuating since 2000. It has induced major changes in living conditions and resources over the region. In the same period, marked changes of land use and land cover have been observed: land clearing for agriculture, driven by high demographic growth rates, and ecosystem evolutions driven by the rainfall deficit. Depending on the region, the combined effects of these climate and environmental changes have induced contrasted impacts on the hydrological cycle. In the Sahel, runoff and river discharges have increased despite the rainfall reduction ("less rain, more water", the so-called «Sahelian paradox »). Soil crusting and erosion have increased the runoff capacity of the watersheds so that it outperformed the rainfall deficit. Conversely, in the more humid Guinean and Sudanian regions to the South, the opposite (and expected) "less rain, less water" behavior is observed, but the signature of land cover changes can hardly be detected in the hydrological records.

These observations over the past 50 years suggest that the hydrological response to climate change can not be analyzed irrespective of other concurrent changes, and primarily ecosystem dynamics and land cover changes.

There is no consensus on future rainfall trend over West Africa in IPCC projections, although a higher occurrence of extreme events (rainstorms, dry spells) is expected. An increase in the need for arable land and water resources is expected as well, driven by economic development and demographic growth. Based on past long-term observations on the AMMA-CATCH observatory, we explore in this work various future combinations of climate vs environmental drivers, and we infer the expected resulting trends on water resources, along the west African eco-climatic gradient.

P-3330-66

Regional climate modelling of the West African Monsoon regime and its use for impacts and adaptation studies in Sahelian countries

ED. Poan (1) ; P. Gachon (1) ; G. Dueymes (1) ; E. Diaconescu (2) ; R. Laprise (3) ; C. Saad (1) ; SI. Seidou (4)
(1) ESCER-UQAM, Atmospheric Sciences, Montréal, Québec, Canada; (2) Environment Canada , Canadian centre for climate modelling and analysis, Montréal, Québec, Canada; (3) Université du Québec, Earth and atmospheric sciences, Montréal, Canada; (4) Centre Régional AGRHYMET/CILSS, Niamy, Niger, Republic of

In the context of climate change, increasingly applications are asked to better adjust adaptation and mitigation policies at regional and local levels. Regional Climate Models (RCMs) appear as useful tools to downscale meteorological and climate information and make it more meaningful to fulfill end-user needs. In the framework of the International Research Initiative on Adaptation to Climate Change (IRIACC) - Faire face aux Changements Ensemble (FACE), a joint effort has been carried out to investigate different aspects and repercussions of climate change on health and agriculture over the Sahelian region in view of various RCM projections. The presentation will focus on the ability of RCMs to improve the climate information at different time and space scales, with respect to large-scale boundary conditions, in particular their performance regarding the intraseasonal variability of the monsoon regime. Precipitation onset, which significantly affects the agricultural activities, meteorological-scale rainy systems as well as daily precipitation indices (related to occurrence, intensity, and duration of daily events) are compared with the recent past observations showing a better agreement compared to global reanalyses and global climate models simulations. However, to be really helpful and oriented to specific applications, some aspects of RCMs, namely their physical parameterizations and/or simulated processes at the scale of meteorological systems, need improvements.

P-3330-67

Defining genotypic adaptation targets via crop-climate modelling

J. Ramirez-Villegas (1) ; K. Ann-Kristin (2) ; A. Challinor (3)
(1) University of Leeds and CCAFS, School of earth and environment and ccafs flagship 1, Leeds, West Yorkshire, United Kingdom; (2) University of Leeds, School of earth and environment, Leeds, West Yorkshire, United Kingdom; (3) Univ. Leeds, Ccafs, Leeds, United Kingdom

Recent literature indicates that, in the absence of adaptation, on average, climate change would reduce agricultural yields globally by 2-10 % per degree of warming. Crop breeding will likely play a critical role in

agricultural system adaptation to climate change by enhancing productivity and improving crop quality traits. Here, we explore the role of crop-climate models in informing breeding, and identify research gaps. We focus in particular on simulation of genotypic adaptation options with crop models, and on assessing the robustness of crop-climate information, with particular focus on Sub-Saharan African maize. First we present an extensive review and meta-analysis of recently published literature with regards to genotypic adaptation. Second, we develop a numerical analysis of climate information using Sub-Saharan African maize as a case study. Our review of modelling literature suggests that yield gains of up to 50 % can be achieved by breeding improved varieties. However, we find that critical knowledge gaps remain if climate model information and/or model-based projections of genotypic adaptation are to be used in the development of breeding agendas. First, certain key processes and their interactions (e.g. ozone damage, CO2 stimulation, CO2 x temperature) are still poorly represented in models, largely due to a lack of understanding, thus stressing a need for further experimentation and model evaluation. Secondly, crop model parameters are often not adequately linked to the effect of alleles on given loci or genes controlling key traits. Finally, model scale mismatches and/or model misuse accompanied with poor sampling of the model and parameter space is likely to underestimate the importance of uncertainty. Assessments of robustness are therefore a critical modelling need to underpin decision-making.

For maize in Sub-Saharan Africa, we used bias-corrected CMIP5 data to demonstrate that climate model information is robust at a range of scales, from sub-national (i.e. ~200x200 km) to the mega-environment scale. With the former being the scale at which national breeding programs set their targets and the latter being the scale at which long-term international breeding goals are set, this means that climate model information can be useful to both processes. We find early and robust changes in crop duration in all mega-environments but weak changes in drought and heat stress. These results suggest that crop-climate models can provide information regarding lead times at which some (though not all) processes become important under climate change, as well as on the rates at which certain crop traits need to change. For some breeding programmes this might enable priority setting for breeding in a changing climate. However, if the full potential of model-based information for breeding is to be realised, we stress that more work is needed on the coupling between genetic and crop growth models, as this will ultimately result in modelled traits that are better grounded in genetic and physiological knowledge. Given the complex nature of the models needed for this endeavour, it is critical that (1) understanding of driving processes under future climates continues is improved (so that traits can be prioritised in target areas), and (2) individual model component testing against observational data is performed.

P-3330-68

Reconciling Past and Future Rainfall Trends over East Africa

D. Rowell (1) ; B. Booth, (1) ; S. Nicholson. (2) ; P. Good (1)
(1) Met Office Hadley Centre, Exeter, United Kingdom; (2) Florida State University, Department of earth, ocean and atmospheric science, Tallahassee, United States of America

It is well known that rainfall during the East African Long Rains season has declined over recent decades, whereas the majority of climate models predict an increase due to anthropogenic carbon emissions. This raises questions about either the reliability of the model projections, or when we might expect this drought to turn to more abundant rainfall and perhaps more frequent flooding.

We first list all hypotheses that may conceivably explain this paradox, our aim being to include all possibilities regardless of preconceptions as to their likelihood:

- A: The recent observed trend is due to poor quality data.
- B: The projected trend arises from poor modelling of key processes.
- C: Trends are due to natural variability.• D: The balance between competing forcings is changing, with the past trend driven by aerosol emissions and the future trend driven by carbon emissions.
- E: The past trend has been driven by land-use changes.
- F: The mechanistic response to CO2 emissions is non-linear
- Some combination of the above.

Regarding A, there is good observational evidence for a recent downward trend in rainfall. Regarding B, careful and substantial further research is essential to confidently refute or accept this idea.

The possibility that the observed trend is due to natural variability (C) is assessed using two approaches. Both suggest that the recent Long Rains droughts are either due to a very unusual natural event of the climate system, or (more likely) are at least partly due to anthropogenic forcing. Hypothesis D, that the recent observed rainfall trend may be due to anthropogenic aerosol emissions, eg. from Asia, is investigated using CMIP5 sensitivity experiments. These reveal a sometimes significant, but highly model-dependent, impact on SST trends over the Indian and Pacific Oceans, which are thought to have caused the recent Long Rains droughts. Other CMIP5 experiments suggest that land-use changes are unlikely to have caused the recent droughts, and that the response to CO2 forcing over East Africa is not substantially non-linear (Hypotheses E and F).

Further work should therefore focus on improving the modelling of aerosol impacts on regional rainfall changes, on providing a well-considered 'expert judgement' of the reliability of the model's projections for the coming century, and better understanding the relevant natural variability.

Crop-Climate ensemble scenarios to reduce uncertainty in agroclimatic risks estimation under 2°C regional warming

S. Salack (1)
(1) Karlsruhe Institute of Technology (KIT), Institute of Meteorology and Climate Research,, Department of Atmospheric Environmental Research (IMK-IFU), Garmisch-Partenkirchen, Munich, Germany

The estimation of the response of rainfed crops to heat stress and water stress requires adequate accounting for the uncertainty in climatic and non-climatic factors that affect impact assessments. The objective of this research is to narrow the range of values characterizing the limits within which estimates are expected to fall in the diagnostics of agroclimatic risks. Assessments are made by analyzing historical observations and evaluating the influence of heat stress and rainfall variability on crop water demand, on biomass and on grain yields of short-cycle cultivars of pearl millet and maize. We use a wide range of consistent and practical sets of crop model ensemble analyses (based on crop management practices: seedling densities, fertilization levels, early/late sowing dates and soil types), and climate model ensembles from two climate change hypothesis (A1b & RCP8.5) over the West African Sudan-Sahel (WASS). Recent rainfall developments shows that hazardous sub-seasonal rainfall distribution affects crop productivity with increased frequency and intensity of daily rainfall, false start, early cessation of the rainy season and decreasing diurnal temperature range. In 2011-2050 perspectives, relative to the 1981-2010 baseline, a slight increase in temperature (i.e. +0.6 to +0.8 ° C) combined with a stationary-to-moderate decrease in precipitation leads to a 10-15% (8-15%) decrease in above-ground biomass production (grain yield). When the warming is moderate (i.e. +1.4 to 1.8°C), the decline in grain yield worsens (10-20%) despite a slight increase in rainfall projections. At these rates of loss in crop production, resilience can be re-enforced. However, it will require that climate-smart crop management practices are embedded in sub-seasonal and interannual monitoring and early warning systems.

P-3330-70

An observatory for farmers adaptation to climate change in Thies district

A. Sall (1)
(1) Centre de Suivi Ecologique, Dakar, Senegal

In 2011, the Centre de Suivi Ecologique and Senegalese partners have developed an innovative participatory observatory. Through exchanges between researchers, policy makers, farmers organizations and NGOs in the Thies district, the observatory plays a crucial role by sharing useful information for vulnerable communities to adapt to climate variability and change. For example farmers selected millet varieties more resilient to increase yields and fodder reserves.

P-3330-71

Assessment of water availability and demand in lake Guiers, Senegal

D. Sambou (1)
(1) West African Science Center on Climate change and Land Use- WASCAL, GRP Climate change/ Water resource, Cotonou, Benin

Water resources are critical to economic growth and social development. In most African countries, supply of drinking water to satisfy population needs is a key issue because of population growth and climate and land use change. During the last three decades, increasing population, changing patterns of water demand, and concentration of population and economic activities in urban areas has pressurize Senegal's freshwater resources. To overcome this deficit, Senegal turned, to the exploitation of the Lake Guiers. It is the sole water reservoir which can be used extensively as a stable freshwater source throughout the dry season, which lasts 9 -10 months a year. Its water is use for irrigating crops and sugar refinery and as a drinking water resource for urban centres, including Dakar, the capital city of Senegal, as well as for the local population and animal herds.

To ensure sustainability, a greater understanding of Lake Guiers's water resources and effective management of its use will be required. In this study we will investigate future water situation (water availability and water demand) in Lake Guiers under scenarios of population growth until 2050 for an efficient long-term planning of water management.

Scenarios of future water availability and water demand will be developed and quantified using the the water management model WEAP (Water Evaluation And Planning system).

P-3330-72

A systemic approach to evaluate shea parklands as possible climate smart agriculture to be intensified in Sudanese Africa : the multidisciplinary RAMSES Project

J. Seghieri (1) ; BF. Brigitte Bastide (2) ; G. Cesaire (3)
(1) I.R.D., DGDS-Département Environnement et Ressources, Montpellier cedex 5, France; (2) INERA, Ouagadougou, Burkina Faso; (3) INRAB, Cotonou, Benin

We have set up a project on the « Roles of shea parklands in Reduction of vulnerability of AgrosysteMs and SociEties in Sub-Saharian Africa » (RAMSES) that has been submitted to several potential funders. This project ambitions to evaluate possible regeneration, extension and ecological intensification of shea production in Sudanese Africa, which is the only area supplying the international market with shea nuts (chocolate industriy) and butter (cosmestic industry). By this agroforestry practices, sub-Saharan societies seem to respond spontaneously to the MEA, diversifying their production while minimizing environmental degradation and deforestation impacts linked to extension of the cultivated areas. However, ecosystem services provided by shea trees are neither known nor quantified. Interactions between shea parklands and their associated socioeconomic systems is also currently in tension between the increasing demand at the international level and local degradations of shea stands with increasingly limited regeneration. This results in a worrying decrease in shea production capacity while enhancing competition between farmers, between genders (shea producers are women, trees and plots belong to men), or between private buyers on which the project propose a diagnosis. The project is based on multi-disciplinary investigations in two countries that are representative of the diversity of biophysical and socio-economic situations of the shea parklands, Benin and Burkina Faso. It ambitions to provide 1) a classification, with a geographic mapping support, of ecological combined to socio-economic conditions in which parklands are still viable from a past half- century diachronic and spatial analysis of their trajectory drivers; 2) under conditions where viability is proven, an assessment of increasing trees density impacts (i) on ecosystem services (ii) on the farms income, by using quantification of the processes underlying services provided by trees, and a bio-economic model to simulate different trees density.

P-3330-73

The ESCAPE project: an inter-disciplinary study on vulnerability, resilience and adaptation of rural societies to environmental changes in Africa

B. Sultan (1)
(1) IRD, LOCEAN, Paris, France

Sub-Saharan Africa (SSA) is known to be particularly vulnerable to climate change due to a combination of naturally high levels of climate variability, high reliance on climate sensitive activities such as rain-fed agriculture and limited economic and institutional capacity to cope with and adapt to climate variability and change. Urgent actions are required to tackle the issues raised by climate change in SSA and these actions need to be supported by the best knowledge available. ESCAPE is a 5-year research project started in 2011 funded by the National Research Agency which aims to revitalize research in SSA in this field through an integrated interdisciplinary framework for increasing our understanding of the problem and support decision making for the future. ESCAPE addresses the vulnerability of rural societies in SSA to climate and environmental changes and explores adaptation pathways to reduce this vulnerability. The project fosters interdisciplinary research, through both retrospective and prospective studies, in Senegal, Niger, Benin and Mali, on the evolution of different agricultural, ecological and social systems interacting together under the global environmental changes.

The easterly water vapour transport from Indian monsoon and its role in the variability of west african monsoon

A. Sy (1) ; D. B. (2)
(1) University Gaston Berger, Saint-Louis, Saint-Louis, Senegal; (2) University Gaston Berger, Saint-Louis, Saint-Louis, Saint-Louis, Senegal

West Africa region is one of the poorest in the world and most of its economic activities depend on the rainy season. In Sahel region and in many other regions of the tropics rainfall is largely related to the intensity of convection. But since the 70s strong of observed variations in rainfall marked by a decrease in rainfall in this area. This work is focused on study of water vapour fluxes at high altitude from Indian monsoon and contributing to the supply of convective systems in Sahel.Squall lines are responsible for a large portion of the rain observed in this area. They are defined as a thick cloud system moving from east to west at a speed of about 14 m / s. Consist of a convective part at the sharp edge of a stratiform part, they have a life cycle left in four (4) phases: training, increased maturity and dissipation (Leary and Houze 1979). Several researchers have studied the advection of water vapour on Squall-lines (Peugeot et al 2011, Meynadier et al 2010, Cadet et Nnoli 1989, De Felice et al. 1982), which plays an essential role in their life. Cadet and Nnoli showed that easterly waves strongly contribute to water vapour transport to West Africa. De Felice et al. think that the amount of water vapour present in the medium and high layers of atmosphere in Sahel could come from the Indian monsoon and neighboring regions and transported by prevailing easterly flux during this period.

For this work we used ECMWF datasets, daily averages wind and humidity measured at 200hPa-1000hPa levels pressure and daily average OLR (Outgoing Longwave Radiation) NCEP / NCAR grid 2.5x2.5 the rainy season June-July-August-September during the period 2001-2010.The study focused on 20°W-90°E Longitude 0°-30°N Latitude area covering West Africa to India. The water

vapour column available in West Africa is the result of a contribution from the south-westerly monsoon (1000-850hPa) on one hand and easterly fluxes (850-300hPa) on other hand (R. Meynadier 2010 Dème A. 2002, De Felice et al 1982). To detect and study the fluxes supposed to come from the Indian monsoon we consider the top (500-300hPa) of the high layer knowing that the middle layer (850-500hPa) brings water vapour through the African Easterly Jet.

We have calculated the fluxes from qV (When q: Specific Humidity, V = u + v zonal and Meridian wind).

We performed Hövmoeller diagrams of fluxes computed on 500-300hPa layers and it appears very clear so water vapor advection in the upper layers of the altitude to Africa from joining the column available water.

These water vapour movements have an intra-seasonal and inter-annual variability during the 2001-2003 and 2006-2010 summers.Water vapour fluxes calculated on the 45oE-70oE area longitude and latitude 10oN-20oN are oriented towards Africa and reach a maximum of about 25 kg/m/s during the summers from 2001 to 2003 and a maximum of 36 kg/m/s observed in 2010 August.

To follow these fluxes up to the Sahel we considered the 40oE-50oE and 15oE-35oE areas further west, on 5oN-20oN latitude.It was noted an increasing of the quantities of westward water vapour advected in this part of the troposphere during the years studied.In June 2010 low values of olr (cloudiness) in Chad appear between 3 to 5 days after initiatiation in India of a westerly flow. The lowest values of olr observed in Chad in late August 2010 follow relatively large amounts (33; 36 kg/m/s) of water vapour flux from India.

P-3330-75

Impact of Climate Change on Freshwater availability for Senegal: Modeling Future Changes in Hydro-climatology of Lake of Guiers

M. Tall (1) ; I. Diallo (2) ; MB. Sylla (3) ; A. Gaye (4)
(1) Laboratoire de Physique de l'Atmosphère et de l'Océan Siméon-Fongang (LPAO-SF), École Supérieure Polytechnique (ESP) / Université Cheikh Anta DIOP (UCAD), Dakar, Senegal; (2) Université Cheikh Anta Diop, Ecole superieure polytechnique, Dakar, Senegal; (3) WASCAL Competence Center, Climate Modeling and Climate Change, Ouagadougou, Burkina Faso; (4) Univ. Cheikh Anta Diop, Lpaosf, Dakar, Senegal

The future climate change could have a major impact on the hydrological systems. The hydroclimatology of the northern Senegal, especially over the basin of the lake Guiers' (north Senegal) for the present and the late 21st century has been analyzed; based on simulation from the Regional Climate Model (RCM) RegCM4. RegCM4 simulations have been performed with a horizontal resolution of 25 km (0.22 X 0.22°) for the 1985-2004 period and 2080-2099 period under both the RCP4.5 and RCP8.5 emission scenario over the West African domain. Initial and Lateral boundary conditions are taken from the ECHAM6 Earth System Model. Overall RegCM4 reproduces reasonably the spatial distribution of precipitations and temperatures as well as its month-to-month variations over both the northern Senegal and the basin of the Guiers' lake area. RegCM4 projects with both emission scenarios a rising of temperatures and a decrease of the rainfall in the late 21st century. Therefore the rising of temperature as well as the weakening of rainfall is more intense in the scenario RCP8.5. On the other hands, RegCM4 projects an evaporation decrease over the lake basin reaching up to 40% under the RCP8.5 emission scenario followed by an enhancement of runoff over the lake basin and the north of Senegal. This increase of runoff would resulted probably from the either the enhancement of the aridity by the end of 21stcentury or and from probably an increase of extreme events such as heavy rains.

P-3330-76

Effect of seasonal variability on the incidence and transmission patterns of malaria in urban, peri-urban and rural communities around Kumasi, Ghana

S. Tay (1)
(1) School of Medical Sciences Kwame Nkrumah University of Science & Technology, Department of Clinical Microbiology, Kumasi, Ghana

Changes in temperature, rainfall and relative humidity are expected to influence malaria directly, by modifying the behaviour and geographical distribution of malaria vectors and by increasing or decreasing the length of the life cycle of the parasite. This study was aimed at investigating the impact of these changes on malaria incidence in the Kumasi metropolis and a rural district in the Ashanti region, Ghana. Data on climatic variables from December 2009- November 2011 were obtained from the Owabi, Emena and Airport weather stations. Data on malaria cases from December 2009- November 2011 were obtained from Nkawie hospital (near Owabi weather station), Aninwaa Medical Centre (near the KNUST Weather station) and Manhyia hospital (near Airport weather station) from December 2009- November 2011. Based on malaria morbidity data, three communities were selected and sprayed for mosquitoes using the pyrethrum spray catch method. Data analysis was conducted with Microsoft Excel and Statistical Software Package, SPSS version (16.0). Pearson's correlation analysis was done to establish the relationship between climatic variables and malaria transmission. In all the communities, Anopheles gambiae was the highest mosquito vector caught with few or no Anopheles funestus over 60% of which were fed with the dry season recording the highest percentage of fed mosquitoes. Over 90% of the fed mosquitoes had fed on human blood. Sporozoite rates for Nkawie were 6% between April and July 2011, 5.6% between August and November 2011 and 2.6% between December 2010 and March 2011. In Emena, the rates were 4.0%, 5.0% and 3.0% between April and July 2011, August and November 2011 and December 2010 and March 2011 respectively while Asawasi had 6.6%, 4.8% and 5% April and July 2011, August and November 2011 and December 2010 and March 2011 respectively. The annual Entomological inoculation rates (EIR) for Nkawie were 245.6, 203.6 and 52.4ib/p/yr April and July, August and November and December 2010 and March 2011. In Emena, August to November recorded the highest annual EIR of 182.5ib/p/yr, followed by April to July with a value of 175.2ib/p/yr and then December 2010 to March 2011with 94.9ib/p/yr. In Asawasi, April to July recorded the highest annual EIR of 245.4ib/p/yr followed by August to November and December 2010 and March 2011with 229.9ib/p/yr and 109.5ib/p/yr respectively. There were direct relationships between minimum temperature and human bite rate, maximum temperature and sporozoite rates, rainfall and number of mosquitoes caught during the study period and between malaria incidence and the entomological inoculation rate. There were also indirect relationship between maximum temperature and the number of mosquitoes caught. This research shows that malaria transmission is caused by a multiplicity of factors including climatic, environmental and socioeconomic factors. These factors play diverse roles on malaria vector biology as well as on the parasite.

P-3330-77

Multi-decadal variability of Sahel Rainfall and African Easterly Waves in CMIP5 Models: Mechanisms, Model Fidelity and Implications for Future Climate Change Projections

C. Thorncroft (1) ; E. Martin, (2)
(1) Professor, University at Albany, Dept. of Atmospheric and Environmental Sciences, Albany, United States of America; (2) The University of Oklahoma, School of meteorology, Norman, United States of America

This study uses models from phase 5 of the Coupled Model Intercomparison Project (CMIP5) to evaluate and investigate multidecadal variability of Sahel rainfall and teleconnections with global sea surface temperatures (SSTs). The simulation of African easterly waves (AEWs) in the CMIP5 models is also evaluated as part of this work.

Multidecadal variability of Sahel rainfall is lower than observed in all historical simulations evaluated. Focus is on teleconnections with North Atlantic SST [Atlantic multidecadal variability (AMV)] as it is more successfully simulated than the Indian Ocean teleconnection. To investigate why some models successfully simulated this teleconnection and others did not, despite having similarly

large AMV, two groups of models were selected. Models with large AMV were highlighted as good (or poor) by their ability to simulate relatively high (low) Sahel multidecadal variability and have significant (not significant) correlation between multidecadal Sahel rainfall and an AMV index. Poor models fail to capture the teleconnection between the AMV and Sahel rainfall because the spatial distribution of SST multidecadal variability across the North Atlantic is incorrect. A lack of SST signal in the tropical North Atlantic and Mediterranean reduces the interhemispheric SST gradient and, through circulation changes, the rainfall variability in the Sahel. This pattern was also evident in the control simulations, where SST and Sahel rainfall variability were significantly weaker than historical simulations. The reasons for these errors will be discussed.

African easterly waves are the major synoptic weather producer in the Sahelian region and the extent to which CMIP5 models represent them is important to know. Changes in AEW-activity may be expected to impact the frequency of extreme rainfall occurrence for example. Large biases exist in the simulations of low-level (850 hPa) eddy kinetic energy (EKE, a proxy for AEW activity) in AMIP and historical simulations. CMIP5 models simulate excessive EKE and deficient rainfall south of 17N. The same biases exist in historical and AMIP models and are not a consequence of errors in sea surface temperatures. The models also struggle to accurately couple AEWs and rainfall, with little improvement from CMIP3 models. Future projections of the annual cycle of AEW activity show a reduction in late spring and early summer and a large increase between July and October that is consistent with rainfall projections in the Sahel but large differences exist in future projections between high and low resolution models. The simulation of AEWs is challenging for CMIP5 models and must be further explored in order to provide appropriate confidence levels of rainfall projections in the Sahel.

P-3330-78

Recent trends in the regime of extreme rainfall in the Central Sahel

T. Vischel (1) ; G. Panthou (1) ; T. Lebel ()
(1) Université Grenoble Alpes, Lthe, Saint Martin d'Hères, France

Ongoing global warming raises the hypothesis of an intensification of the hydrologic cycle, extreme rainfall events becoming more frequent. However, the strong time-space variability of extreme rainfall makes it difficult to detect meaningful trends in the regime of their occurrence for recent years. Using an integrated regional approach, it is shown here that over the last ten years, the Sahelian rainfall regime is characterized by a lasting deficit of the number of rainy days, while at the same time the extreme rainfall occurrence is on the rise. As a consequence the proportion of annual rainfall associated with extreme rainfall has increased from 17% in the 1970-1990 years to 19% in the 1991-2000 years and to 21% in the 2001-2010 years. This tends to support the idea that a more extreme climate has been observed over 2001-2010: this climate is drier in the sense of a persisting deficit of rainfall occurrence compared to 1950-1969, while at the same time there is an increased probability of extreme daily rainfall.

P-3330-79

Climate Change and Agricultural Production: capitalisation of the farming techniques for the food security in Benin

JB. Vodounou (1)
(1) University of Parakou, Département de Géographie et Aménagement du Territoire, Parakou, Benin, Benin

The capitalization of the farming techniques for food security in Benin has been studied. The effects of climate change have impacted the farming techniques of the populations in order to adapt to the new conditions imposed by climate. Throughout the country, the rainfall changeablenesses have modified not only the dates of seedling but also the abandonment of some speculations. In order to ensure their food security, the populations have proceeded to a revision of their farming techniques. The situation in Benin can be summarized as follows three zones (North, Centre and South). As a matter of fact, in the north 40% of the yielded speculations today can be considered as introduced twenty years ago. In this area in the years 60s there are crops such as yam, voandzou, maize, peanuts, and garden pea. The current crops are yam, maize, and sorghum. Crops such as peanuts, voandzou are more and more withdrawn from the speculation ranges. Furthermore, the situation in the centre of Benin is enough animated. In effect, about 65% yielded speculations in the past were abandoned at the profit of new estimated ones more adapted to the current climatic conditions. To ensure their food security, the populations of this zone have spared the speculations such as maize, yam, and peanut. Crops such as sorghum, millet, voandzou and garden peas are almost given up and replaced by soya which represents now the speculation that occupies 45% of the farmed surfaces. In the south of the country, about 30% only of the farming techniques have undergone changes. The climatic changeableness has provoked for instance the introduction of cotton crop which in the past was quasi impossible. But one must understand that in majority the south depends much more on the centre and north as regard food crops.

P-3330-80

Role of groundwater in buffering changes in climatic and anthropogenic conditions: experiences from Sub-Saharan Africa

JM. Vouillamoz (1) ; C. Tindimugaya (2)
(1) IRD, Ird/ujf-grenoble-1/cnrs/g-inp - umr Ithe, Cotonou, Benin; (2) Ministry of water and environment, Commissioner for water resources planning and regulation, Kampala, Uganda

Currently, more than 300 million people in Africa do not have access to safe drinking water. Expanding irrigation to enhance food security is also a growing necessity. Moreover, most countries where population is expected to grow rapidly in the future are the same countries that have high levels of malnourishment and also limited access to drinking water. The proportion of the population that depends on groundwater for its daily water supply is estimated at about 75%. In the future, the ability to increase reliable access to water supplies will also depend on the development of groundwater, which is generally the only perennial water source in arid and semi-arid regions. One of the most important advantages of groundwater as compared to surface water is its much slower response to climate and anthropogenic changes. Indeed, the amount of water stored in the rock reservoir buffers the transient response of the system to conditions that vary over time. Thus, increasing appropriate groundwater supplies in Africa can significantly increase the resilience of communities to climate variability.

One of the most important difficulties in assessing groundwater resources is that groundwater is underground and hence hidden from our eyes. Reliable quantification of groundwater storage and recharge is not straightforward. Moreover, the projected impacts of climate change on groundwater recharge obtained from large-scale models are uncertain, and the scale of models is not appropriate to groundwater systems which are highly spatially heterogeneous over about 40% of Africa surface area where hard rock aquifers occur.

To illustrate the role groundwater can play in buffering changes, we present the results of a study carried out in Benin in a widespread environment of Sub-Saharan Africa (i.e. hard rock aquifers). Thanks to a novel approach, we determined the groundwater storage of our study area (27,200km²) to be 440mm+/-70mm. To assess the buffer capacity of aquifers, we compared groundwater storage to groundwater discharge. Groundwater discharge is the sum of natural discharge plus human abstraction. We evaluated human abstraction at less than 1% of total groundwater discharge. We conclude that increased abstraction due to population growth will probably have a small impact on storage. We calculated buffering capacity as the ratio of current storage to total discharge, and obtained a result of 6years+/-47months. This buffer capacity confirms groundwater's ability to buffer changes. Finally, our study is intended to promote a more quantitative approach to assessing groundwater resources and to support our ability to adapt to future changes.

P-3330-81

Heat effects of ambient apparent temperature on total non-accidental mortality in Cape Town, Durban and Johannesburg, South Africa: 2006-2010

J. Wichmann (1)
(1) University of Pretoria, School of Health Systems and Public Health, Pretoria, Gauteng, South Africa

INTRODUCTION
Although many studies of temperature have been conducted in other disciplines such as climatology, they have only received greater attention in public health and epidemiology in the past decade. However, very few studies have been conducted in Africa and none which also controlled for possible confounding by air pollution. Epidemiological studies are crucial to understand possible local human health impacts due to climate change, and to the development of adaptation strategies to mitigate such impacts.

METHODS
The objective of this study was to investigate the influence of heat effects of ambient apparent temperature (Tapp) on total non-accidental mortality in Cape Town, Durban and Johannesburg, South Africa (2006-2010) using the time-series and case-crossover epidemiological study designs. The heat effect was investigated for apparent temperature above the city threshold, 15°C, 20°C and 13°C for Cape Town, Durban and Johannesburg, respectively. The three cities are classified in different Köppen-Geiger climatic zones: Cape Town has a Mediterranean climate (Csb). Durban has a humid subtropical climate (Cfa), that closely borders a tropical wet and dry climate (Aw). Johannesburg has a subtropical highland climate (Cwb).

RESULTS
In Cape Town, total non-accidental mortality significantly increased by 1.1% and 2.1% for all ages (60228 deaths) and >=60 year olds (28383 deaths), respectively per °C increase in Tapp above 15°C (lag0-1). No heat effect was observed for 0-4 year olds (4649 deaths). The maximum Tapp (lag0-1) observed was 27°C.

In Durban, total non-accidental mortality significantly increased by 1.0%, 1.4% and 1.9% for all ages (95269 deaths), >=60 year olds (28801 deaths) and 0-4 year olds (8628 deaths), respectively per °C increase in Tapp above 20°C (lag0-1). The maximum Tapp (lag0-1) observed was 31°C.

In Johannesburg, total non-accidental mortality significantly increased by 0.5% and 1.2% for all ages (94900 deaths) and >=60 year olds (31859 deaths), respectively per °C increase in Tapp above 13°C (lag0-1). No heat effect was observed for 0-4 year olds (10080 deaths). The maximum Tapp (lag0-1) observed was 24°C.

CONCLUSION
These results indicate that the health of the South African population living in Cape Town, Durban and Johannesburg is at risk with increases in Tapp. The study will be expanded to include four other South African cities located in different Köppen-Geiger climatic zones. Cause-specific mortality, such as respiratory and cardiovascular mortality, will also be investigated.

Participatory approach for the integrated management of a wet ecosystem in a context of climate change: Inner Niger Delta (Mali)

A. Zare (1) ; B. Barbier (2) ; D. Abdoulaye, (3) ; M. Bologo/ traoré (4)
(1) Internationnal Institute for Water and Environmental Engineering (2iE), Laboratory of Hydrology and Water Resources, Ouagadougou, Burkina Faso; (2) CIRAD , Umr geau, Dakar , Senegal; (3) International Institute for Water and Environmental Engineering (2iE), Laboratoire d'hydraulogie et des ressources en eau, Ouagadougou, Burkina Faso; (4) Internationnal Institute for Water and Environmental Engineering (2iE), Ouagadougou, Burkina Faso

Long about 4100 km, the Niger River in its central part in Mali, extends an area which can reach 40.000km2 called the Inner Niger Delta. Largest wetland in West Africa, delta's hydrosystem is constituted by main branches, effluents and distributaries of the river, ponds rosaries, large lakes and channels. Right in the Sahel, the delta is an important productive ecosystem with a rich biodiversity. One million person derive their livelihood from this ecosystem through key activities such as fishing, livestock and agriculture mainly rice farming. With the climate crisis of the 70s, the Niger River Basin and its tributaries are subjected to high rainfall deficit causing a flood decrease in the delta. This resulted in a reduction of 50% of inundated areas. The climate crisis affects the socio-economic activities because the productivity is related to the hydrological regime and maximum areas inundated. There is also a demographic pressure leading to overexploitation and degradation of the delta ecosystem. This situation is not without creating tension in the management of resources, including use conflicts such as agricultural encroachment on pastoral areas; the non respect of transhumance calendar, use of prohibited fishing gear. The delta resources dwindle and production systems degrade and populations have to adapt.

Thus in this study we have developed with local stakeholders, sustainable management strategies of delta resources to deal with the marked variability of climate and demographic pressure. Strategies are a combination of technical options and economic instruments. Technical options include options locally developed complemented by a literature review covering WOCAT (World Overview of Conservation Approaches and Technologies) technicals. Economic instruments have been selected with tools like the DST and DESS developed in the frame of AFROMAISON project. The approach adopted is participative, mainly based on focus groups and workshops with stakeholders. Strategies contribute to the following goals: securing water in the delta, the assurance of integrated resource management; and strengthening the capacity of actors to the mastery of biodiversity conservation techniques and sustainable use of the resources.

Interaction between moist Kelvin waves and synoptic variability of precipitation over Congo basin

S. Zebaze (1) ; L. Andre (2) ; T. Clément (1) ; S. Janicot ()
(1) UNIVERSITY OF YAOUNDE I, PHYSICS, YAOUNDE, Cameroon; (2) University of Douala, Physics, Douala, Cameroon

The synoptic structure and variability of moist synoptic Kelvin waves over the Congo basin during March to June(1979-2010) are explored using satellite-observed brightness temperature (Tb), outgoing longwave radiation (OLR) and National Centers for Environmental Prediction-National Center for Atmospheric Research (NCEP-NCAR) reanalysisdata.We found that synoptic Kelvin waves (SKWs) activity is most predominant during March-May and it is centered at the equator where the convective active phase of these waves favors formation of convective synoptic systems. A brief analysis of an intense Kelvin wave in March-May 1999 (active year) shows a clear impact of the wave on convective development and daily rainfall over Congo basin. Convection is found to be less frequent immediately prior to the passage of the convectively active phase of the convectively coupled atmospheric equatorial Kelvin wave(CCKW), more frequent during the passage, and most frequent just after the passage. Otherwise, Results show marked interannual variability of Kelvin wave activity over Congo basin. The large synoptic variability of precipitation are observed from March-May which clearly denotes synoptic activity in this region. Interannual variability in thefluctuation strength of the wavelet power spectrum as well as in its distribution amount different periods. Strong signalis clearly found at period between 4-6 day and 7-9 day. The location of peak SWKs convection are consistent with high rainfall location and clearly impacted crops yield over this region.

P-3330-84

Extreme condition and climate change in northern Africa during the last century

YD. Zéphirin (1) ; M. David (2) ; C. Romeo (3)
(1) Institut National de Cartographie, Service de climatologie, Yaounde, France; (2) Université de Douala, Cameroun, Afrique, Département de physique, Douala, Cameroon; (3) Université de Yaoundé I, Département de physique, Yaoundé, Cameroon

Four homogenous climatic zones are detected in northern Africa (20°W–40°E, 0–30°N) by applying the Cluster Analysis (CA) method on the rainfall anomalies data from the Climatic Research Unit (CRU).The four climatic zoneswere distributed into Saharan, Sahelian, wet tropical and equatorial climate types. The application of a segment of 15 years with overlap going from 1901–1940 (P0) , and 1961 to2000 (P4) throughout the periods 1916–1955 (P1), 1931–1970 (P2) and 1946–1985 (P3),shows important spatio–temporal modifications of rainfall zones south of 15°N. The semi–aridlands (sahelian) which govern the dynamics of this zone doubled at the end of thetwentieth century, while the wet tropical and equatorial zones decreased at the half.

Temperature trends have a magnitude of up to 1.5 K per century in all the four climaticzones. This warming was mainly observed during the last three decades. During these samethree decades, regional precipitation trends were less significant.For the four climatic zones, the wavelet power spectrum for the time series of yearly average precipitation anomaliesshows the timescale of variability which is governed by 3 main periodicity bands: less than 5 years, from 5 to 30 years and above 30 years.

The extreme conditions in temperature and the precipitation were analysed in terms oftheir persistence. The sporadic long–lasting extreme conditions appear for several years toover 10 years during the last century.

3331 - Forest landscape management to create resilience in the face of climate change in West and Central Africa

Forest landscape management to create resilience in the face of climate change in West and Central Africa

L. Verchot (1) ; DJ. Sonwa (2) ; K. Fernandes (3) ; W. Baethgen, (4) ; M. Pinedo-Vasquez, (1)
(1) CIFOR, Bogor, Indonesia; (2) CIFOR (Center for International Forestry Research), Forest and Environment Program, Yaounde, Cameroon; (3) Columbia University, International Research Institute for Climate and Society (IRI), Palisades, NY, United States of America; (4) Columbia University, International institute for climate and society, Palisades, NY, United States of America

Deforestation in West and Central Africa is driven by economic concerns, primarily associated with the expansion of agriculture. Recent suggestions that deforestation is increasing in Africa are drawing attention for the associated emissions. There has been a lot of discussion and many documents written about the importance of forests in these regions for carbon sequestration. The potential role of forests in adapting to the stresses associated with climate variability and change are less well considered. For example, none of the Congo Basin countries highlighted potential impacts of climate change on forests as a source of national vulnerability in their first national communications to the UNFCCC. Yet evidence is accumulating that climate change has begun to affect the growth and condition of the Congo Basin forests and this will affect communities that depend on these forests for goods and services. A large number of stakeholders believe that climate change and climate variability do not threaten the forest ecosystems in the humid parts of the region. Threats are more readily recognized in the sub–humid and semi–arid regions. Other stakeholders contend that climate change adaptation needs to pay attention to the role forests play in landscapes and there are different opinions about whether adaptation and mitigation need to be considered separately or together. However, when we talk about forests, mitigation and adaptation concerns often go hand in hand. This talk will look at the changing nature of climate and climate variability in the region and posit a number of climate associated risks for local livelihoods and economic development. We will then look at the goods and services provided by forests and examine the evidence that forests have an important role to play in resilience to climate variability and change. Finally we will look at how adaptation interests can be served by increasing tree plantations in rural African landscapes.

The Great Green Wall for the Sahara and the Sahel within the context of Climate Change

M. Malagnoux (1)
(1) French Scientific Committee on Desertification, Allinges, France

Common perception of desertification is the advancement of the desert through sand encroachment on fertile lands. Many images of the desert invading its surrounding lands are widespread in the general public. The idea of halting the desert by planting linear barriers of trees, shrubs and grass, is based on many historical or recent successful examples of shelter belts and greenbelts protecting towns, infrastructures, oases and other fertile lands from shifting sands. In this context, why successful techniques at very local level could not be applied at large scale to halt the desert expansion? Large scale linear barriers have been proposed to control the northern and southern rims of the Sahara. The Algerian Green Barrier is an example of this approach.

However, desertification is defined by the UNCCD as “land degradation in arid, semiarid and dry sub humid areas resulting from various factors, including climatic variations and human activities”. Consequently, desertification is not an advance of existing deserts but rather the effect of localized degradation of the land. It follows deforestation, overgrazing or soil exhaustion due to the over exploitation of natural resources. Thus, desertification cannot be controlled by planting tree lines to stop desert progression. China launched in 1978 a large scale integrated management programme in an area of over 4 000 km long by almost 1 000 km wide named “The Three North Shelter Belt Project”. In 1989, President Deng Xiaoping called this the “Green Great Wall” in reference to the ancient “Great Wall” of China, to highlight the scope of the work. But it is by no way a bulwark against the desert despite what this nickname suggests.

The Great Green Wall for the Sahara and the Sahel (GGW) launched by the African Union builds on these past experiences and aims at the implementation “of multisectoral initiatives and interventions to ensure natural resource conservation and protection with the aim of fighting poverty”. This initiative has been much welcomed since the political mobilization of African countries around this concept is a clear sign of adoption and involvement. However, the scope of the programme is limited to a 15 km wide transcontinental belt running from Dakar to Djibouti. Within this belt some areas need actions while others have a stable environment where no action is needed. The continuity of the belt is not required. On the other side, areas outside the belt may need urgent action and the belt represents a small portion of the affected area of Sahelian countries. The effects of GGW will be limited to the areas under management. Thus, regarding the adaptation of the Sahelian countries to climate change and the mitigation of its effects, the Great Green Wall for the Sahara and the Sahel should be a driving example for the extension of the activities to all the degraded or endangered areas of the whole Sahel.

Adaptive capacity and tree-based livelihood diversification strategies of smallholders in Central Burkina Faso

INS. Djenontin (1) ; H. Djoudi (2) ; M. Zida (1)

(1) Center for International Forestry Research, Forest and Livelihoods Portfolio, West Africa team, Ouagadougou, Burkina Faso, Burkina Faso; (2) Center for International Forestry Research, Forest and livelihoods portfolio, Bogor, Indonesia

Ecosystem-based adaptation strategies are increasingly gaining attention, among researchers and development practitioners, as a diversification option to address climate change. Informed decision on the adequacy of ecosystem-based strategies requires an understanding of the adaptive capacity they confer to households who seek to build resilience toward climate's adverse impacts. This paper analyzes how different trees and forest-based diversification strategies affect household's adaptive capacity in Central Burkina Faso. It uses an integrated approach to select indicators at a household scale, and calculates an aggregate adaptive capacity index (ACI) derived from a combination of both sub-aggregate and sub-composite indexes. Existing ecosystem-based strategies were first identified, and the analyses are done on a sample of 129 representative households who use four different forest and tree-based diversification strategies. Households were interviewed on their assets endowment as well as on the different livelihood outcomes achieved while implementing the strategy. The perceived sensitivity of the strategies to climate risks is also assessed. A cross-comparison of ACI of households under each strategy indicates that while households who engage in eucalyptus plantations benefit a low adaptive capacity index (3.23), those who engage in restored lands and fruit tree plantations have a high adaptive capacity index. The calculated ACI is 4.78 for households who implement restored lands strategy, 4.58 for those using mango plantations strategy, and 4.35 for households who engage in cashew plantations strategy. However, it is important to put on perspective the adaptive capacity index of households using fruit tree plantations, considering the overall situation of environment and biodiversity lost. Restored land shows a better diversity in terms of products harvested, which are available at different times during the year while fruit tree plantations produce a higher economic gain but their role as a safety net in a case of crisis is low and their sensitivity is higher. The integration adaptive capacity analysis to implement ecosystem based interventions could enhance the climate resilience of livelihoods by increasing the adaptive capacity of communities and individuals.

The Great Green Wall : a potential driver of transformation and increased resilience in Sahalian landscapes

D. Goffner (1) ; A. Guissé (2) ; JL. Peiry (3) ; P. Duboz (1) ; G. Boetsch (4)

(1) CNRS, International Research Unit CNRS 3189 Environment, Health, Societies, Marseille, France; (2) Cheikh Anta Diop University, Plant ecology, Dakar, Senegal; (3) Blaise Pascal University, Geolab, Clermont-Ferrand, France; (4) CNRS, International research unit cnrs 3189, environment, health, societies, Dakar, Senegal

The African Sahel is one of the most vulnerable regions on Earth. Although it is comprised of highly diverse landscapes, the increasing ecological and social vulnerability is clearly the common denominator of the entire zone, translating into an urgent call for action. The currently situation is characterized by a downward spiral: vulnerability has been caused by a combination of climatic and human factors resulting in land degradation, which in turn further accentuates human vulnerability. In order to create resilience for the growing populations of the Sahel, innovative, multi-scale strategies must be implemented. The adoption of the Great Green Wall for the Sahara and the Sahel Initiative (GGW) in 2007 is a step in the right direction. For the first time, the African continent stands united to confront the socio-ecological challenges of the Sahel and Sahara. Since its political adoption, the main objective of human and ecological well-being has remained unchanged. From its original configuration of eleven founding member countries across the Sahel, it has gradually begun merging with other ongoing, sustainable development initiatives throughout the African continent, thereby creating even greater potential force. Importantly, it has evolved from its original raison d'être as primarily a reforestation project into a series of multi-sectorial actions that takes into account the diversity of the mosaic landscape it crosses.

The success of the GGW will depend on its capacity to intelligently gather, generate, integrate, and use knowledge derived from a wide range of disciplines, taking into account the nature and complexity of socio-ecological systems. How can scientific research in the GGW context nudge the GGW into an appropriate trajectory for transformation of the Sahel? To respond to this demand, the GGW Human Environment Observatory was created by the French National Centre for Scientific Research (CNRS) in 2009 and groups together international researchers from a wide range of scientific disciplines, all working on a common social ecological system located in the Senegalese Sahel. Research is carried out in close collaboration with natural resource decision makers for the GGW in Senegal (The Senegalese National Green Wall Agency), and in conjunction with local populations. In this presentation, several examples of interdisciplinary research outputs including ecological restoration and monitoring, as well as health and social impacts of the GGW will be presented by observatory researchers. We will provide examples as to how science is already contributing to ecological and human well-being in the region and how scientific data are directly translating into action on the ground and aid in the land use management decisions with the aim of enhancing the resilience of local populations by attempting to provide the appropriate suites of ecosystem services in an equitable manner.

Implementing REDD+ and adaptation to climate change in the Congo Basin: Review of projects, initiatives and opportunities for synergies

AM. Tiani (1) ; C. Pavageau, (1)

(1) CIFOR, Yaounde, Cameroon

In the face of the climate change, two main types of strategies have emerged. While mitigation aims to reduce the sources or to enhance the sinks of greenhouse gases, adaptation addresses the impacts of climate change on societies and ecosystems. Even if adaptation is gaining importance in the international arena, national policies and projects have difficulties to emerge in developing countries. Moreover, forests and forest communities are rarely taken into consideration in debates and policies on adaptation. In addition, Congo Basin countries have limited experiences on reduced emissions through avoided deforestation and degradation (REDD+). Although the forestry sector presents opportunities for synergy between adaptation and mitigation, very few life-size experiments can confirm it.

We explored the state of progress of projects and initiatives to promote adaptation and REDD+ in the Congo Basin region and analyzed opportunities for synergies or trade-off between the two strategies. Between 2008 and 2013, 94 national programs and activities related to REDD+ and 11 on adaptation have been identified in six countries of the Congo Basin. Most projects are at an early stage with more emphasize on REDD+ than on adaptation, due to uncertainties about spatiotemporal patterns of risk occurrence, lack of clear adaptation solutions, insufficient political support or lack of national structuring framework as REDD+ does.

Two main tendencies emerged from REDD+ initiatives: 1) local demonstration activities directly aim to reduce carbon emission from deforestation, forest degradation, and sustainable forest management and increase carbon stocks; 2) readiness activities aiming at creating enabling framework for countries to participate in REDD+ deals and develop strategies accordingly. Adaptation to climate change and REDD+ evolves as two parallel and similar processes. Potential for synergies among the two processes exists but are not fully recognized yet.

To be noted is the emergence of hybrid approach, where most of REDD+ and adaptation projects intend to combine the integrated conservation and development

project (ICDP) approach with payments for ecosystem services (PES). This bears the advantaged of repackaging the on-going efforts, reducing uncertainties and risks of maladaptation and offering some responses to the fragmentation of finance opportunities. In sum, the hybrid approaches present potentials for synergies between adaptation and mitigation.

However, transformational changes are needed to increase the synergy between adaptation and mitigation in the current climate portfolio. In particular, there is a need for tools, information and knowledge to support decision makers to harmonizing climate policies.

Could IFM REDD+ projects incentivize forest concessionaires to reduce greenhouse gases emissions in Central Africa? A lesson from the FORAFAMA project

F. Claeys (1) ; V. Rossi (2) ; D. Bastin (3) ; R. Eba'a-Atyi (4) ; S. Gourlet-Fleury (1) ; G. Lescuyer (5) ; N. Picard (2) ; DJ. Sonwa (4)

(1) Centre for International Cooperation in Agricultural Research for Development (CIRAD), Tropical Forest Goods and Ecosystem Services (BSEF), Montpellier, France; (2) Centre for International Cooperation in Agricultural Research for Development (CIRAD), Tropical forest goods and ecosystem services (bsef), Yaounde, Cameroon; (3) Alpicam, Douala, Cameroon; (4) Centre for International Forestry Research (CIFOR), Yaounde, Cameroon; (5) Centre for International Cooperation in Agricultural Research for Development (CIRAD), Tropical forest goods and ecosystem services (bsef), Bogor, Indonesia

Improved Forest Management (IFM) is an activity eligible to the mechanism of Reducing emissions from deforestation and forest degradation and the role of conservation, sustainable management of forests and enhancement of forest carbon stocks in developing countries (REDD+). In this context, IFM refers to activities that increase carbon stock on managed forest lands by changing forest management practices. As nearly 20 millions of hectares are now managed in the Congo Basin forests, it is a strategy of prime importance in climate policies of Central African states. However, the carbon benefit is generally based on a decrease of felling intensity that means severe income shortfalls for the logger. The extent to which carbon storage could compensate losses of timber income is a decisive factor in the feasibility of REDD+ projects. Given the few number of scientific studies on this subject, and the even fewer number of pilot projects that have been implemented, this issue is still highly in debate.

To assess the potentialities for emissions reductions of IFM REDD+ projects, and to evaluate their financial feasibility, we explored a broad range of scenarios for reducing logging intensity in a typical export-oriented forest concession in Central Africa. For each scenario and for several carbon accounting approaches, we calculated timber income shortfalls and carbon benefit to estimate internal rates of return and break-even prices of carbon credits. As part of the project of «Support for the sustainable management of forests in the Congo Basin and the Brazilian AmazonBasin» (FORAFAMA), a partnership with several forest concessionaires has allowed us to incorporate forest, industrial and economic factors. Parameters uncertainties are explicitly taken into account through a Monte-Carlo method.

We predicted that current voluntary markets conditions do not permit the implementation of IFM REDD+ projects in Central African concessions. Notable exceptions to this statement are Logged to Protected Forest (LTPF) projects, that correspond to an extreme case of a complete cessation of logging. In this case, the non-building of road networks results in substantial savings. The feasibility of other IFM REDD+ projects is particularly constrained by the current approach to addressing the risk of non-permanence. As an example, under Verified Carbon Standard (VCS), the maximum number of Voluntary Certified Units (VCU) available to projects including harvesting, cannot exceed the long-term average carbon benefit. In the Clean Development Mechanism (CDM), an other approach to deal with non-permanency had been proposed with temporary Certified Emission Reductions (tCER). A tCER expires at the end of the commitment period following its issue. Such an approach, that can allow to value the storage of carbon even on short time periods, is much more flexible and adapted to permanent timber production tropical forests. However, even under this accounting method, IFM REDD+ projects prove to be unattractive for Central African timber companies as their feasibility remains conditioned to a major reduction of logging intensity. Otherwise, projects are severely penalized by transaction costs and low carbon differentials.

Our work suggests that current methodologies of voluntary standards are not well appropriate to include IFM within REDD+. Instead of incentivizing to conciliate timber production and carbon sequestration, IFM REDD+ projects rather encourages forest concessionaires to value either carbon or timber exclusively, hence acceptability and additionality issues. To promote the deployment of a truly climate-smart forest management, the incentive system should focus more on practice changes than only on the result expressed in permanently avoided emissions.

P-3331-02

An Economic Impact Assessment of Community-Based Conservation Associations (CBCAs) in the Nzoia River Basin, Kenya: Taking stock of ecosystem services and welfare trends under Climate Change

C. Kombat Lambini (1)

(1) Bayreuth Center for Ecology and Environmental Research (BayCEER), Bayreuth Graduate School of Mathematical and Natural Sciences (BayNAT), Bayreuth University, Germany

Community-based conservation associations seek to address the trade-offs in conservation and development objectives through participatory approaches to sustainable ecosystem management. Some empirical research has been carried out in the past two decades do evaluate the impact of community-based conservation associations. The findings on outcomes are mixed and still a subject of intense debate in the forest economics literature in developing countries. The issue of nonlinearity comes up with the outcomes of these assessments and management institutions hence further research and methods needed to understand these complex conservation problems in developing countries context, especially in Africa which has few impact studies globally. Past assessments of associations in conservation are faced with numerous limitations such as complexities in implementing communities-number of members, social capital, institutional context and programme attributes. Most of these assessments have several problems: methodological limitations, baseline data access, and selection of indicators of outcomes for evaluation, leakages and timescale measurements. Despite the growing literature in community forestry, there are still lack of empirical local studies that can substantiate and quantify the impact on forest ecosystem services and welfare of community-based conservation association members in the Nzoia Basin in Western Kenya. Our economic impact study seeks to address some of these limitations raised above through the integration of ecosystem services and household livelihood outcomes. Field interviews are undertaken with key stakeholders in two forest ecological conservancies out of ten in Kenya (North Rift Conservancy-Trans-Nzoia Zone and Western Conservancy-Kakamega Zone). Sample of three different community-based conservation associations in different communities are considered for the economic impact assessment based on advice from Kenyan Forest Services and Kenyan Wildlife Services. These associations are (1) Kipsaina Crane and Wetlands Conservation Group (Saiwa Swamp National Park-North Rift), (2) Community Forest Associations(Kiptogot CFA, Kimothon CFA, Malava CFA, Muileshi CFA) (3)Kakamega Forest Reserve Conservation Arm(Kakamega Community Wildlife Association) and (4) Non-Members of community-based conservation associations in sampled research area. The study anticipates to (1)Quantify and explain drivers of CBCAs participation that fully capture the significant theoretical expectation, (2) Quantify the impact of community-based conservation association membership and non-membership on forest ecosystem services supply and household welfare based on sets of selected criteria from the household survey, (3)Assess the three (3) CBCAs and evaluate which one is doing the best in the supply of ecosystem services in the Nzoia River Basin and

(4) recommended approach to ''avoid the tragedy of the commons'' in community forestry in the Nzoia Basin under current climate change conditions in Kenya.

P-3331-03

Risks and opportunities of Eucalyptus planting (Case study in the framework of the GIZ-German-Madagascan Environmental program)

L. Prill (1) ; D. Plugge (1)
(1) Institute for World Forestry, University of hamburg, Hamburg, Germany

Growing biomass for rural (energy) purposes in highly productive planted forests can contribute to the preservation of natural forests, the mitigation of climate change and the rehabilitation of degraded land and biodiversity – provided that they are appropriately planned and managed. Since 1996 in North-Madagascar ~7.000ha of former degraded savannah have been afforested with Eucalyptus within the "German Madagascan environmental program" of the "Deutsche Gesellschaft für Internationale Zusammenarbeit" (GIZ) GmbH to supply the Diana Region with sustainable wood energy (charcoal). The GIZ-community-based afforestation approach aims to develop a sustainable charcoal value chain in Madagascar.

Despite the manifold opportunities, cultivating Eucalyptus has often been associated with environmental and ecological impacts that negatively affect environmental sustainability of afforestation projects. Little research in this context was done in Madagascar. Based on a case study the present study aims to analyse ecological risks and opportunities of planting Eucalyptus in projects to promote renewable energy resources in rural areas. Floristic diversity and soil properties of 21 different-aged and -managed Eucalyptus camaldulensis (EC) plantations and adjacent savannah sites around three different villages in the Diana Region were analysed and compared. Research on biodiversity was based on the parameters species richness (number of species, "spR"), plant frequency (plants/hectare), Shannon Diversity (H') and the species composition of predominating plants of woody and ground cover (GV) species. Soil samples of plantation and savannah sites were analysed for their pH value and carbon to nitrogen ratio. Special regard was given to spatial, temporal and management intervention effects. This was achieved by sampling EC-stands with different stand characteristics (e.g. stand age) and through the design of the chosen transect-sample unit.

Soil properties did not vary significantly between savannah and plantation sites although stand volume per hectare and partly stand age negatively affected both soil properties.

In all villages absolute recorded number of woody species was higher in the savannahs than in the plantations whereas GV-species richness was relatively even. Mean woody spR and H' were further elevated in the savannah-units while mean plant frequency was partly higher in the plantation-units. Differences were not significant. Species composition was similar between savannah and EC-stands. Stand density and/or -volume positively affected diversity while plant frequency decreased with higher stand density in some cases. No spatial and temporal effects could further be observed in the study region. This low response is likely due to human interventions and cattle grazing that reduced plant regeneration. Differences in terms of diversity conditions were, however, apparent between the investigated villages. Variations in the distance to remnants of natural forests and site conditions (e.g. soil) of plantations are likely to play a key role in this context.

Plantations established on degraded land in North-Madagascar indirectly preserve natural forests and its biodiversity, thereby help to mitigate climate change and increase the value of degraded land. Results indicate that impacts of EC-stands on biodiversity and soils are small and that the plantations are further able to provide habitat for many (including the predominating) species of the savannah. Nevertheless, a trend towards a reduced diversity in the plantation was observed. In order to reduce the risk of diversity loss further research should focus on the potential of mixed-species stands in the project region including native species with a high relevance for the local population. In this context, also the role of remnants of natural forests and seed dispersal methods should be assessed.

Recent developments have shown that programs that avoid deforestation by supplying local needs such as the presented approach of the GIZ will gain further importance in the future. Considering the expanding land area covered with eucalypts, the objective of enhancing biodiversity and other (ecosystem) services should therefore be incorporated in the land-use planning of programs to promote renewable energy resources in rural areas.

P-3331-04

Forest Ecosystem as Strategies to Face Climate change in Sub-Saharan Africa: Mangrove for Carbon Sequestration in Benin (West Africa)

SH. Totin Vodounon (1) ; R. Bamisso (1) ; E. Amoussou (2) ; M. Boko (3) ; A. Akoègninou (4)
(1) University of Parakou, Geography, Parakou, Benin; (2) University of Parakou, Geograaphy, Parakou, Benin; (3) University of Abomey-Calavi, Geography, Abomey-Calavi, Benin; (4) University of Abomey-Calavi, Botanic, Abomey-Calavi, Benin

The increase of carbon dioxide (CO2) in atmosphere and global warming are becoming a global challenge especially in Africa where adaptation capacity is low. Natural ecosystems as the green forests are known to contribute in controlling of the greenhouse gas through carbon sequestration. Across the world, mangrove forest interested many studies which reveal the potential role of this ecosystem on climate change strategies. This study aims to strength how to use the mangrove ecosystem to face climate change through its capacity of carbon sequestration in Benin.

The study is based on existing literature, mangrove cover estimation from 1980 to 2040 in Benin, assessment of mangrove ecosystem capacity to sequester carbon in Benin based on critical, intermediate and optimist scenarios. On the over hand, climate data such as temperature over the period 1961 to 2014 are analysed to correlate its trend in Benin to the global warming.

In Benin projections show an increase in air temperatures in all regions of Benin around 2100, with the largest increase in temperature, compared to the reference period 1971-2000, of around 3.27°C. In the same time, total greenhouse gas increased from 4797.74 Gg CO2-e to 6251.03 Gg CO2-e representing a growth of 30.29 % over the period 1995-2000. With regard to the principle of the Clean Development Mechanism and to adapt efficiently to this climate change in Benin, mangrove ecosystem can be useful. So carbon sequestration by mangrove in Benin is approximately estimated average of 24 169 t/yr in 2010 and 3580 t/yr in the critical scenario, 17 004 t/yr in the intermediate scenario and 35 423 t/yr in the optimism scenario at the horizon 2040.

Promote mangrove ecosystem protection and development will help increase carbon sequestration in West Africa. So the great need is to enhance local community's capacity on climate change adaptation using mangrove forest to control CO2 emissions based on reforestation, reinforcement of traditional law used for natural resources protection, implementation of Clean Development Mechanism (CDM) projects in Sub-Saharan Africa.

3332 - Asia on the Frontlines: Projected Impacts, Vulnerability and Adaptation

Projected Climate Change Impacts on Terrestrial Ecosystems of the Asian Highlands

R. Zomer (1)
(1) World Agroforestry Center, Center for Mountain Ecosystems Studies, Kunming, Yunnan, China

Rapidly accelerating climate change in the mountains of Asia, notably the Himalaya, Hindu Kush, Tien Shan, and the Tibetan Plateau, is projected to have major implications for montane species, ecosystems, and mountain farming and pastoral systems. A geospatial modeling approach based on a global environmental stratification and a simple in-situ water balance model has been used to explore potential impacts of projected climate change on the hydrology and spatial distribution of bioclimatic strata, across the Asian highlands. Projected climate change impacts on terrrestrial ecosystems, including agricultural and pastoral systems, were modeled based upon an ensemble of 19 Earth System Models (CIMP5) across four Representative Concentration Pathways (RCP). Large and substantial shifts in bioclimatic conditions can be expected throughout the region by the year 2050, across all bioclimatic zones and ecoregions. Potential impacts include upward shift in mean elevation of bioclimatic zones, decreases in area of the highest elevation biomes and ecoregions, large expansion of the lower tropical and sub-tropical zones and ecoregions, and the shifitng or disappearance of specific sets of bioclimatic conditions, threats to agricultural crop species, cropping systems, and genetic resources, the effectiveness of protected areas, and the rapid onset of potentially high levels of biotic perturbance by 2050, with a high likelihood of major consequences for biodiversity, ecosystems, ecosystem services, conservation efforts and sustainable development policies across the region. The importance of improved understanding of the direction and magnitude of climatic change for strategic pand, adaptation, and disaster response, is illustrated with case studies of landscape analsyses and participatory community based approaches from Nepal, Pakistan, and southwest China.

K-3332-02

Response to Climatic Hazard: Vulnerability Measurement of the Coastal People Matters

M. Hossain (1)
(1) Griffith University, International Business and Asian Studies, Nathan, QLD, Australia

In recent years, climatic hazards – extreme weather conditions and rising sea-level – have impacted seriously on economies and daily life in many coastal regions. The present study measures the vulnerability of frontline coastal regions in order to find path-ways for speedy recovery from the socio-economic devastation associated with climatic disasters, and to recommend potential protection measures for coastal people. The study focuses on two vulnerable regions of the Bay of Bengal delta. The outcome of this research will help understand the responses required after a climatic disaster. Governments, NGOs and international communities including Asian vulnerable regions need micro level studies, such as this, on which to develop effective sustainable development policies. The study uses survey data to investigate vulnerability following a recent climatic hazard (cyclone) that have affected Bay of Bengal delta in 2009. More specifically the aims are: 1. to investigate the impacts on socio-economic vulnerability due to climatic hazards in selected regions; 2. to find path-ways for speedy recovery from the socio-economic devastation; and, 3. to recommend protection measures for the coastal people frequently hit by global warming induced climatic hazards.

It is not only a lack of knowledge on the risks from climatic hazards in developing Asia, in other OECD nations policy makers suffer from this knowledge gap. Being a closest neighbour of Asia, it is needed to know how much, for example, Australia spends on climate response aid other than the immediate disaster aid to the victims? Does Australia take climate refugees? Immediate relief while is important, it is also needed to know how were the affected regions cope from a natural calamity? There is, therefore, a serious need for showing results from small-scale micro studies that can develop a theoretical, methodological and empirical foundation to inform climate change adaptation/recovery options for households, governments and communities in front line regions.

The present research has been focused on assessing local level socioeconomic vulnerability of communities living in vulnerable locations of Asia. Vulnerability to climate disasters is a complex concept which has major socioeconomic and political implications. Public policies, including adaptation strategies, disaster risk reduction (DRR), and migration policies have the potential to play a determining role in addressing vulnerability.This paper is based on two villages surveyed from two sides of the Sundarbans on the Bay of Bengal delta and estimates the vulnerability of the coastal people from a category 5 Cyclone called 'Aila' hit in 2009. The villages are located in Bangladesh and Indian (West Bengal) territories. A census of the entire households of the two villages has been carried out in 2011 and 2012. Vulnerability due to natural hazard has been investigated based on econometric models. The vulnerability estimates at local level is essential with a view to develop relevant adaptation policies for the Sundarbans region.

O-3332-01

Climatic Change and Indian Agriculture – A Case Study of West Bengal

R. Chakrabarty (1) ; S. Chakrabarty (1) ; CS. Lahiri (1)
(1) University of Calcutta, Business Management, Kolkata, West Bengal, India

The recent IPCC report (IPCC 2007) and a few other global studies indicate a probability of 10 to 40% loss in crop production in India with increase in temperature by 2080 – 2100. A few Indian studies on this theme generally confirm an agricultural decline with climate change. Recent studies done at the Indian Agricultural Research Institute indicate the possibility of a loss of 4 to 5 million tons in wheat production in future with every 10C rise in temperature.

In this paper we have focused on the impacts of climatic change on agriculture faced by West Bengal. West Bengal is a state of India, which extends from Himalayas in the north and Bay of Bengal in the south. In 1981-82, West Bengal was amongst the lowest in the country with its per capita net agricultural product being 18 per cent lower than the national average. By 1994-95, it was above the national average by about 10 per cent.

Like all natural system, agriculture is linked to climate and there is some observed and projected climatic change in West Bengal also. During1969-2005, a net warming trend has been established in the annual average temperature.

This paper studies whether the relationship between the long term Agricultural Production of India and West Bengal is trend stationary or not. This has been done by using Unit Root technique. It also studies the relationship between temperature and agricultural production. The paper then derives the relation between the GDP and Indian Agriculture Production on one hand and the SDP and West Bengal Agriculture Production on the other hand. This has been compared by using the Co-integration equations.

An in-depth survey has been conducted in six districts of West Bengal and the production of staple crops, rice and potato have been considered. We have carried out mean tests to compare amongst the districts and also with a north Indian state. On the basis of the data long term projection has been made. Finally, the paper hints at considerable policy implications towards adaptation to climate change in the state.

O-3332-02

Mountains and the Anthropocene

J. Xu (1)
(1) Kunming Institute of Botany, Chinese Academy of Sciences, Kunming, Yunnan, France

Mountains change due to volcanic activity or rising tectonic plates; human activity, too, has changed mountains since the beginning of days. The extent and pace of anthropogenic changes to the mountain's climate, cryosphere and biosphere are now so great that ecosystems and societies become unbounded, while the changes themselves become harder to predict and harder to live with.

In the mountains, geography promotes cultural diversity in languages, belief systems, architecture, settlement patterns, and livelihood practices. Mountains are the cradles of many civilizations. People have adapted in ways that demonstrate their intimate relationship with the environment and knowledge about not only plants, wildlife, vegetation, and ecosystems, but also the risks and natural hazards such as earthquake, landslides, droughts and flash floods.

The seeds of "good Anthropocene" – positive visions of futures that are socially and ecologically desirable, just, and sustainable – can be observed in many cultural communities in mountainous regions. We use both participatory approaches and local visualization to solicit, explore and develop a suite of alternative pathways for conservation and sustainable development in southwest China's mountain regions.

O-3332-03

Farmer's perceptions of and adaptations to changing climate in the Melamchi River Valley of Nepal

D. Schmidt-Vogt (1) ; S. Nani Maya (1)
(1) Kunming Institute of Botany, Kunming, China

Climate change is a global challenge that has a particularly strong effect on developing countries such as Nepal, where adaptive capacity is low and where agriculture, which is highly dependent on climatic factors, is the main source of total income and food consumption at household level. Among the biggest challenges to farming communities in future will be adaptation to climate change. As climate impacts are often locally specific, it is essential that large-scale initiatives to support farmers consider local priorities and integrate lessons from local adaptation efforts. But there is very limited knowledge and information available on how specific climate hazards impact livelihoods, and how farmer communities in the mountains of Nepal are responding to climate change. In addition most of the climate change projections using empirical models are unable to capture the local level specification of climate change. Therefore, knowledge of farmers' perceptions of climate change and of their adaptation measure is important to enhance policies addressing the threat of climate change to farmers.

This case study examined farmers' perceptions of and adaptations to changing climate in the Melamchi River Valley of Nepal. We surveyed 365 farmer households and held six focus group discussions using a Community-based Risk Screening Tool – Adaptation and Livelihoods (CRiSTAL) to understand local perceptions of and current adaptation practices to climate changes. Climate trends in the study area were analyzed for the period 1979–2009. Results show that while mean annual temperatures had risen by 0.18° and 0.9°C per decade during the 1980s and 1990s, respectively, the rise in temperature had accelerated to 1.56°C per decade after 2000. The frequency of drought had also increased measurably after 2003. With this change in climatic factors farmers observed increases in crop pests, hailstorms, landslides, floods, as well as thunderstorms and erratic precipitation as climate-related hazards affecting agriculture. Changing farming practices, selling livestock and livestock products, engaging in daily wage labor and seasonal migration were common practices in response to climate and other changes. Diversification of agriculture, improvement of current agroforestry practices, and investment in water-based income-generating opportunities were identified as means of adapting to climate changes.

O-3332-04

Coastal Adaptation to Climate Change in Bangladesh: Challenges and Opportunities for Integrated Legal and Policy Responses

S. Alam (1)
(1) Macquarie University, Law, NSW, Sydney, Australia

The coastal area of Bangladesh comprises the second largest delta of the world. This coastal area comprises distinctive development opportunities which can be instrumental in reducing poverty and contributing significantly to the development of Bangladesh. Over the past few decades, however, the region has come under threat from climate change, and the effects are now starting to be felt. Moreover, unplanned and disorganized coastal adaptation programmes and the absence of climate change considerations in the coastal planning are deteriorating the whole scenario. In response to the challenges posed by the effects of climate change, Bangladesh has adopted several plans and policies including the Bangladesh Climate Change Strategy and Action Plan 2009, the National Adaptation Programme of Action 2005 and the Country Framework to Mainstream Climate Risk Management and Adaptation 2006. However, no laws and policies have been developed to-date targeting specifically the development of coastal areas in the context of climate change. Moreover, the people living in coastal areas of Bangladesh are not adequately consulted and integrated both in policy making and implementation of disaster risk management plans and adaptation strategies. Bangladesh can enhance its coastal management by strategically integrating climate change adaptation, disaster risk management and development into its laws and policies.

In this context, this paper provides an assessment of impacts of climate change in the coastal zones of Bangladesh. It also examines the existing adaptation strategies and policies of the government. With a critical analysis of the provisions for adaptation strategies in international climate change regime, it outlines the necessity for new adaptation strategies and policies in the context of the daunting challenges posed by climate change to the prospects of development in Bangladesh. This paper emphasises the importance of an integrated approach combining both disaster risk management and climate change adaptation in policy making in order to ensure climate resilient and climate compatible development in the coastal areas of Bangladesh. It further advocates for developing community-based adaption arguing that the empowerment of coastal communities who are mostly at risk is essential so that they themselves can identify and prioritise their risks, plan for mitigation and treat their risk factors. Ultimately communities should have direct access to and control over the public resources allocated for them and establish their rights to reduce their risks, be it social, cultural or political, and policy development process.

Adaptation Measures in Dryland Ecosystem: Management of Scarce Water Resources for Rehabilitation of Degraded Lands in Arid and Semi-arid Region of Southern Pakistan

SI. Khan (1)
(1) Pakistan Forest Institute, Range Management, Islamabad, Pakistan

Drylands in southern Pakistan are home to communities living in poverty and depending on livestock rearing for their livelihood. The subsistence agriculture is losing its importance under the effects of climate change i.e. uncertain rainfall and very low productivity. Due to increasing population of livestock, the pressure on silvo-pastures is increasing resulting in degradation of natural resources and loss of soil fertility, a fact that adversely affects the livelihood of communities. The Farm Forestry Support Project (FFSP) of the Intercooperation (IC) and Swiss Agency for Development & Cooperation (SDC), initiated

rehabilitation work in 2003 in extreme dry region of Karak using the silvo-pastoral system with hillside ditches and sand dune stabilization techniques. The objective was to recover vegetation and increase productivity of the area with minimum cost and hence support livelihoods. The activity was carried out with participation of civil society organizations and farmers' associations.

The results recorded in 2008 showed a profuse plant growth in terms of trees, shrubs and grasses with a potential to provide timber, fuel wood and fodder for livestock. Maximum harvesting of rainwater and conservation of moisture also resulted in growth of natural grasses and shrubs. Within a short period of 5 years, plant growth in height and diameter of 6 meters and 20 centimeters respectively was recorded. The average vegetation cover of 45% and increase in soil organic mater and nitrogen content was also recorded. All this happened with a minimum cost of US$ 82 per hectare. The rejuvenation of wells in few cases was an additional positive affect of the activity. On the other hand, an annual income of US$ 735 per hectare from Saccharum spontaneum planted in sand dunes was a real benefit to farmers against the other land-uses in dry sand dunes.

P-3332-02

Mitigation & Adaptation experiences of farmers to drought in Semi-arid region of India

B. Nagaraja (1) ; B. Krishnakanth, (2)
(1) Bangalore University, Environmental Sciences, Bangalore, Karnataka, India; (2) Bangalore university, Environmental sciences, Bangalore, India

Climate change is predicted to have severe consequences on agriculture and the rural poor in South Asia and Africa. Given that approximately three-fifths of the cultivated area in South Asia is rain-fed, the onset, duration, spatial extent, and total precipitation of the monsoon are critical factors in determining the livelihoods of large majority of people in rural areas. The arid regions of India cover an area of 317,090 km and is exclusively depend on rain-fed crops, even modest alteration in the intensity, frequency and timing of rainfall should cause consternation to large section of farming community. Karnataka state in south India ranks second, next only to Rajstahan in India, in terms of total geographical area prone to drought. Among its 30 districts, 18 are drought prone. During 2001-02 and 2002-03 the state faced consecutive droughts; this severally affected the farmer's livelihood. The present study has been visualized to assess the vulnerability and adaptations experiences of poor farmers to repeated droughts in semi-arid regions of Karnataka.

The drought affected regions of Karnataka recorded lower crop yields and consequent increased povertylevels in the region. The repeated droughts have lead to over exploitation of ground water besides increased in fire incidences in arid and semi-arid regions. The two districts of Karnataka (Raichur and Koppal) each belonging to severely affected categories and representing arid climatic condition. The drought affected regions of Karnataka recorded lower crop yields and consequent increased poverty levels in the region. The repeated droughts have lead to over exploitation of ground water besides increased in fire incidences in semi-arid regions. The annual income of the households reduced to half in drought years. The reduction was more in case of the crops followed by labour. In this regard Karnataka state established disaster management authority to undertake mitigation and adoption measures in the region.

The case studies in semi-arid region of Karnataka offer a valuable complement to the macro profile by revealing insights on the determinants of vulnerability at the individual or community levels. Numerous physical and socio-economic factors come into play in enhancing or constraining the current capacity of farmers to cope with adverse changes. Prominent among the physical factors are cropping patterns, crop diversification, and shifts to drought-/salt-resistant varieties. The most important socio-economic factors include ownership of assets (like land, cattle, pump-sets, and agricultural implements), access to services (like banking, health, and education), and infrastructural support (like irrigation, markets, and transport/communication networks). From the last few decades, a growing incidence of seasonal migration is occurring in northern part of Karnataka due to the lack of livelihoods and fodder availability.

The climate change adaptation (CCA) policy approach has also been fragmented, with climate change strategies and plans not strongly linked with existing agricultural policies in the region. The present study documented traditional knowledge of the farmers on climate change mitigation and adaptation, which will help to evolve a policy and shape future research on climate resilient agriculture in semi-arid region of South India. The National Mission for Sustainable Agriculture speaks of attaining "ecologically Sustainable Agricultural Growth through progressive Adaptation and Mitigation. While the noises are sound, the mission still emphasizes the role of bio-technology. The Policy concern is that Growth is linked to extracting a monetary value out of the system, whereas the principle of sustainable practices, means that the outputs, inputs into the system, which is the principle of ecological farming. Whereas bio-technology options tends to be patented means of extracting rents out of discovery. The complex and multidimensional nature of drought in India requires a long term, well organized and coordinated research plan and action involving all the stakeholders. The present study aims to highlight the ongoing efforts of farmers groups, government and Non-government organization in evolving ecosystem-based mitigation and adaptations strategies for the region.

P-3332-03

Measuring Vulnerability of a region in Indonesia

Y. Tjoe (1)
(1) Griffith University, International Business and Asian Studies, Brisbane, Queensland, Australia

For many rural households in Indonesia, yields from subsistence production are the main source of food to maintain their health and livelihoods. The livelihoods of households in dryland West Timor are expected to be affected by climate change due to their dependence on rainwater for their subsistence production. Due to the subsequent poor rainfall and low crop yield, some of the households have begun to adapt to broader modern employment and modified their income sources with males taking up external cash-employment; such as temporary labour in the construction or plantation fields at local cities or overseas. Is this pathway of income adaptation sustainable, compared to the subsistence-based corn farming and traditional forms of livelihood?

This paper investigates factors that contribute to the livelihood vulnerability of the subsistence households to drought. The five major factors include EDU (Education), SCP (Social-Cultural Participation), FS (Food Store), IA (Income through management of agricultural production) and ACC (Access). Primary data are collected through a household survey conducted in three villages of West Timor (total sample 627). Data gathered are then used to produce a vulnerability index, using the following equation:

LVI_v=WEDU EDUv + WSCP SCPv + WFS FSv + WIA IAv + WACC ACCv

WEDU+ WSCP+ WFS+WIA+WACC

LVIv= Livelihood Vulnerability Index for village v

WMi= weight of each major components (e.g. WEDU is the weight of Education)

Mci = average value of major component (e.g. EDUv is the average value of Education)

The Probit analysis is then performed to investigate the relationship between «perceptions of households about causes of drought" and "their readiness to better equip themselves for the future drought or other disasters".

Where Cause_1i is type of cause: 'It has been like this all the time' = 1; otherwise = 0

Cause_2i is type of cause: 'I don't know why' = 1; otherwise = 0

Cause_3i is type of cause: 'God's Plan' =1; otherwise = 0

Cause_4i is type of cause: 'Manmade' = 1; otherwise = 0

Statistical reliability and validity, and factor analysis are conducted using SPSS 22.

The results show that ACC (access to water, local market and health centre), SCP (social and cultural activities), and IA (income through management of agricultural production) are all significantly correlated with a household's vulnerability to drought. Households are less vulnerable when they have better access, agricultural incomes, and when they and their children are actively involved in local agricultural and ritual activities. A poorer access to market and schools may also contribute to increasing household's vulnerability as the youth have to leave the village and stay at urban area for employment or education purposes. Combining all five factors, the overall vulnerability index for individual village shows that the further the village is to urban area (Kupang or Soe) the more vulnerability it is. The furthest village has the highest score (0.503), while the closest village scores 0.234.

Furthermore, the results of Probit analysis show that the tendency to take precautionary measures to anticipate drought and other disasters is related to the perception about the cause of disasters. Households tend to have no planned alternatives such as saving money or preparing water storage in the house when they believe that Gold's plan or manmade are the cause of drought and other disasters.

The paper concludes that the temporary participation in broader modern employment may be an alternative for the households to cope with short-term impacts of drought and low crop yield. However, the social-cultural participation, which maintains local ritual and belief, provides long-term sustainable pathway for dryland ecosystem as it helps to regenerate local knowledge system and conserve the use of natural resources. Future adaption should aim to increase household awareness of the importance of proactive saving (water and money), and to improve infrastructures that help sustain both existing economic and social-cultural activities.

P-3332-04

Local practices of reducing vulnerability, and securing livelihoods in the age of climate change: Lesson learned from the analysis of community adaptation plans and practices in Nepal

DR. Uprety (1)
(1) Multi Stakeholder Forestry Programme (MSFP), Climate change and Forestry, Kathmandu, Nepal

About 25% of the total populations in Nepal live under the poverty line (less than 1.25USD/day) and the country is ranked one of the 5th climate vulnerable countries around the world. Flash floods and landslides, loss of biodiversity, decline in agricultural productivity, increase of invasive species and depletion of fresh water resources are some major vulnerability resulted from the climate change and pushing the lives and livelihoods of over 1.9 million households at risk. Responding to these climates induced adversities, the local communities have started making their adaptation plans (more than 1500) in partnership with growing development institutions at local level. The paper is based on the studies of more than 1000 local adaptation plans, field observation and interaction with more than 500 communities in between 2011 to 2015. The paper analyses of the major vulnerabilities identified in different adaptation plans, local practices of responding these vulnerabilities, tradeoff between growing vulnerabilities, and securing livelihoods challenges through the analysis of the 1000 community adaptation plans in Nepal.

3333 - China's climate policies and low-carbon innovation

ORAL PRESENTATIONS

China's emissions trading schemes

X. Zhang (1)
(1) Tsinghua University, Executive director, institute of energy, environment and economy, Beijing, China

China's government has established seven pilot emissions trading systems. Pilots differ in the extent of sectoral coverage, the size threshold for qualifying installations, and other design features that reflect diverse settings and priorities. We identify issues that have emerged in the design process and the operation of the pilot trading schemes, and outline important next steps for the development of a national emissions trading schemes.

K-3333-02

The Economic Benefits of Decarbonization for China

F. Teng (1)
(1) Tsinghua University, Institute of energy, environment and economy, Beijing, China

China needs to reduce its carbon emissions if global climate change mitigation is to succeed. Conventional economic analysis views cutting emissions as a cost, creating a collective action problem. However, decarbonization can improve productivity and provide co-benefits that accord with multiple national policy objectives. Investment in greater energy productivity and economic restructuring away from heavy industries can bring productivity gains, and decarbonization of energy supply has important co-benefits for air pollution and energy security. To properly identify the true costs and benefits of climate change action requires new thinking in economic analysis. This presentation draws on recent academic papers as well as research contributions to the New Climate Economy report and the global Deep Decarbonization Pathways project.

K-3333-03

Challenges and opportunities for renewable energy development in China

S. Li (1)
(1) Alexander von Humboldt Fellow, Berlin, Germany

China's rapid renewable energy deployment is increasingly well known. The country has set out ambitious targets for wind and solar and is well on track to deliver them. However, this robust development should not be taken for granted over the next few years. As more renewable energy enters into China's power system, energy integration is emerging as the biggest headache faced by the industry. Already over the past few years, while China was busy adding new installations, its existing renewable power plants were curtailed severely. The root cause is China's electricity market design which favors strongly baseload capacity and gives little incentive to clean but fluctuating generation sources. The degree to which China could further reform its aging power market will therefore largely determine whether the country can continue to unleash its immense renewable energy potential.

O-3333-01

Lessons from climate change and energy policy in Western countries

F. Jotzo (1) ; A. Loeschel (2) ; X. Labandeira (3)
(1) Australian National University, Crawford School of Public Policy, Canberra, Australia; (2) University of münster, Center of applied economic research münster (cawm), Münster, Germany; (3) European University Institute, And university of vigo, spain, Florence, Italy

China is planning a national emissions trading scheme and to expand and reform other policy approaches to curb greenhouse gas emissions. Valuable lessons have been learned in Western countries about the design of emissions trading schemes, as well as other policy approaches such as feed-in tariffs for renewable energy and mechanisms to support energy efficiency. Some of the lessons are universal, allowing China to avoid costly mistakes made in

Europe and elsewhere. Others are specific to the context, and effective climate policy instruments for China may look quite different from what works in market economies. In this session we point out key lessons for China from Europe, the United States and Australia. We draw on our own research bridging Europe/Australia and China, and on a recent special issue of Energy Policy journal on emissions trading in China, edited by Loeschel and Jotzo.

O-3333-02

Low-carbon innovation in China: prospects, politics and practices

S. Geall (1) ; A. Ely (2)

(1) University of Sussex, Science Policy Research Unit, Brighton, United Kingdom; (2) STEPS Centre, SPRU – Science Policy Research Unit, Sussex, United Kingdom

This paper explores innovation in China and its potential to contribute to global transitions to low-carbon patterns of development. Building on earlier studies bringing alternative forms of low(er)-technology, 'below-the-radar', 'disruptive' and social aspects into innovation, and drawing on empirical research on electric mobility, solar-generated energy and food systems in China, the paper also pays particular attention to issues of changing power relations and social practices. Taken together, this shift in perspective allows neglected questions in low-carbon innovation to be introduced and points to both opportunities and challenges to low-carbon system transition that are overlooked by an orthodox focus on technological innovations alone.

O-3333-03

Intersections of China's Energy Technology Innovation, S&T Policies and Ongoing Reform

J. Fan (1)

(1) International Energy Agency, Paris, France

China's energy technology innovation, with a strong focus on clean energy technologies, is central to a strategy that faces head-on the dual challenge of satisfying energy demands while safeguarding the environment as part of China's self-proclaimed "Energy Revolution". Combining with the global concern on addressing climate change, China's policies and actions in energy field have been focused on industrial transformation, energy system optimisation, energy efficiency promotion and the environmental protection. Recent energy technology innovation, S&T policies and reforms seek to capture opportunities for economic advantage from the transition to a cleaner, more sustainable and increasingly market-oriented system.

China has demonstrated some progress in its low-carbon and energy sector development. The remarkable progress could be tracked in the development of its Strategic Emerging Industries (SEIs), encouraged by the convergence of energy and S&T policies.

State R&D fund acts as one of the most important financing channels for energy technology innovation. China's funding for research and technology (R&D) as a proportion of GDP (R&D intensity) is increasing, but unprecedented co-ordination among government and institutional actors will be needed to sustain innovation over the long term. Existing gaps create opportunities for institutional reform to promote innovation. A new round of S&T reform is being proceeded in China in aims of offering greater information disclosure and transparency and promoting the efficiency of resource allocation.

The commercialization of technology is another key issue requiring efforts to enhance China's innovation competitiveness. Enforcing IP governance and encouraging the development of public-private partnerships (PPPs) to support innovative approaches to new market have been emphasized by the government.

Monitoring and evaluating innovation measures against energy sector and environmental benefits can help to improve policy implementation over time and lead to more effective innovation systems designed to meet the main public objectives. The effects of China's ongoing reform in the field of energy and S&T are worth a further observation.

O-3333-04

The transportation sector as a lever for reducing long-term Chinese mitigation costs

M. Hamdi-Cherif (1)

(1) CIRED, Nogent-Sur-Marne, France

** Rationale and Objective: Chinese economic development goes hand in hand with (i) a growth of the production that is accompanied with an increase of the freight transport, and (ii) an enriched population and fast-growing urbanization that induce increasing demand for passenger transport (notably an increase of the motorization rate). Given the high reliance of transport on oil products, its increasing energy demand and CO2 emissions, the transportation sector is a crucial sector for China, particularly regarding energy security and climate change issues. In its attempts to have a sustainable development, the transportation sector is indeed particularly challenging for China. To avoid important "lock-ins" in carbon-intensive pathways, especially given the high coal availability and the important life span of infrastructures, China has to redouble its efforts with voluntary schemes promoting mobility growth control.

This paper investigates the role of passenger and freight transportation activities in the transition to a low carbon Chinese society. A particular attention is given to specific measures designed to control the growth of mobility. It is an attempt to quantify the impact of urban voluntary policies on Chinese mitigation costs.

** Modeling approach and Methodology: This article revisits the role of the transportation sector in low-carbon pathways by using the Energy-Economy-Environment (E3) model IMACLIM-R. It is a hybrid multi-region, multi-sector CGE model, which embarks a detailed description of passenger and freight transportation. The standard representation of transport technologies is supplemented by an explicit representation of the "behavioral" determinants of mobility. The model relies on hybrid matrices ensuring consistency between money flows and physical quantities and allows an explicit representation of the interplay between transportation, energy and growth patterns. It accounts for the rebound effect of energy efficiency improvements on mobility, endogenous mode choices in relation with infrastructure availability, the impact of investments in infrastructure capacity on the amount of travel, and the constraints imposed on mobility needs by firms' and households' location.

Moreover, IMACLIM-R represents the second best nature of economic interactions and the inertias on technical systems that limit the flexibility of adjustments, a crucial dimension for emerging economies when envisaging large structural change over the course of the century.

Complementarily to carbon pricing to reach a stringent climate objective (3.4W/m2 in 2100), we consider actions to control the "behavioral" determinants of transportation in the course of the low-carbon transition, and assess their effects on the Chinese economy. More specifically, we consider (i) urban reorganization lowering the constrained mobility (i.e. mobility for commuting and shopping), (ii) reallocation of investments in favor of public modes at constant total amount for transportation infrastructure and (iii) adjustments of the logistics organization to decrease the transport intensity of production/distribution processes.

** Results: This analysis demonstrates the risk of high losses if using carbon price as the sole instrument of mitigation. Transport proves to be the sector for which carbon emissions are the more difficult to reduce. It thus represents a dominant share of remaining emissions in the long-term when ambitious mitigation objectives are set. Because of its weak reactivity to price increases, very high levels of carbon prices are needed in the second half of the century to reach low mitigation targets. We find indeed that they can reach 1400$/tCO2 by the end of the century.

But we find that controlling mobility growth allows limiting these effects by offering mitigation potentials independent of carbon prices. The considered measures allow significant reductions of carbon price levels (on average 25% lower over 2050-2100) and hence help limiting the macroeconomic costs of the mitigation policies (e.g. long-term mitigation costs are reduced by 5 points in 2050 and

by 10 points in 2100).

** Conclusion: This study highlights the role of transport in the mitigation process. Given a climate target, the implementation of measures fostering a modal shift towards low-carbon modes and a decoupling of mobility needs from economic activity prove to modify the sectoral distribution of mitigation efforts and to significantly reduce the mitigation macro-economic costs relatively to a "carbon price only" policy.

Energy Technology Roll-Out for Climate Change Mitigation: A Multi-Model Study for Latin America

B. Van Der Zwaan (1)
(1) ECN / University of Amsterdam, Amsterdam, Netherlands

In this paper we investigate energy technology deployment under climate change mitigation efforts in Latin America. Through several carbon tax and CO2 abatement scenarios we analyse what technologies in the energy sector, and particularly electricity generation, could best be used until 2050 to significantly reduce CO2 emissions in the region. By way of sensitivity test we perform a cross-model comparison analysis and inspect whether robust conclusions can be drawn across results from not only different models but also different types of models (that is, bottom-up versus top-down, and general equilibrium versus partial equilibrium models). Given the abundance of biomass resources in Latin America, they are likely to play a large role in energy supply in all the scenarios we inspect, especially in the climate policy scenarios since some use of biomass can be combined with CCS. We find that hydropower, which today already contributes about 800 TWh to overall power production in the region, could be significantly expanded to meet the climate policies we investigate, on average by 50% but perhaps by as much as 75%. According to all models, electricity generation increases exponentially with a two- to three-fold expansion between 2010 and 2050. We find that renewables such as wind and solar power typically expand at double-digit growth rates, but the robustness of our findings differs substantially between these two options: the climate policies represented in our models raise wind power in 2050 on average to half the production level that hydropower provides today, while they raise solar power to either a substantially higher or a much lower level than hydropower supplies at present, depending on which model is used. For CCS we also observe a large diversity in model outcomes, which reflects the uncertainties with regard to its future implementation potential given the challenges this CO2 abatement technology currently faces. The extent to which different mitigation options can be used in practice varies a lot between countries within Latin America, depending on factors such as resource potentials, economic performance, environmental impacts, and availability of technical expertise. We provide concise assessments of possible deployment opportunities for some low-carbon energy options, mostly for the region at large but with some country-level detail in specific cases. A similar climate scenario study of technology diffusion in Latin America has not yet been made, so we contribute a new piece of work to the existing literature. This study possesses particular relevance for the ongoing climate negotiations leading up to COP-21 in Paris, as was demonstrated by the attention we received by the presentation of this work during COP-20 in Lima in December 2014. Given the theme of this paper, our work, if accepted, could best be presented in session.

Climate Change Mitigation in Latin America

T. Kober (1) ; B. Van Der Zwaan (2)
(1) Energy reserach Centre on the Netherlands, Policy Studies, Amsterdam, Netherlands; (2) University of Amsterdam, Faculty of science, Amsterdam, Netherlands

In this keynote speech we present an overview of today's structure of the energy sector of Latin America and provide a long-term outlook of possible future developments associated to different levels of climate change mitigation ambition in the region. This conference contribution largely builds on the CLIMACAP-LAMP research project (see www.CLIMACAP.org) and highlights its main outcomes. Key findings of the project have already been presented at COP 20 in Lima, and a compilation of the major results scoping on selected regional and topic 'deep-dives' is forthcoming in a dedicated special issue in Energy Economics expected in spring 2015. Almost 20 research teams are involved in this project delivering new energy and climate policy analysis, which is derived from a broad application of model-based assessment tools.

Before highlighting climate change mitigation in Latin America, we discuss the baseline projections for the set of models participating in the CLIMACAP-LAMP project and identify key differences between model projections including how these projections compare to historic trends. We find that population and GDP projections across models span a broad range, comparable to the range represented by the set of Shared Socioeconomic Pathways. Kaya-factor decomposition indicates that the set of baseline scenarios mirrors trends experienced over the past decades. Emissions in Latin America are projected to rise as result of GDP and population growth and a minor shift in the energy mix towards fossil fuels. For the future most models assume a somewhat higher GDP growth than historically observed and continued decline of population growth. We observe minor changes in energy intensity or energy mix are projected over the next few decades.

The climate policy scenarios perform around three main clusters of policy measures: carbon taxes, greenhouse gas emission caps applied to Latin American countries and a globally harmonized scheme for cap and trade of emission certificates to attain different levels of temperature stabilization. Regarding the latter, we explicitly investigate pathways reach a stabilization of the mean temperature increase at 2˚C compared to pre-industrial level. We find that an overall energy emissions reduction of roughly 50% across Latin America is consistent with meeting a 2°C goal at lowest cost. However, a range of other mitigation levels will also be consistent with meeting this goal. Our study confirms the results of previous research that the variation in mitigation costs across models may vary by as much as an order of magnitude. For Latin America as a whole, currently discussed country level policies lower 2030 emissions to a level that are not inconsistent with a 3°C long-term target, but may be inconsistent with a 2°C target. Besides greenhouse gas emission reduction potential related to energy conversion, avoidance of land use and land use change emissions will play an pivotal role, particularly for Colombia and Brazil. These emissions may be alternatively affected by efforts to store more carbon in land and those aimed at producing more bioenergy for low-carbon energy

One of the major economies in Latin America is Brazil for which our results show an increase over time in emissions in baseline scenarios due, largely, to higher penetration of natural gas and coal. Climate policy scenarios, however, indicate that such a pathway can be avoided. While carbon taxes up to 32 US$/tCO2e do not significantly reduce emissions, higher taxes (from 50 US$/tCO2e in 2020 to 162 US$/tCO2e in 2050) induce average emissions reductions around 60% when compared to baseline. Emission constraint scenarios yield even lower reductions in most models. Emission reductions are mostly based on lower energy consumption, increased penetration of renewable energy (especially biomass and wind) and of carbon capture and storage technologies for fossil and/or biomass fuels. The range of mitigation options resulting from the model runs generally fall within the limits found for specific energy sources in the country, although infrastructure investments and technology improvements are needed for the projected mitigation scenarios to achieve actual feasibility.

O-3335-01

The macroeconomic impact of climate mitigation action in Latin America: a model comparison

P. Summerton (1)
(1) Cambridge Econometrics, Cambridge, United Kingdom

In this paper we investigate economic impacts under climate change mitigation efforts in Latin America. Through several carbon tax scenarios we analyse the impact that climate change mitigation policy might have on income, trade and investment in the region. By way of sensitivity test we perform a cross-model comparison analysis and inspect whether robust conclusions can be drawn across results from not only different models but also different types of modelling approach (that is, a hybrid modelling approach that links an energy system model, TIAM-ECN, with a macro-simulation modelling, E3ME, compared to the mainstream general equilibrium modelling approach).

The paper presents the first detailed multi-model comparison of the macroeconomic consequences of carbon pricing action in Latin America. In the short term at carbon prices reaching around $15/tCO2 by 2030 the models agree that the reduction in consumer spending, as a proxy for welfare, is expected to be limited in all countries modelled and across the continent. However, by 2050 and at carbon prices of $165/tCO2, there is much more divergence in the estimated impact on GDP and consumer spending across models and across countries in Latin America reflecting the uncertainty about the cost of technology and substitution between technology options. The insight of the hybrid modelling approach comes through in the comparison of increasingly higher carbon prices in each model. The negative impact of reduced consumer spending and GDP are linear in the CGE models and increase as the carbon price increases; but divergent and non-linear in E3ME-TIAM-ECN reflecting step-changes in technology substitution in TIAM-ECN and the non-linear impact of each technology (its cost, cost composition and supply chain implications) on the economy as represented in E3ME.

A similar mulit-model scenario analysis of economic impacts of mitigation policy in Latin America has not yet been made, so we contribute a new piece of work to the existing literature. This study possesses particular relevance for the ongoing climate negotiations leading up to COP-21 in Paris, as was demonstrated by the attention we received by the presentation of this work during COP-20 in Lima in December 2014. Given the theme of this paper, our work, if accepted, could best be presented in session N° 3335 - Latin America pathways. This has been a multiauthored exercise, led by Philip Summerton, with contributions from Hector Pollitt (Cambridge Econometrics), Unnada Chewpreecha (Cambridge Econometrics), Xiaolin Ren (National Centre for Atmospheric Research), William Wills (Energy Planning Program, Federal University of Rio de Janeiro), Claudia Octaviano (MIT Joint Program on the Science and Policy of Global Change), James McFarland (US Environmental Protection Agency), Robert Beach (RTI International), Andres Camilo Alvare Espinosa (National Planning Department, Colombia), Silvia Calderon (National Planning Department, Colombia), Karen Fisher-Vanden (Penn State University), Katie Daenzer (Penn State University), and Ana Maria Loboguerro Rodriguez (CIAT-CCAFS).

Scenario building and macroeconomic modeling in response to climate change challenges: an overview of the modeling results from MAPS Latin America

AM. Rojas (1)
(1) University of Cape Town - MAPS Programme, Energy Research Centre, Cape Town, South Africa

The Mitigation Action Plans and Scenarios (MAPS) programme is a collaboration amongst developing countries to establish the evidence base for long-term transition to robust economies that are carbon efficient and climate resilient. The programme aims to contribute to ambitious climate change mitigation aligned with economic development. Central to MAPS is the way it combines research and stakeholder interest with policy and planning, through providing robust research to underpin national policy processes. This paper focuses on the scenario building and macro-modelling experiences in each of the four MAPS Latin America countries: Brazil, Chile, Colombia and Peru.

The paper starts with a description of the results on national feasible GHG abatement options and mitigation options that were identified in each case. We then evaluate cross-cutting assumptions, most recurrent/common actions in the four countries and mitigation scenarios packaging criteria. Later, we compare Required by Science and Required Equity scenarios to the mitigation scenarios to assess ambition and equity levels in the four countries.

Next, the paper explains the economy-wide impacts associated to these mitigation options and scenarios. This section includes a summary of the macroeconomic modelling approaches key features and cross-cutting assumptions of each country model (closure rules, exogenous drivers, world prices and sectoral rigidities). This is followed by an analysis of the related impacts of these assumptions on the socio-economic indicators such as GDP, welfare and employment.

Through out the paper, benchmarks and indicators are calculated to evaluate the results.

This analysis draws on four unique Latin American country experiences that could inform and support policy makers in other Latin American countries when examining policy interventions to transition a low carbon economy.

Energy Supply Investments in Latin America under Climate Control Policy

J. Falzon (1) ; T. Kober (2) ; B. Van Der Zwaan (3) ; K. Calvin (4) ; A. Kanudia (5) ; A. Kitous, (6) ; M. Labriet (7)
(1) Energy reserach Centre on the Netherlands (ECN), Policy studies, Amsterdam, Netherlands; (2) Energy reserach Centre on the Netherlands, Policy Studies, Amsterdam, Netherlands; (3) ECN / University of Amsterdam, Amsterdam, Netherlands; (4) JGCRI, Joint Global Change Research Institute , College Park, United States of America; (5) KanORS-EMR, NOIDA, UP, India; (6) DG JRC - European Commission, Institute for prospective technological studies, Seville, Spain; (7) Eneris Environment Energy Consultants, Madrid, Spain

In this conference contribution we present our findings on energy supply investment requirements in Latin America until 2050 investigated through a multi-model approach as jointly applied in the CLIMACAP-LAMP research project. Key findings of the project have already been presented at COP 20 in Lima and are forthcoming in a dedicated special issue in Energy Economics expected in spring 2015. In our analysis we compare a business-as-usual scenario needed to satisfy anticipated future energy demand with a set of scenarios that significantly reduce CO2 emissions in the region. We find that more than a doubling of investments, in absolute terms, occurs in the business-as-usual scenario between 2010 and 2050, while investments may be multiplied by up to three over the same time horizon when climate policies are introduced. However, investment costs as share of GDP decline over time in the business-as-usual scenario, and even under the most ambitious climate policy scenario, due to the rapid economic growth in the region. For the electricity supply sub-sector business-as-usual cumulative investments of 1.4 trillion US$ are anticipated between 2010 and 2050, and become increasingly important when additional climate policies are introduced: under a carbon tax of 50 $/tCO2e in 2020 increasing with a rate of 4% per year, an additional 0.6 trillion US$ (+45%) investment is needed. Further, our analysis suggests that compared to the business-as-usual case an additional 21 billion US$ per year of electricity supply investments is required in Latin America until 2050 under a climate policy aiming at 2°C climate stabilization, which, when compared to the 100 billion US$2020 targeted to be mobilized globally under the Copenhagen accord by 2020, is substantial. In terms of specific low carbon electricity technologies, model results reveal that wind, solar, and CCS applied to fossil fuels and biomass will play an important role under climate policy scenarios, while nuclear power does not. Significant investment opportunities in renewable energy exist in the short- to medium-term, even in the absence of climate policy measures. If climate change mitigation is envisaged policy frameworks with ambitious long-term goals provide

stronger signals to investors than a policy mix with weak goals and fragmented instruments.

These findings have clear implications for policy makers. Moving forward, increased absolute investment in energy supply, even in the absence of climate control policies, is needed to underpin economic and energy demand growth in the region. Mobilizing necessary additional investment capital, in particular for low-carbon technologies, will be a challenge, and suitable frameworks and enabling environments for a scale-up in public and private investment will be critical to help reach required levels.

Quantifying the impact of non-conventional renewable energy sources in reducing greenhouse gas emissions: Chilean experience

C. Benavides (1)
(1) Energy Center, University of Chile, Santiago, Chile

The countries are interested in quantifying the impact of mitigation actions that they have implemented in order to know how far or near they are from their voluntary and non-voluntary pledges. During COP19 in 2009, Chile proposed a voluntary commitment to reduce its GHG emission by 20% by 2020 with respect it 2007 baseline scenario. This commitment was confirmed in the Climate Summit in New York (2014) and during the COP21 in Lima, Peru (2014). In the case of Chile, the reason to select the year 2007 as a reference is because the country wants that the mitigation actions implemented before 2009 are recognized as a national mitigation effort. In Chile, one the main environment policies is the non-conventional renewable energy (NCRE) law implemented before 2009. The first non-conventional renewable energy law was launched in 2008 and it stated that 10% of the total sales would be provided by NCRE sources in 2024. This quota system was updated recently (2013) and the new law states that 20% of the total sales would be provided by NCRE sources in 2025. This paper aims to propose a methodological approach to quantify the impact of the non-conventional renewable energy law in reducing greenhouse gases emissions in Chile. The effectiveness of this policy is analyzed.

In order to quantify the impact of this mitigation action by 2020, this exercise requires projecting at least two scenarios: the baseline scenario, i.e. the GHG emission trajectory considering the implementation of the NCRE law, and the counterfactual scenario. This is an estimate of what would have occurred in the absence of the NCRE law. The methodology used an optimization model in order to project the planning in new power plants in the power sector. This model also projects the electricity generation by power plants and the GHG emissions. The steps of methodology are the following:

1) A gathering information process is done for those NCRE projects installed between 2007 and 2014. The first step of the proposed methodology is to estimate how many of these projects were installed due to the NCRE policy launched in 2008.

2) Construction of periodical baseline scenarios between 2007 and 2013: The model to project the baseline scenario is run activating and not activating the NCRE constraint. The resulted investment plants of these cases (with and without NCRE constraints) are compared in order to estimate the installed capacity in NCRE projects between 2007 and 2013. This projection is compared to the real projects installed in the same period.

3) In order to project the emission reduction by 2020, a Baseline 2014 scenario is projected. The Baseline 2014 is the scenario which considers the current situation and trends of the electricity generation sector: current investment cost projection, fuel price projection, projection of demand, etc. This model is run activating the NCRE constraint (20% of sales will be provided by NCRE sources by 2025).

4) Projection of the counterfactual scenario since 2014: This scenario has two main differences in comparison to Baseline 2014 scenario. The first, this model is run non-activating the NCRE energy law, and the second, is to suppose that only x% of the installed capacity in NCRE project would be installed in 2014. This percentage is calculated from step 2 of the methodology. The Chilean voluntary pledge refers to a Baseline 2007 scenario; however, we propose that a more realistic quantification of the emission reduction of the policy is done using the current trends of the sector.

5) A sensitivity analysis is done in order to capture the uncertainties.

The results of this methodology show that the emission reduction of this policy would be between 1.1 and 6.1 million tCO2 in 2020. This emission reduction is compared to other policies implemented in Chile. The results show that the NCRE law has been the most important policy to mitigate the climate change. However, it has not been enough due to the building of thermoelectric power plants has not stopped in Chile. In effect, between 2009 and 2013, 2263 MW of coal power plants were installed. In addition, there are 611 MW of coal plant under construction. Therefore, by 2016 will be 2874 MW additional in coal plant with respect 2006 installed capacity. It means that at least additional 28 million tCO2 will be launched to the atmosphere by the electricity generation sector.

P-3335-02

The territorialization of climate change in southern rural Chile: linking local knowledge to global environmental change

G. Blanco-Wells (1) ; A. Lagarrigue, (2)
(1) Universidad Austral of Chile, Center for climate and resilience research, Valdivia, Los Ríos, Chile; (2) Universidad Austral of Chile, Instituto de historia y ciencias sociales, Valdivia, Chile

This paper presents findings of a five-year research programme called the Sociology of Climate Change (SCC) carried out in southern Chile by an interdisciplinary team. By means of ethnographic work and extended case methods, the research aims to unravel the processes by which national and international public policies on climate change are territorialized in rural regions of southern Chile by farmers, rural dwellers, scientist, and other local agents. From a social sciences perspective, climate change can be seen as an elusive techno-political object needing complex methods to be represented. However, it has gradually become a transforming driver of rural practices and everyday life in rural territories worldwide.

Therefore, the main focus of the case studies is to present evidence about how local actors internalized the socio-technical object called climate change creating new practices and meaningful representations of an otherwise distant global phenomenon. Most institutional actions by government, universities, and international organizations are loaded with a highly normative approach placing mitigation and adaptation at the centre of their strategies. However, little attention has been paid to understand if and how climate change becomes a local category for farmers and rural dwellers; how are they framing the phenomenon and engaging in new sustainable and/or transformative options.

The results show that local actors are concerned with climate related problems but a process of understanding and translation to local epistemologies and ontologies is needed, a process that we have conceptualized as territorialization. To illustrate this point we present specific findings on the associations between climate change and peasant agriculture on Chiloé Island, in southern Chile. Drawing from Actor-Network and Social Practice Theories, we track interesting changes in the use of local peasant knowledge as it relates to weather and the organization of farming activities. Furthermore, we find evidence concerning the configuration of new territorial assemblages devised to explore the means of facing the negative consequences of this phenomenon, in terms of both production, and the fragmentation of local knowledge.

The conclusions highlight the importance of empowering networks where mentioned responses are produced and diversified, and in which local knowledge can be updated and applied to the organization of rural practices in order to face growing climate variability.

P-3335-03

Guatemalan Advances to climate change adaptation and Mitigation

M. Chacon (1)
(1) Doctoral Program Climate Change, San Carlos Guatemala University, Guatemala, Guatemala

The goal of this essay is to present a comparative review of the advances of Guatemalan national and municipal initiatives to climate change adaptation and mitigation, which includes public policy, private sector strategies, and indigenous communities' practices to make resilient communities. The author of this essay analyzes the limitations and contributions to climate change adaptation derived from the national and local planning policies to address sustainable development with the complexity of poverty and climate change impacts. The author also describes private sector experiences in managing natural resources with environmental social responsibility. In addition, the author identifies the local indigenous community strategies and other local practices and principles to manage local natural resources and biodiversity with an effective climate change adaptation and mitigation and prevention of natural disasters. For instance, in Guatemalan indigenous highlands there are recently introduced a few forested communal parks which are managed by indigenous organizations; interestingly, they aim to increase local economic development, prevent landslides, conserve cultural and natural values, and contribute to reduction of climate change impacts; it is the case of "hearth Municipal Park" located in Atitlan lake's watershed.Because climate change has shown strong effects in Central American countries in impoverished communities in societies where democratic institutions are recently in building process, in this essay the author has given special attention to national policy and local community initiatives for sustainable development programs in order to know the main principles and aspects that should have been considered in the process of making resilient communities by dealing with the social, ecological, cultural, political and economic impacts of climate change effects in the indigenous communities most affected also by poverty. They are the impoverished urban and rural populations which have had increased social, economic an environmental vulnerability because of the climate change impacts. The climate change impact would be deepest since local governments and rural population have little or lack of understanding of the mid and long term climate change effects and strategies to adapt to it in local communities.

Therefore, it is very crucial to review the climate change factors and effects which are affecting communities not only because of atmospheric Nina and Nino phenomena, but also because of the environmental, social, political and economic impacts and constraints for climate change adaptation and poverty alleviation. Conversely, it is fundamental to correlate climate change effects with sustainability challenges such as poverty, population emigration to international labor sites in USA, and in combination with environmental degradation including deforestation, introduction of areas with planting illegal cultivation related other drugs' trafficking activities, rural land fragmentation, erosion; such factors are creating more complexity to democratic institutional capacities and economic development plans and strategies for sustainability and resilience. It is the case of the most attractive touristic spots in Guatemala where economic development derived from international tourism is jeopardized because the environmental degradation; it is the case of millennial Mayan historical places like Tikal, and international most attractive and visited spots such as Atitlan Lake and Flores Lake where level of water is increasing covering the parts of the surrounding towns. The impacts are more destructive in rural lands and towns because of land use location near risky places where there have been landslides and natural disasters from the Mitch Hurricane, Stan Storm. Other impacts are the reduction of environmental values, ecological functions, landscapes values, diminished environmental protected corridors, less touristic demand for potential touristic places losing attractiveness. Moreover, other social economic impacts are the losing the investment of private housing and state investments in municipal parks located in lands occupied by the increased water level of the lakes and rivers, the reduction of areas of agricultural lands affected by the increased water level of the lake and rivers; also, the reduction of productivity in agricultural lands affected by dryness in Niña and Niño phenomena, reduction of health conditions and nutrition of those communities.

P-3335-04

Evidence and Future Scenarios of a Low-Carbon Power System Transformation in Latin America: A Case Study in Nicaragua

D. Ponce De Leon Barido (1) ; D. Kammen (1) ; J. Johnston (2)
(1) University of California, Berkeley, The Energy and Resources Group, Berkeley, California, United States of America; (2) University of Hawaii, Electrical engineering, Honolulu, United States of America

The global carbon emissions budget going forward depends critically on the choices made by fast-growing emerging economies. Yet there are few studies that develop country-specific energy system integration insights that can inform emerging economies in this decision-making process. High spatial- and temporal-resolution power system planning is central to evaluating decarbonization scenarios, but obtaining the required data and models for such analysis can be cost prohibitive, especially for researchers in low and lower-middle income economies. Recent research also highlights that although low-carbon economy transformations in emerging economies could prove challenging and expensive, cost-effective mitigation actions, such as fossil ¬fuel subsidy reform, decentralized modern energy access expansion and fuel switching in the power sector, are not only possible, but feasible.

Nicaragua is a country whose power system, like others in Central America and the Caribbean, has been historically dependent on imported fuel oil. Most recently, however, and despite Nicaragua being the third poorest country in the Western Hemisphere, the country is leading a low-carbon power system transformation in Latin America. In 2013 it produced 40% of its electricity from non-hydro renewable energy and in 2014, on an hourly basis, it produced up to 50% of its generation from wind power alone. Motivated by energy security, industrial development, financial risk mitigation, and the need for increased energy access to its most vulnerable populations, Nicaragua has transformed its energy sector in recent years. Between 2009 and 2014 it installed ~190MW of wind energy capacity (14% of total installed capacity), underwent an intensive geothermal technical capacity training in partnership with Iceland, and between 2006 and 2014 the country received over US$ 1.5bn of cumulative renewable energy investments. Yet, despite this great progress, Nicaragua's own ambitious goals (79% and 93% renewables-based generation including large hydropower by 2017 and 2026, respectively) seem daunting.

Here, we utilize both high-resolution open-access data and electric power system planning tools (SWITCH, an optimization model for planning power system investments and operations developed at the University of California, Berkeley) to demonstrate how low- and lower-middle income economies can develop optimal fuel-switching strategies and scenarios for a low-carbon grid. We choose Nicaragua for our analysis as it has very low electricity access (79%), oil accounts for over 80% of all energy imports (over 55% of Nicaragua's revenue from exports goes towards covering this expenditure), and its current expansion plan (2014-2030) relies primarily on large hydropower development, making the power system particularly vulnerable to hydro-climatological variability. We evaluate eight power system planning scenarios (base case, geothermal and solar development mandates, oil and large-hydro moratoriums, expensive and risky geothermal resource development, cheap fuel oil prices, and a Central American regional interconnection) that can help Nicaragua evaluate pathways for expansion of renewable and conventional generation technologies while achieving important development objectives (energy access, energy security, climate-risk mitigation and economic efficiency). Our results suggest that Nicaragua can cost-effectively achieve a low-carbon grid (≥80%, non-large hydro renewable energy generation) by 2030 while also pursuing multiple development objectives. A regional interconnection (balancing) enables the highest generation from wind and solar (18% and 3%, respectively by 2030), at the lowest cost (US$127/MWh), highlighting the importance of regional cooperation in enabling low-carbon futures. Neither oil price variability (cheap oil prices US$50/bbl increasing 2% per year) nor potentially risky geothermal and hydropower developments (which raise system costs) significantly hinder decarbonization. We conclude with a discussion on the challenges of power system decarbonization for emerging economies, and how they can use analyses similar to this one to develop and evaluate their own low-carbon transition pathways.

Fifth Road Generation: Infrastructure integrated energy systems supporting the transition in the transport energy pool (Session number 3336 :Post-2030 decarbonisation pathways: the electricity and transport sector)

N. Hautière (1)
(1) IFSTTAR, Marne-la-vallée, Champs sur marne, France

The fight against global warming is a major challenge. In the transport sector, it means both the invention of a sustainable mobility for mitigating climate change, but also adapting infrastructure to the same climate change. Being the predominant mode of transport, the road is at the heart of these ecological transition issues, plus its own challenges such as road deaths or the upselling of the corresponding industrial sector.

In developing countries, according the International Energy Agency (IEA), the number and extent of roads will expand dramatically this century. Globally, at least 25 million kilometers of new roads are anticipated by 2050, i.e. a 60% increase in the total length of roads over that in 2010. These new road infrastructures will have to face many important and diverse challenges, such as a strong increase of the land-use conflicts between transport infrastructures and agriculture.

In western countries, even if a shift to other modes of transport is wished for, the road still represents more than 80% of individual trips and of freight transport and the situation is not likely to change. Indeed, the road network has been developed over thousands of years: emerging from the track to the paved road, then to the smooth road and on to the continuous road.

Despite all the progress made in this sector, the environmental cost of current road infrastructures is still too important. There is thus a need of strong innovation in this sector to solve the related issues. Unfortunately, the road sector is experiencing difficulties to innovate. This is partly due in France to a lack of support from public authorities, like the lack of competitiveness cluster, or of an ambitious innovation program. This fragility is even more worrying, since a number of breakthrough innovations are emerging internationally. Among the most promising technologies, one can cite the green materials, the nanomaterials and nanosensors, the electromobility, the energy harvesting, and the cooperative intelligent transportation systems.

The R5G program (R5G for French "Route de 5ème Génération") aims at changing the image of road infrastructures by designing, constructing and operating full scale demonstrators, which implement the innovative solutions, already tested in research centres. Aligned with the Forever Open Road program led by the Federation of European Highway Research Laboratories (FEHRL) since 2011, the program is elaborated in a systemic approach and is divided in three phases: labeling, appropriation and generalization. Among the seven technical challenges, the challenge of positive energy roads is currently debated in the framework of the French energy transition law and is likely to open new business models. The potential benefits of such a program are numerous: Maintaining the RAMS (Reliability, Availability, Maintainability and Safety) of existing road networks, reinforcing industrial leaderships and targeting societal objectives (education, employment, and environment).

Investigation of carbon dioxide fluxes and possibility its storage in Georgia

M. George (1) ; M. Todadze (1)
(1) Institute of Geophysics, Ivane Javakhishvili Tbilisi State University, Tbilisi, Georgia

The major objective of investigation was study the natural CO2 sources, to investigate the properties ofrocks, which contain and absorb CO2 during its emission. Mentioned rocks are considered as anunderground Carbon dioxide reservoirs. For this case created numerical model to determine the potential of save sequestration in Carbon dioxide reservoirs and aquifers and to understand the geochemical and mechanicalprocesses associated with long-term storage of CO2 including methods to assess zones of weakness. Finally was calculated balance of carbon dioxide and how will decrees emission in atmosphere in future.

Governance for resilient cities: insights from the STAR-FLOOD project

A. Crabbé (1) ; C. Larrue (2)

(1) University of Antwerp, Faculty of political and social sciences, Antwerp, Belgium; (2) Institut d'Urbanisme de Paris - Université Paris Est Créteil Val de Marne, Val de marne, Marne la Vallée, France

Between 2000 and 2010, Europe has suffered more than 175 major floods, causing deaths, large economic losses and displacement of people. In the decades to come, climate change is expected to increase the intensity and frequency of flood events. As urbanization in flood-prone areas still continues, the flood issue becomes one of the big challenges for cities in the future. Within this context, it appears that flood risk management is not only about controlling the rivers with protection systems anymore. Since the 1990s, most European countries are developing a multitude of strategies against floods.

Within the STAR-FLOOD project (www.starflood.eu), five Flood Risk Strategies are identified: risk prevention, flood defence, flood mitigation, flood preparation and flood recovery. The project investigates these strategies in six European countries (England, Belgium, France, The Netherlands, Poland and Sweden). Its overall objective is to assess the institutional embedding of these strategies at the national and local scales from a combined public administration and legal perspective. The project aims to contribute to the identification of suitable experiences of Flood Risk Governance in Europe at the scale of urban regions. National country profiles have already been produced and local cases are researched.

In our presentation, we will discuss stability and change in flood risk management in Europe, we will share our (French and Belgian) experiences with designing and implementing governance arrangements for flood risk management and we will highlight the main challenges and opportunities ahead.

K-3337-02

The Resilience Pathway 2.0; a new way of city and area development with promising climate impact

E. Schellekens (1)
(1) ARCADIS and Climate KIC, Water and Environment, Amersfoort, Netherlands

There is an urgent need for climate adaptation to avoid huge socio-economic losses (growing from today's $6bn to $60bn p.a. by 2050 in the 136 largest coastal cities alone). However, non-availability of money and gaps in capabilities are huge barriers. A flow of private money, either besides or apart from public money, needs to be unlocked if adaptation is to happen quickly enough. Research (ABL / Ricardo AEA, 2013, Defra, 2013) shows that many cities (around 80% in Europe) have low or very low capacity and therefore cannot specify required resilience measures.

To unlock money flows and to raise capacity of stakeholders, ARCADIS and TPL have developed and successfully tested a new and unique high level business model, the 'Resilience Pathway 2.0', with European cities and have reached out to potential financial partners, with encouraging results.

Existing high level engineering skills and products and services have been brought together in partnership with leading deal-structuring experts and financial organisations to help riverine and coastal cities to access private and public money for climate adaptation.

Resilience is most needed for long-lasting decisions with outcomes that last 10+ years (e.g. water and other infrastructure), which need to be viable in unpredictable and fast changing future climate and energy scenarios, where the status quo is usually the least likely scenario. These decisions are difficult and / or expensive to reverse (in money and energy terms). This is where identifying 'moments of change' and defining 'investment opportunities' seem the way to go, while creating a 'marriage' between technical, financial and social engineering. The main phases of the Resilience Pathway 2.0 that will be explained with real cases during the speech are as follows;

Phase 1: Scoping. The output of this first phase is a clear briefing document clarifying the challenges to be addressed, also to identify potential opportunities ('moments of change') to address them.

Phase 2: Optioneering[1]. The purpose of the Optioneering phase is to identify one or several promising, fundable and feasible business cases around a development (or a combination of developments). These will provide alternative routes to meeting climate and other objectives of projects that will be attractive to private and other investors. This is a unique and crucial phase, where bringing high-level engineering and financial thinking together is essential in unlocking finance for resilience.

Phase 3: Deal Structuring. The purpose of the third phase, the Deal structuring phase, is to transform the selected intervention opportunity – as identified in the Optioneering phase – into a contract with detailed specifications and financial and legal arrangements (e.g. permitting') to deliver the project objectives: resilient projects with an acceptable (typically low) risk-return profile.

Phase 4: Project implementation
The aim of the project implementation phase is to get the projects or developments realised and well managed. This phase is a missing link in many strategies.

[1] 'Optioneering' is a term used by financial intermediaries to identify potential ways of approaching a major deal.

To be able to implement this Resilience Pathway2.0 mid or high level capacity is needed at the relevant stakeholders. The methodology both to assess and to improve the capabilities needed has been tested en proven.

And last but not least, the Resilience Pathway 2.0 generates high climate impact but also creates promising business opportunities to make it economically sustainable as well.

O-3337-01

Addressing flood risks at urban scale, the case of Geraardsbergen (Belgium)

H. Mees (1) ; VDC. Liesbet (2)
(1) University of Antwerp, Sociology, Antwerp, Belgium; (2) City Geraardsbergen, Geraardsbergen, Belgium

With its location next to the Dender river, the city of Geraardsbergen (32.950 inhabitants) is highly susceptible to flooding. The Dender is a typical spate river; whereas its water discharge is normally low, it can rapidly grow in volume during wet periods. Consequently, the surrounding land along the river traditionally functioned as a large floodplain. With the development of the Regional Spatial Plan in 1978, a significant amount of this floodplain was marked as building zone. As a result, a rapid urbanization of the Dender region took place in the following decades. The consequences of this development became clear in the 1990s. Damage was caused by flooding in 1995, 1999, 2003 and 2010. Whereas the damage of the previous floods was restricted to a small number of properties, the flood of 2010 had a wide-scale impact; 398 houses were flooded with a damage cost of about 5 million euro (Assuralia 2011).

After the 2010 flood, the City of Geraardsbergen has committed itself to a new approach, which aligns with the 3P's prescribed by the Flood Directive (2007/60/EC). A coordinator for integrated water management was appointed, who has the task to keep an overview on the actions carried out by the different departments of the City Administration and to be a medium between the several water managers involved in the basin. The City strictly applies the water assessment tool provided by the Flemish government in the deliverance of permits and has invested in measures to enhance preparedness, e.g. the mobile dams and SMS-warning service.

Improvements in flood risk management are however hampered by a number of factors contributing to inertia. Firstly, the existing legislation on spatial planning limits the political and financial feasibility to avoid further development in flood-prone areas. Recently, however, a new legal instrument was developed which should facilitate municipalities to swap land destinations. Geraardsbergen is currently investigating this possibility.

Secondly, the flood safety of the Dender basin is dependent on the infrastructure on the river. By rectifying the river and building up its floodplains, flood damage is only to be prevented by an efficient drainage of the water discharge. This is currently hampered by the outdated sluice infrastructure, which needs to be replaced. Due to complex decision-making procedures, however, the renovation is consistently delayed.

In our presentation, we want to share experiences on integrated flood risk management at urban scale. We will give an overview of recent developments in the flood management of Geraardsbergen, address remaining bottlenecks and present some possible solutions to be discussed with the audience. The evaluation is based on the results of the STAR-FLOOD project, which analysed flood risk management in Geraardsbergen in comparison to two other cities and the national policy-making level. The research was conducted through juridical and policy analysis of relevant legislation, policy documents and interviews with stakeholders. The results of the research were discussed by the interviewed stakeholders on a workshop held in January 2015.

O-3337-02

Flood risk management and intercommunal cooperation: Lessons learnt from of the experiences of Nevers (Middle Loire, France) and Le Havre (Seine Estuary, France) Agglomerations

M. Fournier (1) ; G. Mathilde (2)
(1) Ecole Supérieure des Géomètres et Topographes - CNAM, Le Mans, France; (2) Université Francois-Rabelais Tours, Umr citeres cnrs 7324, TOURS Cedex 3, France

The coming decades are likely to see a higher flood risk in Europe, both on coastal areas and along rivers in the inner lands. In this context, the EU PF7 project STAR-FLOOD "Strenghtening and redesigning European flood risk practices: towards appropriate and resilient flood risk governance arrangements" assumes that urban areas will be more resilient if the existing Flood Risk Strategies (risk prevention, flood defence, flood mitigation, flood preparation, flood recovery) are implemented simultaneously and aligned. From this assumption, the STAR-FLOOD project questions, in various case studies from six European countries (Belgium, England, France, The Netherlands, Poland, Sweden), the institutional embedding of those different strategies and flood risk governance at the local scale.

In France, responsibilities for those different Flood Risk Strategies are mainly divided between municipalities and the State administration. Municipalities have competences in the fields of flood defence, flood prevention and flood preparation. Such responsibilities are quite heavy and difficult to face for many of them. As a consequence, intercommunal cooperation is becoming more and more frequent in this field. In previous researches, we demonstrated that the setting up of intercommunal structures has progressively allowed local authorities to better deal with environmental issues, leading to the production of new action areas and a rethinking of environmental problems (Larrue, Fournier, 2014; Amalric et al., 2011).

Our contribution will illustrate this evolution and highlight the role of intercommunal structures to better address the flood issue and facilitate alignment of the different Flood Risk Strategies locally. Our presentation is based the example of two French agglomerations: Nevers and Le Havre Agglomerations, which are both of them case studies in the STAR-FLOOD project. Both of them are already strongly involved in flood risk management and it is possible to draw lessons from their experience.

Nevers Agglomeration is a medium-size urban intercommunality, regrouping the commune of Nevers (about 36 000 inhabitants in 2011) and 11 other smaller municipalities (about 68 000 inhabitants in total). It is located at the confluence between the Allier, Nièvre and Loire rivers. It faces slow floods from them and urban runoff. Safety on dikes is also a major issue, as most of them have been built several centuries ago.

Le Havre was about 174 155 inhabitants in 2011. Le Havre is a multi-risk city with an industrial background based on the activity of the harbour. Le Havre is also at the fringe of an agricultural and farming area, composed of intensive agricultural open fields. The main consequence for water management is the increase of soil erosion and land degradation. Above all, Le Havre is losing population since the 1980's. The risk of losing population is considered as an immediate danger by the local stakeholders. Floods are seen as less dangerous than a decrease of economical and urban growth.

In this contribution, we will describe how both Agglomerations are progressively taking the lead for flood management and facilitate coordination between Flood Risk Strategies.

In the case of Nevers Agglomeration, intercommunal cooperation has enabled local authorities to take the lead in a comprehensive approach of the flood risk. In 2007, Nevers Agglomeration launched a major study of the flood risk addressing both hydraulic and vulnerability issues on its territory. This study has provided intercommunal authorities with inputs and resources to negotiate with the State administration on the flood issue. Intercommunal cooperation has also been a real asset to promote innovative strategies, align local protection and mitigation measures and better deal with flood preparation and management crisis locally.

In the case of Le Havre, the intercommunal structure provides a range of resources (human resources, technical skills, engineering response capacity and financial powers) to all the municipalities for risk management, based on a strong local expertise in the field of Industrial Risk Management since the 1970's. The intercommunal structure gathers a joint coalition to negociate the scenario proposed by the State, not only to discuss the implementation but also to define the level of occurrence of flood.

Sharing the funding of Flood Risk Management: The impact of Partnership Funding on the River Thames Scheme, London

AP. Micou (1) ; S. Priest, (1) ; M. Alexander (1)
(1) Middlesex University, Flood hazard research centre, London, United Kingdom

Cities across Europe are suffering increasing flood risks due primarily to urbanization and climate change. As a response to this, a variety of rule changes are being developed to tackle this problem at a European, national and regional level. An assessment of the effects of national policy on the delivery of Flood Risk Management at a local level has been carried out as part of the EU project STAR-FLOOD (http://www.starflood.eu/). In England, the Coastal and Flood Erosion Resilience Partnership Funding ('Partnership Funding' Defra 2011) describes a new approach to funding which requires the costs of many flood risk management projects to be shared between national and local funding sources, such as via local governments, the private sector or civil society The introduction of Partnership Funding was as a direct response to the need to unlock additional revenue streams and broaden risk sharing arrangements under scenarios of increasing risk. However, a consequence of this policy change is also a further impact upon the governance arrangement at a project scale; including the arrangement of actors, their responsibilities, their relationships as well as the power they exert within a decision-making process.

Based on interviews conducted with representatives from the local and national government, this work assesses how the Partnership Funding is impacting on the implementation of one particular project: the River Thames Scheme (RTS), in Southeast England. The RTS involves the construction of three alleviation channels to control floods in the Lower Thames segment (situated West from London), as well as other measures, such as the installation of property level measures and the improvement of warning systems, protecting in total 15,000 properties. The project has been approved but it is still subject to identifying locally sourced funding. The study presents an analysis and evaluation of flood risk governance and highlights the limitations/ barriers of involving local government (of which there are seven separate councils involved) in the development of large scale flood risk management schemes. However, the study also highlights the advantages and opportunities which this new funding mechanism brings to the Flood Risk Management agenda, in particular the increased flexibility which has permitted the previously undelivered flood defence strategies in the Lower Thames. The evaluation considers the impact on efficiency and legitimacy of flood risk governance and on the current and long term societal resilience in the area of interest.

Coupling Mobile Sensing, Earth Observations and E-GNSS in a Novel Flood Emergency Service

C. Rossi (1) ; S. Wolfgang (2) ; B. Conrad (3) ; Z. Gunter (4) ; C. Nina (5) ; P. Davide (6) ; S. Emiliano (7) ; F. Dominici (8)
(1) Istituto Superiore Mario Boella, Microsoft Innovation Center, Torino, Italy; (2) GeoVille Information Systems GmbH, Innsbruck, Austria; (3) EOXPLORE UG, Weil am Rhein, Germany; (4) Terranea UG, Bürgstadt, Germany; (5) NDConsult, London, United Kingdom; (6) UNESCO, Venice, Italy; (7) ALPHA Consult, Milan, Italy; (8) Istituto Superiore Mario Boella, Mobile solutions, Torino, Italy

Periodic flood events devastating urban and suburban areas are an important issue for mankind. Flood events, especially in Europe, have, in recent years, caused significant human and economic losses, especially affecting densely populated areas. The consequences of floods are exacerbated by urban sprawl and climate change, especially in areas close to large streams and rivers. This situation can produce flash floods that are very difficult to predict and hard to manage with respect to citizen alerting, operational planning, and flood evolution prediction. According to recent reports, between 1980 and 2008 there were around 2800 floods worldwide, with almost 280k people killed and resulting in approximately 400 billion dollars of economic damages.

These facts point to the need to improve the timeliness and intelligence of flood emergency systems to help public administrations to better manage flood related emergencies. Indeed, advanced monitoring and forecasting services are becoming mandatory to better address and mitigate crisis situations arising before, during and after heavy flood events.

Today, most advanced flood emergency management systems can rely on Earth Observations (EO) to acquire relevant imagery for processing, spatial analysis and dissemination via a range of technologies including geographic information systems. In terms of crisis management and monitoring of natural disasters, earth observation is one of the leading technologies, as it allows the capturing of important measurements of the hazard, both in near real-time as well as after the event. The Copernicus Emergency Management System provides mapping services for all actors involved in the management of natural disasters, with accurate geospatial information derived from EO and complemented with in situ or open data sources, whenever available. EO satellites support the collection of a wide range of measurements for different natural disasters including forest fires and floods, and they can also be used to produce detailed Digital Elevation Models (DEM) of the Earth. Overall, EO can provide current data of a specific area, allowing the creation of flood delineation maps with different time resolutions, depending on the geographical area and the satellites orbit. However, due to both the administrative operations required by the activation procedures and the need for satellites acquiring current images, some days can pass between the occurrence of a flood and its first mapping. This delay is not ideal during rapidly occurring emergency events such as flash floods, posing a significant limit in quickly providing reliable flood extent and forecast map. To overcome the aforementioned limitations we propose FLOODIS: a novel Copernicus downstream service that exploits existing space assets together with mobile sensing and state-of-the-art cloud systems in order to provide a faster, more flexible and scalable flood emergency response system, extending the capabilities of the current EMS. FLOODIS leverages the mobile sensing paradigm to improve the timeliness of accessing flood disaster related information by letting users report the flood status nearby through their mobile devices (smartphones, tablets). A Report includes a short description, a photo, and an indication of the water level in its location. We integrate these geolocated reports with EO-derived map information in order to provide a decision support system for public administrations, targeting enhanced flood information and early emergency alerts for citizens as well as for Civil Protection rescue teams. With mobile sensing, and EFAS (European Flood Awareness System) data when available, we also enhance flood extent map updates and predictions by implementing a novel flood forecast model. Furthermore, to increase the accuracy of user data, we improve mobile positioning by implementing a cloud-based service on top of the EGNOS Data Access Service (EDAS), which provides differential corrections for GPS, thus achieving both position integrity - in the form of the so-called protection levels - as well as increased accuracy.

In short, FLOODIS aims at achieving the following goals: (i) to provide a flood alert and information service for emergency response teams and affected citizens by leveraging on existing space assets; (ii) to increase social awareness and citizen involvement in flood emergencies through the application of mobile sensing; (iii) to increase the accuracy and the timeliness of flood extent and forecast maps by integrating user reports; (iv) ultimately, to reduce the social impact of floods, both in terms of human as well as economic losses.

P-3337-01

Unpacking the notion of "more resilient flood risk governance" - a framework with examples from flood risk governance in Europe

P. Driessen, (1) ; RM. Van (2) ; D. Hegger (3) ; M. Bakker (4) ; ZW. Kundzewicz (5) ; M. Wiering, (6) ; T. Raadgever, (7) ; A. Crabbé (8)

(1) Copernicus Institute of Sutainable Development, Utrecht university, Utrecht, Netherlands; (2) Utrecht Centre for Water, Oceans and Sustainability Law, Utrecht, Netherlands; (3) Utrecht University, Environmental Governance, Copernicus Institute of Sustainable Development, Utrecht, Netherlands; (4) Utrecht University, Utrecht, Netherlands; (5) Polish Academy of Sciences, Poznań, Poland; (6) Radboud University Nijmegen, Nijmegen, Netherlands; (7) Grontmij, De Bilt, Netherlands; (8) University of Antwerpen, Antwerpen, Belgium

European countries, especially urban areas, face increasing flood risks due to urbanisation and the effects of climate change. In literature and in practice, it is argued that a diversification of Flood Risk Management Strategies makes urban agglomerations more resilient to flood risks. The latter requires innovations in existing flood risk governance arrangements, development of new arrangements and the coordination of these arrangements. We argue that the notion that diversified FRM leads to more resilience to flood risks is a plausible proposition, but one that should be critically scrutinised through comparative empirical research. To do this, we first present a brief overview of the state of the art of literature on resilience of social-ecological systems and flood risk governance. Next, based on the literature review, we operationalise the notion of "more resilient flood risk governance" into five criteria: resistance, robustness, ability to absorb and recover, social learning, and ability to adapt. Third, we use examples from an ongoing research project on flood risk governance in Europe (the EU FP7 project STAR-FLOOD) to discuss to what extent a diversification of FRM strategies is actually taking place and how the dynamics found can be scored using our criteria. The findings reconfirm that one-size-fits-all solutions for achieving resilient flood risk governance do not exist. There are different ways in which flood risk governance arrangements can be made appropriate in different social and physical contexts. We nevertheless will derive some common understandings and main lessons from this comparative research about flood risk governance in practice.

P-3337-02

Probabilistic, multi-variate flood damage modelling supports better decisions in flood risk management

H. Kreibich (1) ; K. Schröter, (1)

(1) German Research Centre for Geosciences, Section Hydrology, Potsdam, Germany

Decisions on flood risk management and adaptation are increasingly based on risk analyses. Such analyses are associated with considerable uncertainty, even more if changes in risk due to global change are expected. Although uncertainty analysis and probabilistic approaches have received increased attention recently, they are hardly applied in flood damage assessments. Most of the damage models usually applied in standard practice have in common that complex damaging processes are described by simple, deterministic approaches like stage-damage functions.

This presentation will show approaches for probabilistic, multi-variate flood damage modelling on the micro- and meso-scale, i.e. for individual objects and for aggregated land use units; and will discuss their potential and limitations.

For instance, we compared the predictive capability of six flood damage models (four deterministic and two probabilistic models) in a spatial transfer context using empirical damage data which are available from computer aided telephone interviews that were compiled after the

floods in 2002, 2005 and 2006 in the Elbe and Danube catchments in Germany. Flood damage estimation is carried out on the scale of the individual buildings in terms of relative damage. For validation a split sample approach was followed. The reliability of the probabilistic predictions within validation runs decreases only slightly and achieves a very good coverage of observations within the predictive interval. Since it is crucial to capture and quantify the uncertainty involved in order to enable informed decisions, probabilistic models are advantageous since they quantify prediction uncertainty. This additional information about the reliability of model predictions improves the usefulness of model results and even more so in spatial transfer applications.

P-3337-03

Lessons learnt in preventing health effects of floods events in the European Region

B. Menne (1) ; V. Kendrovski, (2) ; S. Gerardo (2)
(1) WHO, health security and the environment, Bonn, Germany; (2) WHO, Bonn, Germany

The WHO Regional Office for Europe, within its division on health security, is actively in charge of advising its 53 Member States in predparedness and response of flood events, with a particular focus on health. Between 1990 and 2015, more then 1000 people died and several million were affected during flood events. In this presentation we will briefly outline the health effects, based on several systematic literature reviews and describe the practical lessons learnt during and after 2 major flood events: the 2002 Elbe floods and the 2014 Balcan floods. The presentation will highlight required preflood measures, during flood public health relevant initiatives as well as post flood management. Gaps in flood response will be highlighted in particular with a view of more frequent and intense flood events.

P-3337-04

Climate change adaptation : towards a legal change ?

T. Thuillier (1)
(1) Université François Rabelais, UFR Droit, Economie et Sciences Sociales, Tours, France

The world is facing climate change, which impacts on the international community at large. Such a problem requires a global response followed by local actions to deal with this new challenge. This response is characterized by the crossing of mitigation measures, in order to reduce greenhouse gas emissions, and adaptation measures for reducing the risk and damage from current (ex post aspect) and future (ex ante aspect) harmful impacts. Among the different effects compiled by the Intergovernmental Panel on Climate Change (IPCC), we could note for instance rising sea level or more frequent flash floods and marine submersion. Statistical studies have shown that natural disasters will be increasingly important in the next few years. Therefore, it is urgently necessary to draw up adaptation and risk reduction measures and all the instruments of public policy, such as normative instrument / law, have to be mobilized.

These last years, France has established a real adaptation to climate change policy through the development of the National Climate Change Adaptation Plan (PNACC) provided for in the Grenelle Act of 2009. Indeed, this plan is consistent with the European strategy of adaptation to climate change adopted in 2013 by the European Commission, which invites every Member State to adopt comprehensive adaptation strategies.

When analysing on a legal point of view these different plans or strategies adopted at national or European level, one may see there weak normative force. Even if the Grenelle Act of 2009 makes provision in Article 42 for "the preparation of a National Adaptation Plan for a variety of areas of activity by 2011", one may say that it has no legal value. Indeed, the plan has not been adopted by the French Parliament or the Government through a regulatory act. Only a consultation was carried out in 2010 bringing together panels from the Grenelle Environment Forum (elected representatives and local authorities, the state, employers, employee unions and non-profit associations). At the European level, the Strategy of adaptation to climate change has been drawn up through a communication of the European Commission. These two plans can be both described as soft law instruments used to improve stakeholders support (Dreyfus & Patt, 2011).

Even if such an intention can be laudable, it must be remembered that States are responsible for human security. This responsibility belongs to the political and legal domains. From an intern and European legal point of view, there is no explicit obligation stating that a State has to protect its population against the consequences of climate change impacts. Yet, the French disaster law is composed of the protection principle, which enjoins the State and local authorities to protect effectively their population when a natural disaster happens (Cans at al., 2014). At the European level, the European Convention for the Protection of Human Rights and Fundamental Freedoms (ECHR) protects the right to life and imposes positive obligations on Member States to guarantee this fundamental right (Gouritin, 2009).

In order to avoid any action for damages against public authorities and to constrain actors to prepare effectively to climate change consequences, the implementation of a real arsenal of hard law provisions is necessary.

But how can we incorporate this variable "climate change", characterized by its uncertainty and its permanent evolution in progress, into normative instrument which are traditionally looking for a certain degree of legal certainty?

The purpose of this communication is to analyse some French legislative instruments directly or indirectly used in the field of flood risk management (flood risk prevention plan (PPRI), flood risk management plan [PGRI], local urban planning scheme [PLU], territorial consistency plan [SCoT]) from a climate change perspective. The main issue for this topic is to what extent these different instruments can be a vehicle for adaptation to climate change. On conclusion to this study, concrete propositions will be made in order to better integrate data linked to climate change into these legal instruments.

Floods and International River Basin Districts: Europe stands United?

C. Suykens (1)
(1) Institute for Environmental and Energy Law, Public Law, Leuven, Belgium

Problem definition

Through the introduction of the concept of International River Basin Districts (IRBDs), water law in Europe aims to focus on ecological boundaries as opposed to administrative boundaries. Considering the fact that approximately 60 % of EU water is transboundary, and there are transboundary waters in all Member States with the exception of Cyprus and Malta, solid cooperation and conflict prevention mechanisms throughout EU Member States are critical for ensuring quantitative water security. Indeed, actions upstream (in one country) impact the quality and quantity of water downstream (in the part of the river basin located in a neighbouring country) and vice versa. The floods in Central Europe in 2013 demonstrate the transboundary nature of the phenomena, as the floods emerged in one jurisdiction and proliferated in other jurisdictions. However, as will be demonstrated, solid mechanisms for cooperation are lacking in the European legal framework with regard to IRBDs.

Outline of the presentation

This contribution will review how the EU legal framework drives cooperation in IRBDs, in order to tackle the inherently transboundary issue of flooding. This will be done on the basis of the five pillars of transboundary water governance, as set forth by the Global Water Partnership, namely (i) scope, (ii) substantive rules, (iii) procedural rules, (iv) institutional mechanisms and (v) dispute resolution.

Through the framework of these pillars, the existing bottlenecks in the EU framework will be identified. On the basis of this analysis, ways forward will be set forth, amongst others drawing from a legal comparative analysis with transboundary river governance agreements in the United States.

3339 - Effective design and implementation of EU climate policy

ORAL PRESENTATIONS

O-3339-01

Three stylised policy scenarios

P. Drummond (1)
(1) University College London, Institute for Sustainable Resources, London, United Kingdom

This presentation will focus on the results of a paper assessing the ability of three stylised policy scenarios to deliver the low-carbon energy infrastructure required in the EU by 2050. First, key infrastructure requirements as commonly agreed by modelling studies will be outlined across the key sectors of power generation, industry, buildings and transport, with 'infrastructure' encompassing both stationary and mobile components of the energy system (from power generation to vehicles). The three stylised scenarios will then be introduced, each centred on a particular policy paradigm (market-based, technology-based and behaviour-based). Following this, the key benefits and problems associated with each, and their ability to deliver the energy infrastructure outlined for each sector, will be presented.

O-3339-02

Dealing with uncertainty in the European climate policy

O. Lecuyer, (1) ; P. Quirion (2)
(1) University of Bern, Occr, Bern, Switzerland; (2) CNRS, Cired, Nogent sur Marne, France

While the European climate policy has been the target of a large number of economic analyses, both from academics and from the European Commission services, almost all modelling exercises have been deterministic, allowing at best for testing a few scenarios. Stochastic models have been developed but in most cases without numerical application to climate policies. In the few exceptions, the climate policy only consists in CO2 pricing, implemented either through a tax, an ETS or a rate-based policy (e.g. an intensity target).

Yet the history of climate policy is full of surprises, including the swings in EU ETS allowance price and the unexpected surge in PV installation in Germany. We develop a simple stochastic model of the European energy sector featuring the most important uncertainty sources in this context, i.e. economic growth and the cost of key technologies, as well as the interaction between climate policy and renewable energy subsidies.

It turns out that uncertainty changes the (ex ante) optimal policy choice. In particular, most analysts conclude that if CO2 emissions from the power sector are covered by an ETS, there is no or little rationale for renewable energy subsidies. Yet, if uncertainty is high enough, emissions may fall below the ETS cap in some states of the world, leading to a nil allowance price. Hence, energy subsidies at a proper level are justified as a kind of insurance that at least some abatement will happen in these states of the world, which is welcome since the marginal benefit of GHG abatement is positive in these states of the world also.

This point is not only theoretical: a careful examination of existing and past ETS worldwide indicates that for most of them, emissions have been significantly below the cap during at least a part of their history. Moreover there is no guarantee that the Market Stability Reserve proposed by the European Commission will be adopted by the Council and the Parliament, and most analyses conclude that this mechanism is unlikely to stabilise the CO2 price significantly.

Moreover, we show that the design of renewable energy subsidies should take into account uncertainty. In particular, feed-in-tariff, premium and renewable quota all respond in a specific way to a change in renewable energy cost, in fossil fuels price or in electricity demand. A model is designed to compare them when implemented in isolation, which concludes that a renewable quota is by far the worst instrument, mostly because it does not respond to a change in renewable energy cost or in fossil fuels price. Finally, we analyse how this ranking of renewable subsidy instruments changes when they are implemented together with an ETS, as is currently the case in the EU. Compared to the premium, the feed-in-tariff provides a subsidy which decreases with the electricity price, itself positively correlated to the CO2 price. Hence it helps to stabilise the marginal abatement cost, which is welcome for a stock pollutant like GHG gases, whose marginal benefit curve is flat.

The macroeconomic setting is slowly moving towards financing the green / low carbon economy with diversified private and public oriented sources. Nevertheless, if compared to the mass of potential liquidity this

development is still in its infancy.

Sector, firm based and macro evidence is presented and integrated.

We do highlight three key findings among others.

At firm level, the overall evidence could reinforce the likelihood of a different kind of scenario, where MNEs proactively react to the recession shock and LC economy targets and find ways to bring together competitiveness and sustainability; SME react with more difficulty, some of them 'exploiting' the challenge of financial barriers and (environmental) policies by turning costs into enhanced innovative and economic performances, others failing to innovate. If this is on the one hand a typical and also normal evolution of the economic cycle which depends upon firms' creation and destruction, policy makers should be aware of the possible increasing divergences between sectors, firms, regions in the EU; some of those could possess irreversible features and create 'hot spots', namely structurally underperforming regions / sectors.

Second, financial barriers confirm to be a deterrent for the innovative capacity of EU firms in the current situation, if observe the overall quanti-qualitative evidence. This is true for the economy as a whole, and for manufacturing or construction firms taken alone. Being smaller and having low human capital in the firm also hampers environmental innovations (EI). On the 'positive' side, we note that existing regulations and expected increasing demand for green products support EI adoption. Financial barriers are perceived by firms and influenced by technological lock in, uncertainty on investments, non-competitive markets, and lack of subsidies. While policies are driving innovations to some extent, 'external knowledge sourcing' seems not to play any significant role in this context. This highlights a strong critical issue: external finance elements deters EI and external knowledge is not acting as a potential substitute; firms are currently isolated islands towards the green economy, with respect to other firms and financial institutions.

At macro level, the possibility to use environmental policy reforms is assesses by a dynamic CGE modelling approach that analyzes the case of Green Climate Funds, which are eventually generated out of carbon taxes revenues and might support sector eco innovative dynamics following countries specific needs. Green Climate Funds financed through a levy on carbon can benefit all parties, and larger benefits are associated with energy efficiency in developing countries.

The politics of policy choice. Understanding political feasibility of climate policy instruments in the EU

S. Munaretto (1) ; H. Walz (1) ; D. Huitema (1)
(1) Institute for Environmental Studies (IVM), VU University, Amsterdam, Netherlands

The EU has adopted a mix of policy instruments to achieve its carbon emission reduction targets. However, market and governance failures have led to major inefficiencies, and many call for a revision of the existing instrument mix. But what policy options are politically feasible? Political feasibility is still poorly understood, and the literature falls short in definitions, methods and empirical studies. In this paper we advance the current state of knowledge by developing a systematic framework that integrates 3 key dimensions of political feasibility, namely power dynamics among relevant interest groups, their preferences for policy instruments and the institutional setting in which proposals for instruments are discussed. The study provides novel insights into the relationship between these dimensions and the political feasibility of different typologies of instruments in the context of the EU climate policy. The empirical analysis is based on a multi-method approach that includes interviews, focus groups, an on-line survey and a policy simulation with relevant stakeholders.

P-3339-01

Agriculture: the sleeping beauty of European climate policy? How market-based instruments could reduce emissions

G. Grosjean (1) ; W. Acworth (1) ; S. De Cara (2) ; S. Fuss (3) ; N. Koch, (3)
(1) Potsdam Institute for Climate Impact Research, Potsdam, Germany; (2) INRA, Economics, Paris, France; (3) Mercator Research Institute on Global Commons and Climate Change (MCC), Resources and International Trade, Berlin, Germany

In order to achieve its long-term emissions reduction goals, the European Union has to significantly reduce its emissions from agriculture. The recent reform intended to "green" the Common Agricultural Policy is unlikely to sufficiently reduce agricultural emissions, although it might have other environmental benefits. Therefore, more ambitious mitigation policies will be necessary for European agriculture if policymakers do not want to jeopardize the achievement of the overall long-term targets. Several studies also show that there is a significant mitigation potential in European agriculture that can be harnessed cost-effectively by the implementation of market-based instruments.

Nonetheless, major barriers appear to make agriculture relatively challenging to decarbonize. In particular, this paper argues that challenges linked to (i) transaction costs, (ii) political economy and (iii) behavioral specificities of actors in the sector complicate the implementation of ambitious mitigation policies. Market-based instruments may imply significant transaction costs for farmers, for instance, related to monitoring, reporting and verification. The specificities of the sector and the degree of protection it benefits through the Common Agricultural Policy also make it more delicate to price its emissions. The interaction between a potential climate policy and the existing CAP will in fact likely be at the heart of any mitigation policy in the sector. Finally, it is also important to take into consideration behavioral aspects and that financial incentives alone might not always be sufficient.

To that end, this paper offers a new framework the coverage-stringency-transfer nexus to investigate and map options to implement climate policies in the sector, while taking into consideration the main obstacles. The coverage is the percentage of agricultural emissions covered by a climate policy, which is driven by emissions sources and the farm size in term of emissions included. The degree of stringency is the type of policy implemented. It can be a voluntary or mandatory, going from offsets to full inclusion in the EU ETS or an emission tax. The transfer dimension reflects the net impact on farmers of the interaction between a new climate policy and the existing CAP subsidies. In fact, it is argued that it is necessary to explicitly discuss potential interactions. Simultaneously, the existence of those subsidies might also represent an opportunity to facilitate the political acceptance of a climate policy in the sector.

It is concluded that heterogeneous and multi-speed policies are necessary as a first step to tackle agricultural emissions. In fact, for emission sources where transaction costs are lower, mandatory mitigation mechanism should be applied, while a voluntary approach could be implemented for emissions sources with high transaction costs. This would reduce transaction costs overtime and gradually enable increasing mandatory coverage. In addition, the paper offers different options to choose from that combine different levels of transfer to farmers and various degree of protection against leakage. These options provide alternatives to policy makers to choose from taking into consideration their perceived political feasibility.

Climate change challenges for European Union in the New Millennium

SK. Mishra (1)
(1) S. N. D. T. Women's University, Continuing and Adult Education and Extension Work, Mumbai, Maharashtra, India

Strategies on climate change and development cooperation are both evolving rapidly within Europe. Improved scientific understanding about climate change and responses to it show the need for urgent action. This is the chasm between emission reductions pledged by countries and the actual reductions needed to stay within a safe global carbon budget. The aid landscape is also changing fast, after years of seeming stability. With the emergence of new donors (both sovereign states and private foundations) complexity is likely to increase through to 2020. As a result, the traditional multilateral and bilateral donors are likely to lose influence and power. But within the climate change framework there is still unfinished business for traditional donors, particularly in relation to the provision of finance and technology for developing countries. The European Union (EU) has stepped up to its historic responsibilities and climate change has become an increasingly important component of its development cooperation effort. But how will all this play out over the next decade and what can we learn from recent trends? This paper aims to seek answer to this question. Secondary data have been used in the paper and methodology of analysis is "descriptive research method". Within the framework of this objective, it touches upon relevance from development cooperation for climate change.

Climate Change: Adding Fuel to The Fire of Iran's Inter-provincial Water Conflicts?

H. Najafi (1)
(1) University of Tehran, Tehran, Islamic Republic of Iran

Results recently found in the Iranian third national report on climate change reveal there is evidence that several parts of the country are likely to face hotter and drier climate in the future. Nevertheless, climate impact studies still have not been incorporated into decision making processes not only in the most recent national comprehensive water plan but also as a compulsory analysis of any development schemes at the implementation phase. This paper aims at highlighting the imperative role of climate change impact assessments studies on regional conflicts over shared water resources in Iran. Two of the most important river basins at the western part of Iran are illustrated, Lake Urmia and Karkheh. The former is shared between three provinces where the latter is shared between seven riparian ones. Lake Urmia has suffered serious environmental challenges in recent years. Thirteen main rivers flowing into the lake are all experiencing decreasing surface runoffs in recent fifteen years ranging from 26 to 70 percent compared to their long term average of 1969-1999. Likewise, changes in potential renewable water resources have dropped by one forth in Karkheh river basin attributing to several factors including decreasing trend of precipitation as well as increasing infiltration and overuse of water consumption. With the observed trends in decreasing streamflow, policymakers have seriously attempted to attribute the contribution of each of the climate variability and change as well as basin-wide water consumptions. In retrospect, aggressive development projects threating sustainability of resources should have been avoided. Meanwhile, recent impact studies over the two river basins have suggested that climate change is expected to aggravate available water resources challenges under some projections of the IPCC's AR4 emissions scenarios. Surprisingly enough, the competition over exhausting water resources is likely to turn out to be the Tragedy of the commons under compounded impacts of climate change and mismanagement measures leading to conflicts arising when available resources are diminished.

Each of the so called inter-provincial basins are managed by regional (provincial) water companies. The paper suggests that in addition to the past mismanagements which have been found as a driving force of current inter-provincial conflicts, increasing temperature together with a decrease in mean annual rainfall and runoff in the face of climate change inevitably intensifies competition over the limited available resources. When surface water is not available then other sources will be sought after such as groundwater. Consequently, conflicts begin over the use and ownership of water in many settings. From 1974 to 2012, an average of 27 MCM of decrease per year in groundwater volume occurred in twelve aquifers adjacent to the Lake Urmia. In the view of this situation, neglecting to consider climate change projections is likely to expose natural systems to serious damage, even potentially irreversible in many unsustainable ecosystems such as Lake Urmia and Hoor-Al-Azim marshland at the outlet of the Karkheh river basin. Considering the high vulnerability of water resources systems, agriculture, and energy sectors together with fragile socio-economic features, conflicts over these common pool resources, will probably be unavoidable. Ultimately, understanding the effects of current development plans and climatic changes on the status of the mentioned sectors can help taking timely actions to alleviate probable conflicts. Given such a scenario, there have recently been progressive attempts in the Iranian Ministry of Energy (MOE), the main organization responsible for water resources planning and management to launch a specialized working group to address climatic change related predicaments. However, this paper argues that there are some main stumbling blocks still remained untouched on the subject. Implementation of integrated river basin management, developing climate risk frameworks based on integrating Top-down and Bottom-up approaches, thorough uncertainty analysis in addition to hedging between adaptation strategies and mitigation must be performed circumventing such a situation. At the end, the paper suggests that climate change is likely to add salt to the wound of the current challenges from a multi-sectoral point of view and that comprehensive assessment of the impacts of climate change on water bodies followed by conflict resolution provides alerting symptoms for future decision making processes and further action plans.

O-3340-02

Climate-related disasters and armed conflict outbreaks- Evidence for significant co-incidences from the observational record

CF. Schleussner (1) ; J. Donges, (2) ; R. Donner, (3)
(1) Climate Analytics, Berlin, Germany; (2) Potsdam Institute for Climate Impact Research, Earth System Analysis, Potsdam, Germany; (3) Potsdam Institute for Climate Impact Research, Potsdam, Germany

Armed conflicts are the result of a highly context-specific mixture of a variety of socio-economic factors and their multiple causality structure, which renders the attribution of armed conflicts to single factors a practically impossible task. Nonetheless, there is great interest in empirical evidence if and how much changes in potentially determining factors, in particular such related to climate change, alter the risk of conflict outbreaks at the global scale. Whether or not climate change is already contributing to armed conflict outbreaks and conflict risk is very controversial, in particular since the numerous interactions between climate change and socio-economic factors are difficult to capture by standard statistical methods.

Here we address this question regarding the specific case of climate-related extreme economic damage events. We present a comprehensive analysis of the co-occurrence between such events and conflict outbreaks for the period 1980-2011. While there is no significant statistical relationship between extreme damage events and the outbreak of armed conflicts at the global scale, for subsets of particularly conflict-prone countries of up to 10% or more of all conflict outbreaks robustly coincide with climate-related extreme economic damage events.

Our analysis reveals that climate-related extreme damage events, while not directly causing armed conflicts, can indeed significantly contribute to conflict risk in environmentally vulnerable and conflict-prone regions and possibly trigger the timing of conflict outbreaks. Given the still high number of countries at risk and the observed and projected increase in severe climate extremes, this relation represents a serious risk to societies globally.

O-3340-03

Climate change induced migration and conflicts in Nigeria

O. Ovuyovwiroye (1)
(1) University of Benin, Geography and Regional Planning, Benin City, Edo State, Nigeria, Federal Republic of

The challenges associated with climate change have started threatening the common future of the world inhabitants. While the challenge of some localities is associated with too much water, other areas are faced with the problem of too little water available for use. Nigeria is being threatened by these two climate change challenges and each of these scenarios will result to forced migration. While the southern part of Nigeria is experiencing coastal inundation due to sea level rise, the north is being afflicted with the burden of desertification. These combined forces of climate change impact in Nigeria, prompted this study that investigated the impact of climate change on migration and possible conflicts in Nigeria. Climatic data (air temperature, rainfall amount and rainy days) for 60 years (1955 –2014) from 30 synoptic stations in Nigeria were analysed to evaluate the possible signals of climate change. With the aid of Geographic Information System (GIS) techniques, the vulnerable areas due to coastal inundation and desertification were modelled, population affected was determined and the ecological zones that will absorb the potential migrants and the expected conflicts due to such migration were analysed. The GIS technique was also used to construct the isohyets and isotherms so as to analyse the changes in climatic patterns. Time series analysis was employed for the climatic trends. 600 copies of a questionnaire were administered in six states (three in the coastal area and three in the semi-arid region) randomly selected to solicit information on the level of vulnerability, impacts and local adaptation strategies to climate change and possible migration and conflicts. These were analysed using different statistical and cartographic techniques. The results show rising temperature of 1.92OC for the 60 years. Although decreasing rainfall amount and rainy days were observed, a slightly increasing rainfall amount was noticed in the coastal area in the past two decades. A gradual shift in reduced rainfall during the short-dry-season from August to July was noticed. Another observed pattern is the southward shift in the line dividing the double rainfall peaks, thus increasing the tropical continental climate area and decreasing equatorial climatic region. Moreover, while sea level rise of 1 metre will affect 5.4% of Nigeria's landmass and 16% of the population, desertification will affect 38% of the landmass and 33% of the population. Both events may force about 49% of Nigerians from the coastal and semi-arid regions to the guinea savannah and the northern part of the forest ecological zones. This will result to scramble for arable land for farming, grazing and water resources, among others. Conflict between farmers and herdsmen is already on in Nigeria and this may intensify with increasing impact of climate change on natural resources (arable land, grasses and water). The conflicts between farmers and herdsmen have claimed 496 lives in the guinea savannah and the northern part of the forest ecological zones of Nigeria between 2013 and 2014. Adaptation measures are recommended to reduce the impacts of climate change and also to minimize migration and the associated conflicts.

Sovereignty: The Unfocused Era of 'loss and damage' at Climate Summit

A. Naznin (1)
(1) Australian National University, Fenner School of Environment and Society, Canberra, ACT, Australia

One of the major decisions of COP19 is a new "Warsaw International Mechanism will be created to provide help for poorer countries hit by extreme weather events" for loss and damage issue under the Cancun Adaptation Framework-CAF. However beneath this major outcome there is a deep concern and state security associated which is yet, uncounted and overlooked. Slow onset events under loss and damage were identified as "sea level rise, glacial retreat and related impacts, salinization" etc., however, in the case of Bangladesh, "the discussion on sea level rise and salinization centred on approaches rather than needs" which indicates the uncertainty and lack of investigation and measurement in this area. The technical paper of CAF and Warsaw negotiation text both have missed the dilemma of state security while they are concentrated on 'Vulnerable developing countries will be the hardest hit due to their low adaptive capacity'; 'Slow onset events are already affecting developing countries and the resulting loss and damage'. The CAF and Warsaw agreement both have clearly missed the regional security aspect; for example, the economy of Bangladesh is poor than India which should mean that India has better adaptive capacity than Bangladesh. Since Bangladesh and India share borders, and economic opportunity is far better in India, there is potential that India will be severely affected from any emergency or slow onset climatic events in Bangladesh. This paper investigates potential geographical changes following mass migration flow brought by the loss and damages in reference to water stress in regional scale. Using high level policy interviews conducted in Bangladesh and comparing two census data of Bangladesh-India, this paper presents two tipping points which offers an important insight of the state security risk.

Forecasting Armed Civil Conflict and the Conflict Trap along the Shared Socioeconomic Pathways (SSPs)

E. Gilmore (1) ; H. Hegre, (2) ; J. Nordkvelle, (3) ; S. Waldhoff, (4)
(1) University of Maryland, School of Public Policy, College Park, MD, United States of America; (2) Uppsala University, Uppsala, Sweden; (3) Peace Research Institute,Oslo, Oslo, Norway; (4) Joint Global Change Research Institute, PNNL, College Park, United States of America

We investigate how "conflict trap" dynamics, specifically through reduced economic growth as a result of armed conflict, may lead to new and more persistent conflicts over the century. Intrastate conflict has widespread impacts on socioeconomic development. Importantly, conflict depresses economic productivity which in turn lowers the opportunity costs for renewed conflict. Further, economic impacts may be further exacerbated by climate change. To examine how these dynamics may evolves as a function of different expectations of economic growth, we generate our projections along the five Shared Socioeconomic Pathways (SSPs) developed by the climate change community to evaluate the impacts of climate change and policy.

To develop our projections, we first generate a model where armed conflict and economic growth are endogenous. We estimate the reduction in GDP per capita from the incidence of conflict, the duration and the effect of neighboring countries in conflict as well as the post conflict recovery using historical data. Second, we use a simulation approach to project the onset, incidence and termination of armed conflict along the five alternative economic scenarios represented by the SSPs, revising the GDP projections for conflict.

We find that the projections of armed conflict are a strong function of the assumptions about economic growth. Scenarios lower GDP growth over the course of the century experience higher propensities for armed conflict. Adjusting the expected GDP growth for armed conflict worsens the expectations, especially for regions which already experience conflict. As the projected damages from climate change increase in severity, the ability to update the SSPs for these impacts will be become more important for evaluating the full range of damages over time.

3341 - Gender and Climate Change: From Vulnerability to Mainstreaming in Adaptation and Mitigation

ORAL PRESENTATIONS

K-3341-01

Is gender being meaningfully engaged in climate change adaptation, resilience, and vulnerability research?

A. Bunce (1) ; J. Ford (1)
(1) McGill University, Geography, Montreal, Canada

The last decade has experienced a rapid growth in climate change adaptation, resilience and vulnerability (ARV) research. Concurrently, there is growing recognition that climate change impacts and experiences are gendered, and must be accounted for in research. Yet some have argued that engagement with 'gender' has been tokenistic, simply stating that climate change will have differential impacts. It is therefore necessary, given the rapid expansion of literature in this field, to critically analyze the framing of concepts of gender within the literature. In order to determine how meaningfully gender is being addressed in ARV research, we created a conceptual model capturing key components of 'meaningfulness.' Meaningfulness is ascribed as being a function of gender mainstreaming, the experience of gender, and the degree of action being taken. Using a systematic literature review methodology, 123 peer reviewed ARV articles with a gender focus were analyzed.

While 41% of analyzed articles were found to have high levels of meaningfulness, significant variations across regions and disciplines emerged. Research occurring in Sub-Saharan Africa was found to consistently engage with gender in a highly meaningful manner. Although a great deal of gender focused ARV research is occurring in Bangladesh and Australia, overall these nations exhibited low levels of meaningfulness. Health, environmental management, and hazards research emerged as disciplines engaging with gender in the most meaningful manner, although areas needing improvement became apparent. Gender focused work in this field focuses almost exclusively on women, with very little research examining male experiences and no work accounting for those identifying outside the gender binary. While meaningful work is occurring, 31% of the surveyed research was found to have low levels of meaningfulness, demonstrating a need to highlight meaningful methods to reconcile climate change and gender. This conceptual model provides a baseline understanding of how ARV research is integrating concepts of gender into their work which researchers can use to ensure more meaningful engagement with gender in future research.

O-3341-01

Looking beyond gender in humanitarian interventions: a study of a drought-stricken region of Kenya

W. Ndenyele (1)
(1) Technical University of Mombasa, Liberal Studies, Mombasa, Kenya

Slow-onset disasters such as droughts usually occur with such frequency that peoplehave no time to recover before the onset of the next drought. All members of thecommunity suffer as a result of recurrent droughts, but the effects are often more severeon vulnerable groups such as children, elderly people, and some women. This paperuses the experiences of the relief organisation Kujenga Maisha East Africa (KUMEA)to understand the importance of looking beyond gender in humanitarian interventions.Here we focus on the importance of understanding the socio-economic and politicalcontext surrounding the drought and the associated humanitarian interventions,using a feminist lens to assess power relations. This includes looking into the aspectsof vulnerability and resourcefulness in the context of food security, food distribution,nutrition, and livelihood assistance. Such knowledge is vital in improving existingapproaches to gender programming in humanitarian organisations.

O-3341-02

The importance of marital status and intrahousehold relations in climate change adaptation: Evidence from rural Tanzania

K. Van Aelst (1)
(1) Institute of Development Policy and Management, University of Antwerp, Antwerp , Belgium

Even though scholars have widely recognized that women in developing countries are more vulnerable to the impacts of climate change, only scant attention has been drawn to how women and men are practically dealing with these differential vulnerabilities. Climate change scholars have recognized gender as an influential factor in climate change adaptation, but generally simplify and dichotomize between men and women as homogeneous categories. Gender analysts however, have recognized the importance of the intersections between gender and other socio-economic characteristics like class, household structure, life cycle stage and age. Based on both quantitative and qualitative methods, this research examines how women's adaptation strategies are mediated through their marital status in rural Tanzania. This study finds evidence, first, for female divorcees' and widows' disadvantaged position in agricultural water management compared to married women. Second, with regard to livelihood diversification, evidence is found of a diversification at household level, combined with a specialization at individual members' level, as well as of female divorcees' high involvement in off-farm income-earning activities. We develop a typology to illustrate how adaptive capacity relates to marital to status and intrahousehold relations, and suggest that the respondents' current climate change adaptation strategies risk increasing married women's dependence on men and worsening their intra-household bargaining position.

O-3341-03

Women in Changing Climate: Findings from Cyclone Aila Affected Coastal Communities of Bangladesh

MA. Nahian (1) ; GT. Islam, (2) ; SK. Bala, (2)
(1) International Centre for Diarrhoeal Disease Research, Bangladesh (icddr, b). Dhaka, Bangladesh., Center for Population, Urbanization and Climate change (CPUCC), Dhaka, Bangladesh; (2) Bangladesh University of Engineering and Technology (BUET), Institute of water and flood management (iwfm), Dhaka, Bangladesh

Climate change is harsh reality in Bangladesh in terms of gradual changes and disaster events. The country has been identified as most vulnerable to tropical cyclones, third most vulnerable to sea level rise and sixth most vulnerable to floods. However, climate change associated adversity and vulnerability is contextual and gender specific and is magnifying the socially constructed inequalities between men and women where women are always the worst victim due to their gender differentiated roles and lack of access and control over resources. The study, carried out in three major cyclone Aila affected unions- tried to explore the gender dimension of climate change induced vulnerability considering women not only the victim rather an agent of change. Contrary to common vulnerability analysis and studies, this study tried to quantify vulnerability with a developed matrix framework in a scale of 3.0. The gender dimension of climate change induced vulnerability has been assessed in terms of exposure, sensitivity and adaptive capacity; considering both gradual changes or climate events and disaster events or climate extremes. The primary idea of the vulnerability assessment has been derived from the concept of Sustainable Livelihood Framework and Harvard Gender Analytical Framework. Using the basic and simplest equation of "Vulnerability = (Exposure x Sensitivity) / Adaptive Capacity," the matrix framework calculated contextual vulnerability and total vulnerability based on community (women group only) perception. The vulnerability assessment of gender community, i.e. women has been done in Padmapukur and Gabura unions from Shyamnagar upazilla, Satkhira and

Dakhin Bedkashi union, Koyra upazilla of Khulna in 2012 where the impact of cyclone Aila was most pronounced and after effect was lasted for several years. The climate change induced vulnerability of gender community of Padmapukur, Gabura and Dakhin Bedkashi was 2.56, 2.53 and 2.61 respectively. It was found that, respondents from Padmapukur and Gabura unions perceived themselves more vulnerable to climate change associated gradual changes or climate events whereas Dakhin Bedkashi respondents identified themselves more vulnerable to climate change associated extremes or disaster events. Interestingly, the perceptions greatly coincided with direct impact, number of causalities, damage done and post disaster response and development intervention as well as location of study areas. The basic idea behind the vulnerability assessment matrix development was to provide tool that can capture overall gender dimension of vulnerability due to climate change impact. Community, based on their perception ranked impact (exposure), effect (sensitivity) and effectiveness (adaptive capacity) to assess their geo-specific vulnerability; the total vulnerability score for all three study area lied in moderate to extreme category. The linkage among exposure, sensitivity and adaptive capacity showed that Bangladesh had achieved remarkably success in disaster preparedness; but significantly lacked experience to deal with the ongoing changes taking place in climate. The study also explored various complexities experienced by only women due to climate change associated events and extremes and accumulated suggestion for disaster preparedness, improvement in cyclone warning signal and modification for gender friendly design of cyclone shelters. Key suggestions also been assessed in line with climate change coping, adaptation and mitigation directly from the climate vulnerable community. Women is the integral part of the society and sustainable development initiatives and based on the overall findings, the study suggested 'bottom up-top support' institutional framework for gender mainstreaming.

O-3341-04

Household Dynamics in Adoption of Resilient Farming technologies in Semi-arid Kenya

D. Kangogo (1)
(1) International Development Research Centre (IDRC), Agriculture and Food Security, Nairobi, Kenya

Countries in sub-Saharan Africa are particularly vulnerable to climate change, given their limited capacity to adapt. Strengthening agricultural production systems is therefore a fundamental means of improving incomes and food security for the largest group of food insecure households. To build such systems, development practitioners have advocated for climate smart agriculture, a system that sustainably increases productivity and system resilience while reducing vulnerability of smallholder farmers. This requires a substantial investment in agricultural technology innovations. While climate smart agriculture through agricultural technology innovations have been introduced in Kenya, their proliferation has been low, slow and incomplete among the smallholder farmers. To address this, a participatory action research project funded by the Canadian International Food Security Research Fund endeavoured to catalyze large scale adoption of agricultural innovations that enhance social and ecological resilience in Kenya's Semi-arid lands. The study focused on the adoption of three technologies; improved maize seeds, improved green gram seeds and indigenous chicken. Based on household survey data collected from Machakos and Makueni counties of Kenya, this study sought to determine the gender differences in the adoption of multiple resilient farming technologies among the smallholder farmers in semi-arid eastern Kenya using gender of the farm manager as the gender identifier. It also examines the factors that influence household level of resilience measured by the number and types of technology adopted. The results show that male-headed households differ significantly with the de facto female-headed households in terms of age, education, number of trainings and the adoption of a combination of improved maize and indigenous chicken. On the other hand, de facto and de jure female-headed households differ significantly with regard to age, education, crop mix, remittances and the adoption of improved maize, improved green grams and a combination of a combination of improved maize and indigenous chicken. Ordered probit model results on determinants of household resilience indicate that household type, education, land size, crop mix and market opportunity groups are key in influencing household resilience. This emphasizes the need for greater investment in gender and rural agricultural development to ensure equitable and sustainable livelihood improvements.

O-3341-05

Policy Gains and Implementation Opportunities: Progress on the Gender and Climate Change Front

M. Granat (1) ; L. Aguilar, (1)
(1) International Union for Conservation of Nature, Global Gender Office, Washington, DC, United States of America

In Jordan, women's management of small-scale irrigation projects and involvement in water harvesting and soil conservation improves the efficiency of water use. In Nepal, women farmers avoid crop failure in the face of changing weather patterns by growing off-season vegetables and bananas, which are more resilient to flood and drought. In Mozambique, women's groups and traditional healers can offset the impacts of climate change and improve community health with 'climate change health kits'—comprising traditional and local medicinal plants, like citronella to ward off mosquitoes. Women often lead the way in adapting to climate change impacts, but they also play a key role in mitigating climate change by optimizing energy efficiency, using low-footprint energy sources and techniques, playing a vital role in forest management and mechanisms such as REDD+, and influencing a household's and community's consumption patterns.

Until recently, policy at the global and national level did not reflect this reality. For more than twenty years gender was absent from the United Nations Framework Convention on Climate Change (UNFCCC) and in the decision making by its Parties and in subsidiary bodies. This lack of a connection at the global and national level between gender and climate change prompted action on the issue. Now, after years of advocacy, outreach, capacity building, and awareness-raising, governments have agreed multilaterally that advancing gender equality is a key component in achieving climate change goals.

Since 2008, nearly 40 UNFCCC decisions on climate change have integrated specific text on gender concerns. From promoting women's participation and leadership to gender safeguards and assessments, all vital areas of climate change response include key issues for women's and gender equality—all toward ensuring more effective climate change policymaking and planning. At COP20 in Lima, Parties decided on further action for implementation of the mandates through a specific gender decision and the creation of the 2-year Lima Work Programme on Gender.

This session will explore the opportunities for implementation of the Lima work programme and how it will advance gender balance and enhance gender-responsive international climate change policy. A critical step in the implementation process will be presented at this conference: how to effectively anchor the international agreements on gender and climate change within the national contexts.

Over the last five years, International Union for Conservation of Nature's (IUCN) Global Gender Office (GGO) has spearheaded innovative work on this very topic. It has supported, to date, 15 countries through processes to develop national Climate Change and Gender Action Plans (ccGAPs.) This unique effort was born in response to the changing political context and subsequent official requests from governments all over the world to 'turn words into action' and develop concrete action plans on gender and climate concerns. Participants in this session will learn how the ccGAP process facilitates, via a participatory, multi-stakeholder and multi-sectoral approach, gender mainstreaming throughout a country's priority sectors, especially integrating gender concerns and gender-responsive components into national climate change strategies, communications, programmes, and projects. An important principle of the ccGAP methodology is to empower women as valuable partners in climate change response—so women and men alike are not merely victims but resilient agents of change.

O-3341-06

Mainstreaming gender in climate compatible development

V. Le Masson (1)
(1) Overseas Development Institute, Social Development / Climate and Environment, LONDON, United Kingdom

While there has been progress on acknowledging the gender dimension as an integral part of climate policy at international, national and local levels around the world, there is still a long way to go to promote gender equality in climate negotiations.

Yet, recognising and exploring the gender dimension of climate change enables responses to be more grounded in people's daily realities. Through highlighting societal factors that influence people's vulnerability to environmental shocks and stresses, a gender perspective helps uncovering for instance, how men are distressed to the point of suicide in India due to agricultural losses leading to an inability to repay loans[i]; and the way in which women are more likely to die from floods because they have not learned to swim[ii] and cannot leave their houses without being accompanied by a male relative[iii].

A gender analysis in climate research allows understanding of socially constructed gender roles, relations and discrimination that shape the way climate change is perceived by men and women, how it will affect them differently and how they might organise different responses to mitigate greenhouse gas emissions and adapt to longer-term impacts. This recognition has influenced the climate change and development communities to adopt various mainstreaming approaches to integrate gender into projects and programmes.

This presentation will document a few examples where projects have integrated gender considerations to highlight :

- what knowledge a gender approach enabled to uncover ;
- challenges and opportunities to implement gender integrated planning ;
- potential negative impacts of a gender-blind approach ;
- any opportunities to foster greater gender equality and better climate compatible development outcomes.

Lessons from these examples will serve to draw recommendations for future projects and for policies to ensure that attention to gender equality is not sidelined in climate debate and programming. This is particularly crucial for supporting the Lima Work Programme on Gender which aims to promote a greater awareness and consideration of gender issues within climate policy for COP21 and beyond.

Vulnerability and Adaptation to Climate Change and Extremes: Learning from Women's Livelihood in the Coastal Area of Bangladesh:

M. Asaduzzaman (1) ; S. Momtaz (1) ; M. Sherval (1)
(1) The University of Newcastle, School of Environmental and Life Sciences, Ourimbah, NSW, Australia

Bangladesh is frequently cited as one of the most vulnerable countries to climate change because of its disadvantageous geographic location; flat and low-lying topography; high population density; high levels of poverty; and reliance of many livelihoods on climate sensitive sectors. It is assumed that women are particularly the most vulnerable group affected by the climate change impacts. Rural women are educationally, politically and socially disadvantaged, resulting in economic dependency and vulnerabilities. Growing empirical evidence supports the broad view that women's overall lower access to assets, service and voice makes women more vulnerable than men to the effects of climate change and natural disasters (World Bank, 2011). This study particularly examines the context of vulnerabilities of women in the disaster prone areas of Bangladesh, the impact of climate change and extremes on women's livelihood, and the adaption approaches that are followed by the women in response to climate change and extremes. The study was conducted following questionnaire survey method, focus group discussion, and key informants' interview in Shyamnagar upazila (sub unit of district) of Satkhira district. Shyamnagar is the most southern upazila of this district, and the Sundarban laid down in the major part of this upazila. The upazila occupies about 2000 km² area including 1630 km² forest area. The upazila consists of 13 unions (lower administrative unit), and the average population of each union is 24137 (Banglapedia, 2011). This area is situated in the most southwest part of the country, and widely exposed to the Bay of Bengal. Therefore, sea level rise, salinity, water logging, water surge, cyclone, increased temperature, all these climate change impacts are prominent there. This area is also known as the most affected area by the severe catastrophic event 'cyclone Aila'. During the cyclone Aila in 2009, this upazila was severely affected, almost 100 percent of the households were affected and their livelihoods were lost (UNDP, 2009). The sustainable livelihood framework (SRF) has been applied to analyse the data of the present study. Sustainable Livelihoods Approach serves as an instrument for the investigation of poor people's livelihoods, whilst visualising the main factors of influence. The result shows that several climate change events are simultaneously affecting this area increasingly for decades. These include salinity, frequent occurrence of disasters (e.g. cyclone), extreme weather condition (e.g. high temperature), water logging, flood, and sea level rise. Almost 100% of the respondents in personal interviews and focus group discussions identified these observations about climate change effects over time. The major effects they identified are income loss (95%), damage of livestock and poultry (80%), infrastructural damage (95%), and health damage (65%). Women are particularly affected as they have less income opportunity, facing health problems, food deficiency, malnutrition, and problems of housing and drinking water. Moreover, women are particularly vulnerable to climate change impacts since they have less mobility and less education due to social and religious norms. The absence of empowerment restricts women to take decision in any kind of natural and other events. Their options for adapting with climate change effects are also very limited which put them in a very insecure position. The common adaptation practices they follow are reduce food intake (90%), selling of assets (80%), receiving credit (98%), using saving (100%), seek alternative livelihood (95%), and use of social cards (92%). The adaptation options are mostly temporary and do not ensure the sustainable livelihood of women. They are struggling to adapt with the climate change scenario yet they have to do a responsible job for their entire family. In practice, concerted efforts from all concerned are required both at the national and the grass-roots levels to uphold the present distressed condition of women in the study area and to get adapted them in the ongoing challenges of climate change.

P-3341-02

What does it take to see transformative adaptation? Evidence from sub-Saharan Africa

Q. Bernier (1) ; P. Kristjanson (2) ; R. Meinzen-Dick, (1)
(1) IFPRI, Washington, DC, United States of America; (2) ICRAF, Washington, DC, United States of America

Throughout sub-Saharan Africa, men and women are already adapting to climate change. However, these changes are often small, incremental changes that

modify existing practices, such as modifying planting dates or changing crop varieties (Twyman et al. 2014). Encouragingly, we do see some farmers taking up what we term transformative practices – practices that contribute to diversified livelihoods, aim to buffer the household against climate changes, increase assets, and have a longer-term time horizon, but also require investments of time, labor, or cash. Transformative adaptations are both technological and behavioral and may require an adjustment in how resource are allocated, changing priorities and norms (Kate, Travis, and Wilbanks 2012). These transformative adaptations face significant barriers, including uncertainty in climate changes, perceived costs, and institutional and behavioral barriers (Ibid). Using a data set collected under the Climate Change, Agriculture, and Food Security Research Program of the CGIAR, this paper analyzes the social, behavioral, and institutional determinants of transformative adaptations in Kenya, Uganda, and Senegal, including perceptions and experiences of climatic risk and shocks, and identifies differences between men and women in terms of developing and promoting adaptive capacity. This information will be important for practitioners and policymakers seeking to identify barriers and manage tradeoffs in adaptation options at individual and household levels, as well as ensuring that both men and women have the capacities and resources to adapt to long-run climate change.

P-3341-03

Rebuilding Home-Women's Informal Participation in the Post-disaster Reconstruction and Recovery in Rural Areas, Sichuan, China

C. Hou, (1) ; H. Wu (1)

(1) Sichuan Agricultural University, School of architecture and urban-rural planning, Dujiangyan, Sichuan, China

The vulnerable population, such as females, seniors and youths, is possible to be hit the hardest by the climate changes. Their capacity to response and their resilience towards climate changes are much lower than other groups. In the rural area of Sichuan, China, due to the fact that the adult men are usually migrant workers in the urban area, their wives, elderly parents and children are the main residents in the local rural area. Hence, facing the extreme events (such as flood, landslide, earthquake, etc.) caused by the climate changes, the adult women play an important role in dealing with those crisis as well as the reconstruction and recovery issues after those crisis's. According to the Chinese governance, however, the different levels of government conduct almost all of these reconstruction and recovery projects. This kind of government-led model extremely limits local inhabitants' participation in the process of reconstruction and recovery and most local dwellers could be only informally involved into this process. Therefore, under this unique situation, this paper examines how the local adult female residents' informal participation contributes to post-disaster reconstruction and recovery. Conducting the in-depth interviews and participated observations with the local adult woman in the reconstruction area, this paper explores the role of the adult female residents' engagements into place-making process of rebuilding their own housing in the reconstruction stage. This paper argues that the local women's limited informal participation in the reconstruction promotes their emotional attachment towards the newly built environment. This kind of emotional attachment could ease their relocation and resettlement process and eventually identify the newly built environment as their new home.

P-3341-04

Poverty-Environment mainstreaming role of improved stoves in the fight against climate change

T. Jean Michel (1)

(1) Environement Recherche developpement (ERD), Yaoundé , Cameroon

As part of improving the living conditions of local populations and promoting environmental education, Environmental Research Development (ERD) organization with assistance from GEF Small Grants Program realized in 18 months, a pilot project to fight against the effects of climate change. The project was oriented towards school children in their campuses as part of their initiation to trees planting, and to the population of the five target areas the promotion of sustainable development at local level: Bockle, Sangere-Paul, Ndiam-Baba, Sangere-LANAVET and Sanguéré-Gal. Among other activities, training in the construction and use of improved wood burning stove has been a flagship activity.

A total of 278 people were trained theorically and practically on improved stove manufacturing technics: Ndiam-Baba: 40 people (35 women 5 men), Sangere-LANAVET: 69 people (60 women + 9 men), Sanguere-Gal: 60 people (57 women 3 men), Bockle: 55 people (54 women +1 men) Sangere-Paul: 54 people (49 women 5 men). The great campaign of improved wood burning stove construction yielded 263 cookstoves: Ndiam-Baba (36) Sangere-LANAVET (65) Sanguere-Gal (55) Bockle (54) and Sangere-Paul (53).

Indeed, it should be noted that 85% of the trainees are now use improved stoves. The use of these stoves have a positive impact on climate change in these localities as the people who use them save half of the wood needed for cooking their meals. The people who use these stoves save half of wood needs for cooking. In addition, this reduction on wood consumption thus shows an interesting decrease of pressure on the trees in these targeted communities. Similarly, say the past, the use of improved wood burning stove has positive health impacts and some family expenses related to the acquisition of wood and cleaning cooking pots

Project sustainability is ensured by the ownership communities through the Environmental Watchdog Committee (EWC) and organized the improved wood burning stove construction sessions to improve their different locations and at the same time to train and sensitize those who are slow to adopt this good practice management of natural resources such as trees.

Women's Adaptive Innovations in Land and Water Management under Climate Change in Himalaya: An Illustration of Gender Mainstreaming in Climate Change Adaptation in Marginalized Mountain Environment

B. Joshi (1)

(1) Government Post Graduate College, Geography, Rudrapur, Uttarakhand, India

In Himalaya, constraints of terrain and climate impose severe limitations on carrying capacity of natural system, productivity of resources as well as on efficiency of infrastructure and services. As a result, subsistence agriculture constitutes main source of rural livelihood for more than 75% population even though the availability of arable is severely limited and agricultural productivity is low. Owing to the constraints of subsistence agricultural economy and lack of other viable means of rural livelihood, a large proportion of youth male population out-migrates the region in search of livelihood and employment. Consequently, women have become 'primary resource developers' and 'backbone of mountain agricultural economy', and this resulted in feminization of agriculture and process of natural resource development in Himalaya. During recent years, a variety of changes have emerged in traditional agro-ecosystem in response to population-growth, rapid urbanization and economic globalization resulting into depletion of natural resource base and land use intensifications. Moreover, climate change has stressed traditional agricultural-system through rise in temperature, changes in precipitation pattern and increased frequency of extreme weather events increasing vulnerability of large population, particularly the poor and marginalized to food and livelihood insecurity. Women, experience these changes differently and disproportionately and respond them in varying manner because of socially constructed gender relations. However, feminization of agriculture facilitated women to develop critical knowledge in agricultural resources management and adaptation of their livelihood and food system to climate change.

The paper aims at analyzing innovative adaptation mechanism evolved by indigenous women to climate

change and assessing its impact on their role in decision-making and empowerment in agricultural resources and assets and reducing gender gap with case illustration of Kumaon Himalaya in India. The study employed comprehensive socio-economic investigation techniques and empirical field observations methods, and surveyed 2197 households in 62 villages using exclusively framed schedules. Results indicated mountain women make use of their critical traditional knowledge and experience in land and water management and adapting their agricultural and food systems to climate change. It was observed that: (i) women in 27% villages replenished water sources employing traditional water conservation practices; (ii)19% women changed cropping pattern, (iii) women in 25% villages developed indigenous rainwater harvesting system; (iv) 21% women adjusted crop-rotation; and (v) 27% women relocated agriculture; (vi) 55% women taking all decisions related with management of land and water resources; and (vii) 37% women are now solely responsible for of utilization, processing and marketing of their agricultural products. It was observed that women's innovative adaptation measures are not only building climate change resilience in subsistence mountain farming system, but reducing gender gap by providing women with the opportunity to come closer to mainstream of sustainable development through increased participation and decision-making in natural resource management, improved opportunities of rural livelihood and opening access to market for their farm products. However, the knowledge and skills of mountain women; and their contributions towards climate change adaptation through sustainable resources development, household well-being, community sustainability need to acknowledged and valued, and be integrated into climate change adaptation policy planning all across the Himalayan mountains.

P-3341-06

Unraveling the gendered effects of climate change related policies in climate smart agriculture in Uganda and Tanzania

AF. Mariola (1)
(1) International Institute of Tropical Agriculture (IITA), Kampala, Uganda

Achieving long-term gender-sensitive climate change adaptation at local and national level requires supportive climate policy framework, especially in vulnerable and food insecure countries such as Tanzania and Uganda. Intertwined with the multiple climate change related regulatory frameworks and action is the recognition and examination of the differentiated needs, constraints and preferences that men, women and different socio-economic and cultural groups have in a changing climate. However, the way gender is understood and articulated in climate change discourses will influence and shape how gender issues are dealt with in policies and interventions. Discourses on gender and climate change will determine which lenses are being used to study social vulnerability and adaptability to climate change and consequently shape what are the perceived problems and potential solution. Differing gender considerations in policy and programs might subsequently ameliorate, perpetuate or exacerbate pre-existing social inequalities. Taking a poststructuralist reflexive approach to narrative policy analysis, this study unfolds different understandings of gender issues in climate change adaptation policies in agriculture and analyzing the effects of gender discourses in climate-smart development projects in rural communities of Uganda and Tanzania. The study answers the research question: What does gender-sensitivity policy implementation mean to the variegated actors and groups in the context of climate-smart agriculture in Uganda and Tanzania and what are the effects of the prevailing meanings?

Methods are directed to identify emergent gender discourses in climate change adaptation policies in agriculture and to analyze the effects that these discourses have in the implementation of climate adaptation policies in rural communities of Uganda and Tanzania. Throughout the research, narratives are taken as a central object of study by focusing on the diverse ways in which people make sense of their lived experiences. This research examines both narratives originated in non-structured interviews and in more informal accounts such as ordinary conversational exchanges. For the latter, narrative research is combined with observational data and ethnographic methods of data collection. The research is embedded within the Policy Action for Climate Change Adaptation (PACCA) project led by the International Institute of Tropical Institute and funded by the CGIAR Research Program on Climate Change, Agriculture and Food Security (CCAFS).

The role of gender in improving adaptation to climate change among small-scale fishers

L. Musinguzi (1) ; N. Vianny (1) ; R. Ogutu-Ohwayo (2)

(1) National Fisheries Resources Research Institute (NaFIRRI, Fish habitat Management, Jinja, Uganda; (2) National Fisheries Resources Research Institute (NaFIRRI), Jinja, Uganda

Climate change, which has intensified during the last three decades of the 20th century, disproportionately affects marginalized groups in developing countries, especially women. To guide integration of gender roles in interventions to improve adaptation to impacts of climate change, gender roles were examined in a community of fishers on Lake Wamala in Uganda, which has been increasingly affected by climate change and is a designated environmental change hotspot. Data was obtained from a lake wide frame survey and qualitative surveys using daily activity analysis and benefit analysis flow chart tools, modified from Socio-Economic and Gender Analysis Approach (FAO, 2001). There was lower participation of women than men in fishing activities, with 99% of fishers and 92.9% of fish processors and traders being men. The men had more fishing experience, started fishing at a younger age and exited at a later age, targeted more species, used more fishing gears and bought more fish for processing and trading. Although there was observed diversification to non-fishery livelihoods, such as crop and livestock production to increase food security and income among others, income from these activities was not controlled or shared equally between men and women. Compared to men, women worked longer hours, engaging in more simultaneous activities both in and out of the home and reported less time resting. Most of the income generated and controlled by women was used directly to meet household needs, suggesting that adaptations adopted by women have greater potential to build resilience to the influence of climate change. Drawing from these observations, the implications of the differences between men and women for adaptation, what men and women can do best to enhance adaptation and how some adaptation practices and interventions can be implemented to benefit both men and women are presented.

P-3341-08

Engendering climate smart agricultural Innovations in East Africa

M. Nyasimi (1) ; R. Aura (2) ; M. Phiri (3) ; C. Mungai (1)
(1) Climate Change Agriculture and Food Security, East Africa, Nairobi, Kenya; (2) Egerton University, Faculty of law, Nakuru, Kenya; (3) COMESA, Climate change, Lusaka, Zambia

Gender differences amongst African societies persist particularly in social, cultural and economic roles and responsibilities, access to information and agricultural inputs. Long-term climate change in Africa will have an impact on food security and incomes, and this is likely to have ramifications for gender relations. Studies have shown that gender in conjunction with other factors such as age, wealth, religion and class determines the ways in which the changing climate is experienced. This is because extreme weather events and climate related disasters in juxtaposition with socio-economic, institutional, cultural and political factors tend to intensify existing gender inequalities and responses to climate change in the agriculture sector. In East Africa women make up a large number of the poor in communities that are highly dependent on agriculture for their livelihood and are disproportionately vulnerable to and affected by climate change. Their limited access to resources and decision-making processes further exacerbates their vulnerability to climate change.

Against this backdrop, a study was conducted in east Africa with the aim of contributing new knowledge on how men and women adjust their livelihoods and coping strategies at individual, household and village level

in response to climate risks. Using integrative gender scoping tools and methods, a qualitative and quantitative research study was carried out. The objectives of the study were a) to characterize gendered climate risks over the past five decades, b) to identify the coping strategies that men and women farmers utilize in order to ensure a measure of food security in response to climate variability, c) to understand the resources available to men and women and the decision making processes utilized, and d) to identify the institutions that support women and men's decision making with regard to climate, agriculture and food security.

Two hundred farmers, half of whom are women were interviewed and 5 focus group discussions held. Research findings show that women perform 65% of off-farm work during drought because only a few of them have property rights (25%) and hence cannot sell/or trade any household goods to fill in the food shortage gaps. In terms of perceived changes in weather-related shocks over the last fifty years, more women than men report having observed floods, erratic rainfall and droughts.

The study shows that both genders are adapting to changing climate, and their changes are seasonal rather than transformational. 64% of men and 57% of women reported to have made changes in their agricultural, livestock or livelihood practices in response to the climate risks. Most women reported that they ration foods and just a few of them reported constructing water pans to store runoff and for use during drier periods, selling baskets and ropes, altering crop varieties and planting dates. However, this is done after seeking consent from the heads of households. Without the power to decide on family resources, women's ability to manage risks for example, by diversifying crops and livestock, altering planting dates is limited. In terms of accessing weather forecast and agro-advisory services 80% of men and 40% of women report having access to information on seasonal weather forecasts, inputs supplies and extension services. Women's inability to access new knowledge makes them more vulnerable to climate impacts than men and therefore, gender transformative activities including empowerment might be one approach to adaptation.

In the interest of gender equity and climate change adaption efficiency and resilience, these barriers must be alleviated or removed. Policy, strategies and investment responses at local and national levels must meet the specific needs of women and men. The methodology developed through this study as well as the research findings will be provided to policy and decision makers to develop Local Adaptation Plans of Actions (LAPAs) and National Adaptation Plans (NAPs) at County and National levels, respectively in a pragmatic manner.

P-3341-09

Adaptation and resilience of farming households to climate change using their indigenous knowledge: A study of the Niger Delta region

CD. Onyige (1)
(1) University of Port Harcourt, Sociology, Port Harcourt, Rivers State, Nigeria, Federal Republic of

The Niger Delta region in Nigeria is home to over 30 million people (Nigerian Population Commission, 2009), the bulk of which live in the rural areas. This region is characterized by immense poverty, and has suffered from a long history of socio-economic neglect and environmental degradation such as oil pollution caused by the multi-national companies operating in the host communities in the Niger Delta region. Thus the paradox of the Niger Delta is that of a region rich in natural resource but with significant percentage of its population living below the poverty line. Apart from the problem of environmental degradation caused by oil exploration in the region, the people have to contend also with the recurring problem of climate variability and climate change. The impact of climate change increases livelihood vulnerability of the rural farming households in this region. Climate change makes access to food sources unpredictable and increases poverty and disease. Women bear the brunt of all these and the resulting impacts of climate change affects them disapropriately. Women in this region constitute the most vulnerable group since they have limited access to land, which is a crucial determinant of their access profile. Climate change according to the United Nations Development Programme (UNDP, 2005) magnifies already existing inequalities, especially gender inequality. When confronted with the problems associated with climate change, the people of the region respond to this situation by developing coping strategies, on an individual and on a collective level. How the rural people respond to and adapt to the changes in their livelihood base using their indigenous knowledge are some of the questions my research intends to answer. Specifically the study examines how women who are the most vulnerable and marginalized group adapt and respond to climate change using their indigenous knowledge, in spite of the obvious gender inequality pervasive in the society.

P-3341-10

How Climate induced male migration critically affects women left behind?

MG. Rabbani () ; ZM. Khan (1)
(1) Bangladesh Centre for Advanced Studies (BCAS), Dhaka, Bangladesh

Cyclones, floods and droughts have been on the rise in both intensity and frequency over the last decades, leaving many citizens with few or no options to earn an adequate living to sustain themselves and their families in Bangladesh. As a direct result, migration has been increasing, with large numbers of people, mostly men, travelling to other regions in search of a better life and livelihood. The female population in areas of Bangladesh not only have to cope with the increasing effects of climatic change and natural disasters, but also the increasing patterns of migration of male family members. Most often women stay behind, usually with children and other members of the family, and take care of the household and try to make ends meet. This paper is based on a study conducted in 40 villages of 10 out of 64 districts in Bangladesh with support from UN Women and Norad.

The main objective of the study was to explore how climate induced migration of male members affect the women left behind. The study interviewed 40 local women (four women from each location-two local government representatives and two community representatives) from the climate vulnerable districts. The women were selected from the households from which at least one male member migrated mainly because of climate-induced hazards e.g. cyclone, increased tidal surge, salinity intrusion in surface water and soil, drought, water logging caused by tidal surge/excessive rainfall etc. Secondly, 20 Focus Group Discussions were conducted to meet the objective of the study. The secondary literature were collected and reviewed to determine tools and complement and verify the study findings.

The study denotes that migration of a male member from a family has various social, economic and mental impacts on the females and children of a family. The left behind family members feel insecure and face many problems including decision-making. The workloads on the female members also increase accordingly. The adaptive capacities of individuals greatly depend on income, education, health and access to natural resources. Scarcity of food can worsen a woman's nutritional status due to her marginalization within a household. Also, as women are mainly responsible for gathering water for the household, paucity of water might increase the burden on women. The impact on women is likely to be worse in developing countries like Bangladesh because of the deeper economic and social gender divide. It was found that women, mostly living alone with children and other female members and in-laws face adversity on a day-to-day basis. In most cases it was found that the male members were unable or in cases simply unwilling to send money back to their households, leaving the women to find any means of survival during these periods of migration. In some situations, women were being looked down upon by the other members of their society due to the absence of their male family members, some reported harassment and assault. In some regions, women living without their male family member have become targets and thieves are targeting their households. Still existing social norms and practices across the country lead to the discrimination of women and their rights, which are only exacerbated during times of male migration. On top of unpaid care work such as fetching water, cooking and taking care of children, women who can find employment often have unstable income with some women reporting an increase in physical, emotional and mental stresses. Moreover, women eat less and work more, either because

they cannot earn enough, or because of social norms and practices that dictate women must to feed their families first. With a lack of social support mechanisms and adequate policy environment to protect women's rights, the process of male migration due to climate change may in fact contribute to a worsening situation for gender inequality.

Yet, in spite of the negative impacts of migration in most cases, if not all, migration can help families to stay afloat, and in even improve overall financial conditions. Thus, in a disaster stricken country like Bangladesh, migration can be a negative and positive approach to dealing with climate change.

P-3341-11

Gender Justice and Sustainability in REDD/REDD+ Climate Change Projects in Indonesia and the Philippines

E. Wornell (1) ; A. Tickamyer (2) ; S. Kusujiarti, (3)
(1) The Pennsylvania State University, Rural Sociology and Demography, Pennsylvania, United States of America; (2) Penn State University, Agricultural Economics, Sociology, and Education, University Park, PA, United States of America; (3) Warren Wilson College, Sociology, North Carolina, United States of America

Women's empowerment and indigenous rights have been widely embraced as foundational principles of international social and economic development for several decades in recognition of the transformational potential for achieving intertwined goals of human rights and sustainable development. Programs to address climate change are no exception, and the growing urgency of finding means to mitigate its potential ravages requires finding effective ways to fully incorporate women and other marginalized groups into these efforts. A growing body of literature documents the importance of gender justice to this effort, yet achieving it often remains illusive. A prime example is found in REDD/REDD+ projects, the United Nations collaborative program for Reducing Emissions from Deforestation and forest Degradation. As a key initiative for preserving forest resources and associated ecosystem services, it is equally important for goals of sustainability, gender equity, and empowerment of marginalized groups.

According to the UN, REDD "is an effort to create a financial value for the carbon stored in forests, offering incentives for developing countries to reduce emissions from forested lands and invest in low-carbon paths to sustainable development. 'REDD+' goes beyond deforestation and forest degradation, and includes the role of conservation, sustainable management of forests and enhancement of forest carbon stocks" (http://www.un-redd.org/aboutredd/tabid/102614/ default.aspx, accessed May 25, 2014). These projects have been initiated in a variety of countries and regions with significant forest resources and forest resource loss, and different levels of economic development. The goal of REDD/REDD+ is to encourage developing countries to conserve and maintain their forest resources by making standing forests more profitable than felled forests. In addition to creating an economic incentive for the conservation of these forests, REDD/REDD+ was envisioned as catalyst for addressing social issues facing these countries, including poverty and inequality. In theory, REDD/REDD+ projects must both comply with gender mainstreaming practices and benefit indigenous communities. A major criticism of REDD/REDD+ is that, as a neoliberal policy that prioritizes economic growth, the principles of gender mainstreaming and community inclusion remain lofty policy ideals rather than on-the-ground reality. Due to limited capacity for monitoring and evaluating projects, as well as on-going corruption and mismanagement, the fear of critics of REDD/REDD+ is that disempowered groups, including women and indigenous communities, will be further marginalized through the implementation of REDD/REDD+, despite stated policies to the contrary.

This paper is based on the comparative research on challenges and progress toward effective gender equity and mainstreaming as well as involvement of indigenous communities in REDD sites in Indonesia and the Philippines. We focus on these two countries because of the similarities in the level of economic development and the characteristics of the ongoing REDD/REDD+ projects. We interviewed scholars, community members, policy analysts, and activists who have been involved in designing and implementing various REDD/REDD+ programs in these two countries. The results highlight the development and obstacles of these two resource rich countries in implementing REDD/REDD+ programs.

3342 - Developing Capacity through Low Carbon Initiatives, Climate Adaptation and Increased Resilience to Climate Impacts in the Asia-Pacific Region

Adaptation pathways for inland aquaculture in northern Thailand

L. Lebel (1)
(1) Chiang Mai University, Unit for Social and Environmental Research, Chiang Mai, Thailand

Background: Aquaculture systems are likely to be impacted by changes in climate; not all impacts are expected to be negative, and in some situations aquaculture may become an alternative to land-based agriculture. Most aquaculture systems, however, are vulnerable to water scarcity, and their interactive effects on water quality, as well as extreme floods, storm surges and sea-level rise. Inland aquaculture in Northern Thailand is important for livelihoods and a significant economic activity that is sensitive to climate variability and water management. Aquaculture production for commercial purposes, as well as direct consumption, takes place in earthen ponds, and in cages in rivers and reservoirs. Adaptation pathways with inland aquaculture in Northern Thailand are needed which allow reasonable actions to be taken now, for instance, to strengthen management of climate-related risks, while also leaving flexibility in households, and the sector as a whole, for adjustment of strategies in the future.

Purpose: The purpose of this paper is to report on the findings of the AQUADAPT research and assessment process to: (1) identify the key sensitivities of inland aquaculture systems to climate-related risks; (2) assess farm household efforts to manage those risks under current climate variability; and (3) apply this understanding to identify strategies for building the resilience of aquaculture social-ecological systems, and in developing plausible, context-specific, adaptation pathways for aquaculture in northern Thailand.

Methods: Combination of new research, review of past work, expert synthesis and participatory, local assessments, was used. Four qualitative climate change scenarios - wetter, drier, more seasonal, and less seasonal - were constructed, based on a set of downscaled climate projections for 2040-2059, to capture key uncertainties in future climate in northern Thailand. Scenarios were also developed for water and fish demand to complement the four for climate yielding a total of 16 combinations or final scenarios. These 16 scenarios were used to explore the robustness of proposed adaptation strategies at various levels, and construct alternative adaptation pathways.

Results: Adaptation measures or strategies are being pursued, or have been proposed, at the farm (household), watershed (community) and sector (national) levels. At farm level the focus is on rearing practices and business management. At the watershed level important actions relate to sharing of warning information, and the formation of fish farmer's groups to influence water resources management. At the sector level insurance, voluntary standards, and investments in research and development

are frequently recommended. Examples of measures emphasizing the management of specific climate risks, as well as broader strategies for building resilience of the aquaculture social-ecological system, were found at each level. The emerging adaptation pathways for aquaculture include some contradictory elements reflecting uncertainties about effectiveness, differences in development ideologies and expectations for the sector. Either way, it is clear that adaptation strategies need to be integrated with other efforts to improve sustainability, for instance, encouraging best practices in disease management or waste water treatment and disposal

Significance: Identifying adaptation pathways for aquaculture in northern Thailand, in particular, and in the tropics or subtropics, more broadly, seems plausible as key species can be reared in a broad range of systems in the warm waters and the sector has significant capacity for self-organization and innovation. At the same time there are widespread concerns about the availability of suitable quality water for production in the future, underlining the importance of sustainability of water use and aquaculture practices to adaptation. Public sector support for building climate resilience of aquaculture industry in northern Thailand should: (1) strengthen the knowledge foundations for adaptation; (2) support improvements in the management of climate-related risks under current climate variability; (3) improve water and watershed management; and, (4) acknowledge in policy and planning that adaptation will need to be context specific.

P-3342-02

Coastal hazards and climate change in the Loyalty Islands (south-west Pacific), multi-disciplinary approach

M. Le Duff (1) ; M. Allenbach (2) ; P. Dumas, (1) ; O. Cohen, (1) ; T. Hoibian, (3)

(1) University of new caledonia, Cnep, Noumea, New Caledonia; (2) University of new caledonia, Noumea, New Caledonia; (3) University of new caledonia, Ppme, Noumea, New Caledonia

This communication presents the objectives and preliminary results of a study concerning the evolution of atoll's coastlines with climate changes and their social involvement. This work is carried out in the southwest Pacific and is funded by the Government of New Caledonia, the European Union (Program INTEGRE) and the French Ministry of overseas territories (Program MOM). In order to provide some guidelines for the Ouvea (Loyalty Islands, New Caledonia) stakeholders involved in costal risks management, a dual methodological approach is undertaken to understand the complexity of the relationships between social and physical processes associated to coastal evolution of atolls with climate changes.

Concerning the physical process, the geomorphologic vulnerabilities of islands are first studied in relatively large spatial and temporal scales, using diachronic analysis of aerial and satellite imagery of Ouvea Island over the last 60 years. At the same time, a monitoring of current coastal sediment dynamics is realized on the sandy shores of the Island. A continuing survey over two years is planned on the main beaches of the Island, which strongly suffer from erosion processes. The goal of this survey is to obtain in-situ data concerning the impacts of rapidly evolving phenomena such as cyclones, tsunamis, tornadoes, or blows. As an example, we will present a quantified analysis of the impact on the northern part of Ouvea Island after the passage of the cyclone PAM (Category 5, 894 mbar, mid-March 2015) that hits the Vanuatu archipelago, which is close to Loyalty Islands. The topometry measurements are performed through two approaches: (1) various specific and expensive methods (DGPS, Photo restitution from aerial surveys by UAV) and (2) less sophisticated methods (up to the frame, site level) less precise but less expensive and without requiring specific technical skills, allowing the involvement of local people. In a Pacific area bereft of resources, the purpose is to provide methods to survey environmental phenomena affecting small isolated islands. The aim of this approach is to initiate a participatory monitoring program of the coastline. Training observers throughout this project, coupled with the creation of wide information campaigns / awareness raising and maintaining a strong link with the local administrative structures and tribal representatives are essential for long term success in Oceania. This approach is particularly vital for theses islands, where the land planning and management is almost exclusively under tribal authorities. Therefore, it is essential to involve people in the implementation of these strategies. The recognition of tribal law in New Caledonia prohibits any top-down or bottom-up process in management.

Another aspect of the method is the creation of a quantitative and qualitative database of extreme weather events, such cyclones and tornadoes, based on the processing of historical archives. The aim is to better understand the current evolutions of the region from the perspective of the dynamics of the hazard (time, power, path ...) by providing additional analysis of documents and data, now available to the Caledonian Weather Service. Moreover, we will address vulnerability issues (human, environmental, economic) and capacity and / or resilience strategy developed in societies studied for over 150 years. Mastering these issues related to the past and present social and climate change will help to better understand the abilities of atoll's stakeholders in terms of adaptation and limitations to which these strategies will be faced by the end of the century. A database of more than 285 extreme weather events that impacted the New Caledonia since 1830 has been established and is being analyzed. The case study of the tsunami of March 28th 1875 to determine the exact impact of this major event on the Loyalty coastlines will be presented.

In conclusion, we point out the importance of developing integrated, holistic approach of coastal dynamics, both from physical and socio-cultural perspectives, and so to provide the best adaptation strategy regarding the evolution of atoll's coastlines with climate changes.

P-3342-03

Balancing Consumers' Satisfaction with Water Quality and Reducing Energy Use: A Case Study in Japan

V. Shinde (1) ; N. Hirayama (2) ; S. Itoh (3)

(1) Asian Institute of Technology, Water Engineering and Management, Bangkok, Thailand; (2) National Institute of Environmental Studies, Centre for materials cycle and waste management, Tsukuba, Japan; (3) Kyoto University, Environmental engineering department, Kyoto, Japan

Japan ranks fifth among the countries that produce the highest Greenhouse gases (GHG) emissions (UNFCC, 2012). In light of the Fukushima nuclear disaster in 2011, the country has revised its GHG reduction targets to 3.5% in 2020 from 2005 levels. The Fukushima disaster led to the shutdown of atomic power plants leading to rise in the use of fossil fuels, which makes this reduced target also look daunting. Although the water supply sector in Japan accounts for less than 1% of the total emissions, it is important for this sector to reduce energy use since it is only through collective contributions of all sectors that the GHG reduction vision can be achieved.

Japan has a well-developed water supply system and over the years, there has been a systematic progress in the nature and type of water treatment. However, in recent years the consumers' expectations of water quality in Japan have been on the rise. A survey conducted in Osaka by the authors in 2007 revealed an increase in the number of complaints with regard to water quality in the last decade, suggesting a decline in Consumers' Satisfaction with Water Quality (CSWQ). CSWQ can be improved with advanced water treatment like membrane filtration, ion exchange etc., but the energy requirement for such processes is high. Hence, it is difficult for the utilities to meet the GHG emission reduction targets as well as maintain/improve CSWQ. There is a need to arrive at an optimal balance between the two, which is the objective of this study.

The rationale behind the study's methodology is to link the energy source with CSWQ so that when scenarios of reduction in energy use are considered, corresponding changes in the CSWQ can be observed. Data required for this study was procured from Kobe City Waterworks Authority (KCWA), Japan. The study involved three distinct stages:

(a) Evaluating CSWQ: An internet based questionnaire survey was used to assess the CSWQ, in which respondents were asked to evaluate eight items. Factor Analysis was then performed to quantify CSWQ, as presented in

Equation 1.

CSWQ = (0.347 x Trust in water utility) + (0.313 x Good quality water) + (0.197 x R&D in water utility) + (0.162 x Equity of distribution) + (0.144 x Price of water).....(1)

(b) Developing a mathematical model to link CSWQ with energy use: To do so, a two-step procedure was followed. In the first step, ten services areas were chosen from where maximum questionnaire responses were received, and the CSWQ for each area was calculated using Equation 1. After this, for the same service areas the magnitudes of selected Performance Indicators (PIs, developed in our earlier study) of water supply delivery— Financial Sustainability (FS), Green Water Supply (GWS) and Economic Value of Water (EV)—were evaluated. The relationship between the CSWQ and the PIs was then established using multiple linear regression, (Eqn 2).

CSWQ = 2.083 – 0.004 FS – 0.001 GWS + 0.001 EV.....(2)

In the second step, relationships of the PIs with energy use were established. To do so, a series of models were developed. For KCWA, the main source of GHG emissions is due to energy use (power). Hence, the first model, Model 1, was developed to relate the GHG emissions with Power Consumption (PC), using appropriate emission factors. A second model was developed to relate PC and water production volume (eqn 3), and water production volume was linked to the three PIs through models 3, 4 and 5 (Eq 4, 5, and 6).

Model 2: Water production volume = 1.75 + 2.68 x 10^ –3 Power Consumption.....(3)

Model 3: Financial Sustainability = 2.07 – 5.34 x 10^–3 Water production volume.....(4)

Model 4: Green Water Supply = 4.78 – 0.14 Water production volume.....(5)

Model 5: Economic Value of Water = 17.06 + 0.41 Water production Volume.....(6)

(c) Balancing CSWQ and reduction in energy use: In order to do so, five scenarios of reduction in GHG emissions from the base condition (2010 level) were considered: 5, 10, 15, 20 and 25%. On one hand, the reduction in PC required for each scenario was calculated. On the other, the CSWQ for each scenario was calculated using Equation 2, with the corresponding values of the three PIs (using models 1 and 2 consecutively). The optimal GHG reduction is found by equating the two trends. The study revealed that the KCWA can target only 3.5% GHG reduction for balancing CSWQ and reducing energy use.

Fugitive methane emissions from Indian coal mining and handling activities: Estimates and opportunities for its utilization to generate clean energy

AK. Singh (1) ; J. Kumar (1) ; A. Garg (2)
(1) CSIR-Central Institute of Mining and Fuel Research, Methane Emission and Degasification Division, Dhanbad, Jharkhand, India; (2) Indian Institute of Management Ahmedabad, Public systems group, Ahmedabad, India

Fugitive methane emissions from coal mining and handling activities are a prominent source of greenhouse gas (GHG) emissions from India. The total GHG emissions from India's energy sector were around 1.4 million Gg-CO2 equivalent in 2007, out of which ~34,000 Gg-CO2 equivalent belonged to fugitive emissions from fuel extraction [1]. The fugitive emission estimates calculated mainly by using India-specific emission factors developed by CIMFR suggest that Methane emitted annually to the atmosphere from Indian coal mining and handling systems has gone from 0.555 Tg for the year 1991 to 0.772 Tg in the year 2010.

The Integrated Energy Policy of the Government of India projects that coal consumption in India shall grow at the rate of 6 per cent per year. The current production is projected to touch 630 million ton in 2015 and around a billion ton by 2020. Taking the future projections of coal production and consumption, we also project the future trend of methane emissions from coal mining and handling activities of India.

The methane generated from coal mining and also as coalbed methane has the potential to serve as a clean fuel. There are several opportunities for this methane to play its part in the meeting of sustainable energy demands in India. This is more so relevant with the Indian government showing signs of encouraging clean coal technologies (CCTs). There are several mechanisms for this in the Indian context. This includes:

1. Coal Mine Methane (CMM): We completed a project recently funded by the US EPA for feasibility of CMM in three major coalfields in eastern India, viz. Jharia, Bokaro and Raniganj coalfields. At first glance, it appears that Kalidaspur and Ghusick collieries in the Raniganj Coalfield, Murulidih, Amlabad, Sudamdih and Parbatpur mines in the Jharia Coalfield and Jarangdih and Sawang collieries in the East Bokaro Coalfield are promising sites for CMM recovery. The measurements and potential for CMM in these mines shall be talked about in details in this paper.

2. Ventilation Air Methane (VAM): CIMFR, along with Southern Illinois University at Carbondale completed a joint project on VAM utilization in India. We have made some assumptions with the (½) × 10 model, wherein it is assumed that fifty per cent of the CMM resource within a mine boundary can be exploited in 10 progressive years. Our calculations suggest that installation of just two rotary kilns, revenue of US$ 2.8 million can be generated in two years. The details about VAM opportunities shall be covered in detail.

3. Abandoned Mine Methane (AMM): There has not been any effort to identify the abandoned mines and quantify the AMM resource in India. It is thus, imperative to undertake a study to evaluate the AMM resource potential of the country before any utilization potential is planned.

4. Coalbed methane (CBM): An estimated potential of 400 BCM of coalbed methane exists in three states alone (Jharkhand, West Bengal and Chhatisgarh). Efforts are already underway for exploitation of CBM in India [2].

Such mechanisms, if employed shall serve as a useful tool to reduce atmospheric emissions as well as to find new avenues of cleaner energy in India. This is even more important because India is naturally devoid of high natural gas reserves and such methods can help in bridging the gap for this.

It is hoped that this paper shall present a useful analysis for policy makers and the industry to get an overview of the scientific status for clean energy in India through methane emissions from coal mines.

Linking Climate Change and Disaster Risk Reduction in Asia and the Pacific

LA. Stevenson (1)
(1) Asia-Pacific Network for Global Change Research (APN), APN Secretariat, Kobe, Japan

Climate change adaptation is receiving increased attention, particularly among developing countries. As part of the work under the Cancun Adaptation Framework, UNFCCC Parties established the Warsaw International Mechansim for Loss & Damage associated with Climate Change Impacts at COP19 to consider approaches to address loss & damage associated with extreme and slow-onset events, particularly for countries most vulnerable to climate change.

Under its Climate Adaptation Framework, the Asia-Pacific Network for Global Change Research is addressing adaptation through approaches that support research, data collection, enhanced coordination, enhanced regional cooperation and strengthened institutional arrangements. Specifically, the APN launched a special focussed activity that aims to link climate change adaptation (CCA) with disaster risk reduction (DRR) and loss & damage (L&D). A series of projects are underway that are addressing such

issues as the risk of slow onset events, economic and non-economic L&D, CCI on most vulnerable, approaches to slow onset and extreme weather events, integrating slow onset and extreme events into climate resilient development processes, and how climate change is affecting patterns of mitigation, displacement and human mobility.

The presentation will provide an overview of how APN's Climate Adaptation Framework is responding to climate change challenges by providing a flavour of the fifteen projects currently underway in the Asia-Pacific region, all of which are undertaking regional-based research activities and/or capacity building with specific foci on linking CCI, DRR and L&D. The session will then go into more detail by providing information and important outputs to date from projects being conducted in South and Southeast Asia.

Topics covered will include:

(1) major low-lying coastal cities Southeast Asia that are severley impacted by severe flood events and how sectors, such as agriculture, in these areas will face increased challenges as impacts of extreme events are projected to worsen;

(2) solutions-oriented research outputs of how best to integrate climate change adaptation with disaster risk, particularly for slow onset events; and

(3) work being undertaken to address the important need to integrate adaptation to climate change into development planning in policy- and decision-making communities.

4401 - Sustainable development goals and the new climate regime : synergies for change ?

ORAL PRESENTATIONS

K-4401-01

Sustainable Development Goals, Science and Politics

C. Körösi, (1)
(1) Office of the President of the Republic of Hungary, State secretary, director for environmental sustainability, Budapest, Hungary

Based on his experience as co-chair of the Open Working Group (OWG) on Sustainable development goals (SDG), Mr C. Kórösi will be talking about the lessons for the SDGs learnt from the OWG negotiation process, especially focusing on science policy interface. This will include his personal reflection of the OWG process in terms of science and policy, and personal views on how science could contribute to the post-2015 development agenda and their implementation process.

O-4401-01

Governance through Goals: Options and Opportunities for the SDGs

N. Kanie, (1)
(1) Keio University, Professor, graduate school of media and governance, Tokyo, Japan

Two unanticipated consequences in formulation of the Sustainable Development Goals (SDGs) from the outcome of Rio+20 are of great importance for governance for sustainability: that the SDGs would link sustainable development to the continuation and strengthening of the Millennium Development Goals (MDGs) in a single agenda at the centre of a post-2015 development framework; and that their negotiation would entrench "goal-setting" as a dominant strategy in global governance. This single, goal-oriented agenda, is not simply a continuation of unfinished elements of the MDGs, but it aspires to build from their central mission of poverty eradication and social inclusion a universal, integrated agenda that also responds to growing social and planetary complexity in the twenty-first century. While the very notion of negotiating a set of SDGs is remarkable in its own right, they mark an equally significant shift in global governance strategy: from norm promotion and rule-making to goal-setting.

O-4401-02

Allocation of resources to LDCs for adaptation - A climate vulnerability index

P. Guillaumont (1)
(1) FERDI – Université d'Auvergne, Clermont Ferrand, France

An amount of resources, still to be determined, will be made available for the adaptation to climate change in developing countries, in particular to Least Developed Countries. Since these countries are not responsible for the global impact of climate change, it seems equitable to allocate concessional resources mainly according to their vulnerability to climate change (beside their low level of income per capita). For doing that we suggest to use a physical index of vulnerability to climate change reflecting the likely shocks resulting from climate change and faced by each country independently of its will, what means an index not taking into account any policy factor of resilience. Such an index has been built on an exploratory basis at Ferdi with this aim in view. Complementarity and consistency with the allocation of development assistance models using income per capita, structural economic vulnerability and governance indicators as criteria will be also underlined.

O-4401-03

A poverty – adaptation –mitigation window within the Green Climate Fund

S. Mathy (1) ; O. Blanchard (1)
(1) PACTE, EDDEN, Grenoble, France

The stakes for poverty alleviation and the measures required to avoid unbridled climate change are inextricably linked: on the one hand, climate change may slow down and even reverse trends in poverty reduction; on the other hand trajectories consistent with a 2°C – temperature increase require poverty alleviation strategies to integrate the constraint of a low carbon development.

Existing climate funds have failed to target poverty alleviation as a high priority of adaptation strategies

It is important to distinguish adaptation actions that are purely aimed at adapting to impacts of climate change and would not otherwise be initiated, from broader adaptation needs and development-related actions to reduce climate change vulnerability, i.e. actions to reduce the adaptation gap. The existing project-based approach of the Adaptation Fund is more adequate to deal with the first category of adaptation actions, while it is likely that poorer regions and communities need to look more specifically to the adaptation deficit. How can a single financial instrument address both in an optimal manner? So far, all attempts to create aggregated vulnerability indicators relying on a single number have revealed unsatisfactory to determine where available funding should be used in priority, as these indicators lead to contradictory results and often depend on value judgments on which there is no consensus.

Allocation of climate funds focusing on development-related actions to reduce climate change vulnerability requires defining a set of indicators that reflect factors of poverty.

Existing climate funds and the CDM have failed to target poverty alleviation as a necessary component of a low carbon development

Existing climate funds and the CDM have mainly allocated resources to high-emitting developing countries, or to countries with a rapid growth in their GHG emissions. To maximize the environmental efficiency, climate funds and financial mechanisms favour projects or actions that maximize the quantity of emission reductions. Such indicators are not adequate with poor countries with no mitigation potential relative to a historic reference because the development deficit leads to low initial emission levels.

To favour low carbon development opportunities in poor countries, other indicators than emission reductions relative to a historic reference scenario should be used.

Description of the poverty-adaptation-mitigation window (PAM-W)

To go beyond these obstacles in targeting poverty alleviation as an adaptation strategy and as a component of a low carbon development, we propose to complement the existing adaptation and mitigation windows of the Green Climate Fund (GCF) with a window focusing on synergies between poverty alleviation, adaptation and mitigation.

Actions funded within this window would either be sectoral programs or policies in order to be consistent with the GCF objective of paradigm shift.

A series of macro indicators that reflect factors of poverty would be used for the selection of beneficiaries.

The aid mechanism would be based on national or regional benchmarks reflecting the per capita cost for providing a specific basic need (the cost of providing access to sanitation to one additional person, the cost of providing access to electricity to an additional person).

Part of the funds allocated would be transferred based on the actual implementation of the action. The allocation metric would be the actual net changes in the number of people gaining access to the concerned basic need. Countries would be free to develop their own strategy, and they would have to finance it initially, from domestic resources, existing development aid channels or international private capital.

Given the huge financing needs to address GCF objectives, available financial resources for the PAM-W would be limited and financial modalities within the PAM-W would have to limit windfall profits and to vary according to income category of countries. Additional conditions could reinforce the appropriation of actions by countries: co-financing for low income countries, private financing for upper -middle income countries.

O-4401-04

SDGs as way to better mobilize funding for climate and for development ?

D. Vencatachellum (1)
(1) African Development Bank, Director, resource mobilization and external finance department, Tunis, Tunisia

Based both on his expertise in development economics and on his experience as an economist within a multilateral development bank (the African Development Bank), Dr D. Vencatachellum will present his analysis of how SDGs could help better mobilizing funding for climate and for development, and will also react to the proposals made by other presenters in the panel.

O-4401-05

Raising the ambition: How the global climate agreement can affect the achievement of the Sustainable Development Goals

N. Walmsley (1)
(1) HR Wallingford, Water Group, Wallingford, United Kingdom

N. Walmsley (HR Wallingford), A. Ansuategi (Metroeconomica), P. Greño (Metroeconomica), V. Houlden (HR Wallingford), A. Markandya (Metroeconomica), L. Onofri (Metroeconomica), G. Tsarouchi (HR Wallingford) and H. Picot (CDKN)

In the coming year, key decisions will be made on several intergovernmental agendas, including climate change, disaster risk reduction, sustainable development and financing for development. The impacts of climate change resulting from varying levels of ambition over long-term horizons (e.g. to 2050 and beyond) are a current focus of much global research effort. However, little is known about the projected impacts of the climate deal on development in the shorter term.

This paper seeks to fill a knowledge gap by investigating the development impacts projected for varying levels of climate ambition in the 2015 climate deal, as such a deal will necessarily impact on national decision making around resource allocation and development priorities. The Sustainable Development Goals (SDGs) are used as a lens through which to measure and frame the question: How can the global climate agreement affect development in the period to 2030? Using a combination desk study, integrated assessment modelling (IAM) and information from the literature, a subset of the 17 proposed SDGs are assessed according to the projected socio-economic outcomes of binary climate ambition scenarios.

Two scenarios are considered: a high ambition agreement (to limit global warming on pre-industrial levels to 2C by 2100) and a low ambition agreement (to limit global warming to 3-5C by 2100). These scenarios are represented by coupled representative concentration pathways (RCPs) and shared socioeconomic pathways (SSPs). This allows both climate impacts and socioeconomic impacts of a high or low ambition 2015 climate deal to be considered, and the impact on national and regional development pathways to be investigated.

A broader regional scale assessment of Africa, Asia and Latin America and the Caribbean (LAC) is complemented by deep dives into 3 case study countries/regions: Uganda, Pakistan and the Caribbean. This selection of climate vulnerable countries gives a representative coverage of a least developed country (LDC), a middle income country (MIC) and a small island developing state (SIDS), all of which are groups of countries with particular development challenges.

Our findings show:

- The decisions taken at UNFCCC COP21 in Paris will have a significant impact on global development by 2030, even before the resulting climate impacts are felt.
- A high ambition agreement that aims to minimise global warming to 2C by 2100 on pre-industrial temperatures is essential to have the best chance of achieving the SDGs by 2030.
- A high ambition agreement is most crucial to achieving the draft SDGs on poverty (SDG 1), inequality (SDG 10), climate change (SDG 13) and global partnerships for sustainable development (SDG 17).
- Country case studies were used to compare and contrast with the above high-level regional findings.

Negotiators and the development community should find the outputs of this research useful to advocate for a stronger climate deal, and to ensure that the SDGs deliver climate smart development in the poorest and most climate vulnerable countries.

4401-POSTER PRESENTATIONS

P-4401-01

Bottom-up formation and stabilization of a grand climate coalition under rationality

J. Heitzig (1) ; U. Kornek (2) ; K. Lessmann (2)
(1) Potsdam Institute for Climate Impact Research, Transdisciplinary Concepts and Methods, Potsdam, Germany; (2) Potsdam Institute for Climate Impact Research, Sustainable solutions, Potsdam, Germany

After the Copenhagen failure, recent negotiations have seen a shift from the Kyoto top-down agreement to the Durban bottom-up process of national pledges. Economic models had predicted that an effective (near-)global climate protection "coalition" was likely "unstable". The public good character of emissions reductions, related positive externalities, and the resulting incentives for noncompliance and freeriding pose difficulties for achieving sufficient levels of international cooperation (Barrett 2005). Although the bottom-up approach may enhance negotiations, Lima has again shown the slow progress and the large uncertainties involved about the process. Formal analyses of the strategic interactions can shed light on the negotiators' behaviour, but often neglect the time-evolving ("dynamic") process inherent in negotiations.

In this talk, we present a dynamic and stochastic game-theoretic model of the process of coalition formation and its implications for the prospects and uncertainties of bottom-up climate coalition formation under the usual assumption of rationality. It includes these novel features: (i) Unlike most existing models, we assume that over time, the major GHG emitting nations can form, grow, merge, shrink, split, or terminate any number of coalitions. (ii) In proportion to bargaining power, players can repeatedly propose changes in the coalition structure, and a proposal will be accepted if it is profitable for the responsible players and not dominated by another move of the same or fewer players. (iii) When assessing profitability, players may farsightedly anticipate later moves to some degree. (iv) Uncertainty about who will propose next leads to unresolvable uncertainty about the sequence of moves (the realised "pathway"), leading to a consistent scenario of different branching pathways and their probabilities. (v) Uncertainty about players' expectations may lead to the existence of several competing consistent scenarios, each of which represents a different (but common to all players) set of expectations.

Our main findings support the hopes that a bottom-up process may work eventually: (1) for each parameter

setting, there is typically more than one consistent scenario, but in all of them a stable global coalition will be formed eventually. (2) No formed coalition will be terminated later although the model explicitly allows unilateral termination of agreements. (3) Typically, there are several handsful of competing pathways towards global cooperation, and they differ in the number of steps needed and in their allocation of mitigation costs. (4) This path uncertainty is largest in the early steps of the process, where typically (a) the most vulnerable nations and those with the lowest mitigation potential ("reluctant" players) exhibit chicken-game-like behaviour by trying to delay their own cooperation, in order to free-ride for as long as possible and to achieve a better bargaining position for their later entrance into an existing coalition, while (b) at the same time, the least vulnerable players and those with the highest mitigation potential ("eager" players) compete for forming a coalition with many reluctant players and few other eager players, in order to get a higher share of the vulnerable nations' gains from avoided climate change via surplus sharing and to get a higher compensation from them for their mitigation services. (5) Surprisingly, in our model these strategic interactions do however not lead to a stalemate without progress since such a stalemate would not form a consistent set of expectations. (6) Among the alternative consistent scenarios, there is typically one "focal" (Schelling 1960), relatively symmetric scenario in which no player has a considerable advantage, and several asymmetric scenarios in each of which one player is at an advantage.

To complete our strategic analysis, we finally present a strategy by which a coalition of rational players may incentivise compliance with their agreement to make the latter self-enforcing (Heitzig, Lessmann, Zou, PNAS 2011). It consists of a simple temporary redistribution of liabilities in proportion to preceding shortfalls and can be seen as a renegotiation-proof improvement of the Kyoto protocol's noncompliance rules.

P-4401-02

Building an Index of Physical Vulnerability to Climate Change

C. Simonet (1) ; P. Guillaumont (2)
(1) Overseas Development Institute, Climate and Environment Program, London, France; (2) FERDI – Université d'Auvergne, Clermont Ferrand, France

The Index of Physical or Geophysical Vulnerability to Climate Change differs from the other indices on vulnerability to Climate Change by only considering this part of the vulnerability which does not depend on the present policy. To this aim it relies only on physical components likely to reflect an impact of climate change, without any use of socioeconomic data. It is an index of physical vulnerability to climate change, changing only progressively and slowly.

It also differs from other vulnerability indices, both from the more general environmental vulnerability indices, which most often include resilience and policy components, and from the Economic Vulnerability Index (EVI) used by the Committee for Development Policy for the identification of the Least Developed Countries (LDCs). The EVI is related only to physical vulnerability, as the present Physical Vulnerability to Climate Change Index (PVCCI), but it differs from the latter: it covers all kinds of exogenous shocks likely to affect economic growth, it refers to a shorter term horizon and it tries to capture a handicap to economic growth rather than a risk of a change in geophysical conditions. Thanks to these features, the PVCCI, set up at the country level, could be used as a criterion for the geographical allocation of the international resources available for the adaptation to climate change. It is a relevant criterion precisely because it doesn't depend on the present policy, and it only gives an indication of the need for adaptation. By the same way the EVI has been proposed as a possible criterion for the allocation of development assistance. The design of the PVCCI draws both from the environmental literature and from the attempt to measure physical economic vulnerability, as it is done by the Economic Vulnerability Index. As an environmental index, the index relies on components reflecting the physical consequences of climate change that can directly affect population welfare and activity, rather than an assessment of their long term economic consequences, which would be more debatable. The index relies on eight components, considered as relevant, reliable, and available for the whole set of developing countries and easily understandable, so that the index can be used in a transparent manner. These eight components respectively capture the risks related to progressive or cumulative shocks due to climate change and the risks related to the intensification of recurrent shocks due to it.

The PVCCI has been calculated on the basis of data covering the last 60 years for 146 developing countries and territories. Results evidence a high heterogeneity among countries in the level of physical vulnerability to climate change and an important vulnerability of SIDs, even within a same regional area. The high physical vulnerability to climate change of the LDCs and SIDs is highlighted by the index. These groups of countries are already found to have aa high economic vulnerability, as evidenced by EVI.

4402a - Low carbon pathways for staying below 2°C: Global requirements

ORAL PRESENTATIONS

K-4402a-01

Dr. Leon Clarke

L. Clarke (1)

(1) Pacific Northwest National Laboratory (PNNL), Joint Global Change Research Institute, College Park, MD, United States of America

The long-term goal of limiting temperature change to less than 2C will require deep reductions in greenhouse gas emissions. Net global CO2 emissions, in particular, must eventually be brought to or below zero to meet this or other long-term temperature goals. Emissions reductions of this magnitude will require large-scale transformations in human societies, from the way that we produce and consume energy to how we use the land surface. The more ambitious the stabilization goal, the more rapid this transformation must occur. A natural question in this context is what are meaningful "transformation pathways" towards stabilization; that is, how do we get from here to there? This presentation provides an overview and introduction for understanding transformation pathways to 2C and other temperature goals.

This presentation will draw heavily from a large body of scenario research summarized in Chapter 6 of the Working Group 3 contribution to AR5. Over 1000 new scenarios published since AR4 were collected from integrated modeling research groups, many from large-scale model intercomparison studies and synthesized in WG3. These scenarios provide important information on key questions such as the near-term emissions reductions consistent with meeting long-term goals, the costs of mitigation, and the energy and land system transformations. In comparison to AR4, new scenarios have considered more ambitious concentration goals, a wider range of assumptions about technology, and more possibilities for delays in global mitigation and fragmented international action than those published previously..

Drawing on this literature, the presentation will address several questions that provide context for understanding transformation pathways. First, to what degree is it possible to link between near-term emissions reductions with the goal of limiting temperature change to less than 2C or other goals? While it is possible to draw some conclusions about this link, the relationship is heavily influenced by assumptions of what sorts of future emissions reductions are feasible. Further, the relationship between any temperature goal and emissions and concentrations is highly uncertain, meaning that this relationship can only be expressed in terms of the probability that temperature will remain below 2C. Second, what are

some key characteristics of transformation pathways that maintain likely temperature change below 2C? Key characteristics include emissions reductions rates, sectoral emissions reductions, economic costs, and technology transformations. Finally, to what degree can scenarios inform questions about which pathways are more feasible than others? Mitigation actions inherently involve a wide range of tradeoffs that link to social and policy objectives such as economic growth, energy and food security, the distribution of economic costs, local air pollution, other environmental factors associated with different technology solutions, and economic competitiveness. All of these linkages will influence the likelihood and feasibility of different pathways. Assessments of feasibility must, in addition, account for the rapidity at which social and technological systems would need to change to maintain temperature change below 2C.

Staying below 2°C: What are the implications of and requirements for short-term policies?

G. Luderer (1) ; E. Kriegler (1)
(1) Potsdam Institute for Climate Impact Research, Potsdam, Germany

Current efforts to mitigate climate change are not in line with mitigation pathways stabilizing global warming below 2°C in a cost-optimal way. Over the past decade, global greenhouse gas emissions have further increased and are projected to reach 50-59 GtCO2e by 2020. This is much higher than emission levels in mitigation scenarios that assumed comprehensive mitigation action towards 2°C stabilization from 2010. The discrepancy between the long-term ambition of climate policy, i.e. limiting global warming to 2°C, and the weakness of mitigation action raises important questions: What are the consequences of delaying comprehensive climate policies? What are requirements for policies and measures to keep the 2°C target within reach?

This presentation will draw on a number of recent studies based on integrated energy-economy-climate models (AMPERE, LIMITS and RoSE multi-model intercomparison projects, as well as single-model studies) to address these questions. There are a number of robust, policy-relevant insights that emerge from these studies about the adverse consequences of a further delay of comprehensive mitigation action:

- Due to the tight constraint on cumulative CO2 emissions implied by the 2°C limit, higher than optimal emissions in the near-term have to be compensated by lower emissions in the long term. This implies a much faster pace of emission reductions in the medium term. Scenarios with high 2030 emission levels feature post-2030 emission reduction rates that are roughly twice as high as those in scenarios with optimal timing of mitigation efforts.
- At the same time, a lack of meaningful mitigation action in the near-term reduces the longer-term mitigation potential. This is due a further lock-in into carbon intensive infrastructure, and insufficient up-scaling of low-carbon technologies. As a consequence, the deep emission reduction required become more difficult to achieve.
- The deep long-term emission cuts also imply a greater reliance on specific technologies and reduced societal choices. In particular, in case of weak short-term policies the 2°C limit can only be kept with large-scale deployment of bioenergy and CCS.
- A further delay of mitigation action results in greater overall costs of the mitigation effort, and a more unequal distribution of these costs over time. In particular, we find that a further delay substantially increases the economic costs during the transition from a weak to a comprehensive climate policy regime, thus raising the barrier to the low-carbon transformation.
- Finally, replacing fossil fuels by climate-friendly alternatives comes with several co-benefits, in particular in the form of decreased air pollution and improved energy security. Delaying climate policy implies that crucial co-benefits, such as decreased air pollution and improved energy security, are foregone.

The presentation will further explore how enhanced near-term action and post-2020 policies can reduce these adverse effects, thus helping to keep the 2°C target within reach.

The energy transformation in 2°C pathways: upscaling technology, investment needs, stranded assets and the role of energy demand

V. Krey (1) ; C. Bertram (2) ; J. Eom (3) ; N. Johnson (1) ; D. Mccollum (1)
(1) International Institute for Applied Systems Analysis (IIASA), Energy program, Laxenburg, Austria; (2) Potsdam Institute for Climate Impact Research, Potsdam, Germany; (3) KAIST Business School, Graduate school of green growth, Seoul, Republic of Korea

A major challenge in limiting temperature change to 2°C compared to pre-industrial levels is the transformation of the energy system which requires rapid upscaling of low-carbon technologies to significantly reduce GHG emissions. Deploying the energy technologies needed to initiate a sustained energy system transformation requires continued research and development as well as significant investments to be mobilized by the global economy.

The timing of mitigation action and in particular the stringency of near-term climate policy determines the challenge we are facing now versus the challenge we may face in a couple of decades. While delaying stringent climate action has the benefit of allowing for more development space over the coming decade or two, it amplifies the need to rapidly decarbonize the energy system thereafter if temperature change should be contained to 2°C or less. An important implication of weak near-term climate policies is the need to prematurely retire carbon-intensive infrastructure such as coal power plants, coal mines or oil wells, once moving to a more stringent climate regime. This trade-off particularly affects developing nations that are still in the process of building up a large part of their infrastructure.

In this contribution we will present results on technology upscaling, investment and decarbonization rates from integrated, model-based scenario studies. These will be put into the context of historical developments, both at the level of countries and regions and at the level of individual technologies.

In addition, the decarbonization of the energy supply sector needs to be complemented by a switch to low-carbon energy carriers in the end-use sectors as well as the reduction of energy demand, both of which are key strategies to reduce GHG emissions. In particular the latter is shown to provide additional flexibility for an energy system transformation by hedging against potential resistance to large-scale deployment of energy supply technologies and by reducing stranded assets as well as generating multiple non-climate benefits.

Global Energy and Climate Outlook: Road to Paris – Economic Assessment of Low Emission Levels under World Action Integrating National Contributions

Z. Vrontisi (1) ; B. Saveyn, (1) ; T. Vandyck, (1) ; A. Kitous, (1) ; A. Labat, (2) ; M. Perry (2)
(1) European Commission (DG JRC-IPTS), Institute for prospective technological studies, Seville, Spain; (2) European Commission (DG Climate Action), Brussels, Belgium

On 25 February 2015, the European Commission has set out its Communication, «The Paris Protocol – a blueprint for tackling global climate change beyond 2020" in the EU's Energy Union package. This paper presents the modelling work undertaken in the context of the abovementioned EC communication regarding the economic impacts of post-2020 global climate change mitigation policies. The analysis presented here mainly lies on results from the economic model GEM-E3, combining the work undertaken with the energy systems model POLES for the purposes

of the EC preparation for the global climate negotiations. It focuses on possible ways to stay below 2°C through processes established in the run-up to Paris COP21 by studying a combination of domestically determined mitigation targets for the period beyond 2020.

The GEM-E3 model is a recursive dynamic computable general equilibrium model which covers the interactions between the economy, the energy system and the environment. The model is calibrated to the 2004 base year of the GTAP 8 database. This version of the model represents 21 sectors, 10 power technologies and 25 regions, including all major economies. The six Kyoto greenhouse gasses represented are CO2, SF6, PFC, HFC, CH4, and N2O. The POLES model is a global sectoral simulation model for the development of energy markets.

The GEM-E3 and POLES models share a harmonised Baseline with population and economic growth projections based on the UN and OECD. The projections do not consider the impacts from unabated climate change. In this Baseline scenario, global emissions would increase at unsustainable levels: from 48 GtCO2e in 2010, 61 GtCO2e in 2030 to 68 GtCO2e in 2050. Along such trajectories, the world is at risk to experience a global temperature increase of +4°C, with sizeable impacts on sustainable growth and vulnerable groups in all regions. The Global Mitigation scenario is in line with staying below 2°C, with global GHG emissions peaking in 2020 and reaching about 43 GtCO2e in 2030, still higher than in 1990 (+20%) but lower than in 2010 (-10%).

The economy-wide impacts are twofold. Firstly there are direct costs of mitigation due to regional emission constraints and the reallocation of resources for the mitigation effort. Secondly there are indirect costs or benefits from changes in competitiveness, production patterns, investment and relative prices of energy, labour and capital. It is seen that carbon-intensive sectors need to adjust their investments in order to reduce their emissions, and sectors with a low emission-intensity are affected according to their level of openness to emitting sectors. The effects analysed include GDP, sectoral activity, exports and imports, employment, private consumption and investment. The results indicate that, although due to reallocation of resources created by a global mitigation effort, negative impacts on GDP are seen for all regions, in effect, climate change mitigation policies only marginally reduce the yearly economic growth rates in fast-growing low-income regions. A decomposition analysis of the drivers of GDP change gives a further insight on the impacts of the global mitigation policies.

Another dimension of the analysis is the choice of policy instruments. For this purpose, we compare the use of free allocation of permits with the use of auctioning or taxation. The revenues of auctioning or taxation are recycled as a lump-sum to households, a reduction in labour taxes or in indirect taxation on consumption and investment. It is found that, depending on their regional economic characteristics, for the majority of the regions the optimum recycling of permit auction revenues is to lower indirect taxes while for some countries it is best to use emissions revenues to reduce taxes on labour. Economic costs can be reduced further if the auction revenues are not used only for tax reductions but are combined with a financial scheme.

4402b - Low carbon pathways for staying below 2°C: Global requirements

ORAL PRESENTATIONS

Regional greenhouse gas emission pathways within the context of the 2 °C target: Insights from the LIMTS project

D. Van Vuuren (1) ; M. Tavoni (2)
(1) PBL Netherlands Environment Agency, PBL, Climate, air pollution and energy, Bilthoven, Netherlands; (2) Fondazione Eni Enrico Mattei , Climate change and sustainable development programme, Milan, Italy

Integrated assessment models can help in quantifying the implications of international climate agreements and regional climate action. In several recent model comparison studies, different possible outcomes of post-2020 climate negotiations were explored in relation to the 2 °C target. The scenarios developed in these projects can be used to derive key information for individual (major) economies and regions. This includes for instance information on emission peaking, regional carbon budgets and emissions allowances. In this contribution, we present these otutcomes (especially those of the LIMITS project) and focus on the differences across these regions. For instance, in terms of mitigation measures, costs and carbon budgets clearly different results can be noted. In our contribution, we also highlight the distributional consequences of climate policies, and discuss the role of carbon markets for financing clean energy investments, and achieving efficiency and equity.

As the models presented in this contribution do have global coverage - the presentation allows also to act as a bridge between the two important parts of the session on low carbon emission pathways (global and regional).

K-4402b-02

National pathways to deep decarbonization - Methodological insights from the Deep Decarbonization Pathways Project (DDPP)

H. Waisman (1) ; M. Colombier (1) ; E. Guérin (2) ; J. Sachs (2)
(1) Institute for Sustainable Development and International Relations, Paris, France; (2) Sustainable development solutions network, New York, United States of America

Can countries take the carbon out of their economies, and still provide economic prosperity for their citizens? National circumstances and approaches differ, but four pillars of decarbonization are identified universally, in developed and developing countries alike: (i) strong improvements in energy efficiency, (ii) making energy carriers almost zero carbon (low-carbon electricity sources, biofuels, hydrogen), (iii) shifting energy use as far as possible to these low-carbon energy carriers , (iv) fostering structural changes reducing output from carbon-intensive activities and (v) reduction of remaining direct emissions, using a variety of technologies.

An initiative of the Institute for Sustainable Development and International Relations (Iddri) and the Sustainable Development Solutions Network (SDSN), the 'deep decarbonization pathways' project (DDPP) analyses how the different pillars of decarbonization can be operationalized in 15 countries representing, in total, 70% of global 2010 GHG emissions: Australia, Brazil, Canada, China, France, Germany, India, Indonesia, Japan, Mexico, Russia, South Africa, South Korea, the UK, and the USA.

The approach of DDPP is to have country research team develop a national-scale pathway analysis for deep decarbonization consistent with the 2°C global target to 2050. This study is supported by expert-based assessments of national decarbonization as basis for an internally coherent and transparent analysis of the country-specific transformations able to satisfy the twin objectives of development and deep decarbonization.

The preliminary results from this work were published in a report for the UN Secretary-General, in support of the Climate Leaders' Summit on September 23, 2014. Revised analysis providing a comprehensive vision of technical, socio-economic and policy aspects of long-term deep decarbonization will be conducted in early 2015 and delivered to the French Government in the lead-up to COP-21.

In this presentation, Michel Colombier, IDDRI's scientific Director, will present the scientific approach and the methodological specificities of the scenario analysis that make the DDPP relevant to inform national and international policy debates. Notably, a focus will be given

to the backcasting long-term approach, the «dashboard» methodology that allows transparent and explicit representation of the pathways and the iterative process for elaboration of the national pathways.

K-4402b-03

Technology Policies and Accelerated Diffusion of Decarbonization Wedges

P. Criqui (1) ; N. Alazard-Toux (2) ; JG. Devezeaux De Lavergne (3)

(1) CNRS and ANCRE, Pacte-edden, 38040 Grenoble cedex, France; (2) IFPEN and ANCRE, Direction economie veille, 1-4 Avenue du Bois-Préau, 92852 Rueil Malmaison Cedex, France; (3) CEA and ANCRE, I-tésé, centre de saclay bâtiment 524, 91191 Gif Sur Yvette, France

The rapid and deep decarbonization of energy systems that is required in the 2°C scenarios will result from a complex mix of institutional, behavioral and technological changes. While many economic models and mitigation scenarios have initially focused on the role of economic instruments for triggering these changes, the role of new technologies have been progressively been made more explicit as a central element for the feasibility of low carbon futures. In particular, filling the gap between bottom-up nationally determined contributions and the requirements of 2°C scenarios will require a worldwide effort to accelerate the diffusion of energy efficiency and low carbon options.

Following to pioneering studies (Stabilization wedges, Socolow and Pacala [2004], Energy Technology Perspectives, IEA, since 2006) the role of new energy technologies has been extensively studied in the past ten years (EMF 24, different projects in European Framework Programs, IPCC AR5…). While a new stage in climate negotiations and policies is expected to start when the Paris Climate 2015 results in a positive outcome, the fulfillment of the announced Nationally Determined Contributions will involve a quick mobilization and scaling-up at world level of low carbon technologies, on the demand as well as on the supply side.

Research projects such as the Deep Decarbonization Pathways Project of UN-SDSN provide clear images of what has to be accomplished in the different countries in order to come closer to emissiontrajectories compatible with the 2°C scenarios. However further enquiry is needed to explore both the radical/systemic innovations and the policy and social dimensions of the accelerated diffusion of low carbon technologies. In this context, the National Alliance for the Coordination of Energy Research (ANCRE), which gathers the scientific resources of the main public research institutions in France, proposes a communication on the development of low carbon energy technologies and systems. These are the "Decarbonization Wedges" that ANCRE is currently exploring in an eponym study that mobilizes the knowledge resources of this organization.

The communication will first identify the main decarbonization wedges to 2050 and analyze their potential, Technology Readyness Level, and expected development in different regions according to international studies such as Deep Decarbonization Pathways. It will then analyze the different types of barriers to be overcome before their rapid and massive diffusion: either technical, economic or social. It will then present elements of consistent RD&D strategies at the international and national level to speed-up the diffusion of these technologies in the different regions of the world.

Analysis of current climate policies, intended national determined contributions (INDCs) and possibilities for strengthened policies at the regional scale

M. Den Elzen (1) ; H. Fekete, (2) ; A. Admiraal, (1) ; N. Forsell, (3) ; N. Höhne (2) ; A. Korosuo, (3) ; M. Roelfsema, (1) ; H. Van Soest (4) ; K. Wouters, (5) ; T. Day, (2) ; M. Hagemann, (2) ; A. Hof (1) ; A. Mosnier, (3)

(1) PBL Netherlands Environmental Assessment Agency, Department of Climate, Air and Energy, Bilthoven, Netherlands; (2) NewClimate Institute, Cologne, Germany; (3) IIASA, Laxenbourg, Austria; (4) PBL Netherlands Environmental Assessment Agency, Climate, Air and Energy, Bilthoven, Netherlands; (5) Ecofys, Utrecht, Netherlands

This study provides an overview of projected greenhouse gas emissions in major emitting countries/regions up to 2030, taking into account the emission trajectories based on the most effective current and planned climate and energy policies, as well as selected enhanced mitigation measures and the intended national determined contributions (INDCs). In addition, we also analyse the ambition of the INDCs using a wide range of methods (see below). The country-specific mitigation policies in promising areas for enhanced actions are in line with national priorities and opportunities (e.g. co-benefits). The analysis focuses on 13 countries/regions (Australia, Brazil, Canada, China, European Union, India, Indonesia, Japan, Mexico, Russia, South Korea, Turkey and the US). The impact of the most effective current and planned policies on greenhouse gas emissions was estimated based on calculations from energy and land use model calculations, and scenarios from national and international studies. The main findings are:

- The degree to which countries/regions are likely to achieve their 2020 pledges under current policies varies: of those considered here, Brazil, China, the EU, India, Japan and Russia are likely to achieve their pledges through existing policies. Australia, Canada, Indonesia, Mexico, South Korea and the US require additional measures to achieve their 2020 pledges. The US and Mexico could achieve their pledges if planned policies are effectively implemented.
- Even though current and planned policies are projected to have an effect on emissions, increases would still occur in Australia, China, India, Indonesia, Mexico and Turkey until 2030. Emissions in Brazil, Canada, South Korea, the Russian Federation and the US would remain stable approximately at 2010 levels. For the EU, emissions are projected to decrease further under current policies, but not enough to meet the INDC of EU of a 40% domestic reduction target by 2030.
- In all the countries/regions considered, significant further reductions are possible through a selection of policy enhancement measures that are in line with national priorities. The selection of policies and measures is illustrative and not exhaustive. With the selected enhancement measures included here, China and Mexico would stabilise emissions by 2030, at the latest. The EU, Japan, South Korea, and the United States would achieve a pathway with further reductions in line with their long-term targets. The EU would meet its INDC for 2030, and the US its announced 2025 reduction target. Emissions in India, Indonesia and Turkey would continue to increase strongly, but less so than under current and planned policies.
- Looking only at 13 major emitting countries/regions, the enhanced policy scenarios in this report could reduce emissions by 6.1 GtCO2e by 2030, compared to under current policies. This is roughly a third of the difference in global emission levels between a scenario consistent with the 2 °C target and a current policies scenario based on the UNEP's Emissions Gap Report 2014.
- Countries' efforts should be of similar ambition. A large variety of methods exist that allow to compare countries' efforts. For a comprehensive ambition assessment we propose to use an array of methods that we group in terms of whether they assess "moral obligation" or "technical necessity".

Applying these methods to existing proposals by the USA, China and the EU, a consistent picture emerges that the proposals by EU and China are more ambitious than the proposal by the USA. The methods do not provide a consistent picture on whether EU's or China's proposal is more ambitious. While China leads slightly on "moral obligation", the EU generally leads on "technical necessity".

A 90% Reduction in Canada's Emissions by 2050: Macroeconomic and physical evolution or revolution?

C. Bataille (1)

(1) Institute for Sustainable Development and International

Relations, Paris, France

What does 90% decarbonization of the Canadian economy look like, physically and financially? Is it a financial evolution, or a revolution? An opportunity or a calamity, and for whom? What are the uncertainties? Canada already has strong and binding long term policies on transport and buildings whereas, with a couple of exceptions, regulations are largely missing for industry. In this analysis I strengthen the existing transport and buildings regulations and add policy for industry. I use a regionally and sectorally disaggregated CGE methodology to model the following policy package. 1) Advanced efficiency regulations for transport, buildings and appliances, on the premise there are significant plausible market failures & pricing policies may be ineffective. 2) Regulations requiring oil and gas fugitive control and CCS on formation gas processing and hydrogen production, with the right to sell verifiable reductions into the following "market". 3) A tradable emissions intensity standard for all large emitter based on sector specific "best-in-class" technology intensity targets. 4) I complete the policy package with an initally low but continually rising British Columbia style carbon tax with 50/50 recycling to labour and corporate labour taxes that eventually eclipses the other policies. For results I will review GDP, emissions, changes in sectoral investment and economic structure. I will conclude with a methodological discussion of the modelling changes that were needed to hit 2 tonnes per capita, including additional decarbonization technologies and changes to the modelling structure.

P-4402-02

Complementing carbon prices with technology policies to keep climate targets within reach

C. Bertram (1) ; G. Luderer (1) ; R. Pietzcker, (1) ; E. Schmid, (1) ; E. Kriegler (1) ; O. Edenhofer (1)

(1) Potsdam Institute for Climate Impact Research, Potsdam, Germany

Economic theory suggests that comprehensive carbon pricing is most efficient to reach ambitious climate targets, and previous studies indicated that the carbon price required for limiting global mean warming to 2 °C is between US$16 and US$73 per tonne of CO2 in 2015. Yet, a global implementation of such high carbon prices is unlikely to be politically feasible in the short term. Instead, most climate policies enacted so far are technology policies or fragmented and moderate carbon pricing schemes. This paper shows that ambitious climate targets can be kept within reach until 2030 despite a sub-optimal policy mix. With a state-of-the-art energy-economy model we quantify the interactions and unique effects of three major policy components: (1) a carbon price starting at US$7 per tonne of CO2 in 2015 to incentivize economy-wide mitigation, flanked by (2) support for low-carbon energy technologies to pave the way for future decarbonization, and (3) a moratorium on new coal-fired power plants to limit stranded assets. We find that such a mix limits the efficiency losses compared with the optimal policy, and at the same time lowers distributional impacts. Therefore, we argue that this instrument mix might be a politically more feasible alternative to the optimal policy based on a comprehensive carbon price alone.

To limit the mitigation costs and risks of achieving the 2 °C target, it is essential to start comprehensive climate policy as early as possible. Recent studies have shown that pledged reductions are not consistent with cost-efficient emissions pathways reaching the 2 °C target. Furthermore, a continuation of climate policy at the current ambition level will not lead to a stabilization of climate change, and the delay of more stringent mitigation actions will significantly exacerbate the challenge of reaching long-term climate policy objectives. Current policies fail to induce the transformation of the energy system to the extent required by long-term climate targets and lead to further lock-in into carbon-intensive infrastructure. Not only do too much emissions occur in the near term, but also mitigation later on is rendered more difficult. It is an important question whether technology policies can reduce such lock-in and mitigate the impacts of delay. Although a few studies based on global energy-economy models have considered single packages of technology policies in their analysis of twenty-first-century mitigation pathways, none of them explored this question.

The environmental economics literature has also not focused on the scope of technology policies for overcoming deficiencies in carbon pricing. In this strand of scholarly work, technology policies have mainly been analysed as means to cure market failures beyond the pure pollution externality, for example, due to learning spillovers, information asymmetries and so on. In contrast, here we analyse their complementary role under sub-optimal carbon pricing. There is wide agreement that market-based instruments pricing the externality of emissions have an advantage in terms of efficiency. At the same time it is debated whether or not setting a price (carbon tax) or a quantity of tradable permits (cap-and-trade) is preferable. Some authors find that the interaction with other instruments favours the price instrument, a finding that our study extends to the case of sub-optimal carbon pricing combined with technology policies.

This study is the first to assess which mix of emission pricing and technology policies is effective in avoiding further lock-in and initiating the transformation required for limiting warming to 2 °C. We thus fill an important gap in the literature by informing the ongoing climate policy debate, which so far revolves around modest approaches to carbon pricing and various forms of technology policies in several countries around the world, tantamount to a lack of comprehensive emissions pricing in line with the 2 °C limit.

Our analysis identifies a policy mix that—based on the positive effects of technology policies under sub-optimal carbon pricing—keeps ambitious climate targets within reach and is possibly easier to implement politically. It does so by addressing two crucial questions: (1) how weaker-than-optimal carbon pricing schemes and additional technology policies interact, and (2) which combination can best reduce the adverse effects of sub-optimal carbon pricing.

P-4402-03

Energy transitions in France: lessons from a forward-looking study

R. Bibas (1) ; JC. Hourcade (1)

(1) International Research Center on Environment and Development (CIRED), Paris, France

The general equilibrium model Imaclim France-R is used to examine various energy transition strategies leading to a path 'Factor 4'.The macroeconomic balance a set of assumptions about the technical conditions of supply and demand for energy varies as it is or not housed in a package that does not come from one area of energy policy: fiscal policies to prevent the spread of the additional costs of energy in the production system, social and wage bargaining to manage the recycling of the product of a carbon tax, reform of financing structures, industrial policies and training for new jobs, infrastructure policies and behavioral change.We then show how a funding policy lowering the coefficient of investment risk 'low carbon' would, by enhancing the credibility of public policies, reduce fears that explain the reluctance of market participants and trigger a shift in investment towards faster simple equipment into energy.The macroeconomic balance changes according to the terms of the transition, but is positive in the medium and long term in terms of growth and employment, this because of the synergy between three mechanisms: decrease of energy imports, energy savings releasing purchasing power of households in non-energy goods and services, lower labor costs allowed by a carbon tax.Economic Support of the Transition is critical to move from a slightly negative balance in the short term to a positive balance sheet, in order to give the 'grist' needed to reduce these tensions.The challenge is an effect credibility 'from the consistent conduct of pricing policies and funding guiding expectations of actors in a negative context.As for the nuclear issue, we see a big difference between a nuclear constrained by increased demands 'precautionary' and a voluntary exit 2050 with a ban on building new plants. This last assumption is to respect the F4, an important and early development of CCS and leads to growth retardation of 4.5 years over 40 years excluding conversion costs, and, conversely, profound changes behavior and economic structures.Scenarios precautionary nuclear 'limit its place around 40% of the energy mix in 2050 and allow a decision to back exit or new deployment that can be taken later «better informed».The challenge now is to get into position to take it with a strong national consensus not only the ultimate technology choice, whatever it is, but also economic and social policies consistent with this choice.

P-4402-04

Technology and innovation to low-carbon pathways in Brazil

B. Bressan (1) ; M. Poppe, (2) ; G. Jannuzzi, (3) ; A. Furtado, (3)
(1) Centre for Strategic Studies and Management in Science, Technology and Innovation (CGEE), Sustainable Development, Brasília-DF, Brazil; (2) Centre for Strategic Studies and Management in Science, Technology and Innovation (CGEE), Sustainable development, Brasilia - DF, Brazil; (3) University of Campinas - UNICAMP , Mechanical engineering faculty, Campinas - SP, Brazil

The UNFCCC intends to approve more stringent targets to reduce carbon emissions globally. One of the instruments that has been created by the Climate Convention is the Technology Mechanism. This mechanism comprises a Technology Executive Committee (TEC) and a Climate Technology Centre and Network (CTCN).

Developing countries are asked to prepare reports detailing their technological needs to develop mitigation and adaptation climate plans. These reports are known as Technology Needs Assessment (TNA) and are prepared according to suggested guidelines and offer the basis for technological procurement and transfer efforts of select stablished solutions very often already dominated and commercialized by industrialized countries.

CGEE (a non-profit organization with the mission of rendering Science, Technology and Innovation as Brazil's best allies for economic growth, competitiveness and well-being) is coordinating, as a subsidy for the Ministry of Science, Technology and Innovation, a group of experts with wide experience on technology development and transfer in order to propose a suitable methodology for the Brazilian reports, oriented to formulate a Technology Capacities and Needs Assessment (TCNA). Therefore, technology needs are associated to national capacities and competencies supporting the designing of a Technology Action Plan (TAP) to fight climate change. Moreover, preparing a TCNA indicates the possibility for developing countries to not only attract know-how and new technologies, but also to be able to offer these resources to other countries.

The contribution aims to improve the assessment and action plans taking into account the opportunity for developing countries to enhance and promote its science and technology base and to create new solutions to more meaningful low-carbon pathways in their own social context. One key step in the proposed methodology is a detailed inventory of local capacities and competences not only within the science and technological communities but also their industrial base. So, it will be possible to enhance the national innovation chain and place developing countries as more relevant international players in the arena of scientific and technological activities, being able to generate more patents and solutions that can be applied in other similar developing countries as well. Additionally the adaption capacity of more vulnerable countries and regions could be upgraded.

P-4402-05

Analogues between rapid mobilisation for World War 2 and the Great Energy Transition: Lessons and caveats

L. Delina (1)
(1) Independent Scholar, South Cotabato, Philippines

To have a high probability of limiting further global warming—at least to stabilise it to an average temperature increase of 2°C—climate science suggests that global greenhouse gas emissions must peak by 2020 and be reduced to close to zero by 2040. Current trend, however, heads towards at least 4°C by end of this century; yet, little effective climate action is being taken. In this presentation, I talk about contingency plans developed for a scenario in which governments are galvanised to implement an urgent transition of conventional energy systems—the biggest GHG contributor—to sustainable renewable energy systems. This Great Energy Transition, climate activists and some academics assert, would be feasible, invoking the magnitude of World War 2 mobilisations. I critically examined the plausibility of this analogue in this talk. The findings, which I published in the journal Energy Policy, suggest some potential strategies especially in areas of finance and labour mobilisations, as well as in the governance and administration of these resources. Nonetheless, the analogue has severe limitations, resulting from its lack of democratic processes, most especially. Moreover, since the threat of climate change is less obvious to many non-scientists, it is unlikely that the public will be unified in support of a highly centralised action. It appears therefore that prosecuting the Great Energy Transition seems to be more complex than prosecuting a great war.

P-4402-06

Global scenarios of greenhouse gas emissions reduction: the 2°C target and less stringent goals

O. Dessens (1) ; G. Anandarajah, (2)
(1) Enegy Institute, University college london, London, United Kingdom; (2) Energy Institute, University college london, London, United Kingdom

In this paper we present a study performed with the latest version of the TIAM-UCL model on the possibility to achieve different targets on the global temperature change due to greenhouse gas emission reduction. The study specifically analyses what will take us to meet the 2°C target in term of peaking years and subsequent reduction rates needed. We also analyse two less constrained targets at 2.5°C and 3°C.

The first part of the study focus on the relationship between the peaking year for emissions (before mitigation policy) and the minimum percentage change in the emissions reduction afterward allowing the target to be achieved. Increasing temperature target (2.5 and 3°C) or the maximum rate of emissions reduction reduces the need of early mitigation policies (before 2025). In the case of the 2°C target, allowing overshooting of the target before stabilisation has the same effect. Given the continuing delay in implementing a global agreement on greenhouse gases emission reduction, we initially examined the window of opportunity to continue increasing emissions whilst still limiting the average surface temperature rise. We found that while it may still be possible to limit the average global temperature rise to the nominal 2°C target agreed on by policy makers, the opportunity window for realising this is closing rapidly.

We study in a second part more specifically the pathways toward the stringent 2°C target. The focus is now on where the mitigation occurs between developed, emerging and developing economies and what technologies and resources are needed. Per capita emissions were found to fall in all regions globally: in high-income regions these drop to less than a quarter of their 2010 level by 2050, while in middle and low-income regions they fall by 50%. On the technology side, we present the deployment rates of the low-carbon technologies needed to achieve the target. The first sector to decarbonise will be the electricity generation; the overall level and rate of installation of new capacity that is required globally is found to be entirely unprecedented at such temporal and geographical scales.

In conclusion, the opportunity to prevent a temperature rise less than 2oC remains possible and is indeed entirely necessary. However perhaps this opportunity becomes increasingly unlikely due to the required scale of the investments required.

Development of pathways to achieve the SE4ALL 2030 objectives

J. Gregg (1) ; T. Kober (2) ; O. Balyk (1) ; CHC. Pérez (1) ; O. Solér (1) ; S. La Greca (1) ; MAD. Larson (1) ; TK. Anderson (1)
(1) Technical University of Denmark, Management Engineering, Roskilde, Denmark; (2) Energy reserach Centre on the Netherlands, Policy Studies, Amsterdam, Netherlands

The objectives of the United Nations Sustainable Energy for All Initiative (SE4ALL) are to achieve, by 2030: 1) universal access to modern energy services; 2) a doubling of the global rate of improvement in energy efficiency (in terms of the rate of energy intensity reduction); and 3) a doubling of the share of renewable energy in the global energy mix (in terms of renewable energy share in the global energy

mix). The study explores the techno-economical pathways of sectoral and regional developments to 2030, taking into account realization of the potential for energy efficiency improvement and renewable energy deployment.

Beyond the reference scenario (which includes no additional policy measures or technology development beyond the current status quo assumptions), we create three alternative scenarios. The first alternative scenario focuses on meeting the SE4ALL 2030 energy efficiency target through a combination of more ambitious technological improvements and policy incentives within end use energy consumption in the buildings, industry and transportation sectors. To create this scenario, we simulate substantial improvements in conventional technologies' efficiencies, phasing out of energy intensive technologies at an accelerated pace (replaced with more advanced counterparts), and the emergence /proliferation of innovative new technologies not yet widely available in the market.

The second alternative scenario focuses on achieving the SE4ALL 2030 renewable energy targets. This scenario sets both global and region-specific targets to closely follow those outlined by the International Renewable Energy Agency Global Renewable Roadmap (IRENA REMap2030).

The third alternative scenario combines the first two.

The alternative scenarios also incorporate the effect of various barriers to energy efficiency development, to simulate various known social, political, and economic effects that curtail adoption of new technologies. This allows for a more effectual representation of meeting the SE4ALL targets.

The technology-rich TIMES Integrated Assessment Model (TIAM) is employed to analyze the various scenarios. From here, we develop technology and policy pathways for different regions for meeting the SE4ALL energy efficiency and renewable energy goals. The pathways are evaluated in terms of cost effectiveness and by assessing the degree to which modern technology is dispersed across the various regional technology profiles (the first objective of SE4ALL). The optimal pathways are converted into policy recommendations and cost estimates for best achieving the SE4ALL objectives.

P-4402-08

Towards a low-carbon Chinese economy: the role of transportation

M. Hamdi-Cherif (1)
(1) CIRED, Nogent-Sur-Marne, France

Rationale and Objective: Chinese economic development goes hand in hand with (i) a growth of the production that is accompanied with an increase of the freight transport, and (ii) an enriched population and fast-growing urbanization that induce increasing demand for passenger transport (notably an increase of the motorization rate). Given the high reliance of transport on oil products, its increasing energy demand and CO2 emissions, the transportation sector is a crucial sector for China, particularly regarding energy security and climate change issues. In its attempts to have a sustainable development, the transportation sector is indeed particularly challenging for China. To avoid important "lock-ins" in carbon-intensive pathways, especially given the high coal availability and the important life span of infrastructures, China has to redouble its efforts with voluntary schemes promoting mobility growth control. This paper investigates the role of transportation activities in the transition to a low carbon Chinese society. A particular attention is given to specific measures designed to control the growth of mobility. It is an attempt to quantify the impact of urban voluntary policies on Chinese mitigation costs.

Methodology: This article revisits the role of the transportation sector in low-carbon pathways by using the Energy-Economy-Environment model IMACLIM-R. It is a hybrid multi-region, multi-sector CGE model, which embarks a detailed description of passenger and freight transportation. The standard representation of transport technologies is supplemented by an explicit representation of the "behavioral" determinants of mobility. The model relies on hybrid matrices ensuring consistency between money flows and physical quantities and allows an explicit representation of the interplay between transportation, energy and growth patterns. It accounts for the rebound effect of energy efficiency improvements on mobility, endogenous mode choices in relation with infrastructure availability, the impact of investments in infrastructure capacity on the amount of travel, and the constraints imposed on mobility needs by firms' and households' location. Moreover, IMACLIM-R represents the second best nature of economic interactions and the inertias on technical systems that limit the flexibility of adjustments, a crucial dimension for emerging economies when envisaging large structural change over the course of the century. **Complementarily to carbon pricing to reach a stringent climate objective (3.4W/m2 in 2100), we consider actions to control the "behavioral" determinants of transportation in the course of the low-carbon transition, and assess their effects on the Chinese economy. More specifically, we consider (i) urban reorganization lowering the constrained mobility (i.e. mobility for commuting and shopping), (ii) reallocation of investments in favor of public modes at constant total amount for transportation infrastructure and (iii) adjustments of the logistics organization to decrease the transport intensity of production/distribution processes.

Results: This analysis demonstrates the risk of high losses if using carbon price as the sole instrument of mitigation. Transport proves to be the sector for which carbon emissions are the more difficult to reduce. It thus represents a dominant share of remaining emissions in the long-term when ambitious mitigation objectives are set. Because of its weak reactivity to price increases, very high levels of carbon prices are needed in the second half of the century to reach low mitigation targets. We find indeed that they can reach 1400$/tCO2 by the end of the century. But we find that controlling mobility growth allows limiting these effects by offering mitigation potentials independent of carbon prices. The considered measures allow significant reductions of carbon price levels (on average 25% lower over 2050-2100) and hence help limiting the macroeconomic costs of the mitigation policies (e.g. long-term mitigation costs are reduced by 5 points in 2050 and by 10 points in 2100).

Conclusion: This study highlights the role of transport in the mitigation process. Given a climate target, the implementation of measures fostering a modal shift towards low-carbon modes and a decoupling of mobility needs from economic activity prove to modify the sectoral distribution of mitigation efforts and to significantly reduce the mitigation macro-economic costs relatively to a "carbon price only" policy.

P-4402-09

A pathway to a low-carbon society for China

Z. Mi (1)
(1) Beijing Institute of Technology, School of Management and Economics, Beijing, China

As the leading primary energy consumer and the largest carbon-emitting country in the world, China is facing great international pressure to reduce its carbon dioxide (CO2) emission, as well as a tight domestic fossil energy supply and a high level of air pollution. In the "U.S.-China Joint Announcement on Climate Change" released on November 12 2014, China announced to achieve the peaking of CO2 emission around 2030 and to make best efforts to peak early. Therefore, this study aims to answer whether and how China's CO2 emission can peak before 2030. A dynamic multi-objective optimization model will be developed based on the multi-region input-output model to explore an appropriate low-carbon pathway for China's sustainable development, comprehensively considering factors like industrial structure, energy structure, energy efficiency, consumer behaviors, and environmental capacity. Under this pathway, China is expected to assume its responsibilities to mitigate global climate change, reduce domestic pollution, and sustain a rational economic growth.

P-4402-10

Pathways to be Opened towards Low Carbon Society – Findings on Multi-model Comparison in ICA-RUS Project

S. Mori (1) ; T. Washida (2) ; A. Kurosawa (3) ; T. Masui (4)
(1) Tokyo University of Science, Department of Industrial

Administration, Noda, Chiba, Japan; (2) Sophia University, Graduate school of global environmental studies, Tokyo, Japan; (3) Institute of Applied Energy, Tokyo, Japan; (4) National Institute for Environmental Studies, Center for Social and Environmental Systems Research, Tsukuba, Ibaraki, Japan

Although the world agrees with the need for the greenhouse gas control in the long views, there are still serious barriers to be resolved towards the near term policy decisions. The scientific and the societal uncertainties in the climate change policies must be the large part of this barrier. Besides the unknown factors in the natural science field, various heterogeneous uncertainties in the macro and micro economic outcomes of mitigation policies, the technology strategies, possibility of adaptation options, and the risk and benefits of the geo-engineering will cause complicated debate. Distribution between current and future generation as well as among regions will also be the problem. The most preferable and acceptable decision making towards the agreement should be established from the risk management perspectives. Quantitative and comprehensive analysis is indispensable as a basis of discussion.

The Ministry of the Environment, Japan established an interdisciplinary research project, Integrated Climate Assessment – Risks, Uncertainties and Society (ICA-RUS) conducted by Dr.Seita Emori, National Institute for Environmental Studies. In order to deal with the various uncertainties, four different type integrated assessment models, i.e. MARIA-14(Mori), EMEDA(Washida), GRAPE(Kurosawa) and AIM(Masui), participate in this project to provide different views and the common information with respect to societal impacts of global warming strategies. For instance, the iterative optimization CGE model EMEDA has a capability to provide gaming simulations among states. MARIA and GRAPE provide detailed technology strategies as well as the land use changes through the inter-temporal optimization. AIM which consists of multiple model modules provides most comprehensive information. In the ICA-RUS project, these models generate various solutions under same SSP and RCP based scenarios, providing common information on economic loss and regional GHG emission pathways. Three models of the above give energy technology option and land use changes while EMEDA provides sectoral impacts. We also employ three "Alternatives left to humanity" represented by mitigation targets, 1.5, 2.0 and 2.5 degrees C global mean temperature increase (with assuming the climate sensitivity of 3.0 degreesC.

The current tentative conclusions are summarized as follows: first, in the stringent climate target, the regional economic losses among models tend to diverge. This variety seems to depend on the assumption on the malleability of the final energy demand, especially of the transportation sector. Second, CCS as well as BECCS will be essential to achieve the stringent climate target. Third, industry structure changes in Asia and Africa will show different patterns depending on the climate policies. Fourth, the models show small changes in the crop production and land-use patterns among various climate scenarios suggesting that the implementation of BECCS and the biomass energy expansion may not seriously conflict with the food supply under the reference optimistic yield assumptions.

Finally, some additional simulations on multi-stage decision making to deal with adaptive energy technology strategies will also be shown.

P-4402-11

Linking leadership to the upcoming global climate regime: Insights from the German Energiewende

M. Pahle (1) ; K. Steinbacher (2)

(1) Potsdam Institute for Climate Impact Reserach (PIK), Potsdam, Germany; (2) FU Berlin, Environmental policy research centre (ffu), Berlin, Germany

In a nutshell, the main current problem with action for climate protection is that too many countries are doing too little. The run-up to COP 21 in Paris will without doubt see the formulation of numerous recipes on how to cope with this challenge. But leadership exerted by frontrunning countries has the potential to stand out in the end as one of the most effective ways of pushing climate action. The particular clout of leadership is that ambitious countries can take immediate action out of their own accord without being thwarted by inconclusive international negotiations. The hope behind this is to attract followers for a similar course of action and thus sidestep global stalemate. It is true that unilateral leadership – i.e. acting when no one else does, with a hope to set an example – entails the risk of being in vain if it lacks followers, resulting in considerable costs for the leader. Nevertheless, in a world of increasingly polycentric climate governance, action at the national level is indispensable – and leadership puts this national action at the service of a common cause. But what does it precisely mean for countries to be a leader and how can leadership be put into practice outside institutionalized multilateral negotiations, in a polycentric regime? Answering these questions is essential to increase the leverage of national action in supporting climate action at the global level. A better understanding of leadership in a polycentric climate regime is thus what we aim for in this paper.

The particular case we look at is the German energy transition, now widely known as the "Energiewende". Formally enacted in 2011, but based on a much longer history of transition, the Energiewende has sparked considerable interest around the globe. Beyond its perception as a potential source of – positive and negative – lessons, choosing the Energiewende as a case is particularly relevant given the fact that gaining followers on the way to a more sustainable energy system has been a main rationale and German decision-makers frequently claim leadership in this field. Our investigation concentrates on "leadership by diffusion" outside multilateral negotiation settings and uses a simple analytical framework derived from the literature on leadership and policy diffusion. In a first step, we analyze the specific motivations for international Energiewende leadership and then review measures taken to translate this aim into action. We subsequently discuss Germany's approach to Energiewende leadership against the background of an evolution of the Energiewende itself. From this analysis, we find that while Germany has been a highly active leader facilitating the worldwide diffusion of renewables, a comprehensive leadership strategy in line with the very high ambitions of the Energiewende – towards a comprehensive energy system transformation – has not yet emerged.

Based on this finding, we discuss the requirements for such a strategy, including consistency across government, transparent communication and open dialogue with potential followers. Given that the main declared motivation for Energiewende leadership is to advance global climate action, this strategy above all needs to be geared towards effective climate leadership. Crucial for this is (a) to safeguard legitimacy of the Energiewende as a policy model by giving priority to climate protection at the domestic level ("sending side"), and (b) to ensure that knowledge created in the implementation process is shared with and adaptable to the local context in other parts of the world ("receiving side"). We eventually lay out how these activities could be linked to and supported by the upcoming international regime, and how in turn the requirements of effective climate leadership can be taken into account in the future course and implementation of the Energiewende.

P-4402-12

Interactions between agriculture mitigation choices and fossil CO2 emissions within integrated low-carbon pathways to limit warming to 2 degrees

A. Reisinger (1) ; A. Daigneault (2) ; J. Rogelj (3)

(1) New Zealand Agricultural GHG Research Centre, Palmerston North, New Zealand; (2) Landcare Research, Governance and policy, Auckland, New Zealand; (3) IIASA, Laxenburg, Austria

Agriculture currently directly contributes 10-12% of global greenhouse emissions, with additional emissions from land-use change and energy consumption in food production, processing and transport. Emissions from agriculture are projected to continue to increase for much of this century as a result of a growing and more affluent population that demands more high-quality and protein-rich food. In total, agriculture is thus responsible for more emissions than global air, land and sea transport, and (depending on the method of allocating indirect emissions) almost as much as stationary energy supply.

This suggests that mitigation of agricultural emissions must be part of integrated abatement strategies, especially for stringent goals such as limiting global average warming to below 2 degrees relative to pre-industrial levels. However, while the challenge of decarbonizing key sectors responsible for emissions of carbon dioxide from fossil fuels is increasingly well understood, there is much less visible action at a global scale to tackle emissions from agriculture, due in part to perceived tensions between food security and poverty eradication on one hand and reducing greenhouse gas emissions on the other. In addition, while there is significant potential to reduce emissions per unit of product for most agricultural systems, there is little prospect of completely 'decarbonizing' food production at the global scale, in contrast to e.g. the electricity and potentially even transport sectors. The limited abatement potential and intersection of food security and poverty with mitigation goals thus tends to relegate agriculture into the 'too-hard' basket for climate policy priorities, and a perception that the global climate benefits from enhanced agriculture mitigation would not be commensurate with the effort and trade-offs required.

Here, we use global integrated assessment models to demonstrate that even though technical mitigation options for agriculture are more limited than for some other sectors, accelerating agriculture mitigation outcomes can make a crucial contribution to keeping the goal of limiting warming to below 2 degrees viable. We show that different assumptions specifically for agriculture mitigation potentials and policy approaches strongly influence global shadow prices for GHGs throughout the 21st century, overall climate policy costs and the timing of the global peak of carbon dioxide emissions from fossil fuels in global cost-effective multi-gas abatement strategies, and also influence the rate of decarbonization required from fossil-fuel intensive sectors after emissions have peaked. We further explore how different approaches to agriculture mitigation (encompassing closing yield gaps, reducing demand, and increasing technical abatement options) could influence global commodity prices and land demand, and thus what measures could enable achieving goals of food security, poverty eradication and limiting climate change jointly.

We conclude that expanding the overall mitigation potential for agriculture-related emissions and supporting practices to realize this mitigation potential in practice are critical components of integrated efforts to achieve low-carbon pathways, and that therefore the role of agriculture in climate policies and integrated approaches to mitigation warrants much higher attention than has been evident in climate policy design to date. Perhaps ironically, we note that in a globally cost-effective approach to mitigation, the greatest near-term benefits from enhanced agriculture mitigation would accrue to the most CO2-intensive sectors and regions due to the ability to defer costly near-term emissions reductions by a few more years. However, even the most ambitious scenarios for agriculture mitigation do not change the fundamental need to achieve net zero carbon dioxide emissions globally by or before the end of the 21st century to retain a reasonable prospect of limiting warming to 2 degrees.

P-4402-13

Integrating domestic political constraints in a global agreement on pollution reduction

A. Staes (1)
(1) Paris school of economics, Paris, France

One of the famous but unfortunately unsuccessful approaches to deal with global warming has been to create the missing carbon market emission. While it appeared at first to be a hope, it failed by not taking into account asymmetric information and transaction costs associated. Mechanism designs coupled with incentives literature constitute a new promising approach. To design optimal contracts, two major constraints appear: countries need to voluntarily participate and they need to provide optimal effort. Taking into account asymmetric information, the first best could not be implemented. Martimort and Sand-Zantman (2012) demonstrate there is a trade-off between the provision of incentives for participating countries and the provision of incentives to participate. To deal with this double free-riding problem, they design menu contracts such that all countries will participate to a fund but only the more efficient would provide efforts to reduce their emission. By taking into account the diversity of countries, global contracts reducing pollution below the non-cooperating level (also called 'business as usual level') could be proposed.

Martimort and Sand-Zantman model (2014) does not take into account domestic political constraints in the design of the global agreement. Starting from their model, my contribution attempts to open the "black box" of government involved in negotiations. National governments face an asymmetric information issue: they are not perfectly informed about the firms' technologies (especially technologies to reduce emissions). Indeed, firms have an informational rent, which is source of distortions. Government could try to collect information on firms -thought bureaucrats for instance-. However, lobbies could try to capture bureaucrat. Avoiding capture for the governments could be costly. To tackle with these domestic constraints various mechanisms such as market or contracts should be considered at a domestic level.

Once taking into account domestic internal constraints, the setting up of general agreement mechanism could be modified. This analysis implies introducing double-edged incentives constraints to tackle asymmetric information issues both across and inside countries.

Research over contracts offers a way to focus on countries' different interests, maybe the more important issue that avoid any common agreement to be reached if denied. The integration of countries' internal political constraints makes more plausible the design of a global agreement. For that reason, this approach is relevant for the theme of day 4 "Collective action and transformative solution".

P-4402-14

Low carbon pathways prioritising human needs and development

J. Steinberger (1) ; W. Lamb (2)
(1) University of Leeds, School of Earth & Environment, Leeds, United Kingdom; (2) Tyndall Centre for Climate Change Research, School of Mechanical, Aerospace and Civil Engineering, University of Manchester, Manchester, United Kingdom

Human societies have always required environmental resources, in the form of energy and materials, to survive and flourish. However, the exact level of resource requirements may be difficult to estimate, since it can depend on many factors. These factors include: local biophysical conditions, such as climate or available crops for food; technological options and efficiencies for delivering key services; but also socio-economic parameters, including consumption levels and inequality in distribution. This talk will present recent advances in the international study of energy requirements for human needs. These results demonstrate that high levels of human wellbeing are attainable at moderate as well as very high energy use, and that the average level of energy use required to achieve high human wellbeing is declining over time. Moreover, it can be shown that energy itself does not play a dominant role in explaining the considerable advances in human wellbeing over the past half century. Research analysing the resource requirements to fulfil universal basic human needs within a low carbon future will be presented. This research must take into account political, social and economic factors, since fulfilling human needs at low levels of resource use most likely requires a fundamental restructuring of social and economic systems alongside technological advances.

P-4402-15

Pathways to Deep Decarbonization in the United States by 2050

MS. Torn (1) ; JH. Williams, (2) ; B. Haley, (2)
(1) Lawrence Berkeley National Laboratory, Earth Sciences Division, Berkeley, CA, United States of America; (2) Energy and Environmental Economics (E3), San Francisco, United States of America

Limiting the anthropogenic increase in global mean surface temperature to less than 2 degrees Celsius will require a reduction in global net greenhouse gas (GHG) emissions on the order of 80% below 1990 levels by 2050. As a result, there is a growing need to understand what would be required to achieve deep decarbonization

in different economies. We examined the technical and economic feasibility of such a transition in the United States, evaluating the infrastructure and technology changes required to reduce U.S. GHG emissions in the year 2050 by 80% below 1990 levels. Using the PATHWAYS and GCAM models, we find that multiple alternative technology paths exist to achieve this level of decarbonization in the U.S., assuming existing commercial or near-commercial technologies, natural replacement of infrastructure stocks, and the same level of energy services and economic growth as a reference case based on the U.S. DOE Annual Energy Outlook. Reductions are achieved through high levels of energy efficiency (1.8 GJ/$2012), deep decarbonization of electricity generation (<20 gCO2/kWh), electrification of most end uses (>50% of final energy), and switching remaining end uses to lower carbon fuels. A highly granular annual infrastructure stock-rollover model shows the physical adoption rates and investment required for key technologies in power, transportation, buildings, and industry. A regional hourly dispatch model of the electricity system for high renewable, high nuclear, high CCS, and mixed scenarios shows that flexible production of fuels from electricity can simultaneously provide both supply-demand balancing for reliability in systems with high levels of inflexible generation (e.g., >75% renewable) and low carbon fuels for applications that are difficult to electrify. Incremental energy system cost is equivalent to <1% of gross domestic product (GDP) in the base case, with an interquartile range of -0.2% to +1.8% across a variety of technology scenarios and cost sensitivities, not including non-energy benefits from avoided climate change and air pollution. The future terrestrial carbon sink and the level of biomass feedstock that can be considered sustainable and low-carbon are key uncertainties for future energy sector emission reduction costs.

P-4402-16

A dashboard and linked, top-down economic and bottom-up energy system models that demonstrate development indicators, technology deployment, investment and economic structure trajectories consistent with emissions pathways to achieve the 2oC goal

H. Trollip (1) ; T. Caetano (1) ; B. Merven (1) ; A. Hughes (1) ; H. Winkler (1)

(1) University of Cape Town, Energy Research Centre, Cape Town, South Africa

Global top-down models indicate that it is possible to achieve global emissions consistent with limiting climate-change warming over the 2015-2050 timeframe to 2 oC. This will require a fundamental techno-economic transformation towards low-carbon societies. However, across nations, historical, social, economical, political, and environmental conditions vary widely and thus credible transition pathways at national level require analysis using national data and proper consideration of national conditions.

Similarly, national statistical, analytical and modeling resources and capabilities used to conduct this analysis vary widely. The global effort requires best possible analyses of national potentials for contribution to global mitigation efforts. A South African team is working with the Deep Decarbonisation Pathways Project (DDPP), conducting such a national analysis. Teams participating in the DDPP are providing similar analyses for countries representing more than 75% of global emissions. The timing of the initiative, and coordination of generation of results from the analyses are designed to support global processes such as the UN Climate Leaders Summit in September 2014 and the 21st COP in Paris.

Over the past two decades the Energy Research Centre (ERC) at the University of Cape Town has been building local capability to model the South African energy and economic systems. This includes aspects related to emissions trajectories consistent with contribution to achieving 2 oC. Building on its rich tradition of research into energy, economy, environment and development, the ERC has been developing a linked economic energy system and emissions model. The ERC team has particular interest in inclusion of development indicators in the analysis, as well as those for climate change. The inclusion of these indicators in the international dashboard is used to provide a common set of data for national and regional analysis and also provides a full set of economic, energy system and emissions data for the pathways.

In addition to providing results coordinated to support global processes the novel combination of a dashboard and soft-linked, top-down economic and bottom-up energy system models also provides impetus and direction necessary to identify key issues to focus efforts for further model refinements and development for ongoing support of these processes, and national level processes.

To support the DDPP the team has worked to provided results consistent with the global initiative while also focusing on model developments relevant to specific South African issues such as high unemployment, existing socio-economic structures, labour force skills profiles and skills development scenarios, and options for future economic structures and other associated socio-economic research and data for informing the development indicators. This novel approach of combining data on multiple issues from multiple sources and tailoring models to address specific challenges is used to provide relevant, credible, evidence-based storylines showing what is required for South Africa to achieve acceptable socio-economic development and greenhouse gas emissions pathways from 2015-2050.

P-4402-17

Back to the future: Assessing the risks of 2˚C pathways

C. Von Stechow (1) ; J. Minx, (1) ; K. Riahi (2) ; D. Mccollum (3) ; J. Jewell (4) ; G. Baiocchi (5)

(1) MCC Berlin, Berlin, Germany; (2) International Institute for Applied Systems Analysis, Energy Program, Laxenburg, Lower Austria, Austria; (3) International Institute for Applied Systems Analysis (IIASA), Energy Program, Laxenburg, Austria; (4) IIASA, Laxenburg, Austria; (5) University of Maryland, College Park, United States of America

According to the most recent contribution of the IPCC, decision makers have some flexibility in terms of climate change mitigation timing and technology choices to achieve ambitious climate targets, such as the 2˚C target. At the same time, they would like to pursue multiple other objectives beyond climate change mitigation that are affected by mitigation timing and technology choices. Depending on locally specific priority settings and risk perceptions, this could imply delaying mitigation efforts and/or ruling out specific technologies compared to the globally most cost-effective mitigation pathways and technology portfolios analyzed by Integrated Assessment Models (IAMs). Understand the implications of deviating from these cost-effective mitigation pathways for other risks related to mitigation choices could allow national decision makers to trade off various risks and priorities in a more informed way when choosing their mitigation policies.

On a global level, alternative mitigation pathways based on IAMs are primarily characterized by (i) the probability of exceeding a pre-determined temperature threshold and (ii) the aggregate economic costs of reaching that temperature threshold. Some studies have also analyzed (i) the potential co-benefits for non-climate objectives (such as energy security and air quality) and (ii) the risks for non-climate objectives (such as land availability and food security). While the first two characteristics have been in the focus of recent model intercomparison projects and scientific assessments (e.g. WGIII AR5/UNEP), and the co-benefits of mitigation pathways have gained in prominence (see, e.g., the Global Energy Assessment), the risks of alternative global mitigation pathways have attracted less attention - possibly except food security - both in the literature and in the public mainly for two reasons: (i) Mitigation risks are challenging to quantify, let alone monetize, on a global level - the discussion thus usually focuses on technology-specific risks, such as those associated with nuclear power, CCS or bioenergy. (ii) The mitigation risks tend to be smaller, less persistent, less prevalent, less irreversible and hence better manageable compared to the risks of unabated climate change (see IPCC AR5 SYR).

This paper aims at improving our understanding of mitigation risks for choosing amongst alternative ambitious mitigation pathways by drawing on IAM results. To this end, the paper will first review literature that has used various IAM outputs to discuss those challenges to mitigation pathways that have a bearing on risks for non-climate objectives and will hence serve here as

risk indicators for attaining/failing these objectives. In contrast to existing studies that focus on specific challenges or IAMs, this paper will proceed to analyze risk profiles of alternative mitigation pathways across a more comprehensive set of risk indicators most directly linked to other non-climate objectives, drawing on multi-model outputs from recent IAM intercomparison projects.

The ambition of the paper is to shed light on the risk tradeoffs involved in pursuing policies not consistent with the most cost-effective mitigation pathways to limit global warming to below 2°C. For instance, recent advances in the IAM literature stress that delaying mitigation efforts beyond 2020/2030 will lead to a lock-in of high-carbon and high energy demand development pathways and hence mitigation costs. But these scenario results have not yet been used comprehensively to evaluate the risks of delayed mitigation efforts for a large set of other non-climate objectives, particularly not in combination with additional technological constraints and/or assumptions for ambitious energy intensity improvements. This paper wants to address this research gap and show in what way the flexibility of future decision makers in choosing climate policy consistent with the 2°C target will be reduced by climate policy decisions today.

Based on a preliminary evaluation of the scenario results, the paper puts forward that delaying mitigation as well as ruling out technologies from the portfolio of mitigation options could lead to problematic risk trade-offs for future decision makers that have to balance increasingly high risks of unabated climate change and increased mitigation risks for those technologies still on the table. These results could serve as a basis for developing new approaches to climate policies more adapted to locally specific priority settings and risk perceptions without endangering globally agreed climate targets.

4403 - Revising the 2015 Paris Climate Change Agreement architecture for better governance and outcomes

ORAL PRESENTATIONS

O-4403-01

«Revising the 2015 Paris Climate Change Agreement Architecture for Better Governance and Outcomes» Session chair

J. De Melo (1)
(1) Ferdi, Clermont-Ferrand, France

The Durban platform calls for "strengthening the multilateral rules-based regime under the [UNFCCC] convention". Issues of particular importance still to be decided are the particular legal form to be applied; if elements of the legal form are to be legally binding; how responsibilities are to be balanced across and among developed and developing countries; and the agreement's role, if any, in regulating or facilitating international emissions trading. Of the three approaches to choose from (expanded Kyoto-like approach, legalization of the Cancùn architecture, multi-track approach), this session will focus on aspects of a multi-track approach. This approach would allow a variable geometry with different configurations of countries involved in different parts of the overall regime. [1]

The session is built around the observation that the climate regime needs innovative modes of governance that recognize that the current regime is a transnational regime complex that is increasingly inadequate for inter-state governance. The chair will then note that the speakers' suggestions are all built around clubs of firms/cities/states that are conducive to the goal of building confidence (e.g. tackling easier problems such as soot with co-benefits; start linking with like systems to build confidence; designing smart border measures). This confidence-building approach is needed to build the collective action that has eluded the climate regime so far.

The chair will close by taking the example of the ongoing negotiations on an Environmental Goods Agreement (EGA), a good example of the three elements that are needed for a successful climate agreement (all were missing from the Kyoto Protocol). First, the treaty must encourage and promote full participation by countries. Second, the treaty must demand that parties change their behaviour substantially. Third, the treaty must provide parties with an incentive to comply with the obligations they have pledged to fulfil. Depending on the willingness of the parties engaged in the ongoing negotiations which should be concluded prior to the COP21, the EGA could turn out to the first global climate agreement. [2]

Revising the 2015 Paris Climate Change Agreement Architecture for Better Governance and Outcomes

D. Esty (1)
(1) Yale University, Yale Center for Environmental Law & Policy, New Haven, Connecticut, United States of America

For two decades, the global response to climate change has centered on a top-down, targets and timetables oriented, government-funded, nation-state-driven framework of regulatory mandates. But this international treaty architecture has produced neither the action orientation nor the on-the-ground results needed to address the build-up of greenhouse gases in the atmosphere. Thus, the 2015 Paris Climate Change Agreement should be recast to support a 21st Century bottom-up climate change policy strategy that focuses on broadening «engagement" to ensure that those who make the decisions that matter from the perspective of changed behavior and transformed outcomes -- Mayors, Governors/Premiers, CEOs, and other civil society leaders — are recognized and given more formal roles in the global community response to the climate challenge.

Professor Esty's presentation will explore three elements of what should be done to advance this strategy of broader engagement: (1) options within the 2015 Paris Architecture for formalizing the role of subnational jurisdictions and the other non-national actors -- and ensuring their "ownership" of and leadership on the climate change challenge; (2) a framework of metrics designed to encourage the contributions of this broader set of actors as well as providing structure and mechanisms of accountability for their actions; and (3) a strategy for dramatically expanding the funding for clean energy and other critical climate change investments through a focus on using limited government funds to leverage private capital. He will further explain how a reframed Paris Agreement that promotes broader engagement offers not just a pathway to more successful climate change action but also a 21st Century model for managing international interdependence.

O-4403-03

De-fragmenting the climate regime for a better international climate governance

S. Maljean-Dubois (1)
(1) CERIC UMR DICE 7318, Aix-en-Provence, France

At the international level, a regime complex could be defined as «an array of partially overlapping and non-hierarchical institutions governing a particular issue-area» (Raustiala & Victor). More precisely, regime complexes form «a network of three or more international regimes that relate to a common subject matter ; exhibit overlapping membership ; and generate substantive, normative, or operative interactions recognized as potentially problematic whether or not they are essential in

identifying regime complexes and analyzing their effects» (Orsini, Morin & Young).

Our contribution will try to give a legal analysis of the regime complex for climate change, which has been until now mainly defined and characterized by international relations and political scientists.

After a legal mapping of the regime complex for climate change, the contribution will wonder what role could play the Paris accord in the «de-fragmentation» of the climate regime. Beyond the well-known finding of a fragmented, polycentric and complex international climate governance, how to build a more integrated and effective regime complex on climate change? Much of the institutional innovation in regime complexes arises at the joints between regime éléments. By drafting the Paris accord, negotiators should pay attention to various emergents networks of norms and actors. Finally, how to inject new life into the global community's response to climate change through systematic links (legal or institutional, formal or informal) to other regimes like for example the trade regime, the ozone regime or the biodiversity regime?

Our work forms part of a collective interdisciplinary project funded by the French National Research Agency and named CIRCULEX (Circulations of Norms and Actor Networks in Global Environmental Governance <ANR-12-GLOB-0001-03 CIRCULEX>). Concerning the international regime complexes for climate change and biodiversity, the first objective of CIRCULEX is to highlight the plurality of "sites of governance» and formal and informal links between these sites. This work highlights the diversity of actors involved and their modes of interconnection, as well as the diversity of standards that circulate in the complexes, in terms of origin, content and scope. A first set of conclusions could be drawn about the internal dynamics of regime complexes, conflicts and convergence of standards and interconnections with other regimes. We describe also the modalities of circulation of norms and experts in the regime complexes, and measure the permeability of economic actors to environmental governance standards, evaluate the interrelationships between public and private actors in the regulation. Finally, our project highlights the impacts of norms and networks of actors on the functioning of regime complexes, especially in terms of implementation and effectiveness. Does permeability favor a greater effectiveness of regimes or not ?

O-4403-04

The role of the trade system in promoting climate action

S. Hawkins (1) ; R. Meléndez-Ortiz (2) ; I. Jegou ()

(1) International Centre for Trade and Sustainable Energy, Climate & Energy, Geneva, Switzerland; (2) ICTSD, Geneva, Switzerland

COP21, scheduled for December 2015 in Paris, is expected to deliver a "protocol, another legal instrument or an agreed outcome with legal force under the Convention applicable to all Parties". Whereas the exact shape of the future climate change architecture is still to be defined, the work under the ADP, including the INDC-process, indicates that we are heading towards an approach of best-endeavor pledges by countries on individual mitigation contributions.

An advantage of this scenario is that it gives much leeway to countries to design and implement climate policies which suit their individual situations, needs and capacities. Among the challenges to be addressed are first how to ensure that the individual contributions add up to an ambitious enough response to climate change, and second that they are if not coordinated so at least mutually supportive.

In this context, the emergence of collaboration between groups of countries in "clubs" is an interesting and noteworthy development. Indeed, framing climate deals in smaller groups, designed in a way that encourages expansion of membership and linkages among groups over time, could be an effective way forward which complements multilateral efforts and reinforces the dynamic towards reaching collective agreements.

Taking into account the complexity of designing deals in the UN-oriented system of diplomacy, encouraging smaller club-like initiatives could contribute to the larger climate goal.

A recent ICTSD paper[1] identifies six main tasks that clubs could perform. They could provide a forum for enthusiastic countries to "do the deals" that would get reluctant countries to make bigger efforts; play a role in designing smart Border Carbon Adjustment Measures, BCAs; craft conditional commitments; craft and demonstrate technology strategies; tackle easier problems and last, learn how to help countries adapt.

In order for clubs to be effective and eventually attract new members, they will need to rest on coercion and on positive incentives working to ensure the realization of real gains. In this context, there may also be a need to develop benefits that are exclusive to club members. In the area of climate change, this is particularly challenging as the main gain of joint action on mitigation is aggregate emissions abatement, the benefits of which accrue to the whole world.

The possible linking of clubs, as well as the creation of certain exclusive benefits, are pertinent questions with respect to the world trade system. Can and should trade governance play a pro-active role to promote and facilitate the interplay between clubs, and if yes in what respect?

This intervention, based on recent and upcoming work in ICTSD, in particular under its joint E15-initative, will address such questions. [2]

O-4403-05

Internal coherence of the Paris outcome and connections to other regimes : conditions for confidence, cooperation and ambitious action for climate

T. Ribera (1)

(1) Institute for Sustainable Development and International Relations, Paris, France

From the experience of the last Conferences of the parties to the UNFCCC, many things have changed in a very short time. Climate negotiations are not any more to be considered a zero sum game, but are now explicitly aiming to gather all countries in order to strengthen cooperative approaches, learning processes and mutual reinforcement of each one's efforts towards their own decarbonized and climate resilient future. The biggest challenge is to consolidate confidence, among governments and also from other stakeholders, both on the ability of governments to act and implement climate policies now, and on the ability to build a consistent framework to incentivize further and more ambitious action in the future.

This means, at least, two new streams of work. The first one could be defined as a positive differentiation within the multilateral platform: how to integrate plurilateral action in the multilateral context in order to ensure a common learning process from plurilateral experiences and benefiting from constructive attitudes to speed up the transformation, while also ensuring the capacity to maintain a full multilateral perspective and a global adequacy assessment mechanism. The second one relates to the bridges between the climate community of stakeholders and the outside world, between the climate regime and other regimes of governance at different scales : the objective is to build a new normality where climate action is consistently mainstreamed in other decision processes -either public or private, policy or investment measures, be they sectoral, regional or local-. What are the conditions for such an integration in a diversity of decision frameworks ?

Building the internal coherence of the Paris outcome as well as ensuring its connections to other regimes and fora will be two key milestones for the decades to come. This communication will develop some proposals concerning the expected Paris agreement and the organization of the post COP21 climate regime.

P-4403-01

Avoiding dangerous climate change: the role of shipping in delivering on the IPCC's latest carbon budgets

K. Anderson (1) ; M. Traut (1) ; A. Bows-Larkin (1)
(1) Tyndall Centre for Climate Change Research, University of Manchester, Manchester, United Kingdom

In 2015 and with global emissions rising at unprecedented rates one clear certainty is that the future will be very different from the past. Whether the world continues to follow a trajectory of greenhouse gas emissions exceeding those in RCP8.5, the highest in the IPCC's suite of scenarios and associated with an expected temperature increase of between and 3°C and 5°C, or whether we begin a programme of stringent mitigation, is a decision for the international community. These two paths lead to very different futures, each radically different from the past. This paper reflects on and analyses the role of the global shipping industry as an important player in both these potential futures.

The Kyoto Protocol has called on the International Maritime Organisation (IMO) to "... [control greenhouse gas emissions from shipping]". In 2009, the then secretary general of the IMO concluded that "our collective way of life has become unsustainable" and stressed "the need to make some tough decisions ... and ... to start putting life ahead of lifestyle". In contrast, the baseline suite of six shipping emissions scenarios in the 2nd IMO GHG Study (2009) has CO2 emissions between 2007 and 2050 rise by a factor of between 2.2 and 3.1. Similarly, the 3rd IMO GHG Study (2014) presents a suite of sixteen scenarios, with rises of up to 3.5 times those estimated for 2012.

It is important to that the updated emissions estimates in the 3rd IMO GHG Study (2014) demonstrate a fall in CO2 over the period 2007 to 2012. It argues that much of this emission reduction was due to slow steaming in response to a global economic downturn. Recent emissions reductions may, therefore, represent 'latent CO2', that could be realised once the economic situation changes and vessels revert to pre-crisis speeds.

The paper contrasts the different emissions pathways for the shipping sector, placing them in the quantitative context of global emissions scenarios and associated temperature responses. It concludes that steering a mitigation course has never been more critical, nor the choice more stark.

P-4403-02

Opportunities and challenges for decarbonising the shipping sector

W. Conor (1)
(1) Tyndall Centre for Climate Change research, manchester , United Kingdom

The growth in transport emissions poses a particular challenge in meeting wider 2 °C emission targets. The demand for shipping experienced a significant period of growth during the first half of the previous decade, prompted by growth in regions such as Asia in conjunction with an increasing trade in manufactured material and dry bulk goods. This incentivised speculative ordering of new ships which meant that the fleet experienced over-capacity during the subsequent reduction in demand during the economic downturn. The third greenhouse gas report commissioned by the IMO estimates that between 2007and 2010 CO2 emissions due to international transport decreased by 13%. This can be attributed to an increase in ship size in some instances but also due to a reduction in ship speed, made possible by the overcapacity of ships. Therefore a reduction in ship speed and an increase in ship size (in conjunction with a reduction in demand) represent an opportunity to reduce the emissions associated with the shipping sector.

As the ships which experienced the greatest reduction in speed appeared to be the fasted ships, (such as large container vessels) it could be argued that such vessels will have the most to gain by resuming pre-existing speeds once demand returns. Therefore the cyclical nature of the shipping sector may be seen as an opportunity for opportunistic emissions reductions but makes realising long term savings difficult. Through the generation of alternative scenarios for future global shipping emissions, this study seeks to better understand the elements, both internal and external to, the shipping sector which may assist or hinder it in reducing its emissions, commensurate with meeting wider 2 °C targets, which require a significant reduction in carbon emissions by 2050. For example while a significant reduction in speed is necessary, it must also be compensated for by making sure sufficient fleet capacity (in terms of number and size) is available to ensure adequate scheduling needs are met.

Furthermore as shipping remains a derived demand, changes to existing trading patterns will influence the extent to which the sector can decarbonise. However the shipping sector itself cannot readily influence the demand for trade. Scenario results show that under a different decarbonisation scenarios, a reduction in fossil fuel trade may be compensated for by an increase in biomass trade, or the successful implementation of carbon capture and storage technology may allow fossil fuel trade to continue. A scenario in which the future demand for trade is projected to increase makes decreasing the carbon intensity of shipping even more important. In that regard, decarbonisation cannot be envisioned without penetration of both appropriate technologies and the availability of alternative low carbon fuels. The scale of the emission reduction necessary implies that widespread uptake of new-build and retrofit technology will be necessary. The efficiency of former will depend on levels of ship turnover which also reflect fluctuations in the shipping market. Supporting technological uptake will necessitate the availability of appropriate financing and opportunities to de-risk the uptake of new technologies. This will require identification of the most appropriate technological solutions, such as identifying the optimal routes for the application of wind technology. However lack of available berth space as well as a lack of appropriate training can impede the uptake of retrofit technologies.

Despite the scale of the challenge, the shipping sector arguably has greater opportunity to decarbonise than other sectors, such as aviation sector. However, given the urgency, it is imperative to identify synergies which may assist in sectorial decarbonisation in the near term. A reduction in trade demand, in conjunction with an increase in ship size will make a reduction in speed more viable, which can increase the impact of low carbon technologies. Modifying the conditions of vessel hire or enhancing supply chain flexibility will also assist in making fuel savings more attractive and viable. In summary, allowing shipping to meet its commitments within a 2 °C framework may not be wholly within the gift of the sector itself and will require support from the wider system of which shipping is a reactive part.

P-4403-03

Geography of International Trade, Maritime Transport and Climate Change in XXI Century: A Descriptive Basis for Multilateral Action from a South Perspective

E. Tancredi (1)
(1) Universidad Nacional de Lujan, Departamento de Ciencias Sociales, Lujan, Argentina

This paper puts the focus of its analysis in the relationship among the main tendencies of the international trade of goods, the essential characteristics of the seaborne trade and the challenges of climatic change. From the beginnings of the XXI century, three economic characteristics can be pointed out. First, the significant expansion of the global value chains that represent the new form of disintegration and de-localization of the production of goods and services which has driven to a new international division of the production (WTO, 2014). Second, the deepening of the regional integration and the cooperation South-South that reconfigure the seculars unequal relationships between the North and the South. In third place, the exponential growth of commercial exchanges. In this context, 80% of the world trade is carried out by maritime mean. Supply places have been diversified due to technological improvements and transport efficiency. Marine routes have been enlarged and new ones have been open (i.e. Channel of Panama and Artico routes). While some emergent economies (specifically in South Asia) reorient their exports toward medium and

high technological incorporated manufactures, many other monopolize their exports in agricultural products or mineral resources. Volumes expanded at the rate of 3.8% of nearly 9.6 billion tons. Of these shipments, dry cargo (major and minor dry commodities carried in bulk, general cargo, breakbulk and containerized trade) accounted for the largest share (70.2%), followed by tanker trade (crude oil, petroleum product and gas) which held a 29.8% share (UNCTAD, 2014). Developing countries have increased their contribution to these flows, although in an uniqual contibution at individual terms. Regionally, Asia remained the main loading and unloading area in 2013 with its share of imports (unloading) being particularly dominant. Americas is the other major loading area and Europe on the unloading side. These shares are likely to further evolve with changing trade patterns and partners, the emergence of Africa and developing America as areas with a significant growth potential, and fast growing trade on secondary container trade routes supporting South-South and intraregional trade. Global containerized trade is projected to grow, given among other factors by improved prospects for mainlane East-West trade. The global fragmentation of the production and the development of multimodel systems of international transport are the elements that also lead to a reorganization of the ports.In this context, the sector of marine transport needs to adjust its commercial strategies to adapt to the changes of the world economy and rules of the trade, besides risks and current environmental uncertainties. As world seaborne trade increases, the main challenges - especially from the perspective of a social and environmentally sustainable development, as well as from the point of view of the transport and trade facilitation - consist in reducing the GHG (mainly CO2) emissions from international shipping and define mitigation and adaptation policies. In terms of CO2 emissions/ transported ton, it is recognized that the marine transport is the more effective one. Nevertheless, due its enormous scale, it is estimated that ship emissions (especially from oil-tankers and container ships) represent 11,8% of the emissions of the transport sector and 1,6 to 4,1% of the CO2 world emissions resulting from burning; according to the International Maritime Organization (OMI), they will increase in a factor from 2,4 to 3 between 2007 and 2050 (UNCTAD, 2008; OMI, 2009; OMC/ PNUMA, 2009) This linking of climate change challenges with the tendencies of international seaborne trade and their emissions of GHG have relatively little presence in the multilateral negotiations. But OMI has recently adopted a group of technical and operative measures to improve the energy efficiency and of GHG emission from ships with the aim to promotes trade but in turn energy efficiency and sustainable development, according to the principle of the common but differed responsibilities among developed and developing countries. In this sense then, it is sought to advance in this proposal a detailed characterization of the main tendencies of international trade and seaborne trade in the XXI century, analyzing their complex links with climate change, and the main challenges for a negotiated multilateral action, putting the accent, as case analysis, in the emergent economies of Latin America (in particular Brazil, Mexico and Argentina).

4404 - Climate finance: New sources, new instruments, more effects ?

ORAL PRESENTATIONS

K-4404-01

Sources and instruments for climate finance

A. Torvanger (1)
(1) CICERO, Oslo, Norway

Long-term investments in climate-friendly and climate change resilient infrastructure, buildings and energy is essential to both mitigate greenhouse gas emissions and adapt to climate change impacts. Such climate finance is particularly in need in many developing countries due to limited economic resources and expected impacts from climate change. Direct government contributions can help, but a large share of the agreed 100 Bill. USD annually from 2020 for climate measures in developing countries can only realistically come from the private sector.

What is the status of sources and channels of long-term climate finance? I present a new status report on the most promising sources of climate finance. Relevant sources are public carbon-related revenues (taxes and emissions trading), carbon offset markets, international transport, removal of fossil subsidies, direct budget contributions, finance development institutions, private flows, green bonds, 'debt-for-climate' swaps, and export credits.

What can developed country governments do to catalyze private sector investment in developing countries? There is a range of de-risking interventions and instruments available, from credit enhancement to guarantees.

Green bonds finance low-carbon or climate-robust projects. Private sector investment in green bonds has tripled in each of the last two years. Pension funds, insurance companies, and socially responsible investors are increasingly investing in green bonds. Can the momentum of the green bond market be harnessed to make a real difference to the climate and for climate finance in developing countries? Can Green Bonds funding be combined with multilateral climate finance such as the Green Climate Fund?

Key issues discussed are:

- What are the most promising sources of climate finance?
- What is the scope for government de-risking of private finance?
- What government measures are most efficient to stimulate private finance?
- To what extent can Green Bonds make a difference in climate mitigation and adaptation?
- How can Green Bonds be adapted to the needs of developing countries?

How can governments facilitate Green Bond investments in developing countries?

K-4404-02

Mobilising capital for green infrastructure investments

C. Kaminker (1)
(1) OECD, Environment Directorate, Paris, France

A keynote presentation focusing on OECD analysis on what developed country governments can do to catalyse private sector investment in green infrastructure of developing countries.

The presentation would cover key lessons from the following OECD work streams: Mapping Channels to Mobilise Institutional Investment in Sustainable Energy: An OECD Report for G20 Finance Ministers and Central Bank Governors; which uses an empirical base of 70 deals to identify barriers and advise on how governments can overcome them to mobilise institutional investment in sustainable energy and how governments can support the development of potentially promising investment channels and consider policy interventions that can make institutional investment in sustainable energy infrastructure more likely.

Green Bonds: a new report will analyse the potential, barriers and policy solutions for scaling up green bonds across their various different forms (including municipal, corporate, asset-backed, covered, project).

The OECD-led Research Collaborative on Tracking Private Climate Finance, an OECD-led network of governments, research institutions and international finance institutions. Over the past two years it has explored data and a range of methods to estimating private finance mobilised by developed countries for climate action in developing

countries. In 2015, work conducted under and in co-operation with the Research Collaborative will focus on the further development and ground-testing of estimation methods in the context of pilot measurements of mobilisation for climate-relevant sectors, different types of interventions/instruments, as well as at the level of individual/groups of countries and public finance institutions.

The OECD Policy Guidance for Investment in Clean Energy Infrastructure: Expanding Access to Clean Energy for Green Growth and Development is a good example of our efforts to improve the enabling conditions for private investment in clean energy infrastructure. Non-prescriptive tool to help governments identify ways to mobilise private sector investment in clean energy infrastructure, annexed to the Communiqué of G20 Finance Ministers in 2013.

OECD report on Overcoming Barriers to International Investment in Clean Energy discusses the rise of hidden indirect protectionism in clean energy since the 2008 financial crisis. The report provides empirical evidence on the negative impact that LCRs have on international investment in solar PV and wind energy, as they increase the cost of inputs for downstream segments of the value chain like renewable energy-based electricity generation. By assessing the impacts of measures such as LCRs across different segments of the value chains, this report provides policy makers with evidence-based analysis to guide their decisions in designing clean energy support policies.

O-4404-01

Result Based Financing for Mitigation: choosing the right "triggers" to drive a "paradigm shift"

R. Spalding-Fecher (1)
(1) Carbon Limits AS, Pelham, United States of America

Results-based finance is an emerging tool to link public and private financing to a more sustainable and climate-friendly future. The main goal of many of these new funding sources is to create a "paradigm shift" towards low carbon and climate resilient development. But what does this mean for how new mitigation financing could be allocated and what types of projects, programmes or larger policy changes could be targeted? This contribution explores two specific question in the RBF decision making process. This first is how to ensure that RBF for climate finance promotes mitigation even after the payments for emissions reduction stop, and supports technologies and practices that are part of the "end game" for climate stabilisation. Long term results typically require policy and institutional changes, which are not normally linked to project or programme-based financing. In addition, focusing on long term results means avoiding technology "lock in" and driving innovation in mitigation technologies. The second question is what type of non-climate criteria are needed for RBF, including environmental and social safeguards, and how might these be integrated in the payment system. In other words, how might non-climate impacts not only be monitored, but how would their achievement (or avoidance) affect the results-based payments.

O-4404-02

Smart Unconventional Monetary (SUMO) policies: giving impetus to green investment

R. Morel (1) ; B. Leguet (1)
(1) CDC Climat, PARIS, France

Today, given the amount of investment needed to reach a 2-degree emissions reduction target and the tight budgetary constraints of governments worldwide, public spending alone will not be sufficient alone. Therefore, there is a double need to not only shift private financial flows from "brown" sectors to "green" sectors, but also to leverage new sources of financing. Addressing the second challenge, this study reviews three families of proposed funding mechanisms based on unconventional monetary policies targeting "green" or "climate" investments. These "Smart Unconventional MOnetary" (or SUMO) policies include: (i) the use of Special Drawing Rights (SDRs) issued by the International Monetary Fund (IMF), (ii) green quantitative easing and (iii) the issuance of Carbon Certificates.

This contribution will first present the basic elements of these three approaches. It will then identify and discuss the implementation challenges to overcome. These include both concerns over inflationary worries as well as the difficulty to reach multilateral agreements in the short run, and the involvement of the private sector. Finally, the presentation will look at the key conditions for ensuring the environmental integrity of the unconventional monetary policies, both ex-ante - during the selection of eligible projects - and ex-post . This contribution will look at lessons drawn from Monitoring, Reporting and Verification (MRV) methods used in the Clean Development Mechanism as well as other existing schemes (white certificates, etc.).

P-4404-01

Public Financial Institutions and the Low-Carbon Transition: Five Case studies on Low-Carbon Infrastructure and Project Investment

I. Cochran (1) ; V. Marchal (2) ; R. Hubert (1) ; R. Youngman (2)
(1) CDC Climat, Paris, France; (2) OECD, Climate, biodiversity and water division, Paris, France

This study, jointly undertaken by the OECD and CDC Climat Research, analyses the role of Public Financial Institutions (PFIs) in fostering the low-carbon energy transition through domestic climate finance activities. The study maps the key tools and instruments currently used by five institutions to mobilise private sector investment in low-carbon infrastructure projects in OECD countries in three sectors: sustainable transport, energy-efficiency and renewable energy. Between 2010-2012, these five institutions - Group Caisse des Dépôts in France; KfW Bankengruppe in Germany; the UK Green Investment Bank; the European Investment Bank and the European Bank for Reconstruction and Development - have provided over 100 billion euros of equity investment and financing for energy efficiency, renewable energy and sustainable transport projects. The results of the study indicate that these institutions play a key role in leveraging private sector participation in low-carbon, climate-resilient investment through the use of traditional and innovative approaches to link low-carbon projects with finance through enhancing access to capital; facilitating risk reduction and sharing; improving the capacity of market actors; and shaping broader market practices and conditions.

P-4404-02

Tracking low-carbon investment in France in 2011: a landscape of sources, flows and channels

R. Morel (1) ; I. Cochran (1) ; R. Hubert (1)
(1) CDC Climat, PARIS, France

This report presents the first comprehensive view of climate finance flows in France to reduce GHG emissions. Funding for the energy transition is a central issue for which the available data are often incomplete. This report aims to further the current debate by providing economy-wide estimates. This study identified and analyzed the investment spending in France in 2011 that contributed directly or indirectly to the reduction of greenhouse gases emissions (GHG); this corresponds to investment in low-carbon infrastructure and fixed assets (renewable energy, building high environmental quality, public transport, etc.). This information has been used to identify the distribution of flows across sectors, the share of different instruments, their use and the role of different actors.

This analysis has identified EUR 22.2 billion of investment in France in 2011in physical or tangible assets that reduce greenhouse gas emissions. Across all sectors, renewable energy accounted for EUR 9.0 billion of investment, including investment subsidies of 1.0 billion EUR. Energy efficiency was the second largest area of climate investment, totaling EUR 8.3 billion. The share of grants and concessional loans - with thus a cost for the public sector - totaled EUR 2.3 billion. These investments are

concentrated in the construction sector (buildings) (EUR 6.7 billion).Private actors financed 75% of renewable energy and energy efficiency investments. In the transport sector, the picture is less clear as project were initiated principally by public bodies, and with financing provided (through debt and other means) in part by private actors. The EUR 22.2 billion annual investment estimated by this report – and excluding investments in the nuclear energy – is below the annual flows identified as necessary to achieve long-term objectives. The financing challenge should thus not be underestimated. The Panorama France 2011 suggests that part of the funding needed for the energy transition is already being provided, however efforts are still needed to reach long-term climate and objectives.

4405 - On the macroeconomic opportunity of climate policy

Why finance ministers might favor carbon taxes, even if they do not believe in climate change

O. Edenhofer (1) ; M. Franks, (2) ; K. Lessmann (3)
(1) Potsdam Institute for Climate Impact Research, Potsdam, Germany; (2) Potsdam Institute for Climate Impact Research (PIK), Potsdam, Germany; (3) Potsdam Institute for Climate Impact Research, Sustainable solutions, Potsdam, Germany

The economic forces of globalization constrain democratic governments increasingly. According to Dani Rodrik, we cannot have democracy, national sovereignty, and hyperglobalization at the same time (Rodrik, 2011)[1]. Hyperglobalization impinges on democratic choices within sovereign nations by giving rise to corporate tax competition, which "restricts a nation's ability to choose the tax structure that best reflects its needs and preferences" (ibid., p. 193). Declining corporate tax rates, complemented by a rising share of labor taxes, give evidence of the resulting race-to-the-bottom.

The fact that this race-to-the-bottom impedes a government's ability to raise sufficient funds has far reaching consequences. Funds are required, e.g., not only for health care or education, but also for productive public infrastructure, which is important for both efficiency and equity. Accordingly, an emerging consensus in the empirical literature suggests that these stocks are underfinanced. This raises the question how to reduce exposure to tax competition and generate funds to finance essential public goods.

We identify taxes on the use of carbon resources as a superior alternative to capital taxes. Even though fossil resources are also traded internationally, there is an asymmetry in efficiency between capital and resources as tax base. While ownership of fossil resources gives rise to a rent, capital does not. Taxes on either factor cause an interregional reallocation by driving economic activity out of countries with relatively high tax rates. The carbon tax has the advantage, though, of capturing part of the resource rent. Governments can use the appropriated rent for productivity enhancing infrastructure investments, which in turn attracts investments in domestic capital stocks.

Further, it turns out that a carbon tax may not only have fiscal benefits. When the motivation to tax the use of fossil resources is based exclusively on fiscal needs, then resource exporters react by reducing both the rate (a timing effect) and the cumulative amount of resource extraction (a volume effect). Thus, carbon taxes do not cause a green paradox in this situation, but can be part of an effective green tax reform. Governments may not take climate externalities into account, as modeled in our paper. In that case, timing and volume effects per se do not affect decisions about fiscal policy. Nevertheless, these observed effects show that a unilateral tax reform which introduces a carbon tax also has beneficial environmental implications.

Our contribution is thus twofold. First, we bridge the gap between horizontal fiscal federalism, in particular the tax competition literature on the one hand, and the economics of exhaustible resources on the other. Using a numerical general equilibrium model we compute optimal tax portfolios and precisely assess their opportunity costs. To our knowledge, our model is the first to combine the following key features. We implement a decentralized market economy with several representative agents and strategically interacting governments. The tax instruments, which governments use to finance productive infrastructure stocks, are determined endogenously for both cooperative and non-cooperative behavior in the Nash equilibrium. Capital and fossil resources are traded on international markets. Finally, we include the intertemporal dynamics of capital accumulation and resource extraction (based on the respective models of Frank P. Ramsey and Harold Hotelling). Second, we shed light on the supply side dynamics of fossil resource extraction. So far, most of the research on the conditions under which a green paradox occurs has used partial equilibrium analysis. Only recently has this strand of literature been extended to general equilibrium. Now, we take even one step further. Our model allows strategic interactions between fossil fuel selling and buying countries, as well as among the governments of buying countries themselves.

We conclude that even when governments do not intend to address climate change, they still have an incentive to implement a carbon tax to improve their fiscal policy. Then, the carbon tax nevertheless helps mitigating the adverse effects of climate change. It is thus not only the environmental ministers who should favor carbon taxes, but also the ministers of finance.

Climate change and adaptation. A new opportunity for public debt relief?

E. Delpiazzo (1) ; C. Carraro (2) ; F. Bosello (3)
(1) CMCC, Venice, Italy; (2) FEEM, Climate change and sustainable development, Milan, Italy; (3) University of Milan, FEEM, and CMCC, Dep. of economics, Milan, Italy

Notwithstanding a consolidated and vast literature on the possibility to conjugate development and environmental protection, a view still rooted in the policy domains considers the environment as a luxury good less important than social goals like growth or employment. This is epitomized by the climate change challenge. On the one hand the trade-off development/ GHG mitigation is at the heart of the difficulty to involve developing countries in an international agreement on emission reduction. On the other hand, especially in a background of a financial crisis along with high levels of indebtedness and aging population, high unemployment levels and the need for fiscal outlays for unemployment compensation or welfare benefits, climate change policies seem to appear as something which would not be regarded as an urgent policy also in many European countries. In fact, in a situation where public budgets are overstretched due to economic crisis, there is an increasing need to understand the implications of climate change impacts, climate change mitigation and adaptation policies on the fiscal side.

This is particularly true for those countries which experienced growing levels of deficit and debt in the last decades, and especially for adaptation that typically implies an increase in expenditure coming from the public sector. In this context, cuts in public expenses to reduce the gap between revenues and expenditures might appear to be the winning strategy, however there are also impacts to cope with whose timing and magnitude are uncertain as uncertain are their fiscal effects. Policy intervention may lead to an inefficient result with negative ramifications for the economy if adaptation measures are either too paltry or too ambitious. Different options also have different implications for fiscal costs and government revenues.

We tackle these issues using a recursive-dynamic Computable General Equilibrium (CGE) model: the Intertemporal Computable Equilibrium System (ICES) model, enriched with a more realistic description of the government sector both on the revenue and the expenditure side. The relations between debt sustainability and climate change are analyzed both in their short-term

and long-term dimensions.

More specifically: firstly, we assess the "direct" or "first round" effects of climate change on the public budget through changes in total tax revenues induced by impacts on production, consumption patterns and trade structure. This also originates indirect fiscal costs (or second round effects) as it impacts governments' fiscal capacity.

Then, we introduce the possibility of adaptation expenditures to reduce the climate change impacts. We explore adaptation long-run effects on fiscal capacity and fiscal flexibility under different assumptions of financing. Could there be room for issuing more debt (adaptation bonds) to cover climate adaptation expenditure inducing anyway in the long term a decrease in the debt/GDP ratios exploiting adaptation effects on avoided future damages? Even though possible, would it be more efficient and growth enhancing to support adaptation expenditure with revenues from other, e.g. carbon-energy, taxes? What are the different crowding out effects on public/private investment?

It can be established, that climate change has introduced a new aspect into the structure of public finances both in expenditure and in revenue side. In the context of the current multi-year crisis, public finances in the EU are strained, and thus the fiscal consequences of climate change are important to estimate and the worst case scenarios need to be avoided. From few case studies in literature, it is evident that the fiscal consequences are not negligible. However, there has not yet been any study that satisfactorily addresses the way climate change and adaptation affect the state budget, and particularly its stability, in a general equilibrium framework.

Complexity and Green Growth: A Practical Perspective

S. Van Der Leeuw (1)
(1) Arizona State University, Tempe, Arizona, United States of America

Practical policy aiming to seize macroeconomic opportunities for climate policy has to deal with complex interactions between macro-variables and the many processes that may or may not lead to such opportunities. The Global Institute of Sustainability at Arizona University is presently involved in a Chinese initiative to implement a green growth strategy in a poor rural region where these interactions can be investigated in real time.

The initiative is based on the seminal report «China 2030» produced by the Development Research Council (DRC), the think-tank of the Chinese prime minister, together with the World Bank. This report outlined the new growth strategy pursued by the Chinese leadership installed in 2013. The key macroeconomic variables relevant for the initiative are straightforward: GDP, employment, etc. The policy variables, however, are much more complex than typical discussions about simple variables like carbon prices, government deficits and the like suggest.

The initiative started by outlining a shared vision in an intense dialogue between the provincial government, DRC and international partners like Arizona State University and the Global Climate Forum. This on-going dialogue involves a wide variety of local actors. An instructive example is the founder of a large company for electric bicycles who established a green theme park in the region in question. A key instrument to launch this dialogue was a trans-continental conference on green growth connecting audiences in America, Europe and China. On this basis, a selection process is presently under way in order to determine initial intervention points. These may include sites for a green community center and an international study center, collaborations between specific enterprises and research institutions, platforms for e-commerce and e-learning, product designs to create a regional green growth brand, and more. A commercially operating green-growth investment funds will be established by leveraging contributions from the provincial and central governments. In a step-by-step process these initial interventions shall lead to new, environmentally friendly jobs and revenues, expanding up to the point where macroeconomic advantages for the region in question become visible and can be reproduced in other regions.

The initiative is based on a series of theoretical conjectures and insights. They include the following:

- the environmental crisis is fundamentally due to the inability of present societies to process the complex information flows generated at the interface between society and environment
- therefore, effective crisis responses require an enhancement of the societal capacity to process complex information by combining new information technologies with new concepts and institutions
- in particular, this means to increase the division of labor by reducing transaction costs, in line with the insights of Adam Smith, Xiaokai Yang and others
- it also means to embed climate policy in a comprehensive vision of green growth
- this strategy fosters cultural diversity by treating money not as the common denominator of preferences and values but as one of several dimensions of social status competition
- a competition for successful models of green growth is a promising way towards a transition to global green growth.

K-4405-04

Modelling the macroeconomic opportunity of climate policy

S. Wolf (1) ; F. Schuetze, (1) ; C. Jaeger (1)
(1) Global Climate Forum, Berlin, Germany

Economic policy analysis modelling has largely depicted climate change mitigation as a drag on economic development. In contrast, concepts as green growth or green economy and results of recent studies, such as the New Climate Economy Report, suggest that reducing emissions need not slow down but may benefit the economy.

The possibility of protecting climate while enhancing economic development deserves to be carefully researched; economic models constitute an important tool for doing so. Unfortunately, this possibility is beyond the horizon of the marginal analysis conducted with many conventional climate policy analysis models. Rooted in the general equilibrium framework, these models mostly find economic costs of mitigation when optimizing in the vicinity of a «business as usual» equilibrium.

A survey of models that can represent economic benefits from climate change mitigation reveals a large spectrum of approaches for going beyond this standard modelling setup. At the more conventional end of the spectrum, the literature provides theoretical model extensions, for example to address external effects, that open up the possibility of positive economic effects from climate policy. Computational models further away from the general equilibrium and optimization approach, such as system dynamics models or a macroeconometric model for climate policy analysis, can be viewed as the other end of the spectrum. Within the general equilibrium framework, but outside common modelling practice, several studies conceptualize the current fossil-fuel based economy and a low carbon economy as different equilibria of the economic system. For example, inframarginal economics generalizes the marginal analysis approach by considering different structures of specialization and division of labour. By modelling structural change to the division of labour that is triggered by mitigation policy, the possibility of green growth can be represented and analysed. Similarly, an analysis of a virtuous circle of expectations, investment and learning-by-doing has shown that investment oriented climate policy can induce a shift to a new growth path with lower emissions but higher growth and employment.

This contribution focuses on the question how climate policy can facilitate a recoordination of investors' expectations so as to induce a transition to a green growth equilibrium and how this can be modelled.

Overview of climate finance at scale

TE. Downing (1)

(1) Global Climate Adaptation Partnership, Oxford, United Kingdom

Climate finance is essential to reducing climate risks, and take advantage of emerging opportunities. This presentation introduces a panel on Climate Finance At-scale. Four questions drive the search for solutions:

1. Three major domains--sustainable development, climate change and disaster risk management--are negotiating goals, governance and finance in 2015. What modalities of governance achieve synergies?

2. Achieving at-scale impacts requires transformative investment: What are the modes and prospects for engaging the private sector?

3. Negotiations on loss and damages are well advanced and widely seen as a mechanism for scaled up finance. What are the prospects for a robust analytical regime?

4. Transformation of climate resilience requires leadership that recognises emerging good practice: What does recent research offer to inform sound investment in adaptation?

O-4405-02

Managing Climate Change Risks and Vulnerabilities: A Microfinance and Climate Finance Perspective

D. Chirambo (1)
(1) Seeds of Opportunity, Blantyre, Malawi

Climate change touches upon a myriad of inter-related and multi-dimensional aspects of societies, economies and the environment. From an African perspective, climate change may be considered as a phenomenon that may seriously hamper the continent's future development and pose as an additional impediment to sustainable development. Since climate change impacts are anticipated to vary across countries and localities with some geographic regions being anticipated to suffer more from climate change than others due to variations in national capacities, it can be argued that the poorest and most vulnerable groups and countries will likely be the most affected, consequently increasing world inequality.

Even though different countries have various models and approaches for climate change risk assessments and management, it is widely believed that in-order to reduce the impacts of climate change on various countries, and to ensure that international consensus and policies for climate change mitigation, adaptation and financing can be achieved, the post 2015 development agendas should increase funding towards climate change initiatives most notably in developing countries and promote mechanisms for raising the capacity for effective climate change management in Least Developed Countries (LDCs), including focusing on women, youth and local and marginalised communities

To date, most climate financing modalities and projects in Africa have had limited or no effect in terms of poverty alleviation and sustainable development due to a lack of emphasis on strengthening the participation of marginalised groups, and the continent's adaptation deficit as caused by a lack of institutional, financial or technological capacity to adapt effectively to climate change. In addition to this, even though climate financing for mitigation and adaptation should be addressed with the same priority, research has shown that the implementation of climate finance modalities are highly construed towards mitigation efforts whereby 91% of climate finance flows are for mitigation efforts, 7% for adaptation efforts and 2% for activities with both mitigation and adaptation objectives. Cumulatively, these issues suggest that most communities in Africa could be becoming more vulnerable to the impacts of climate change.

Recent research shows that almost three-quarters of climate finance flows are invested with the expectation of earning commercial returns, hence signifying the need for innovative climate financing models that provide win-win situations for funders and recipients, as well as the world at large as the risks and consequences attributed to climate change can be minimised. In-order to determine the opportunities that exist in enhancing the capacities and opportunities for microfinance for climate change mitigation and adaptation initiatives, and disaster risks and management, this paper expounds the Microfinance-Climate Finance Framework that was shortlisted for the 2014/2015 UNDP MDG Carbon Climate Finance Innovation Award. Using this framework, it is possible to highlight the challenges and opportunities that microfinance institutions could have in the mobilisation of funds and resources from various types of funders, and redistribution of funds and resources to various types of recipients. This paper concludes that fostering international and domestic policies that encourage remittances and financial inclusion may be an effective strategy to encourage microfinance based climate change management funding.

Relative price adjustment of energy and labour: The case of energy-dependent and small open economies

E. Combet (1)
(1) Centre International de Recherche sur l'Environnement et le Développement (CIRED), Nogent-sur-Marne, France

The increase in energy prices is the corner stone for policies that seek to manage efficiently energy systems in the long run (including climate policies). However, such a price increase may harm the economy during the transition, when substitutions have not yet taken place. In this paper, we consider an increase in the relative price of energy with respect to labour, and we analyse its consequences for aggregate domestic production and employment. We develop a general equilibrium model of small open-economy assuming unemployment and high dependence to imported energy. Simplified enough to be solved analytically, this model does not restrict the analysis to the neighbourhood of an optimum. We examine how the qualitative result - a net positive or negative impact on production and employment - is sensitive to a set of debated parameters on 1) the behaviour of the economy (the reactions of domestic wage and the response of external trade), and 2) the initial state of the economy (the levels of energy consumptions, unemployment and wages, the import price of fossil energy, and the relative initial taxation of energy and labour).

P-4405-02

Carbon Tax, Pensions and Deficits

E. Combet (1)
(1) Centre International de Recherche sur l'Environnement et le Développement (CIRED), Nogent-sur-Marne, France

This paper aims to draw attention on the consequences of the prevailing intellectual compartmentalization between 'energy and climate', on the one hand, and 'the viability of social security systems', on the other. We take the methodological venture of building a general equilibrium model to analyse jointly these issues. The model is applied to France and projected to a future horizon (2020). It ensures consistency by linking together 1) a description of the future constraints on energy and demand, and 2) a partial forecasting scenario of the pension system. First, we analyse two types of archetypical reforms that use one instrument to meet one objective. The first type recourses to one of the present instruments of the pension system (social security contributions on wage income, age of retirement). The second type absorbs the deficits of the pension system by preempting revenues generated by the climate policy (here a carbon tax). After examining the limitations of those single-instrument/single-objective policies, we provide an example of a multi-objective policy package that enables the limitations to be removed. In so doing, we present a way of exploring potential synergies between long term development goals.

The role of transparency and accountability for impact investment

B. Fernandez Milan (1) ; M. Hoffmann, (2)
(1) Mercator Research Institute on Global Commons and Climate Change, Berlin, Berlin, Germany; (2) Software Systems AT, Finance & ethics research group, Diex, Austria

Today's financial markets are characterized by globalization and interdependence, while nations around the world are still suffering from the economic and social aftershocks of the global financial crisis. Politicians, economists, NGOs and concerned citizens have scrutinized the weaknesses of the current financial system. A consensus is emerging that the current financial and economic structures are not sustainable and the danger of another socioeconomic crisis persists in spite of a plethora of regulatory changes. A grass-roots movement for sustainable development is leveraging investments as a tool to achieve social and ecological benefits while promoting fundamental structural changes in the finance industry and in public finances. A variety of innovative investment strategies including ethical, "green", "social", "responsible" investments as well as social banking and sustainable investing combine social, ethical and/or ecological objectives with financial returns, distinguishing them from so-called mainstream investments pursuing only risk-adjusted returns. At the same time, many large financial institutions have jumped on the "sustainable investment bandwagon", trying to profit from the rapidly growing demand for sustainable investment products by "greenwashing" conventional investment products, which do not offer any sustainability benefits. Contradictory marketing claims confuse potential investors and prevent the successful mainstreaming of genuine sustainable investment products. False marketing claims lead to consumer cynicism and growing mistrust towards the financial services industry. We draw upon a case study of "Impact Investments" to explore this issue. We are going to utilize analogous cases in different industries to draw lessons for marketing and certification strategies for Impact Investments. In view of the insights from diverse economic sectors, e.g., the chocolate, forestry and fishery industries, we observe that certification systems are an efficient mechanism to foster principles of sustainable development within a globalized market economy (i.e. Fair Trade, Forest Stewardship Council, Marine Stewardship Council). We further identify the current certification schemes existing in the financial sector and discuss their repercussions, also considering ongoing projects that seek to tailor accounting guidance to different actors of the financial system. Based on the insights taken from these case studies, we plead in favour of the idea that a standardized international certification would help to restore trust in financial services and help to mainstream impact investing (getting it out of the «green niche»). Certification could help impact investments gain the necessary «critical market share», and ultimately, intentionality to consume impact investment products.

Impact of community own revolving fund in adapting with changing climate in Nepal

S. Paudel (1)
(1) The Small Earth Nepal, Kathmandu, Nepal

By now the scientific community agrees that climate change is occurring and its impacts are more in low income countries. Nepal is experiencing significant changes in climate, which have a direct and severe impact on the livelihood of its people, most of whom are still rural. A study has been undertaken to look at the impact of a community own revolving fund – a concept of micro-financing in adapting the changing climate in Nepal. The farmers in three agro-ecological zones of Nepal have been provided with the bucket drip irrigation set for their kitchen gardening, the system which is highly water efficient and less time consuming. The farm cooperative is charging NPR 100 (~USD 1) per set and the money is collected as a source of revolving fund. The money has now been given to the needful member of the cooperative which needs to be invested only in vegetable cultivation sector which gives quicker income. After six months, the amount is offered to the second needful persons and so on. In this particular paper, we describe the fund circulation mechanisms, community engagement on the project and its benefits in short and long run.

Nexus of climate mitigation and key development objectives - An analysis for South Africa

J. Schers (1) ; F. Lecocq (2) ; F. Ghersi (2)
(1) CIRED, Nogent sur Marne, France; (2) Centre International de Recherche sur l'Environnement et le Développement, Nogent sur Marne, France

South Africa is a rapidly growing middle-income economy with a coal-based energy system that generates high greenhouse gases emissions, on par with the richest economies in the World. The country has pledged to significantly reduce its emissions (by 34% in 2020 and by 42% in 2025 relative to business-as-usual, under the condition of finance and technical support from the international community). It is actively discussing policies to achieve this goal, including a carbon tax.

Yet, climate mitigation is not the only challenge that South Africa faces. Despite significant progress in overcoming the inequalities inherited from the Apartheid era and in improving quality of life since the onset of the democratic regime in 1994, economic growth has slowed down in recent years, poverty remains high and large inequalities persist. In particular, the South African economy is still experiencing very high unemployment, in particular amongst low-skill individuals, while there is shortage of high-skill workers.

The present paper aims to provide some insights on the nexus between South Africa's mitigation objectives and the key development challenges outlined above. It focuses in particular on economic growth and unemployment, in the context of inequality and education. For this purpose we developed IMACLIM-SA a dynamic, computable general equilibrium of the South African economy. IMACLIM-SA represents the South African economy as a small, opened economy with ten sectors (five energy, five non-energy) and five household classes. Calibrated on 2005 data, the model produces an equilibrium of the economy in 2035 based on assumptions about change in key parameters.

Particular attention is paid to the input data, with the production of a revised social accounting matrix to match monetary flows drawn from macroeconomic statistics and energy flows drawn from energy tables. The model also captures differences in the prices of goods and services (notably energy) between firms, households, the public sector and exports. We use outcomes of runs of the SA TIMES model of the Energy Research Center of the University of Cape Town to inform changes in electricity production in IMACLIM-SA. Particular attention is given to the labour market, in terms of supply—with three skill classes—, labour demand in production and market functioning and imperfections.

In the reference scenario, given our assumptions, GDP grows at an average rate of 3.4% per year, and GDP per capita more than doubles over the period. It must be noted

that to generate such level of growth in the baseline, we must assume not only capital and labour productivity improvements, but also an increase in international prices relative to domestic ones, thus improving competitiveness of South African products on the export market. Unemployment decreases markedly, though it remains important in 2035, and shortage of high-skill labour persists. In the reference projection, emissions increase substantially, despite implementation of the Updated Integrated Resource Plan of 2013.

We then explore seven policy packages based on the imposing a carbon tax of 100 Rand (ZAR 2005) per tonne of CO2 with different recycling schemes. We find that CO2 emissions in South Africa are sensitive to even a relatively "small" carbon tax by international standards, though it is high relative to 2005 domestic prices of energy. A R300/tCO2 carbon tax might help achieve the country's pledges. This is consistent with prior literature on mitigation in South Africa. Impacts on GDP growth and on unemployment reduction can be significant, with total GDP in 2035 at 2.5% to 15% lower for a R300/tCO2 carbon tax, but strongly depend on the revenue recycling mechanism.

Amongst the recycling options we test, using carbon tax proceeds to reduce a sales tax results in GDP growth on par with the reference projection, plus in a higher level of employment, while CO2 emissions decrease. Using carbon tax proceeds for lump-sum transfers to households underperforms the reference in terms of GDP and employment, but achieves a strong reduction of inequality. Using part of the proceeds to invest in education results in accelerated growth, reduced employment and lower emissions—but this result depends on assumptions concerning the impact of additional investment in education, namely a joint increase in growth of labour and capital productivity relative to the reference projection.

O-4406a-02

A Dynamic General Equilibrium Assessment of the Energy-Climate-Development Link in Mexico

F. Grazi (1) ; G. Landa (2) ; FX. Bellocq (3) ; F. Reynès (4) ; I. Islas Cortes (5)

(1) Agence Française de Développement (AFD), Research Department, Paris, France; (2) OFCE, Paris, France; (3) Agence Française de Développement (AFD), Paris, France; (4) TNO, Delft, Netherlands; (5) National Institute of Ecology and Climate Change, Directorate for sectoral policy, Mexico City, Mexico

This paper offers an empirical application of the notion of energy transition to the Mexican economy and takes the next step of simulating medium- and long-term impacts of proposed and future energy policy on the environment and the Mexican economy. The starting point of the analysis comes from ThreeMe framework, a Multi-sectoral Macroeconomic Model for the Evaluation of Environmental and Energy policy, which is motivated by neo-Keynesian theory. It is designed to address dynamics of global economic activity, energy system development and carbon emissions causing climate change. The ThreeMe model is well suited for policy assessment purposes in the context of developing economies as it informs the transitional effects of policy intervention. In particular, disequilibrium can arise in the form of involuntary unemployment, inertia of technical systems and rigidity of labor and energy markets, as a result of delayed market-clearing in the goods markets and slow adjustment between prices and quantities over the simulation time path.

Calibrated to updated aggregate and sectoral national accounts data, a Mexican version of the ThreeMe is developed that accounts for 24 commodities-including 3 energy sources-and 32 sectors, with an explicit distinction between 11 energy sectors and 7 transport sectors. Electricity production is disaggregated into 9 technologies: hydro, geothermal, wind, solar, biomass, nuclear, coal-based, oil-based and gas-based. The ThreeMe-Mexico model is used to gauge the economic and environmental effects of energy fiscal policy measures in Mexico (namely the phasing out of energy subsidies and the implementation of a carbon tax). Different policy scenarios are assessed, each reflecting a different strategy of fiscal revenue recycling. We consider fiscal policy for energy transition in Mexico of the type of carbon tax and simulate the effects on Mexico's economy and carbon emissions of alternative government's patterns of transferring tax revenues. The level of the carbon tax is endogenously computed to meet national emissions reduction targets, as stated in the Mexican "Climate Change Law". In line with government's "IDEAL scenario", we consider emissions cuts of 40% in 2030 50% in 2050 as compared with the baseline and the 2000 levels, respectively. This requires carbon tax to reach US$ 100 in 2030 and US$ 867 in 2050. We take the case with no tax compensation for the first. Because of substitution effects in energy-intensive production inputs and consumption goods, the policy is successful in reducing CO2 emissions by more than 80% by 2050 with respect to BAU. But the environmental goal is achieved at very high economic costs, with GDP dropping by more than 10% after 2040.

Then we test the hypothesis of full redistribution of carbon tax revenues among consumers (through reducing household income taxes) and producers (through compensating for social security payroll taxes), which appears as a way to reconcile environmental and economic goals. It is shown that such pattern of revenue transfer has beneficial impacts both on GDP and CO2 emissions reduction. With respect to the no-redistribution pattern scenario gains on latter feature slightly lower (75% vs 80% decrease in emissions, respectively) because of rebound effects: increased economic activity from redistribution leads to enhanced production and consumption, which ultimately drive energy use. Our results support the notion that promoting a carbon tax is compatible with both environmental and economic gains. Sensitivity tests are undertaken including utilizing alternative parameter values for the alternative substitution mechanisms. It is found that CO2 emissions reduction is low when the elasticity of substitution between capital and energy is constant (in absence of endogenous energy efficiency) and when the elasticity of substitution across types of commodities is low. Moreover, the economic gains from the tax crucially depend on the inflationary pressure resulting from the taxation policy (and therefore on the wage setting process) and on responsiveness of Mexico's economy to foreign competition.

This paper is the result of a two-year research collaboration involving the National Institute of Ecology and Climate Change (INECC) the French Economic Observatory (OFCE) and the French Agency for Development (AFD).

The Interaction of Climate Mitigation and Universal Energy Access Policies

S. Pachauri (1) ; N. Rao (2) ; K. Riahi (3)

(1) International Institute for Applied Systems Analysis, Laxenburg, Austria; (2) IIASA, Energy, Laxenburg, Austria; (3) International Institute for Applied Systems Analysis, Energy Program, Laxenburg, Lower Austria, Austria

The vast majority of scenarios assessed in the IPCC's AR5 focus attention on mitigating greenhouse gas emissions, but fail to sufficiently analyze some of the critical linkages between climate and development (IPCC, 2014b). One of these linkages is the risk that higher energy prices from mitigation policies exacerbate energy poverty, which can in turn increase mortality from indoor air pollution. Four million lives are lost every year from traditional stove use (Pachauri et al, 2013). In India alone, over 700 million people still depend on solid fuels for cooking, whose eradication is an important development objective. With increasing pressure from the international community to undertake mitigation efforts, including removing fuel subsidies, the risk of slowing modern energy uptake is real.

No studies have examined the interaction between policies to promote (fossil-based) modern energy access for cooking and climate mitigation policies. The distributional outcomes depend on existing subsidy policies, patterns of income growth, and the types of climate policies. This paper presents a rigorous assessment of these issues using the MESSAGE-Access model, a household

fuel choice model that is part of the MESSAGE integrated assessment model at IIASA. The regional focus of this paper is South Asia. The paper will present outcomes of solid fuel dependence, income shocks, policy costs and environmental impact under different climate and access policies.

4406b - Climate change and Development: Alleviating poverty and achieving inclusive development within the constraints of a global carbon budget and other planetary boundaries

ORAL PRESENTATIONS

K-4406b-01

Climate change and poverty

S. Hallegatte (1)
(1) Climate Change Group , Washington , United States of America

Climate change and climate policies will affect poverty reduction efforts through direct and immediate impacts on the poor and by affecting factors that condition poverty reduction, such as economic growth. This presentation will summarize a research program conducted at the World Bank with many external partners to explore this relation between climate change and policies and poverty outcomes by examining three questions: the (static) impact on poor people's livelihood and well-being; the impact on the risk for the non-poor individuals to fall into poverty; and the impact on the ability of poor people to escape poverty. The presentation proposes four channels that determine household consumption and through which households may escape or fall into poverty (prices, assets, productivity, and opportunities). It then discusses whether and how these channels are affected by climate change and climate policies, focusing on the exposure, vulnerability, and ability to adapt of the poor (and those vulnerable to poverty). It reviews the existing literature and offers three major conclusions. First, climate change is likely to represent a major obstacle to a sustainable eradication of poverty. Second, climate policies can benefit the poor provided that (i) poverty concerns are carefully taken into account in their design and (ii) they are accompanied by the appropriate set of social policies. Third, climate change does not modify how poverty policies should be designed, but it creates greater needs and more urgency. The scale issue is explained by the fact that climate will cause more frequent and more severe shocks; the urgency, by the need to exploit the window of opportunity given to us before climate impacts substantially increase.

Planetary Boundaries: Abundance within a Global Carbon Budget

J. Rockström (1)
(1) Stockholm Resilience Center, Stockholm university, Stockholm, Sweden

Planetary Boundaries: Abundance within a Global Carbon Budget

Extraordinary climate stability since the end of the Holocene 11 000 years ago, has provided the necessary conditions for human development. Human activity is now pushing the Earth system towards the limits of its ability to support further unsustainable development, in many cases posing the greatest threat to the survival of the poorest and most vulnerable societies. These planetary boundaries describe the human influence on and limits to Earth's life-support systems. Within the current paradigm of development, we have already crossed planetary boundaries associated with carbon dioxide levels driving climate change, the loss of biodiversity, the addition of phosphorus, nitrogen and other nutrients to ecosystems, and deforestation. The latest research shows that in some cases these changes may be irreversible, having crossed a tipping point.

A new framework of sustainable development is required to ensure that humanity remains within the 'safe operating space' of the planet defined by the planetary boundaries, whilst allowing all societies to become more prosperous on a resilient planet. 2015 offers a unique opportunity to address key aspects of this existential challenge. Negotiations on the new Global Climate Agreement in December and discussions on the UN Sustainable Development Goals in September, are important fora for charting a holistic path to an equitable and safe future for all societies. The risk of crossing additional planetary boundaries will rise with delayed action on both these fronts, driving the Earth system further away from the stable conditions that have supported human development until now. In particular, a global climate change agreement that limits warming to well below 2 degrees and respects key equity principles is necessary to enable achievement of development objectives.

This contribution draws on recent new research on Planetary Boundaries and on the Earth Statement project led by the Earth League.

Feasible Mitigation Options for Developing Countries

J. Steckel (1) ; M. Jakob (2) ; N. Rao (3)
(1) Mercator Research Institute for Global Commons and Climate Change, Climate and Development, Berlin, Germany; (2) Mercator Research Institute for Global Commons and Climate Change, Berlin, Germany; (3) IIASA, Energy, Laxenburg, Austria

This talk will emphasize challenges and possibilities for climate change mitigation in the context of sustainable development imperatives. Mitigating global climate change will require large scale reductions of GHG emissions not only in industrialized, but also in developing countries. However, historically, economic and social development has been highly correlated with fossil fuel use. In the recent past, economic growth in China, which has lifted hundreds of millions people out of poverty, has gone hand in hand with a dramatic carbonization of the Chinese energy system. As other newly industrializing countries are currently following the same track there is a risk of creating a lock-in of carbon-intensive energy infrastructures which will render ambitious climate stabilization targets difficult to achieve.

Even though the recent surge in coal has been accompanied by a market-driven proliferation of renewables in emerging economies such as India and China, the question arises how, and to what extent, the pursuit of economic growth and poverty alleviation can avoid the repetition of historical carbon-intensive development patterns.

While mitigation costs are expected to be moderate on the global scale, they still can - depending on the burden sharing scheme in place - pose serious challenges for financially and institutionally constrained developing countries. For these countries, other considerations, such as poverty alleviation, are likely to constitute more pressing short-term policy objectives. Even with financial support from the global community, there are serious concerns regarding the potential negative effects of financial inflows e.g. on the development of advanced industries.

Various approaches have been proposed to support developing countries in formulating national climate polices, including financial assistance of USD 100 bn per year from the Green Climate Fund. Such transfers can only be effective if they are designed in a way that minimizes potential adverse effects by means of transparency mechanisms, monitoring and conditionality. They also need to guarantee ownership by recipients by embodying a broad perspective on climate change that takes into account particular countries' specific development objectives. In this regard, recent research has highlighted that policies that do not only aim at reducing emissions, but also leverage substantial co-benefits are most likely to be politically feasible. Prominent examples of such 'win-win policies' include clean-air policies, reforming fossil fuel subsidies, and improving public transport systems, as well as improved agricultural practices and inclusion of climate change considerations in regional trade agreements.

As a consequence, these policies have the potential to overcome the "dangerous climate change vs. dangerous mitigation" dilemma. By defining appropriate guardrails for natural as well as social objectives, they incorporate a multi-dimensional perspective of sustainable development. Such sustainable development objectives could further advance bottom-up incentives for individual countries to embark on climate-friendly development pathway which provide an important entry point for more ambitious climate policies – including an internationally binding agreement – in the future.

Human development in a climate-constrained world: what the past says about the future

W. Lamb (1) ; N. Rao (2)

(1) Tyndall Centre for Climate Change Research, School of Mechanical, Aerospace and Civil Engineering, University of Manchester, Manchester, United Kingdom; (2) IIASA, Energy, Laxenburg, Austria

Energy consumption is necessary for the delivery of human development by supporting access to basic needs, services and infrastructures. Given prevailing technologies and the high degree of inertia in practical rates of decarbonisation, raising global living standards may entail growth in energy consumption and consequent greenhouse gas emissions (GHG) impact on the climate system. Yet despite considerable elaboration in the literature on equity proposals and the 'fair burden-sharing' of emissions rights between industrial and developing nations, there is very little research on the actual energy use necessary for development and likely arising emissions. This is a prescient issue in the context of on-going international negotiations, where it is now recognized that the participation of all major emitters, including key developing countries, is required to break the climate impasse. Our question thus focuses on extrapolating existing trends in energy growth, emissions and human development progress; highlighting the level of policy ambition that will be necessary to meet the twin challenges of climate change and poverty alleviation.

We build on recent work analysing the interaction between human development, energy use and GHG emissions [1-3] and base our presentation on a forthcoming publication in Global Environmental Change [4]. Yearly cross-section regressions on 3 pairs of country development and environmental impact indicators are performed for the period 1990-2010: life expectancy, access to basic needs and GDP per capita as dependent variables; per capita final energy consumption as an independent variable. Access to basic needs is a composite indicator comprising six dimensions of the bare minimum requirements for development (access to sanitation, electricity, water, food supply, education and a survival rate). Following Steinberger et al. [1] and Costa et al. [2], we estimate hyperbolic saturation curves from this historical data, on the basis of which we project future energy for 'development as usual' (DAU) to threshold levels of each human development indicator. This scenario incorporates the observed autonomous improvement in the efficiency of delivering human development, but assumes no near-term climate policy. In the final stage of our analysis, the DAU scenarios are translated into GHG emissions using intensities from an integrated assessment model (IAM) and the resulting pathways are compared to a cost-based allocation of emissions rights. This allows us to contrast likely development emissions with a mitigation scenario in which only economic efficiency is prioritised.

We find an unbroken, near-continuous trend in human development improvement over the past two decades. As in previous studies we find a high rate of decoupling between human development and energy consumption, but with regionally distinct patterns leading to diverging estimates of the total GHG emissions required for meeting development needs. Nonetheless, in the absence of policy, human development in these regions is likely to generate approximately 1000Gt CO2eq by 2050, a quantity unlikely to be compatible with internationally agreed goals to limit climate change to 2oC. The results are sensitive to the rate of decoupling and level of ambition in human development progress, with existing examples of more efficient pathways offering hope that such emissions may be avoidable. Compared with the IAM scenario, a cost-based allocation of emissions rights also appears difficult to reconcile with poverty alleviation; while high levels of basic needs and life expectancy can be satisfied at lower levels of emissions than continued economic growth.

Projecting Household Surveys to Assess the Impact of Future Economic Conditions and Climate Change on the Poor

J. Rozenberg (1) ; S. Hallegatte (2)

(1) World Bank, Climate Change Group Chief Economist Office, Washington DC, United States of America; (2) Climate Change Group , Washington , United States of America

This paper quantifies the potential impacts of climate change on poverty in 2030 and 2050, in 92 countries covering 90% of the developing world population. It accounts for the deep uncertainties that characterize future socio-economic evolutions. It also considers many impacts of climate change, based on original work commissioned by the World Bank.

To build scenarios, we use a micro-simulation model based on household surveys and explore a wide range of uncertainties on future structural change, productivity growth or demographic changes. This results, for each country, in the creation of several hundred scenarios for future income growth and income distribution. We then explore the resulting space of possible futures, using several indicators of poverty and income distribution and use scenario discovery techniques to identify the main drivers of inequalities and poverty reduction. Inequality and poverty depend on drivers that differ across countries. We find that in many countries, redistribution and structural change are powerful drivers of poverty and inequality reduction, except in low-income countries. In the poorest countries in Africa, for instance, reducing poverty cannot rely on redistribution but requires low population growth and sustained productivity growth in agriculture.

Once we have explored the space of possible outcomes for poverty and inequalities in each country, we choose two representative scenarios of the best and worst cases and model the impacts of climate change in each of these two scenarios. Climate change impacts are modeled through 4 channels. First, climate change has an impact on labor productivity growth for people who work outside because of higher temperatures. Second, climate change has an impact on human capital because of more severe stunting in some places. Third, climate change has an impact on physical capital via more frequent natural disasters. Fourth, climate change has an impact on consumption because of changes in food prices. Globally, we find that climate change increases poverty in the two scenarios. Impacts are very heterogeneous across countries and

are mostly concentrated in African and South-East Asian countries. For high radiative forcing (RCP8.5), the impact of climate change on poverty is 6 times larger in the pessimistic scenario than in the optimistic scenario, illustrating how development and poverty reduction are powerful adaptation tools. Our results stress the urgency of achieving poverty eradication by 2030 in order to limit the negative impacts of climate change on the poor.

Climate resilient development: indicators and selection criteria for climate aid financing

A. Miola (1)
(1) EU Joint Research Center Institute for Environment and Sustainability, Climate risk management unit, ispra, Italy

This work aims to contribute to the debate on climate change policies and their link to development. We adopted a climate resilient perspective to understand how climate change policies objective can be reconciled with development goals and to explore win-win opportunities given by the integration of the climate change and poverty reduction policies.

First, we review the main theoretical concepts that characterise the scientific literature on climate risk and vulnerability assessments, and identify climate resilient indicators accordingly.

This made it possible to build the theoretical foundations for a newly design index, design to improve our understanding of the implications of aid financing on reversing unsustainable paths, reducing vulnerability to climate change related hazards and get more equitable outcomes.

The novelty of our contribution lies on the emphasis given to economic aspects related to climate risk assessment, most notably: the concepts of loss and damage, the understanding of factors enhancing economic resilience, the links between climate change policies and development (besides economic growth) and the acknowledgment of the role of natural capital in pursuing development policies.

By reviewing grey and peer-reviewed literature, we identified 133 suitable indicators, which have been grouped along six components. These have been selected from a preliminary list of 300 indicators, on the basis of general criteria like validity, data availability and their value in terms of information potential. Other specific criteria have been considered, to ensure that the indicators shortlisted are theoretically robust.

O-4406b-04

Historical analogies to forecast climate change induced fluctuations of Western African countries' macroeconomic indicators

F. Baarsch (1) ; M. Schaeffer, (1) ; J. Granadillos (1) ; AS. Lüttringhaus (1) ; D. Coumou (2) ; B. Hare (1) ; M. Krapp (1) ; A. Robinson, (3) ; R. Makhaza (1) ; R. Schwarze (4) ; M. Knaus (2)
(1) Climate Analytics, Berlin, Germany; (2) Potsdam Institute for Climate Impact Research, Potsdam, Germany; (3) Universidad Complutense de Madrid, Madrid, Spain; (4) UFZ, Leipzig, Germany

Due to the increased impacts of climate-related extreme events, a rapidly growing literature has documented the relation between macroeconomic outputs, climate variability and human induced climate change. Methodologies either rely on modelling or on statistical approaches showing that climate variability and future human induced climate change could have effects on gross domestic product (GDP). However, current statistical approaches mostly rely on linear econometric regressions with limited specifications of climate variables, while models have a limited evidence basis.

Using a statistical approach for its evidence basis, we investigate the relationships between macroeconomic variables (investment, trade balance, sectoral value added and GDP) and climate variables in Africa from the 1960s to the present. The approach is based on a nonlinear econometric model using a piecewise regression function adapted from Schlenker and Robert (2009). Time-lagged effects are also investigated. A large set of specifications of climate variability is assessed as regressors including among others: weighted anomaly standardized precipitation, and Palmer drought severity index. For each "piece" of climate variability in Western Africa we infer climate analogy coefficients estimating the relation between climate variability and a climate-induced fluctuation of macroeconomic output.

Applying the inferred coefficients to projections from global and regional climate models, we estimate their effects on GDP and adjust African Development Bank's forecasts for Western Africa.

This research project is supported by the United Nations Environment Programme (Regional Office for Africa), the African Development Bank and the United Nations Economic Commission for Africa.

P-4406-01

Underlying causes of the growing adaptation deficit in the context of development

I. Burton (1)
(1) University of Toronto & IPCC (AR5 WGII Chap. 20), School of the Environment, Toronto, Ontario, Canada

Evidence is presented to show that climate change adaptation (CCA) and disaster risk reduction (DRR) are promoted and implemented with little or no reference to the development practices that are generating increased risk. The reverse is also true. Aggregate public annd private investments made largely regardless of their contribution to increased exposure and vulnerability, exceed by orders of magnitude the present and projected expenditures on CAA and DRR. Reports on Inclusive Green Growth (World Bank 2012) and cumulative evidence on the changing pathways to impact (van de Berg and GEF 2013) provide information to show that the «cure to damage» ratio is in the order of 1:1,000. In the public sector a current estimate of what funds are available annually to developing countries for adaptation ($1 billion) compares with $1 trillion as a conservative estimate of amounts of public funding available for harmful practices such as subsidies for fossil fuels, water practices that deplete resources, fisheries and agriculture (IMF).

A similar story applies to increasing losses from «natural» disasters that will be increasingly related to weather and climate. The dominant economic and investmeent paradigm of development accords little attention to the incidental effects, in increasing exposure and vulnerability. Thus the adaptation deficit (Burton 2004) contines to grow along with the disaster risk reduction deficit.

Development investments (especially in the private sector) that increase risk are being explained as «the cost of doing business», or simply as «externalities». This is reminiscent of the problem of acid precipitation and other pollution issues of a generation ago, where eventually transboundary and regional agreements were achieved through the recognition of «the polluter pays principle». If humanity is to move more effectively towards a common future there will have to be a similar recognition of the principle «the creators of disaster risk and the adaptation deficit pays». Without such transformation the adaptation deficit and the disaster risk deficit are likely to keep on growing with serious consequences for our common future.

P-4406-02

Climate policy architecture for the Cancun's paradigm shift: Building upon the lessons from history

C. Cassen (1) ; JC. Hourcade (2) ; PR. Shukla (3)
(1) CIRED, PARIS, France; (2) International Research Center on Environment and Development (CIRED), Paris, France; (3) Indian Institute of Management, Ahmedabad, India

In the succession of Conferences of the Parties (COP) since Copenhagen, the Cancun conference (COP-16) marked a turning point at least on paper: it calls for "...a paradigm

shift towards building a low-carbon society that offers substantial opportunities and ensures continued high growth and sustainable development'' (paragraph 10). It introduced a notion of ''equitable access to sustainable development" (EASD) "in the context of "shared vision for long-term cooperative action" and "global peaking of GHG emissions"". The economics of climate policy after Rio led to a climate centric paradigm which departs from the original UNFCCC's cooperative framework for setting climate policies in the perspective of sustainable development. This resulted in a pure cap-and-trade approach of which adverse effects on development should be mitigated through appropriate transfers. This "fair burden sharing" paradigm could not but fail to untie the development-climate Gordian knot and lead to lose sight of the benefits of cooperation in a global agreement to abate GHGs emissions.

The challenge is now to align development and climate objectives considering the changing context since the nineties with both a re-equilibrium of the world economic balances and the adverse context created by the 2008 financial crisis. This paper proposes an organization of carbon finance as part of a general reform of the financial system, with the adoption of a carbon value as a notional price to trigger a wave of low carbon investments in the world and redirecting parts of the global savings towards low carbon investments, thus providing a lever for an equitable access to development.

The paper begins first by elucidating the misconceptions about the Kyoto Protocol (KP) so as to identify which of these may impair any approach to enforce the Cancun's paradigm shift. Second, it discusses the rationale for an international climate regime when the Nationally Appropriate Mitigation Actions (NAMAs) embarked in the INDCs are considered as the primary tool of GHGs abatement. Third, it lays out the principles of a climate regime centered on scaled up climate finance, through the issuance of a carbon asset by the Central Banks of volunteering Parties. A right balance between an aspirational regime and a least common denominator regime should follow five principles: a) preserve the idea of allocating targets and timetables for countries with a controlled degree of "when" and "where'" flexibility (COP3, 1997), b) leave latitude to Parties to select the NAMAS apt to align their climate and development policies so that there is no misgiving about environmental colonialism, c) follow principle of "common but differentiated responsibilities (CBDR)" in accordance with the article 3.1 of the UNFCCC, d) ensure that renegotiations every five years will not generate instable signals for economic agents, e) motivate countries to respect announced emissions pledges and to narrow the gap between these pledges and an emissions trajectory compatible with the 2°C target, and f) deprive a defaulter country of the benefits of the system approach of technological cooperation or in varied scholars' proposals of a "carbon club" of voluntary countries.

A mechanism organized around carbon based assets could meet these principles through a pull-back force anchored around two pillars. The first pillar rests on allocating to each participating country a part of the global emissions budget. What makes a compromise easier with this mechanism force compared to the cap and trade system is that the pull-back force does not trigger immediate adverse impacts for households and industry. The second pillar rests on emissions pledges and commitments to issue carbon assets as means of motivating each country to announce emissions target at every five year period and to comply with their commitments.

The key features of this regime does not prescribe the content of the climate architecture several decades ahead but launches a learning process that follows principles robust enough to align climate and development policies without abandoning the 2°C stabilization objective.

P-4406-03

Can climate compatible development provide an alternative development pathway for the global south?

L. Ficklin (1) ; S. Sallu (2) ; L. Stringer (2) ; A. Dougill (2)
(1) University of Leeds, Sustainability Research Institute, Leeds, West Yorkshire, United Kingdom; (2) University of Leeds, Sustainability research institute, Leeds, United Kingdom

Climate compatible development (CCD) is increasingly important to policy makers as a 'triple-win' strategy, combining climate adaptation and mitigation with development (Mitchell and Maxwell, 2010). CCD characterises a development pathway in that it is multi-sector, multi-stakeholder and multi-scalar (Stringer et al, 2014). What is less clear is if in bringing together climate adaptation and mitigation with development, CCD is creating an alternative development pathway or providing a mechanism with which to connect already existing development trajectories to wider mitigation and adaptation initiatives. This is an important distinction, yet there has been little research addressing it, both conceptually and empirically.

To date much of the empirical research on CCD has been at the project level, analysing how initiatives such as climate smart agriculture are simultaneously lowering carbon emissions and improving rural livelihoods (Lipper et. al., 2014). However, there has been significantly less research on the institutional adaptation and implantation of CCD at the national level where such initiatives and policies are developed and approved (Ficklin et al, forthcoming). This is, in part, due to the complexity of contextualised framings of climate change and development issues and the diversity of how they are being integrated into policy frameworks. However, we argue that it is also because CCD is an emerging concept and there is not a clear conceptualisation of what CCD is, and how it differs from other development pathways such as 'climate resilience', 'green growth' and 'low carbon development'.

In this paper we compare and contrast the opportunities and challenges, motivations and resistance to creating an alternative CCD development pathway in Tanzania and Swaziland. The research presented draws from semi-structured interviews conducted with national policy makers and stakeholders in the NGO and private sectors working at and across multiple levels, to provide the institutional perspective of CCD that is missing in the current literature. In addition, analyses from existing and forthcoming climate adaptation, mitigation, and development policies for each country are presented. The data presented was analysed with coding software and thematic matrices to source similarities and distinctions between the two country contexts. We draw out key discourses around adaptation, mitigation and development, identify what kind of CCD is occurring, and how it is being presented in national polices. We present further findings on stakeholder engagement, analysing how CCD is being contextually understood and practised and whose definitions and values count at different levels.

Our data suggest that CCD rhetoric in policy is in its infancy and that its component parts are framed differently in each country context. Therefore triple-win thinking with adaptation, mitigation and development is not as yet being extensively considered in policy. However, as it is emerging it is provoking questions and debate about the definitions of adaptation, mitigation and development in policy and by extension the coherence of these definitions between institutions, policies and financers. Our data from Tanzania and Swaziland makes an interesting comparison between different contextualised national framings of climate change and development issues and how this affects the opportunities, challenges, motivations and resistance to CCD as a development pathway in two contrasting country contexts.

In analysing CCD as an alternate development pathway, this paper presents data about the conceptualisation and framing of climate change and development issues in Tanzania and Swaziland. Furthermore, it analyses how CCD rhetoric is shaping how adaptation, mitigation and development are defined in national policies and institutions, and the impacts this has on the opportunities and challenges presented by a CCD development pathway. Our analysis suggests that although CCD rhetoric is only just emerging, it is gaining traction with international financers and national policy makers. As such further research on CCD development pathways in both national and regional contexts is required.

P-4406-04

Ending Energy Inefficient Foreign Aid

D. Hamza-Goodacre (1)
(1) ClimateWorks, CA, United States of America

Improving energy efficiency is one of the most effective

ways to reduce energy demand and energy-related greenhouse gas emissions around the world. However, the adoption of energy efficient infrastructure and technologies often faces many barriers. One of the biggest barriers in the developing world, where many of the largest opportunities for improving energy efficiency reside, is finance—access to predictable and affordable capital for infrastructure and manufacturing.

One of the most significant and influential sources of capital in developing nations is official development assistance (ODA) flowing through bilateral and multilateral development banks, such as US Agency for International Development and the World Bank.

Unfortunately, ODA may actually be helping to perpetuate the use of inefficient infrastructure and technologies in development countries. While international development agencies do finance energy efficiency investments—$200 billion between 2007-2013—they invest far larger sums in infrastructure and industry, without necessarily considering energy efficiency impacts. The extent to which ODA may actually be locking in energy inefficient infrastructure and industry —and thereby contributing unnecessarily to climate change, energy poverty, air pollution and other development challenges—is not well understood. And standards and best practice for mainstreaming energy efficiency into the core lending portfolios of international development institutions are not well developed.

ClimateWorks and Climate Advisors are currently researching and assessing the potential for energy efficiency improvements in current ODA financing in order to make recommendations to end energy inefficient ODA. Though difficult to quantify now because data is limited, such changes could deliver a massive reduction in climate emissions in key developing nations. The project seeks to measure the global mitigation potential of ODA reform relating to energy efficiency and assess the politically feasibility of securing those reforms. The latest project research will be shared at the conference and discussion stimulated about the sectoral, institutional and regional focus, to ensure maximum progress in ending energy inefficient foreign aid.

P-4406-05

Need for Subtle Policy Changes to ensure Food Security under Climate Change: Perspective from Global South

LB. Kamepalli (1) ; SK. Pattanayak (2)

(1) Karnataka State Women's University, Vijayapur, India; (2) Gulbarga University, Environmental sciences, Gulbarga, India

Food basket, in India as well the global South, over the years, became Wheat/rice based but with inherent limitation of irriated land. For instance, India has only 42.9% land equipped with irrigation. Rest of region that cultivates Coarse Cereals such as Pearl millet, Finger Millet, Sorghum, Barley, but were left out as their produce is no more part of food system. On the other hand, there was a spike in global food prices in 2008. Some say that it is Indian attempt to offset its shortfall in paddy production from international market was the cause, making 'food affordability' a global concern. Put differently, this interlinkages stresses the need for diverse food basket for food security. On the other hand, records show that in India, from 2001 to 2011, an area of 3,768,000 ha which was under coarse grains such as Pearl millet, Finger Millet, Sorghum, Barley was put to other crops. Another angle of Indian agriculture is its changing land ownership pattern. With economy growing, contribution of agriculture as sole source of household income decreased. It contributed for increased absentee land ownership and lease farming. Neither of it cares for maintaining / promoting land fertility nor the global food security. However, we argue that with suitable subtle policy changes such as a) shift to more effective and direct transfer of benefits, b) promotion of coarse cereals, c) Focused target group benefits would help achieve food Security sooner.

P-4406-06

Development perspectives of Sub-Saharan Africa under climate policies

M. Leimbach (1) ; N. Roming (2) ; A. Schultes, (3) ; G. Schwerhoff (3)

(1) Potsdam Institute for Climate Impact Research, Postdam, Germany; (2) PIK, Postdam, Germany; (3) Potsdam Institute for Climate Impact Research (PIK), Potsdam, Germany

Reduction of global greenhouse gas emissions at acceptable costs requires the inclusion of developing countries into a climate policy regime because their emissions grow rapidly. But the less developed countries fear to suffer in terms of economic growth and domestic wealth. This study focuses on Sub-Saharan Africa as the lowest income region and demonstrates how it could benefit from joining an international climate agreement without delay. Based on a scenario analysis with the Integrated Assessment model REMIND, we estimate the economic costs and transformation needs under different assumptions on the climate stabilization target, cooperation and technology diffusion. From simulation results it turns out that Sub-Saharan Africa will suffer aggregated consumption losses of up to 3% under a global tax regime, but can even gain under a cap-and-trade climate policy regime that starts early with cooperative action and consistently follows acknowledged equity principles.

P-4406-07

Trading off climate change mitigation and poverty eradication in developing countries: drivers and constraints to institutional change

B. Rennkamp (1)

(1) University of Cape Town, Energy Research Centre, Cape Town, South Africa, France

The assumption of a trade-off between climate change mitigation and poverty eradication generally goes unchallenged. The UN Framework Convention on Climate Change established this trade-off, arguing that climate change responses take "into full account the legitimate priority needs of developing countries for the achievement of sustained economic growth and the eradication of poverty" (UNFCCC 1992). Developing countries can in theory call for support under the principle of shared but differentiated responsibilities, but the attempts to support Nationally Appropriate Mitigation Actions (NAMAs) haven't materialized at a large scale. Currently, countries focus on defining intended nationally determined contributions (INDCs). The results will be presented in the next Conference of the Parties (COP) in Paris.

This contribution is part of a research project that challenges this assumption asking the question whether this trade-off is always there or if win-win situations are possible? [1]

The main question of this contribution to the conference is to find out how the trade-offs between climate change mitigation and poverty eradication translate into the national climate policy process in developing countries. The findings can inform climate responses that can solve this trade-off and meet both climate and development objectives. Another purpose of the research is to better understand who benefits and loses from climate response and how barriers to institutional change can be overcome.

The theoretical contribution of the paper adds to the literature on institutional change in the studies of political economy. The paper identifies the drivers and barriers to institutional change in the existing literature (e.g. Streeck and Thelen 2005). It establishes the argument that trade-offs and distributional conflicts are significant determinants of success or failure of institutional change.

The methodology is an innovative discourse network analysis combining qualitative discourse and quantitative network analysis (Leifeld 2012). The analysis shows how actors organize in competing coalitions in relation to others depending on whether they support or oppose a specific policy intervention.

The research design consists of three climate change mitigation policies in South Africa. (There will be more results from Mexico and Thailand coming out later this year). The three policies are the carbon tax, the renewable energy program as part of the electricity sector reform, and the National Climate Change Response White Paper (NCCR) process (RSA 2011). South Africa exemplifies the need for urgent emissions reductions and poverty eradication. The country's emissions range with 0.9 Mt per capita at levels similar to Germany, while poverty

levels remain at 39% counting the national poverty line of 390 Rand/~ 30 Euros per household per month (NPC 2011). The main source of greenhouse gas emissions is the coal dependent electricity and liquid fuels sector. All three policies were announced before the 17th COP held in Durban in 2011, but only the renewable energy program and the NCCR are under implementation. The analysis shows that the discourse in the debate on the carbon tax establishes trade-offs between economic growth, poverty alleviation and emissions reductions. Mechanisms to offsetting the carbon tax attempt to minimize these trade-offs. The reason for the lack of implementation lies in the distributional conflicts. The negotiations between the competing coalitions occur mostly without the participation of poor parts of the population and lack clear evidence of the impacts on low-income households.

Climate Change-related loss and damage: An opportunity for transformative change?

E. Roberts (1)
(1) King's College London, Geography, London , United Kingdom

The residual impacts of climate change - or loss and damage - are already being experienced in both developing and developed countries and given current emission trajectories the level and extent of loss and damage will almost certainly increase. The fact that loss and damage is being incurred now is evidence that the global community has not been successful at achieving the objective of the international climate change regime, to prevent dangerous anthropogenic interference on the climate system. Clearly the collective global mitigation effort has been insufficient to avoid loss and damage. However, it could also be argued that business as usual efforts at addressing the impacts of climate change through adaptation have also been insufficient to avoid the residual impacts of climate change. In fact, in many parts of the world the limits of incremental adaptation are being reached and human societies are being forced with a choice between incurring loss and damage or undertaking transformation. This paper will argue that the loss and damage agenda should be used as both a vehicle through which to implement comprehensive risk management frameworks and a platform to transform both development and adaptation to address the underlying drivers of vulnerability and enhance resilience.

4407 - The Challenges and Opportunities of Multilevel Adaptation Governance

ORAL PRESENTATIONS

K-4407-01

Adaptation principles and their application: Effective determinants for multilevel climate governance?

S. Kreft (1)
(1) United Nations University, Institute for Environment and Human Security, Bonn, Germany

The UNFCCC COP 21 climate summit in Paris at the end of 2015 is expected to yield a new agreement on climate change, that will provide the framework for international climate policy cooperation in the coming decades. Advancing adaptation to climate change is a political priority for many countries, especially island states and least developed countries, and a major expectation towards the outcome of COP 21.

At the international level there are emerging norms on the conduct of adaptation interventions - for instance through adaptation principles stipulated by the UNFCCC's Cancun Adaptation Framework decided in 2010. The presentation addresses the question of how these principles are taken into account in programming adaptation actions by international climate funds and bilateral initiatives. Initial results based on a standardized analysis of board and programme policy documents as well as project documentation point to an uneven uptake and effect of internationally agreed adaptation principles on these institutions. I use these insights to discuss the effect of broad level policy principles on multilevel climate governance and adaptation practice, and to debate the relevance of an evolution of adaptation norms in the context of advancing the climate regime in Paris.

Challenges of scales: exploring pathways to integrate locally-developed adaptation initiatives with national and regional development plans and adaptation policies

S.Huq (1)
(1) International Institute for Environment and Development, United Kingdom

Abstract not communicated

O-4407-01

Opportunities for municipal climate adaptation: aligning local adaptation plans with provincial and national policy in South Africa

G. Ziervogel (1)
(1) University of Cape Town, Environmental and Geographical Science, Cape Town, South Africa

While some argue for a dedicated policy domain to focus on reducing climate impacts, others suggest that more comprehensive responses that integrate climate into existing policy domains are important. This presentation seeks to share the opportunities that enabled a local government municipality in South Africa, the Bergrivier municipality, to develop an adaptation plan that aligned with local development policy, provincial climate change initiatives and developments in national climate policy. We suggest that multiple opportunities converged to enable a municipal plan to be rapidly developed through a collaborative process that aligned with policy across different levels. The process built on the successful partnership between a range of scientists, local government and provincial government actors that worked together to develop a municipal adaptation plan. Key elements of success include ways that scientists worked with different levels of government, the flexibility of the process and the knowledge sharing and capacity strengthening this enabled. This knowledge exchange helped to strengthen understanding across the science - policy - practice divide, resulting in climate scientists having a better understanding of the multiplicitous complexity of local level governance and service delivery challenges, and by the same token, provincial and local officials and councilors gaining a better understanding of the complexity involved

in producing locally relevant climate information. The research suggests that mainstreaming local climate adaptation plans with local development plans on one side and aligning local climate adaptation plans with provincial and national priorities on the other side, can help to create a conducive environment to co-producing local adaptation plans that aim to reduce both specific climate risk and meet generic socio-economic development needs.

Limits and opportunities of private finance for adaptation in Least Developed Countries

D. Adis (1) ; T. Corrado (2) ; P. Pauw (3)
(1) Stockholm Environment Institute, Stockholm, Sweden; (2) Stockholm Environment Institute, York, United Kingdom; (3) German Development Institute, DIE, Bonn, Germany

Interest in private finance for climate resilience is increasing rapidly. A wide range of actors – finance institutions, intergovernmental organizations, policy-makers, negotiators, research institutions, insurers and reinsurers, and private investors themselves – have been quick to join efforts to further identify opportunities for private investment in developing countries. However, it is far from clear how the private sector might make a substantial contribution, particularly for adaptation, where attempts to assess the finance landscape have so far been unsuccessful. Research has shown that private adaptation finance has yet to prove its worth and the role of the private sector in adaptation and adaptation finance has received little attention from developing countries in the UNFCCC climate change regime.

This paper considers the limits and opportunities to stimulating private sector contributions for climate-resilient development. Its focus is on three aspects of climate finance governance – enabling environments, established and innovative mobilisation mechanisms, and delivery mechanisms – as well as their ability to ensure scaled-up finance for climate resilience, and developing-country accessibility to this finance.

Specifically, the paper questions the potential of private finance for adaptation in Least Developed Countries (LCDs). National Adaptation Programmes of Action (NAPAs) are used to indicate overall national adaptation priorities, and complemented with national development plans for selected countries. Foreign Direct Investment (FDI) is analysed as a proxy for where foreign private sector investment flows autonomously. This is complemented with qualitative assessments of alternative forms of private investments, including green bonds, risk guarantees and mutual approaches. Through policy analysis and semi-structured interviews the paper: 1) highlights the institutional and regulatory frameworks, as well as knowledge and cognitive aspects, which are currently a barrier for an investment friendly enabling environment for the private sector; 2) the paper assesses existing and innovative mechanisms for mobilisation of private sector investment; and 3) the paper's third focus on delivery mechanisms maps private sector investments through participation (purely private and public-private) and scale (micro, meso, macro).

It is found that private sector flows to adaptation priority sectors are scarce, and their impacts on resilience often unclear. Increasing these flows would require that country-specific challenges be addressed. The paper highlights a lack of innovative mechanisms for LDCs and discusses limits and opportunities for multilateral climate funds, such as the Green Climate Fund, to attract and leverage private finance for adaptation in key sectors, including food security, water resources, health, and energy security and access. It concludes that climate funds need to seek a combination of climate change adaptation and social and economic development and employment in order to maximise private sector contribution, both financial and non-financial.

Bridging Communication and Trust Building for Local Climate Adaptation: A Case study of Tainan, Taiwan

R. Chen (1) ; HC. Lee (2)
(1) Chinese Culture University, Taipei, Taiwan; (2) National Central University, Chung Li, Taiwan

Local implementation is a key to the overall efforts in response to climate change. In local settings, adaptation planning copes not only with various consequences induced by climate change, but the multiple interests raised by those affected stakeholders. Dissonance is commonly seen among different sectors with regard to agenda setting and resource prioritization. This study, as a part of state-funded program, "Taiwan Climate Change Adaptation Technology" (TaiCCAT), is designed to reveal and remedy the discrepancy among different policy sectors by focusing on a Taiwanese city, Tainan.

With a long colonial history Tainan is a vivid city of tourism and cultural events. However, as a municipality Tainan has an extensive jurisdiction covering urban, coastal, and rural areas. This diversity in life styles and ecosystems has invited severe vulnerability to extreme weather and its impacts, both floods and droughts. The primary investigation of this study has shown there are a series of asymmetries existing in policy participation, information sharing, resource allocation, and action taking among different sectors. Employing social network analysis, text mining techniques, and co-design research principles, this study further examines the contents of these discrepancies and aims to identify the key actors who are in the best network positions to smooth the channels of communication and trust building for local adaptation initiatives and water resource management.

Climate Change Adaptation: A Community Adaptation Small Grants Facility in South Africa

MA. Baudoin (1) ; M. Barnett (2) ; A. Bourne (3) ; C. Forbes (4) ; H. Karathanassis (4) ; Z. Jakavula (4)
(1) Climate and Development Initiative, Cape Town, South Africa; (2) South African National Biodiversity Institute , Cape Town , South Africa; (3) Conservation South Africa, Springbok, South Africa; (4) SouthSouthNorth, Cape Town, South Africa

Internationally, there is increased funding for Climate Change Adaptation (CCA) projects, especially in support of bottom-up or locally-driven initiatives. This recent emphasis stresses the relevance of local knowledge and practices in risk management – including dealing with climate variability and change. It also attempts to avoid top-down adaptation plans that often fail to address local climate vulnerability and needs. As a response to climate change, bottom-up approaches build on existing knowledge and practices to propose locally-relevant adaptation strategies. Moreover, bringing adaptation to communities provides more tangible impacts at the local level.

The Adaptation Fund (AF) is one of the international institutions promoting this approach. The AF is currently pioneering a direct access climate finance modality where developing countries can directly receive financial support for CCA, without working through an intermediary. This presentation describes the project "Taking Adaptation to the Ground: A Small Grants Facility for Enabling Local Level Responses to Climate Change», which is an initiative of the South African National Biodiversity Institute (SANBI). SANBI is the National Implementing Entity for South Africa, accredited by the AF, and works with and through the Department of Environmental Affairs, who is the National Designated Authority. The Community Adaptation Small Grants Facility (SGF) project aims to enhance resilience to anticipated climate change impacts in two project target areas in South Africa: the Mopani District Municipality (Limpopo Province) and the Namakwa District Municipality (Northern Cape Province). The project's Executing Entity is SouthSouthNorth. The Facilitating Agency for Namakwa is Conservation South Africa and the Facilitating Agency for Mopani is still to be appointed.

Poor, vulnerable communities often lack the capacities to access adaptation funding and to implement well-informed adaptation measures. To ensure that climate finance for adaptation activities reach those most at

risk, the SGF pioneers a community-driven CCA initiative that involves engagement with local stakeholders and beneficiaries in project development and implementation. Three main components will be implemented: 1) providing small grants to vulnerable communities for projects that deliver tangible and sustainable benefits; 2) empowering local institutions to identify and implement adaptation actions; and 3) compiling and sharing lessons to facilitate future up-scaling and replication of enhanced direct access modalities.

The SGF approach is, thus, an example of an internationally-funded initiative that is rooted firmly "on the ground". It is designed specifically to pilot an enhanced direct access modality for climate finance under the AF. Through the learning component of the project, lessons will be identified, collected and shared in order to provide recommendations for scaling up and replicating enhanced direct access in South Africa and beyond. This presentation will explore opportunities and challenges of bottom-up approaches for adaptation and the interplay between adaptation governance, management and execution at different levels of the SGF project.

P-4407-02

Considering one's options when the fish leave: A case study of the traditional commercial hand line fishery of South Africa's Southern Cape region

L. Gammage (1) ; C. Mather, (2) ; A. Jarre, (1)
(1) University of Cape Town, Marine Research Institute (MARE) & Department of Biological Sciences, Rondebosch (Cape Town), South Africa; (2) Memorial University, Department of geography, St john's, Canada

Many pressures (socio-economic, resource scarcity, policy, and regulation) make small-scale fishers and their communities vulnerable on a variety of fronts. Fishers need to cope with local and global changes and require systems that support their strategies to achieve resilience. The impact and interplay of these stressors at multiple scales need to be taken into account to develop a clear understanding of social-ecological linkages if sustainable livelihoods are to be promoted and guaranteed. There is however, a shortage of appropriately scaled, context-specific data, which is needed to inform various decision-making processes.

The present study researched vulnerabilities, as well as coping and adaptation in the small-scale, commercial handline fishery in six communities of South Africa's Southern Cape region: Witsand, Vermaaklikheid, Stilbaai, Melkhoutfontein, Gouritsmond and Mossel Bay, using semi-structured interviews, available census data and literature. Participants comprise boat owners, skippers, rights holders, crew, spouses/partners, as well as fish buyers and other persons associated to the fishery. Faced with multi-scalar changes to the broader fishery system, these fishers are forced to employ a wide range of strategies to cope and adapt to change. These changes, driven by multiple stressors on various spatial and temporal scales, affect not only the region overall, but display much variation in the impact felt by both individuals and individual communities. Not only are fishers required to cope with, and adapt to variability in the biophysical system, but they are also subjected to social and economic pressures as well as those created by policy and management decisions. Examples of such pressures include variability found in the natural environment with specific reference to weather fluctuations and the scarcity of the primary target species, pressures created by a perceived inadequacy of regulatory oversight and the administration of fishing rights as well as pressures created by increased input costs and cost of living. Notably, these fishers have very little to no control over most of these stressors, as many of these changes are the result of larger, macro-scale events and developments, from which they are disconnected.

The coping and adaptation strategies employed by these fishers can be grouped into three main groups with socio-economic conditions and life histories of individuals within the six communities seemingly the biggest determining factor in decision-making. Both cognitive and reflexive decision-making processes are shaped by the experience of their past and present environments of both individuals and their communities and cannot be understood by direct impacts of stressors alone, which highlights the need to understand indirect effects and feedback loops in the future. Practical implications of actions are not always the overriding concern in decision-making, underscoring the importance of culture and belief systems in decision-making. The severity of the challenges experienced with policy and regulatory processes may be exacerbated by a strong resistance to change, and the varying levels of resilience displayed by the different communities may be viewed in both a positive and negative light. Whereas one group of fishers have modernised their business strategies and intensified their fishing by going further offshore on larger, but more economic craft, the second and third group of fishers navigate the status quo because it is "what they know". The second group, characterised by low formal education, poverty and political marginalisation, mostly waits for help from the outside (e.g. through government poverty relief programmes or international aid). The wide array of alternative income options displayed by the third group in particular has so far allowed them to make it through hard times whilst always resuming fishing with largely changed business and fishing strategies. Tightening regulatory frameworks are forcing fishers to make decisions that particularly those in the third group are not comfortable making, especially when considering implications of the implementation of a recently legislated small scale fisheries policy. Coupled to this is an unwillingness to accept that the biophysical system may not always return to, or be able to return to, its former state, exacerbated by current considerable scientific uncertainty of climate dynamics in this region.

P-4407-03

The approaches to learning in multilevel adaptation governance research – a systematic literature review

J. Gonzales Iwanciw (1) ; A. Dewulf, (2)
(1) Universidad Nur, Development Studies, La Paz, Bolivia; (2) Wageningen University , Public administration and policy group, Amsterdam , Netherlands

Within just the last few years the governance of adaptation to climate change has become a truly multilevel affair from global to local levels. International institutions like the UNFCCC are currently building an institutional framework to support adaptation governance at national and local levels; but also "local" and national actors are increasingly taking an active role in international policy processes and seeking to shape these creating an emerging multilevel institutional context. In this context learning has been recognized as a central mechanism for individual and collective actors in adaptation at different governance levels to better adjust their responses to environmental change and uncertainty.

Climate change adaptation has been addressed in the literature mainly as a local or regional activity and thus learning has been also explored principallly linked to the participation of local actors. From a multilevel perspective learning and learning-loops happen in layers from individual to groups to institutional/social at different governance levels. In the context of adaptation governance, as the one shaped by the UNFCCC learning will be needed across different governance levels to be effective in pursuing adaptation goals, adequate to the scale and magnitude needed, and ensure a better fit between top-down and bottom-up approaches.

This motivated the systematic literature review of learning in multilevel governance of adaptation to climate change presented in this paper.

The paper analyzes how learning has been addressed both in the general multilevel governance literature and in the climate change adaptation governance literature. The paper summarizes a typology of learning as described in multilevel governance and climate change adaptation literature, discussing the concept of learning emerging from this two literature branches, the main methodological approaches used to assess and measure learning, different learning types and the factors that typically foster, blockt or inhibit learning in the way it is viewed by the literature.

The review contrasts these results with additional insight from policy learning and social learning approaches frequently used in multilevel governance and climate change adaptation literature to discuss the implications for multilevel governance and climate change adaptation governance literature and extract the elements for conceptualizing multi-level learning in the governance of climate change adaptation.

P-4407-04

The role of residents in climate adaptation: a systematic overview of default and alternative roles

D. Hegger (1) ; P. Driessen, (1) ; H. Runhaar (1) ; H. Mees, (1)
(1) Environmental Governance, Copernicus Institute of Sustainable Development, Utrecht university, Utrecht, Netherlands

Literature on roles and responsibilities of public and private actors in climate adaptation has hitherto devoted limited attention to the roles of residents (homeowners/tenants). Yet their role is crucial in addressing non- or maladaptation, as their initiative or consent is often necessary to take private property level adaptation measures. This paper provides a systematic sketch of default and alternative roles of residents in climate adaptation, based on a review of literature on the climate adaptation actions of residents. This covers three forms of residents' commitment to adaptation: (a) as citizens falling under the jurisdiction of various governmental levels; (b) as consumers (including home owners) in the market; (c) as civil society members. The overview suggests that there would be scope for alternative roles for residents in climate adaptation, especially regarding the latter two forms of commitment. The paper also discusses implications for research into and practice of adaptation governance.

P-4407-05

Sustainable Climate Change Adaptation through Community Organizing and Participation: The Case of Bakhawan Eco-Park in Kalibo, Aklan, Philippines

E. Serrano (1)
(1) University of the Philippines Los Baños, Institute for Governance and Rural Development, College of Public Affairs and Development, Los Baños, Laguna, Philippines

This study aimed to analyze how community organizing and participation helped ensure sustainable climate change adaptation in Kalibo, Aklan, Philippines. Through key informant interviews, focus group discussions, and other personal communications, data were collected primarily from community members, local leaders, and development workers. Data were analyzed qualitatively.

It was found out that sustainable climate change adaptation takes place through collaborative action. It involves the participation of the local government, people's organization, community members, the academe, the private sector, and other government agencies. Findings also show that pooling resources, mobilizing the community, and providing livelihood opportunities enhanced adaptive capacity.

Since sustainable climate change adaptation requires the active engagement of different sectors of society, community mobilizing and participation should be given more importance in climate change adaptation interventions.

P-4407-06

Interpretation of adaptation to climate change and governance

G. Simonet (1)
(1) CDC Climat Recherche, Paris, France

Over the last decade, many studies have focused on the institutions responsible for managing climate risks by analyzing responses, limits or barriers. Several studies have explored this path by focusing on the sources of the cognitive barriers that prevent actions, on the reasons and aspects of interests that motivate the denial and on the influence of cognitive factors on decision-making. Today, it has been widely acknowledged that people's beliefs and perceptions influence implementation of climate change adaptation. Regarding perception barriers, some authors keep highlighting the confused definition of adaptation and its various interpretations. However, few studies explored these issues directly with local policy makers who work directly on the elaboration or the implementation on adaptation strategies to climate change. Moreover, a clear definition of what really means "adaptation to climate change" is still working in progress, letting local authorities with their own interpretation of the notion.

Based on this framework, the ABSTRACT-colurba was launched in January 2014 by CDC Climat Recherche and two French public agencies (ADEME and AFD). The project proposes to increase knowledge on climate risk management at the urban scale by analyzing the levers and barriers (economic, organizational, cognitive) attached to decision-making processes upstream to the implementation of adaptation strategies to climate change. Based on a field study through 10 French local urban communities, the project is conducted within an action-research approach integrating local stakeholders. More specifically, the focus of the project is made on the intermediate size urban areas (50.000-100.000 inhabitants) chosen through different criteria (local dynamism, awareness, diversity of issues). Based on interviews and focus groups directly collected in the chosen case studies, the project analyzes the way the local communities elaborate and implement their own actions to reduce the vulnerabilities to climate change of their territories. The first results of the project show that each urban community has its own way to interpret what does "adaptation to climate change" mean, depending of the local issues, the local stakeholders dynamism or the allocated resources. The study aims to contribute to better define the shape of adaptation strategies to climate change once implemented and to better understand the influence of the cognitive factors on the decision-making process linked with local climate policy. Through restitution to the local stakeholders, the results participate to reinforce the capacity of local authorities to cope with the new climate realities.

P-4407-07

A field study at the urban scale on adaptation: the ABSTRACT-colurba project

G. Simonet (1)
(1) CDC Climat Recherche, Paris, France

Launched in January 2014, the ABSTRACT-colurba project proposes to increase knowledge on climate risk management at the urban scale by analyzing the levers and barriers (economic, organizational, cognitive) attached to decision-making processes upstream to the implementation of adaptation strategies to climate change. Based on a field study through 10 French local urban communities, the project is conducted within an action-research approach integrating local stakeholders. The contribution aims to present the original approach and the preliminary results of the ABSTRACT-colurba project and to contribute to continue to define what adaptation to climate change means at local level.

P-4407-08

Current status and future prospects of community based adaptation: sharing experience of coastal Bangladesh

S. Uddin (1) ; M. Azam (2)
(1) Prodipan, Climate Change Section, Daulatpur, Khulna, France; (2) Prodipan, Climate Change Section/Macquarie University, Daulatpur, Khulna, Bangladesh

This study investigates the impacts of climate change on the two most vulnerable coastal districts of Khulna and Bagerhat in Bangladesh by analysing both current and predicted changes to the coastal environment and livelihood patterns. In particular, it examines the climate change adaptation strategies undertaken at the grass-roots level, in order to propose improved strategies for mainstreaming climate change adaptation and mitigation. Although some community based adaptation strategies through livelihood diversification have already been implemented to mitigate the impacts of climate change, but there seems to be a lack of adoption of these initiatives at the local level. Accordingly, this paper examines ways to more effectively implement strategies that will mitigate the impacts of climate change in the affected communities. Our first principal finding is that the coastal region of Bangladesh currently experiences livelihood and food insecurity as a result of the impacts of climate change. In particular, large numbers of people are being

displaced, either through a temporary move to find work during the lean seasons, or a permanent move to another place to avoid the unstable living conditions experienced in these vulnerable coastal districts. Our second finding is that the climate change adaptation initiatives currently implemented in the vulnerable coastal districts of Bangladesh are inadequate to support the huge number of people affected by the impacts of climate change in a way that will ensure the security of their livelihood. Accordingly, we conclude that less overlapping and more effective integrated actions between communities, civil society organisations, NGOs and various local government departments are needed in order to support community based adaptation and build a climate change resilient community at the grass-roots level.

The role of insurance for flood risk reduction in London: An agent based model approach

K. Jenkins (1) ; J. Hall (1) ; S. Surminski (2) ; F. Crick (3) ; I. Nikolic (4) ; J. Dubbelboer (4)
(1) University of Oxford, Environmental Change Institute, Oxford, United Kingdom; (2) GranthamResearch Institute on Climate Change and the Environment|, London, United Kingdom; (3) GranthamResearch Institute on Climate Change and the Environment, London, United Kingdom; (4) Section Energy & Industry, Faculty of technology, policy and management, Delft University of Technology, Netherlands

Flooding is recognised as one of the most common and costliest natural disasters in England. In London surface water flooding is considered to be the most likely cause of flood events, and probably the greatest short-term climate risk. More than 800,000 properties are estimated to be at risk, and while most drainage systems are designed to cope with a 1/30 year storm event, maintenance is often poor and so parts of the network can perform below these standards.

A particularly interesting aspect of flood management in England is the public-private partnership on flood insurance between the UK government and the insurance industry. Flood insurance is underwritten by the private market, while government commits to flood risk management activities. However, this agreement is currently under review with a new insurance system, Flood Re, proposed. The proposed system, which creates an insurance pool for properties at high risk of flooding, is presented by government and industry as a roadmap to future affordability and availability of flood insurance, with an anticipated run-time of 20 to 25 years. The mechanisms of the new Flood Re scheme are still being negotiated, and to date there is little mention of how the partnership between government and insurers, and the new Flood Re scheme could also promote effective flood risk reduction measures.

In order to investigate this partnership an Agent based Model (ABM) has been developed for Greater London. The ABM characterises five different agents: property owners, insurer, developer, government, and bank, which interact within the environment. The ABM has been designed such that it can investigate the public-private partnership and the specific issue of surface water flood risk, and analyse how the current and future proposals for the partnership could influence London's resilience to surface water flood risk today and in the future under various scenarios of climate change. Important questions it can address include the effect of surface water flood risk and insurance on household wealth; consequences of flood damage and insurance (un)availability for the housing market; and the role of incentives for risk reduction among different partners (including the government, insurers, and developers) to support flood defences, household level flood protection, and more appropriate spatial planning.

Ultimately, the model aims to highlight the potential benefits and limitations of the proposed Flood Re scheme for risk reduction, and test various options for the scheme, such as the inclusion of certain types of properties, and the financial implications of different transitional pathways to risk-based pricing of insurance in the longer-term. The model and research is highly relevant for the ongoing regulatory and political approval process for Flood Re, which have until now not received sufficient attention due to lack of data or analysis.

The presentation will provide an overview of the ABM, the modelling of a spatially coherent probabilistic surface water flood event set, and highlight the key findings of the analysis of the current and proposed public-private partnership for risk reduction. It will highlight benefits and limitations of the current and proposed scheme, and provide recommendations for the scheme in order to help promote flood risk reduction and increase resilience in London.

O-4408-02

Implications of risk based insurance premiums for flood preparedness and affordability of coverage

P. Hudson (1) ; W. Botzen (2) ; L. Feyen, (3) ; J. Aerts (4)
(1) IVM, VU University Amsterdam, Amsterdam, Netherlands; (2) VU University Amsterdam, Institute for environmental studies - ivm, Amsterdam, Netherlands; (3) JRC, Ispra, Italy; (4) VU University Amsterdam, IVM, Amsterdam, Netherlands

In some countries, such as Germany and France, it has been proposed that a movement towards risk based pricing of natural disaster insurance can stimulate investments in flood risk mitigation measures by policyholders. However, providing financial incentives for risk reduction activities through charging risk based premium may conflict with the affordability of insurance. This study examines the potential trade-off between risk reduction and affordability in a model of (risk based) public-private flood insurance in France and Germany that includes household flood preparedness decisions. Flood risk preparedness is modelled over time to examine adaptation to changing flood risk caused by climate change. In order to do so a risk flood risk misperception distribution is calibrated from observed survey data in order to provide a baseline estimate for the current employment rate of household flood risk reduction measures in order to judge the aditional risk reduction benfits of insurance based financial incentives.

The results show that an insurance scheme offering premium discounts for reducing risk is potentially unaffordable for, at most, 23% of households at risk. Risk based incentives are able to promote the employment of risk reduction measures in both France and Germany. In particular, flood risk can reduce by 13% in Germany and 23% in France by 2040 compared with the current situation in which financial incentives for mitigation are absent. The higher level of flood risk in France results in a strong incentive to reduce risk in the present. Rapid growth of flood risks in Germany results in more effective financial incentives in later periods. The trade-off between affordability and financial incentives can be overcome via a voucher scheme. Providing these vouchers after 2040 is estimated to result in a level of damage reduction that is larger than the cost of the vouchers. A policy recommendation is that there is ample room for these countries to link flood insurance with financial incentives to guide household adaptation to changing flood risk.

O-4408-03

What is the Role of Insurance for Addressing Climate-Driven Extreme Events?

I. Schumacher (1)
(1) IPAG Business School, Paris, France

The insurance of climate-driven extreme events is widely viewed as a potential ex-post means of reducing the damage born by those affected. However, while there are certainly valid arguments that support the use of insurance

when it comes to climate-driven extreme events, it is also clear that insurance cannot be the first-best solution to dealing with this mankind-induced problem.

In this article we discuss under which circumstances insurance may be viewed as a complement to adaptation and mitigation measures, and in particularly we shall focus on the following aspects: 1) when is the insurance of extreme events a desirable alternative to adaptation and mitigation policies; 2) how much value should be placed on the insurance of extreme events relativ to adaptation and mitigation policies; 3) how important are the aspects of the insurance industry for these trade-offs, in particular the transparency of the insurance sector when deciding upon its premia; the investment perspective of the insurance industry; the coverage of the insurance industry and its interplay with a social security system.

Weather index insurance in a changing climate

J. Daron (1) ; DA. Stainforth (2)
(1) UK Met Office, Applied Climate Science, Exeter, United Kingdom; (2) London School of Economics, Grantham Research Institute, London, United Kingdom

Insurance and risk transfer products are increasingly being made available to low income households in developing countries to protect livelihoods from extreme weather and climate events. Index insurance products – where premiums and payouts are based on a proxy for loss (e.g. total seasonal rainfall) rather than the actual economic losses suffered – typically have lower administration costs, and therefore premiums, than traditional claims based insurance. Furthermore, payouts are made immediately when the proxy is triggered, thus reducing the time between a loss event and the receipt of an insurance payout. Various proponents, including the United Nations, have therefore supported the widespread dissemination of weather index insurance as a means to reduce vulnerability to weather extremes in low income communities. However, like most lines of climate-related insurance, weather index insurance products are typically designed using historical observed data only. It has not previously been well investigated how climate change might impact the viability of weather index insurance products.

It is with this background that we developed and demonstrated a method for assessing the viability of weather index insurance under altered climate conditions (Daron and Stainforth 2014). We utilise Bayesian Networks, which are graphical networks that propagate probabilities between variables and outcomes of interest. In our study we develop them as a tool for exploration – to help understand sensitivities and support insurers in assessing pricing structures and assumptions with different climate information. We apply the tool to a case study of weather index insurance for the rice crop in Kolhapur, India.

A hypothetical weather index insurance product is used in Bayesian Networks of increasing complexity that include different sources of climate information. We include observational rainfall data in addition to output from the UK Met Office Hadley Centre regional climate model (HadRM3), driven by model reanalysis data (ERA-Interim) and general circulation models from the Hadley Centre (HadCM3) and Max Planck Institute for Meteorology (ECHAM5). We show that the model data significantly underestimates the historical observed data and therefore question the reliability and utility of the climate model output. Furthermore, we discuss how observations can also be subject to errors and uncertainties.

Depending on the choice of input data, and the process of combining different datasets, we determine very different implications for the viability of the weather index insurance product under climate change. Yet the purpose of the study is not to provide definitive answers of how climate change might impact weather index insurance in the case study region. Rather it is to demonstrate a possible method for combining multiple data sources to inform insurance decisions.

We conclude that without consideration of multiple sources of climate information, and an acknowledgement of the associated biases and errors, insurers are likely to miscalculate and misrepresent the underlying climate hazard risks with potentially adverse implications for policyholders. Used to understand the sensitivities of pricing structures and premiums to different sources of climate data, the Bayesian Network method shows promise as a potential tool to help insurers in making pricing decisions. However, the current generation of climate model output is shown to be of limited value and difficult to use by index insurance practitioners. We therefore caution that in the context of climate change, the absence of reliable, robust, quantitative model projection data means that choices considered optimal based on today's available model information may lead to maladaptation and risk significant losses to insurers in the future.

Sharing of Climate Risks across World Regions

J. Emmerling (1)
(1) FEEM, Milano, Italy

Uncertainty is prevalent in the context of climate change impacts. Moreover, the distribution across the globe is not uniform. We analyze how climate risks could be reduced via an insurance scheme at the global scale across regions and quantify the potential welfare gains from such a scheme. Starting from the standard welfare analysis in Integrated Assessment Models (IAMs), which assumes no risk sharing across region, we introduce global risk sharing via a market for state-dependent Arrow-Debreu securities. We show that this allows equalizing relative consumption differences between states of the world across regions. We estimate that such risk sharing scheme of climate risks could lead to welfare gains reducing the global costs of climate change by up to one third, while the amount of transfers required is substantial. This provides arguments for considering risk sharing in IAMs, but also for potentially welfare increasing negotiations about sharing risks of climate change at the global level.

O-4408-06

On the cost of climate change for an insurance company

E. Masiello (1) ; D. Kortschak (2) ; P. Ribereau (1)
(1) Université Lyon 1, Institut Camille Jordan, Lyon, France; (2) Institute for Economic and Innovation Research, Joanneum research, Graz, Austria

Climate change is of great concern for insurers because of increasing in frequency and intensity of extreme weather events which may represent some very serious insolvency issues. From a mathematical point of view, we derive asymptotics for the ruin probability of the insurance company in a risk model which has been updated in a way to take into account projected changes in some specific weather-related events like tropical storms for exemple. In practice, the results obtained so far are used to try to calculate the cost of climate change for an insurance company in a simplified portfolio. Some examples are presented to illustrate the theory.

The Evolving Role of the UNFCCC in Global Climate Governance: From Regulator to Facilitator?

H. Van Asselt (1) ; F. Zelli (2)
(1) Stockholm Environment Institute, Oxford, United Kingdom; (2) Lund University, Lund, Sweden

It is widely acknowledged that the United Nations Framework Convention on Climate Change (UNFCCC) does not operate in isolation in global climate governance. Governance of climate change and options for improving its effectiveness are not properly understood through an exclusive focus on one of its elements (e.g. the UNFCCC process), but require examining how various elements work in conjunction. Such a broadened focus draws attention to the (potential) facilitative and catalytic role of the UNFCCC, an aspect that has been largely overlooked by commentators and has only recently received more attention in the Durban Platform negotiations on a future climate agreement. The paper explores this possible new role for the UNFCCC, in which it can keep track and review the outcomes of other actions, and strengthen them where possible. It explains the rationale for the new role, and highlights opportunities for as well as risks of 'outsourcing' parts of global climate governance to other international and transnational institutions, focusing in particular on the case of short-lived climate pollutants (SLCPs). The case is of high relevance since a variety of intergovernmental and public-private institutions have started to tackle SLCPs, such as black carbon and tropospheric ozone, including intergovernmental agreements such as the Montreal Protocol as well as new public-private partnerships such as the Climate and Clean Air Coalition. The paper concludes that a better understanding of the UNFCCC's facilitative role leads to a more nuanced assessment of the achievements of the UNFCCC in global climate governance.

National climate governance. National Climate Policy Activity

D. Huitema (1) ; A. Jordan (2)
(1) VU University Amsterdam, IVM, Amsterdam, Netherlands; (2) Tyndall Centre, ENV, Norwich, United Kingdom

States have been widely criticized for failing to advance the international climate regime. Many observers now believe that a "new" climate governance is emerging through transnational and/or local forms of action that will eventually plug the resulting governance gaps. Yet states, which remain oddly absent from most discussions of the "new" governance, will remain key players as governance becomes more polycentric. This presentation is based on two special issues (both edited by Andrew Jordan and Dave Huitema) that explore the ability of states to rise to these interconnected challenges through the analytical prism of policy innovation. We reveal that policy innovation is much more multi-dimensional than is often thought; it encompasses three vital activities: invention (centering on the 'source' of new policy elements), diffusion (that produces different 'patterns' of policy adoption), and the evaluation of the 'effects' that such innovations create in reality. The papers in the special issues, which range from qualitative case studies to large 'n' quantitative studies, offer new insights into the varied roles that states play in relation to all three.

They show, for instance that: the policy activity of states has risen dramatically in the past decade; that state innovation is affected to similar degrees by internal and external factors; and that policies that offer flexibility to target groups on how to meet policy goals are most effective but that voluntary reporting requirements are ineffective. This presentation draws upon these and many other insights to offer a much more nuanced reflection on the future of climate governance; one that deservedly puts states at the front and center of analysis.

K-4409a-03

Transnational Climate Governance: Performance and Future Prospects

M. Betsill (1)
(1) Colorado State Univ, Political Science, Colorado, United States of America

Today, the governance of global climate change takes place in a complex, multi-level and multi-actor landscape through a wide range of mechanisms such as multilateral treaties, carbon markets, certification schemes, urban planning codes, corporate sustainability programs, and so on.

Critical to this transformation is the emergence of transnational governance arrangements which cut across traditional state-based jurisdictions and operate across public-private divides. This talk will present the findings from a recent international research collaboration (Bulkeley et al., Cambridge University Press, 2014) analyzing 60 transnational climate governance arrangements to better understand the emergence, nature and consequences of this phenomenon and consider the broader implications for global climate governance.

K-4409a-04

'The political economy of contending pathways to de-carbonisation'

P. Newell (1)
(1) University of Suussex, Brighton, United Kingdom

Drawing on recent work on the politics of green transformations, this presentation will apply insights on competing pathways to sustainability to the case of de-carbonising the economy. It will look at a range of state-led, market-led, technocentic and civil society-led transformations, drawing both on contemporary and historical examples, to explore what light they shed on our ability to de-carbonise the contemporary global economy.

4409b - Climate Governance: New and emerging challenges after Paris

ORAL PRESENTATIONS

K-4409b-01

Paris and beyond: strengthening the research-policy interface

A. Sagar (1)
(1) Indian Institute of Technology Delhi, Humanities and Social sciences, Delhi, India

While there has been some progress in the climate negotiations as well as in the broader climate arena, this still is not commensurate with the magnitude and urgency of the climate challenge. Therefore identifying the key issues underlying major roadblocks in the climate policy arena and then exploring way of realistically overcoming such roadblocks could be of great help. The Global Climate Policy Conference, which will be held in Delhi in April-May 2015 aims to provide an opportunity to research scholars

from around the world, selected through a competitive, rigorous evaluation process, to present their ideas on how to overcome roadblocks in the climate policy arena and also bring together a set of leading international experts to discuss specific key policy issues where research and analysis could contribute to improved climate policy-making. This session will present the best ideas discussed at the conference, along with their anticipated impact on climate policy-making at Paris and beyond.

K-4409b-02

Transparency and Accountability in Global Climate Governance

A. Gupta (1)
(1) Wageningen University, Environmental policy group, Wageningen, Netherlands

In this paper, we review recent scholarship and the state of the art on the nature and consequences of a transparency turn in global climate governance. Transparency, as information disclosure, is being embraced by public and private climate governance arrangements, including, inter alia, the United Nations Framework Convention on Climate Change (UNFCCC) and the Carbon Disclosure Project, as a way to monitor and/or reward various actors' climate mitigation actions and performance. Such "governance by disclosure" is intended to further a variety of goals, including empowering recipients to exercise informed choice or hold disclosers to account for their (non-) performance, and improving sustainability performance. Our review assesses these posited relationships between transparency, accountability and sustainability in climate governance. We conclude by deploying our own "critical transparency studies' perspective, one that views information itself as fundamentally contested political terrain, to assess the transformative potential of transparency and informational governance in the climate realm.

The Legal Nature of the Paris Agreement: Much Ado About Nothing?

F. Sindico (1)
(1) Strathclyde Centre for Environmental Law and Governance, 16 richmond street, Glasgow G1 1XQ. Scotland, United Kingdom

In 2009 at the Copenhagen UNFCCC Conference of the Parties protesters had banners stating "We will not leave until we have a fair, ambitious and legally binding agreement". Ever since Copenhagen the international climate change legal regime has experienced a metamorphosis from a top down to a bottom up approach, that does not rely (or does not have to rely) on a legally binding agreement. Nevertheless, the ADP is currently negotiating a protocol, another legal instrument or an agreed outcome with legal force under the Convention applicable to all Parties. Against the backdrop of the increasing debate between legally binding and non-legally binding climate change policy avenues, this presentation will discuss each one of these three options and its relevance post Paris.

In the first part of the presentation the status of the current negotiations will be addressed in order to determine whether a protocol, another legal instrument or an agreed outcome with legal force under the Convention applicable to all Parties has received more traction. Taking as a starting point that the level of ambition embedded in any of the three outcomes will most likely need to be upgraded if the Paris Agreement is to meaningfully deal with climate change in the long term, the second part of the presentation will seek to explain why some countries are still advocating for a legally binding outcome, despite the turn towards a bottom up approach. In the third and last part of the presentation the options that may not fall neatly under the rubric of legally binding will be explored. The rationale and their effectiveness will be presented.

In conclusion, it would not be a surprise if banners appear once again in Paris seeking for a fair and ambitious outcome. Whether or not those banners will also ask for a legally binding agreement is more dubious. The three do not necessarily go hand in hand, and a legally binding agreement can also be unfair and not very ambitious. So, is the debate about the legal form of the Paris outcome much ado about nothing, or will the legal nature determine (at least partly) not only the success of the outcome, but also its Post-Paris effectiveness?

K-4409b-04

Accepting reality: we need new post-Paris governance for effective long term climate transformation

G. Huppes (1) ; P. Drummond (2)
(1) Leiden University, CML, Industrial Ecology, Leiden, Netherlands; (2) University College London, Institute for Sustainable Resources, London, United Kingdom

Using the Grubb framework for analyzing climate policy, it seems that current negotiations center around short-term policy approaches in his Domain 1 and 2, while our common future depends on deep long-term transformations, in Domain 3. Also, the Domain 1 UN discussions assume some central authority to ultimately regulate behavior on this globe, with a Binding Agreement on yearly allowable emission capped per country. This seems not feasible for basic reasons. First, risks are uncertain and are very different for different countries. Next, there is no agreed-upon equity principle, with deeply conflicting justice concepts. Also, under a binding agreement, countries growing faster than expected would have to buy permits from lower growth countries. Next, effective implementation is not feasible politically and administratively in many if not most countries. And economically, if a binding cap were implemented through tradable permits, the inherent price instability of a fixed cap could hardly guide long term technology development and implementation. Most basically, the Binding Agreement would not really be binding because there is no global enforcement agency. With only partially applied cap-and-trade systems at the national level those getting around the many corners - politically and administratively or through corruption - will earn substantial amounts of money. It seems quite unrealistic to expect such an interventionist type of policy to drive deep societal transformations.

The current move in discussions towards more bottom-up governance mechanisms is an essential step, as it is at that decentralized level that creativity resides. However, bottom-up governance can hardly counter strong market forces in a globalized capitalist system. Cheap coal, oil and gas are available way beyond the 2, 4, and even 6 degrees climate target. Incentive structures will have to be changed in the core institutions of our global capitalist society for the deep transformations required.

For climate effectiveness generic, encompassing emissions pricing therefore is a sine qua non. Expectations on long term cost for non-fossil energy are to be made lower than for fossil energy. When fossils start to get pressed out of the market, their prices can be very low, for a very long time. Coal, always cheap, is joined by cheap oil and gas. At $40 per barrel of oil equivalent, the extreme CO2 emission reductions required for climate stabilization just will not happen, how good intentions may be. Renewables will lose the uphill battle, even if winning some niche fights. So generic table carbon pricing is a must, replacing partially applicable and volatile cap-and-trade systems like the EU-ETS.

The administrative implementation of carbon pricing, through Duties & Excises, is relatively simple. Most countries have hundreds of years of experience. A post-Paris agreement can be based on an equal level of national emission taxes, administered upstream as an excise on primary fossils production and imports, with a refund upon export and CCS, similar to taxing alcoholic drinks. A CO2 emission tax would result.

The post-Paris agreement would have at its core an equal level of the emission tax between Parties, slowly but steadily rising to relevant levels, in the order of maybe $300 per ton of CO2 in 2050. With that level, natural gas would press out oil and coal, unless CCS would become cheap enough. Relative to intermittent renewables natural gas might remain competitive, but then only in large scale applications combined with CCS. The proceeds of the tax would correspond to actual national emissions, also in EU member states. Nobody will pay more than what is due, and tax authorities don't go for less. Such opposed interests are essential for effective implementation.

The agreement does not need to be a global one to start with. Major powers, like China, EU and US, could start as the Climate Block, open to all others to join on equal conditions. Those not joining would be confronted with an excise on their fossil energy products upon export to the Block. This is not an import tax but an upstream emission tax, treating imports the same as national production. Border Tax Adjustments might also be introduced, on imported products with high emissions abroad, not yet taxed there. Joining the group of emission taxing countries would be attractive. This simple international climate agreement seems most feasible politically, administratively and economically. This institutionalist approach seems a most realistic post-Paris option.

Lima Dialogues 2014 &Local Government Climate Roadmap at COP20 (CMP10): Malaysian Position on Climate Targets and Preferences for Emissions Reduction

AQ. Al-Amin (1) ; R. Rasiah (2) ; F. Walter Leal (3) ; C. Eduardo (4)
(1) Universiti Teknologi Malaysia, International business school (ibs), Kuala Lumpur, Malaysia; (2) University of Malaya, Faculty of Economics and Administration,, Department of development studies, Kuala Lumpur, Malaysia; (3) Hamburg University of Applied Sciences, Faculty of life sciences,=, Hamburg, Lohbruegger Kirchstraße 65, Germany; (4) San Macros University, Foreign relations, Lima, Peru

This study critically evaluates the Malaysian position on climate targets and preferences in the Lima Dialogues in 2014. To capture the local government climate roadmap and Malaysian emissions reduction agendas at the COP20 (CMP10), an 'Empirical Regional Downscaling Dynamic Integrated model of Climate and the Economy' is deployed following the top-down disaggregation strategy. The model takes account of national macroeconomic indicators with various climatic variables, such as a temperature increase limit of 20C (agenda for COP20), carbon cycle, carbon emission reduction, climatic damage, carbon control, and carbon concentration, adapted from observational records of global warming climatic factors; and predicted climate targets for the years 2010 to 2110. Four scenarios forecasted based on the vision of the Copenhagen agendas, reintensified in COP20, are analysed and the results are contrasted with the prevailing baseline scenario of the Malaysian climate vision:2040, with Nordhaus and Stern proposing suggestions and calibrations. According to the COP20 targets, the findings indicate that the cumulative cost of climatic damage over the period 2010-2110 will amount to MYR40,128.1 billion under the present climatic regime in Malaysia, however, it would fall to MYR5,263.7 billion under the COP regime. Thus, the climate results are tempting in terms of prioritizing emission reduction and climate change mitigation for the future looking at the 'local government climate roadmap', but there are a number macroeconomic costs that the national economy needs to take on and these are critically raised for further action. The critical evaluations from this study would help national policy makers to take a proper climate decision in Malaysia before the COP21, scheduled to be held 2015 in Paris and elsewhere with similar economic environments.

Citizenship participation in the public policy making processes in Chile: A glance back

G. Araya (1)
(1) Center for Climate and Resilience Research, Human Dimension, Santiago, Chile

The citizenship participation in the environmental issues has been a standing requirement of the legal systems as of the principle 10, established in the Rio Declaration. In line with the above, the international law regime of the United Nations Framework Convention on Climate Change has promoted, in a systemic manner, that climate change governance must be developed and pursued by the States involving to the citizenship in the decision making process. This article explores the evolution of the citizenship participation in the Chilean climate change governance, mainly expressed during the public policymaking processes, leads by the Environmental Ministry. The different state of proceedings information, the public consultation process, and the answers to the questions raised have been fundamental to monitor the real impacts of the citizenship intervention.

As a global conclusion is possible to observe a slow but sustained and effective increase in the participation levels, contrasting with others on-going process which are being carry out in the region.

P-4409-03

Preferences for Energy Efficiency vs. Renewables: How Much Does a Ton of CO2 Emissions Cost?

A. Bigano (1) ; A. Alberini, (2) ; I. Zverinova, (3) ; M. Š□Asný, (3)
(1) FEEM/CMCC, Milano, Italy; (2) University of Maryland, Arec, Washington D.C., United States of America; (3) Charles University Prague, Charles university environment center, Prague, Czech Republic

Concerns about climate change are growing, and so is the demand for information about the costs and benefits of mitigating greenhouse gas emissions. This paper seeks to estimate the benefits of climate change mitigation, as measured by the public's willingness to pay for such policies. We investigate the preferences of Italian and Czech households towards climate change mitigation policy options directly related to residential energy use. We use conjoint choice experiments, which are administered in a standardized fashion to representative samples in the two countries through computer-assisted web interviews (CAWIs).

In our choice experiments, the alternatives are policy packages described by four attributes: i) the goal of the policy, i.e., addressing energy efficiency or promoting renewable energy; ii) the policy mechanism(s) (which may entail one or more of the following: incentives, taxes on fossil fuels, standards or information); iii) the reduction in CO2 emissions per household, and iv) the cost of the policy to the respondent's household. Items iii) and iv) are expressed as per year for each of 10 years.

The questionnaire was self-administered using CAWI by a total of 1005 respondents. The Italy survey was conducted in July 2014. The Czech Republic survey was similarly structured, and the section of the questionnaire dedicated to the renewables or energy efficiency policies, and the associated discrete choice experiments, was identical to that in the Italy survey instrument (translated into the Czech). The design of the choice experiments was likewise identical across the two surveys. The Czech Republic survey was conducted in August and September 2014 using CAWI and yielded a total of 1385 completed questionnaires.

The responses to the policy choice questions appear reasonable: About 40% of the Italy survey respondents selected program A, 37% program B, and 23% opted for the status quo. The Czech shares are, 33%, 36% and almost 31%. Clearly, the Czech respondents choose the current situation more often than the Italians, implying that their WTP for the policy packages is lower. Responses are stable over the choice exercises, and there is no evidence of anomalies or unusual response patterns. This is the case for both the Italy and the Czech Republic respondents.

We fit the conditional logit models separately for the Italy and Czech Republic samples. The results from the Italy sample are reasonable and suggest that individuals were correctly trading off the attributes of the policies when selecting their most preferred ones. The status quo is the omitted category, and so the positive and significant coefficients on the energy efficiency and renewables dummies indicate that these policies were generally preferred over the status quo. However, the coefficient on the renewable dummy is greater than that on the energy efficiency goal dummy, and a Wald test indicates that they are significantly different from one another at the conventional significance levels. Our survey respondents also have a preference for incentives over other implementation options. The coefficient on fossil fuel taxes is negative and significant, and similar in absolute

magnitude to those on energy efficiency standards and information-based approaches, but the latter two are statistically significant only at the 11% and 5% levels, respectively.

The larger the CO2 emissions reductions delivered by the program, the more likely is a respondent to choose a policy, and the lower the cost, the more attractive the policy, all else the same. These effects are strongly statistically significant at the conventional levels. The results from the surveys indicate that respondents prefer policies that promote renewables over policies that target energy efficiency, and, all else the same, they prefer incentive-based policies over standards and information-based approaches. The respondents in the two countries differ sharply in terms of their preferences for fossil fuel taxes: The Italians have a strong dislike for them, but the Czechs are relatively neutral. The willingness to pay per per ton of CO2 emissions avoided is €130 from the Italy sample and CzK 1514 from the Czech sample, and implies an income elasticity of willingness to pay equal to one.

P-4409-04

'Top Down' AND 'Bottom Up' AND 'Sideways' Climate Governance Solutions: The Realities, Potentials and Perils of a Pluralistic International Institutional Landscape

T. Brewer (1)
(1) ICTSD, Climate Change Global Platform, Geneva, France

The chapter on 'International Cooperation' in volume 3 of the IPCC AR5 documents that the international climate change institutional landscape already consists of a variety of institutional arrangements that include hierarchical 'top down' relationships (as in the multilateral UNFCCC) as well as 'bottom up' initiatives (such as unilateral subnational mitigation and adaptation programs). There are 'sideways' relationships (such as those among cities), and there are also 'sideways' relationships between climate and non-climate regimes. Institutional proliferation along multiple pathways seems likely, including for example 'sideways' linkages among carbon markets. These realities of a pluralistic institutional landscape should be taken into account in order for effective new international institutional arrangements to be devised; ignoring these proliferating tendencies could result in a dysfunctional fragmented international 'system.' Each pathway has its own distinctive combination of advantages and disadvantages vis-à-vis standard evaluative criteria: effectiveness in promoting climate change mitigation and/or adaptation, equity in the distribution of benefits and costs, economic efficiency, political viability and administrative feasibility. Analytic work and diplomatic initiatives are needed to develop pathways that will ensure collaboration and coherence among diverse institutional arrangements.

This presentation explores the implications of these observations for international institutional design. Empirical data and case information are drawn from the energy sector and the international transport sector, which are of course inherently significant in terms of their contributions to greenhouse gas and particulate emissions. The sectors are also significant for international institutional design issues because of their differences and interactions. The international maritime shipping industry is subject to regulation by the International Maritime Organization (IMO), as per provisions of the UNFCCC. The sector's emissions of carbon dioxide, methane and black carbon are thus potentially covered by the IMO. At the same time, the Arctic Council and the Clean Air and Climate Coalition (CACC) also have black carbon and methane on their agendas, and the World Trade Organization has some aspects of international maritime shipping within its purview. There are therefore many potential 'sideways' relationships among them. Yet, the memberships of these various international institutions vary from only 8 member states in the Arctic Council to 39 in the CACC to 170 in the IMO, and their decision-making procedures are quite disparate. In short, there is already a complex mixture of sectoral, multilateral, regional and plurilateral institutional arrangements concerning emissions of black carbon, methane and carbon dioxide. Yet, there is not yet an adequate institutional arrangement in place to address the carbon black and methane emissions issues in the international maritime shipping sector. The presentation thus proposes the negotiation of an Arctic Black Carbon Agreement (ABCA) and an International Maritime Methane Agreement (IMMA). The proposals take into account 'top down' as well as 'bottom up' and 'sideways' institutional relationships.

The presenter is: IPCC Lead Author, 'International Cooperation' chapter, AR5, volume 3; author of articles in the refereed journals Climate Policy and Energy Policy; author of The United States in a Warming World: The Political Economy of Government, Business and Public Responses to Climate Change. Cambridge University Press, 2014; and Senior Fellow, International Centre for Trade and Sustainable Development, Geneva. All views expressed are entirely his own as an independent scholar.

P-4409-05

Global emissions chains and multinational enterprises: measuring responsibilities following the control criterion

MA. Cadarso (1) ; L. Lopez (2) ; J. Zafrilla (1) ; G. Arce (3)
(1) University of Castilla-La Mancha, Economic Analysis and Finance, Albacete, Spain; (2) Universidad de Castillla La Mancha, Albacete, Spain; (3) University of Castilla – La Mancha, Albacete, Spain

The Kyoto Protocol framework establishes the Production-based (PR) criterion (IEA, 2001) as the emissions responsibility allocation method. Greenhouse Gases emissions (GHG) are assigned depending on the country where they occur, regardless of the country where the consumption is done. This approach has generated controversy and is the point at which many emerging and large exporting countries base their refusal to sign the emissions reduction international agreements. Emerging countries argue that they are adversely affected in a context where production and consumption decisions are increasingly separated in different parts of the world. Moreover, carbon leakage through international trade threatens national reductions achievements at global level. One of the most popular scientific literature on alternative approaches proposes to shift responsibility to the consumer (Peters and Hertwich, 2008 or Davis et al., 2012). A country would be responsible for the emissions generated in the production of goods that are consumed within its borders, independently where the goods or services are produced. However, the consumer responsibility criterion (CR) has not managed to become part of international environmental legislation yet.

The global nature of climate change requires the establishment of allocation responsibility criteria that allow to involve more participant agents of different countries in the process: governments, consumers, suppliers, workers, investors (Hoekstra and Wiedmann 2014). Taking into account the presented context, in this paper a control-based criterion is proposed, previously presented in López et al. (2014), in order to allocate the responsibility to the firms that take decisions, in many cases, of locating thousands of kilometres away in countries with weaker environmental policies. This criterion assign to those firms all the emissions embodied in linkage effects along the production chain. Taking into account the control criterion, the limits of enterprises' responsibility is not determined by the country's borders, this limit is given by the control that the parent companies has on its subsidiaries firms and suppliers too, regardless of geographical location and where are citizens of the world that are consuming the goods produced by these enterprises.

Therefore it is necessary to find new frameworks that encourage more countries to sign emissions reduction international agreements and also that allow the responsibility transfer to companies and citizens as main actors' in the mitigation of climate change. To shift the focus to the role of companies, instead of nation-states, has some advantages as, for instance, not to deal with the problem of restricting responsibility to territory (PR) or of the ability of governments to act beyond their frontiers (CR). Moreover, recent research states that nearly two-thirds of historic emissions can be attributed to 90 companies (Heede 2014). Companies, and thus consumers, do not become knowledgeable about the environmental impacts of their production networks (O'Rourke, 2014); these firms do not take responsibility for the external costs associated to these impacts. The quantification of these emissions under the control criterion and the allocation of responsibility to firms would help to provide positive incentives for the more efficient

management in environmental terms of the global value chains by the companies.

The aim of this paper is to calculate a control-based criterion for China in a multiregional input-output context (MRIO), which allows the assessing of the impact of international trade considering all the emissions associated with the entire global value chains. The Chinese choice is due to foreign enterprises operating and exporting in China account for 54% (Feenstra et al., 2013) and have a strong potential influence over the global production chains with respect to technology and emission intensities (Skelton, 2013). Estimations will be done using the World Input-Output Database (WIOD) that provides information about 41 regions with a sectorial disaggregation of 35 industries. These data will be combined with information about multinationals operating in China for the year 2009.

P-4409-06

Preventive communication and risk preventive policy in Guadeloupe

V. Charneau (1)
(1) Université des Antilles, Science-Politique, Pointe-à-Pitre, France

Located in an area geographically and geologically unstable, the Caribbean basin, is regularly attacked by natural hazards. Thus, earthquakes, hurricanes, volcanic eruptions and all their consequences are an integral part of the lives of various people and institutions in the Caribbean area. The threats that people must face and that institutions must support the policies of prevention and risk management. Since the recent decades, the focus was on climate change by the scientific community. The result is party to the increase in the temperature of which one of its consequences is the increase in the frequency and magnitude of natural hazards.

The Guadeloupe is part of the French Departments of America, it has implemented the risk of public policies, among them measures relating to the dissemination of preventive information. Because, recently, the effectiveness of natural risk prevention and management plans based on the citizens' information procedures. But public policy risk through natural risk prevention plan does not clearly define the information broadcasts measures. Thus it is clear will to respond to threats that raise natural hazards and of involving people in the management of these, the association «consensus-communication» under the Risk Prevention Plan. Then, reaching to emerge, communication as a «means to mobilize» in the context of preventive actions, and also prevent the risk from climate upheaval.

This study aims to analyze public policies for risk management and dissemination process of preventive information. To do this, it will make a brief review of the history and contributions of the state of the scientific literature in the humanities and social sciences, the concept of risk, highlighting briefly science developments information, communication, and finally, it will analyze synthetically the natural risk prevention plan for the city of Petit-Bourg in Guadeloupe, especially for highlighting the organization of public consultation required by the plan.

P-4409-07

Climate Change and Collective Action: Lessons from Elinor Ostrom and the Bloomington School of Political Economy

D. Cole (1)
(1) Indiana University, School of Law and School of Public & Environmental Affairs, Bloomington, IN, United States of America

Climate change has been largely mischaracterized as a "public good" subject to a Prisoners' Dilemma game, where it is in the individual interest of each country to continue emitting greenhouse gases, even though it is the global interest for each country to curtail its emissions. Given this characterization, the collective action problem posed by anthropogenic climate change is practically insurmountable.

But climate change is, in fact, a different type of good and subject to a different kind of game to which a cooperative solution is available (though not guaranteed). Whereas prior to the Industrial Revolution it made sense to think of the climate as a "public good" (in its strict sense), the very existence of the climate change problem indicates that the climate is now more in the nature of a "common-pool resource" (CPR) with characteristics similar to many situations Elinor Ostrom studied during her storied career, albeit at a much larger scale. As a "common-pool resource" (CPR) the global climate is subject to the same kinds of analytical frameworks, theories, and methods that Ostrom and her colleagues in the Workshop in Political Theory and Policy Analysis at Indiana University have used over the past 45 years to study other types of CPRs.

Like virtually all other CPRs, the collective action problem posed by climate change really is not in the nature of a Prisoners' Dilemma, but more like an "Assurance Game," as originally defined by Amartya Sen. In contrast to a Prisoners' Dilemma, an Assurance Game has both cooperative and non-cooperative equilibria. Which equilibrium solution is reached depends largely on the level of reciprocal trust among the players. The higher the level of mutual trust, the higher the payoffs from cooperation, relative to non-cooperation.

In a variety of experimental and field settings, Ostrom and her colleagues found that, under the right conditions, mutual trust can be fostered over time, raising the perceived returns to cooperation. Among the conditions they found that fostered trust are frequent opportunities for communication and interaction. Specifically, Ostrom found that increased communication (1) facilitates development of socially optimal strategies; (2) allows for exchanges of promises; (3) increases mutual trust; (4) adds value to payoffs; (5) reinforces shared norms; and (6) promotes the development of shared or group identities. However, the building of mutual trust does not depend on communication alone but also on the ability to observe and verify that others are acting in a trustworthy fashion. Thus, monitoring and accountability are crucial parts of the puzzle for successful collective action to resolve any kind of CPR problem, including climate change. Trust is not a matter of blind faith; verifiability is part and parcel of trust.

Beyond culling lessons from Ostrom's large corpus of empirical, theoretical, and analytical studies, I will exemplify those lessons by reference to recent trust-building, cooperative ventures on climate policy between the US and China. The regular, bilateral negotiations of the "US-China Climate Change Working Group" already has achieved substantial positive outcomes for climate policy, and more quickly than anyone had imagined possible. Meanwhile, cooperation is ongoing at various levels of governance, including the local government level and even in private governance. Thus, climate negotiations are becoming increasingly "polycentric," as Vincent and Elinor Ostrom defined that term.

Far from being a threat to global negotiations under the UNFCCC and its Protocols, these lower-level negotiations should be perceived as activities in furtherance of goals established in global-level agreements. They are the kinds of interactions that are in fact necessary to build, over time, the kind of mutual trust that is required to make further progress on climate change mitigation at the global level. The increasing bilateral and multilateral communications and agreements we have been witnessing do not guarantee a cooperative outcome to the Assurance Game of climate change, but without them a non-cooperative outcome is almost guaranteed.

P-4409-08

Explaining climate bargaining strategies of developing countries

V. Costantini (1) ; G. Sforna (1) ; M. Zoli (2)
(1) Roma Tre University, Department of Economics, Rome, Italy; (2) University Rome Tor Vergata, Rome, Italy

Although the efforts made during the last COPs, Parties are still far from achieving an agreement for the implementation of a new climate regime. As demonstrated by the debate about the interpretation of the Common But Differentiated Responsibilities principle, the growing role played by developing countries in negotiations is one of the main causes behind the deadlock. For this reason, attention should be paid to the composition of the negotiating coalitions of developing countries. By applying a cluster analysis, this paper aims at investigating the role played by the heterogeneity in structural features of

developing countries in forming bargaining coalitions in the climate negotiation.

The final cluster structure reveals that developing countries are grouped into nine clusters, which are very different from each other depending on some crucial characteristics. The principal driving forces forming the clusters are related to the energy system, the climate vulnerability and the economic development level.

It is worth noting that these are all crucial variables for climate change negotiations and might help better understanding the reasons behind bargaining positions of these countries, as well as the effective impacts of a potential climate agreement on heterogeneous interests.

Turning to the specific results of this statistical analysis, four out of the nine clusters deserve particular attention. A first group represents large energy exporting countries, mainly formed by OPEC countries. A second group very closed to the first one is formed by small energy exporting countries. Even though this second group has different structural features from the first one, the driving force played by the particular vulnerability to climate agreement caused by the dependency on energy exports might influence this second cluster to make a coalition with the large energy exporters, thus influencing substantially the negotiations outcome. The first policy suggestion for climate governance is to refine the criteria to protect energy exporting countries in order to account for their relative dependence on fossil fuels export with respect to their economic sustainability.

The third cluster gathers the largest number of countries, grouping together the Least Developed Countries in Africa and South East Asia. This group is characterized by a high vulnerability degree to climate change and a low responsibility in GHGs emissions. This explains why LDCs ask for a stringent agreement including emerging economies. In terms of climate governance, this group might influence the final agreement in the direction of a challenging mitigation action but they also need a strong financial support for recovering climate damages. This particular double interests position might reduce their bargaining influence in the climate negotiations since they will not contribute to mitigation costs and they will benefit the most from international assistance.

On the contrary, the fourth cluster reveals that there are countries whose structural features put them in a contrasting position with respect to any potential climate agreement outcome. More specifically, these are poor and vulnerable countries with a strong economic dependency from fossil fuels export. This means that if a challenging mitigation action will be settled, they will be negatively influenced by the reduction in international energy demand. At the same time, if the current GHGs emission pathway is not corrected by a climate agreement, these are countries that would face several damages caused by global warming. This can lead these countries to advocate different interests, joining alternative bargaining coalitions (LCDs as well as fossil fuel producers) during different COPs. Given that whatever the results in negotiations, they always lose as they have to sacrifice an improvement in terms of vulnerability in favour of economic benefits or vice versa, this specific group represents a source of particular uncertainty in the climate governance process.

The results obtained by applying a statistical cluster method to group developing countries involved in climate negotiations help highlighting the specific features driving vulnerability as well as bargaining positions. This brings to suggest to policy makers that in order to facilitate climate governance is highly recommended to take into account the largest number of vulnerability sources to climate issues, in order to design specific complementary measures necessary to minimize costs for every country.

Renewable energy: past trends and future growth in 2 degrees scenarios

W. Crijns-Graus (1)
(1) Copernicus Institute of Sustainable Development, Department of innovation, environmental and energy sciences, Utrecht, Netherlands

Many studies agree that a transition to a sustainable energy supply is needed in order to safeguard the supply of energy for future generations and abate greenhouse gas emissions. Limiting the average global surface temperature increase to 2°C, compared to pre-industrial average, is commonly regarded as an adequate means of avoiding dangerous climate change. In many scenarios that envision a development of energy supply that would be in line with a 2 degrees target, a large component of the solution consists of renewable energy and energy efficiency. Renewable energy would be in the range of 200-300 EJ in 2050, equivalent to 40-80% of total primary energy supply in 2050. This means an increase by a factor of 3 to 4 compared to 74 EJ in 2012 (IEA, 2014).

In spite of a significant increase in the use for renewable energy in the period 2000 to 2012 (from 54 EJ to 74 EJ), the share of renewable energy in total energy use has remained constant at 13%. A reason can be found in the growth of total energy use and hence non-renewable energy use, which increased likewise.

This research explores past growth rates for different types of renewable energy and required future growth rates in available 2 degrees scenarios. For this purpose past trends in renewable energy use in the period 1971 to 2012 are analysed and future contributions are explored.

From the analysis of past trends it becomes clear that in spite of comparatively high growth of renewable energy in the period 2000-2012, the share of renewable energy stayed the same due to similar increases in non-renewable energy use. Only a few countries managed to increase the share of renewable energy in their fuel mix. Most notably Germany demonstrated an effective increase in renewable energy from 3% in 2000 to 11% in 2012. This was achieved by a high overall growth rate for renewable energy of 11%/yr and a decrease in primary energy use of 0.7%/yr. Energy and climate policies in EU28 overall showed an effect by increasing the share of renewable energy from 6% in 2000 to 11% in 2012 with slightly decreasing energy use. China and India showed decreasing shares of renewable energy due to a high growth rate for total energy use combined with more moderate overall growth rates of renewable energy.

The overall increase in renewable energy amounted to 2.2%/yr in the period 1971-2012 and 2.6%/yr in the period 2000-2012. In order to be consistent with a 2 degrees pathway these growth rates would need to increase to 3-5%/yr. Biomass is at the moment the largest source of renewable energy used globally, equivalent to 10% of total primary energy use in 2012, followed by hydro power responsible for 2%. A transition of energy supply in order to help achieve a 2 degrees target would not only require a strong growth of renewable energy in absolute and relative sense, but also a strong shift to other renewable energy sources than biomass and hydro. Especially high growth would be required for wind, solar and geothermal in the order of 10%/yr. This would lead to a change in the mix of renewable energy used, with a much higher share of variable renewable energy sources (VRES). Overall wind and solar energy use would need to increase by as much as a factor of 30-60 in 2050, in comparison to 2012 (from 3 EJ to 58-155 EJ). The share of renewable energy would be in the range of 40-80% of energy use, with the share of wind and solar amounting to 25-54% of renewable energy use.

However most notable from the assessment of future needed growth rates is, the strong difference in the required development of energy use, compared to past trends. For decades primary energy use needs to consistently decrease by 0.1-0.5%/yr for OECD regions. A decrease in energy use has not occurred in the past 40 years in OECD countries, except for a couple of years during a time of recession. This would therefore require a breach from past trends. But especially for non OECD regions the needed change is large. Regional growth rates for energy use in the period 2000-2012 range from 1.5%/yr to 5.5%/yr and should decrease to be within the range of -0.2%/yr to 0.9%/yr. Therefore, a main challenge, besides increasing the uptake of renewable energy, would lie in the decrease of energy use growth rates in non-OECD countries.

Routes to an ambitious climate agreement in 2015

C. De Perthuis (1) ; PA. Jouvet (2)
(1) Climate Economics Chair, PARIS, France; (2) Paris Ouest Nanterre University, Economics, Nanterre, France

As shown by the collective action for the protection of the ozone layer under the Montreal Protocol, the success of a multilateral agreement rests on three pillars: strong political commitment, an independent and rigorous monitoring system, and economic instruments that transmit the right incentives. For it to be a success, the 2015 Paris climate conference will need to make progress on each of these three pillars. The Climate Economics Chair has focussed its research efforts on the pillar of economic instruments.

- The Fifth Assessment Report of the IPCC states unequivocally that from 2020 all major emitters of greenhouse gas emissions must participate in the global effort to reduce emissions and limit average warming to no more than 2°C.
- In order to drastically curb emission trajectories, global carbon pricing should be rapidly introduced, so as to put pressure on governments to act cooperatively and to encourage economic actors to reduce emissions at the lowest cost.
- To encourage governments to reach a global agreement, a bonus-malus carbon pricing system, calculated on the basis of average emissions per capita, could be introduced at a rate of $7-9 per tonne of CO2 equivalent from 2020.
- The most realistic way of introducing an international carbon price into the global economy is to lay the foundation, between 2015 and 2020, of a transcontinental carbon market, based on prototypes developed in Europe, China and the United States.
- The introduction of double carbon pricing would be subject to the principle of "common but differentiated responsibilities", aimed at reconciling joint action on climate change and the priority of access to development.

P-4409-11

How to increase mitigation? Some lessons from the Montreal Protocol on the protection of the ozone

J. De Sepibus (1)
(1) University of Benr, Law Faculty, Bern, Switzerland

The necessity to increase mitigation efforts, while addressing carbon leakage and generating climate finance, represents one of the most daunting challenges of the future climate regime. We argue that these goals could be achieved through the adoption of an agreement (hereafter the "Agreement") by a group of countries that set ambitious mitigation targets for specific sectors and impose border tax adjustments on commodities from non-parties that do not meet comparable carbon standards. The institutional architecture of such an agreement would be construed along the lines of the Montreal Protocol on the protection of the ozone layer, i.e. it would contain rules that assure that non-participants loose more from being outside the agreement than they gain. Moreover, to induce countries to participate, carrots would be offered in the guise of financial and technical assistance, based on the principle of common but differentiated responsibilities.

As the Montreal Protocol the new Agreement would a) provide for majority voting for the adoption of amendments b) have effective compliance mechanisms and c) rules ensuring due process of law. It would depart from the model of the Montreal Protocol insofar as 1) it would not address a progressive phase-out of specific substances, but aim at a progressive tightening of mitigation goals in specific carbon-intensive sectors, 2) it would not use trade bans of controlled substances from non-parties but adopt carbon taxes at the border 3) it would principally depend on the revenue of carbon taxes to pay financial and technical assistance. To ensure the comparability of mitigation efforts the Parties would inter alia develop common rules for sector data requirements, measurement, reporting and verification practices, methodologies underlying the calculation of the level of BCA from non-parties.

P-4409-12

Does fragmentation pay? Multiple international environmental agreements with asymmetric countries

A. Hagen (1) ; K. Eisenack (1)
(1) Carl von Ossietzky Universität Oldenburg, Oldenburg, Germany

While the negative effects of greenhouse gas emissions and the global climate change are relatively well acknowledged amongst scientists, solutions for what should and could be done to tackle these problems are less agreed upon. Spillovers and the absence of clear property rights make it difficult to reach effective cooperation through international environmental agreements (IEAs). In light of the slow progress in international climate negotiations, the idea of climate clubs is getting increasing attention while the aim of negotiating one single universal agreement is identified as one primary obstacle to a global treaty within the United Nations Framework Convention on Climate Change (UNFCCC).

We investigate whether global cooperation for emission abatement can be improved if asymmetric countries can sign multiple parallel environmental agreements. In a two-stage game, countries first choose whether they sign one agreement, or to be a non-signatory. In the second stage, each coalition acts as a unitary actor in a non-cooperative Nash game between the coalitions and the non-signatories. We compare emissions abatement and coalition stability in the multiple IEAs case with the standard case where not more than one IEA is possible. After solving the model for the case of constant marginal benefits from abatement and constant marginal costs of abatement with two agreements we relax our assumptions and allow for multiple coalitions with multiple types of asymmetric countries. We then analyze the effect of multiple coalitions for the case of increasing marginal costs of abatement as well as for decreasing marginal benefits of abatement more generally. The results are sensitive to the assumptions on the benefits from abatement. For constant marginal benefits, the possibility of multiple agreements increases the number of cooperating countries and total abatement (compared to the standard case with a single agreement). For decreasing marginal benefits, total emissions are independent of the number of admitted agreements.

The comparison of the different cases shows that the effect of climate clubs substantially depends on the qualitative properties of abatement benefit functions. However, we can generally show for the above made assumptions that climate clubs are at least not detrimental to global cooperation. This paper already shows how different assumptions lead to different effects of country clubs. It is thus a consequent stepping stone towards a more detailed understanding of the determinants for beneficial or detrimental effects of climate clubs. In any case, it has to be concluded that the idea of climate clubs enhancing global climate protection has to be taken with precaution, but that it clearly deserves more analytical attention.

P-4409-13

Adapting, transforming, strategising: A conceptual capacities framework for transilience climate governance

K. Hölscher (1) ; N. Frantzeskaki (2) ; D. Loorbach (3)
(1) DRIFT (Dutch Research Institute for Transitions), Rotterdam, Netherlands; (2) Erasmus University, Rotterdam, Netherlands; (3) Dutch Research Institute for Transitions, Rotterdam, Netherlands

Climate change will profoundly shape the future of human societies (IPCC 2014, Smith et al. 2011). Addressing climate change requires sustainability transitions of deeply entrenched drivers of climate change (Meadowcroft 2009). Uncertainties, the likelihood of surprises, non-linear and extreme impacts resulting from climate change demand managing social-ecological resilience across scales and times (Pelling 2011, Nelson 2011, Wise et al. 2014, Jäger et al. 2012). From the integration of transitions and resilience scholarships, we developed a conceptual framework for dealing with high uncertainty contexts and navigating through high level of complexity found in these contexts (Hölscher et al. 2014). The developed

governance framework conceptualises about the different types of agency capacities needed so as to reorient and/or transform on-going processes towards sustainability while fostering system's resilience, transilience.

Transilience governance requires scale- and time-dependent stabilising and maintaining of system functions (adapting), creating of fundamentally new system structures and functions (transforming), and strategising towards sustainability within environmental and social preconditions. The governance capacities reside in public and private actors at local, regional, national and international levels and their abilities to "define the content of public goods and to shape the social, economic, and political processes by which these goods are provided" (Knill and Lehmkuhl 2002:43). In this paper we will address the following research question: How do certain agency factors shape the capacities for transilience governance?

We approach this question by developing and testing a conceptual capacities framework that is based on a literature review of transition studies, resilience thinking, social-ecological systems and climate change literatures. Our framework encompasses adaptive, transformative and strategic capacities that together enable transilience governance (Table 1). We conceptualise that the capacities are interrelated (Marshall et al. 2012, Wilson et al. 2013). The capacities are produced by the collective abilities of actors (individuals, organisations, networks) in social-ecological-technological systems. One actor can also enact different capacities.

Table 1: Definition of adaptive, transformative and strategic capacities

Adaptive capacity	Transformative capacity	Strategic capacity
The ability to adapt system structures in order to maintain and stabilise system functions, reduce and/or enable coping with disturbances and/or operate upon origins and attributes of disturbances	The ability to transform system structures and functions in order to create fundamentally new system structures and functions when limits of adaptation are met and/or to operate upon origins and attributes of disturbances	The ability to strategise towards sustainability goals within environmental and social preconditions to orientate, balance and build adaptive and transformative capacities.

The collective abilities of actors to adapt, transform and strategise are determined by actors' willingness and skills and the strategies they employ to mobilise (human, mental, natural, artifactual, financial) resources (Adger et al. 2004, Armitage and Plummer 2010, Avelino 2011, Brown and Westaway 2011, Farla et al. 2012, Folke et al. 2002, Moore and Westley 2011, Westley et al. 2013). Adaptive skills and strategies accumulate resources, e.g. building reserves for protection or recovery of infrastructure, densifying networks, or institutionalising. Transformative skills and strategies draw and/or appropriate resources and/or mobilise latent or unused resources through e.g. networking, innovating, creating disturbances or visioning. Strategic skills and strategies orientate, divest and/or invest resources through e.g. goal-setting, bridging across scales and time, encouraging stakeholder participation and designing contingency plans for those loosing from trade-offs.

We test our capacities framework by conducting an exploratory, comparative case study (Yin 1994) of the Rotterdam Climate Initiative and New York City's PlaNYC programme. Both programmes are set up to establish and implement sustainability and resilience policy goals in important urban deltas adversely affected by climate change. We explore how agency factors shape the capacities to transilience governance. This yields insights on how the three capacities interrelate over time and how climate governance could be facilitated.

Co-producing climate change responses: incorporating practitioner knowledge in the IPCC Process

C. Howarth (1)

(1) Global Sustainability Institute, Anglia Ruskin University, Cambridge, United Kingdom

The process and flow of information and expertise on climate change is complex. The multiple interfaces existing between scientists, policymakers and practitioners are far from well understood to adequately assess and refine strategies for climate adaptation. The gathering of evidence for the Intergovernmental Panel on Climate Change (IPCC) reports is an exercise conducted primarily by the scientific and political communities, and does not take into account the needs, and the role, of the experts working on the ground. Although increasing efforts are being made to improve the science-policy interface, the disconnection between science and practitioners remains a key barrier to progress in climate change adaptation.

The latest findings from Working Group 2 on Impacts and Adaptation of Climate Change remain largely inaccessible to practitioners and do not fully incorporate their ongoing work on climate change issues. This is mainly the result of the IPCC process being highly academic-oriented and based on the peer-review mechanism with long lag times, and communication challenges, including different language and cultural interpretations. Building on the IPCC's recent review of how to make its reports more accessible going forward, this research assesses the extent to which models of co-production can capture the depth and breadth of the practitioner community's work and effectively incorporate this into the IPCC process. For example the practitioner community is starting to adopt the term "resilience" instead of adaptation.

The premise for adopting models of co-production acknowledges that knowledge from different stakeholders (e.g. academics, policy, media, NGO, business, public, and practitioners) can be seen as 'useful frames for capturing different approaches to knowledge production'. Such a process would ensure that future IPCC reports are more up-to-date, robust and complete in their analysis and that the climate change resilience solutions proposed incorporate the most practically viable research.

Through a series of workshops and interviews with academics, policy officials and practitioners in the United Kingdom this research focuses on the following three questions:

1. Can a co-production process facilitate the incorporation of practitioner expertise in IPCC reports?
2. What are the limits and opportunities from (i) adopting such an approach and (ii) incorporating practitioner based evidence?
3. How can the role of those involved in this process ensure better communication of the IPCC and wider climate messages and better co-design climate resilience?

This presentation will outline preliminary findings from these workshops and interviews and will provide valuable insights into how a co-production approach and the incorporation of practitioner based evidence could improve the production, dissemination and use of IPCC WG2 reports going forward in designing strategies for climate resilience.

Closing the emission price gap

M. Jakob (1) ; O. Edenhofer (2) ; F. Creutzig (3) ; C. Flachsland (4) ; S. Fuss (5) ; M. Kowarsch, (1) ; K. Lessmann (2) ; L. Mattauch, (1) ; J. Siegmeier, (1) ; J. Steckel (6)

(1) Mercator Research Institute for Global Commons and Climate Change, Berlin, Germany; (2) Potsdam Institute for Climate Impact Research, Potsdam, Germany; (3) Mercator Research Institute on Global Commons and Climate Change, Land use, transport and infrastructures, Berlin, Germany; (4) Mercator Research Institute on Global Commons and Climate Change (MCC), Berlin, Germany; (5) Mercator Research Institute on Global Commons and Climate Change

(MCC), Resources and International Trade, Berlin, Germany; (6) Mercator Research Institute for Global Commons and Climate Change, Climate and Development, Berlin, Germany

Even without internationally concerted action on climate change mitigation, there are important incentives for countries to put a price on their domestic emissions, including public finance considerations, internalizing the climate impacts of their own emissions, and co-benefits, such as clean air or energy security. Whereas these arguments have been mostly discussed in separate strands of literature, this article carries out a synthesis that exemplifies how policies to put a price on emissions can be conceptualized in a multi-objective framework. Despite considerable uncertainty, empirical evidence suggests that different countries may face quite different incentives for emission pricing. For instance, avoided climate damages and co-benefits of reduced air pollution appear to be the main motivation for emission pricing in China, while for the US generating public revenue dominates and for the EU all three motivations are of intermediate importance. We finally argue that such unilateral incentives could form the basis for incremental progress in international climate negotiations toward a realistic climate treaty based on national interest and differentiated emission pricing and describe how such an agreement could be put into practice.

P-4409-16

Adaptation of Legal Framework to Combat Climate Change in India

KN. Joshi (1)

(1) Institute of Institute of Development Studies, Natural Resources Management and Environment (Remote Sensing), Jaipur, Rajasthan, India

India is facing challenge of sustaining rapid economic growth while dealing with the global threat of climate change. The threat mainly is from increasing greenhouse gas due to industrialization, automobile, intensive agriculture, reduction in green cover and high consumption life styles. This phenomenon may alter the distribution and quality of India's natural resources and adversely affected the livelihood of its people. With the economy closely tied to its natural resource base and climate-sensitive sectors such as agriculture, water and forestry, India may face a major threat because of the projected climate change. Recognizing this fact and knowing that climate change is a global challenge, India has entered actively in multilateral negotiations in the UN Framework Convention on Climate Change, in positive, constructive and forward-looking manner.

India signed the United Nations Framework Convention on Climate change (UNFCCC) on June10, 1992 and ratified it on November 1, 1993. It ratified the Kyoto Protocol on August 26, 2002, with the objective to establish an effective, cooperative and equitable global approach based on the principal of common but differentiated responsibility, enshrined in the UN framework.

India is one of the leading developing countries in so far as having incorporated into its Constitution the specific provisions for environmental protection in year 1950. Article 48A of the Constitution of India provides that 'the State shall endeavor to protect and improve the environment and to safeguard the forests and wild life of the country'. Similarly, Article 51A (g) makes it obligatory for every citizen of India, 'to protect and improve the natural environment including forests, lakes, rivers and wild life, and to have compassion for living creatures.' Despite the fact that India's contributions to greenhouse gas emissions are very small, the Government of India has taken many measures to improve the situation in this regard. India has initiated several climate-friendly measures, particularly in the area of renewable energy. It has one of the most active renewable energy programmes besides having a dedicated Ministry for non-conventional energy sources in general and mitigation of greenhouse gases in particular.

This paper is an attempt to provide an overview of the legal framework for combating climate change in India and to examine the existing environmental law and policies which can reduce greenhouse gas emissions. It reviews existing national legislation, relevant overarching policies in the environmental field so as to reduce their impact specifically on climate change.

P-4409-17

Climate Diplomacy from the Perspective of the Emerging 'Climate Security Paradigm'

M. Katriona (1) ; B. Mohamed (2) ; O. Barriere (3)

(1) Fellow, Ecologic Institute, Berlin, Germany; (2) Head, Research Laboratory on Territorial Governance, Human Security and Sustainability (LAGOS), Public law department, faculty of law, economics and social sciences of agadir, Agadir, Morocco; (3) Researcher in Environmental Law and Anthropology, Institute of Research for Development (IRD), Umr espace-dev, Montpellier, France

Within the UNFCCC process, various efforts have been made to craft a regulatory system for managing climate change, which gave birth to a complex of tangentially connected regimes and various bilateral and unilateral initiatives from top-down and bottom-up approaches. To engage effectively with this complex framework, state actors are supposed to go beyond conventional and reactive forms of diplomacy to take an approach that merges climate and foreign policy in creative, proactive, and preventive ways. At the upcoming UNFCCC meeting in Paris 2015, it is hoped that nations will commit to a new and binding agreement on climate. At present, the goal of climate diplomacy is to build the political conditions to make this goal achievable. However, the current failure to agree on how to limit dangerous climate change through an effective and equitable regime is generally pointed out as one of the greatest ongoing failures in modern diplomacy. Many observers consider the weak political will and leadership among main carbon emitters and the lack of trust within the international community as the key factors behind this failure. This has been heightened by the fact that some nations have backtracked on their commitments to reduce emissions or to provide assistance to countries with limited adaptive capacities, while other nations' efforts to reduce emissions have gone unacknowledged. This fractured political environment hinders advanced commitments and deepens the North-South divide, especially with regard to the question of how to best allocate the critical global mitigation responsibility.

Within this context, climate diplomacy may present a way to overcome existing dilemmas since it is essentially an interface between national interest debates and international cooperation. It is capable of ensuring the accurate assessment of other countries' interests and intentions, and finding the needed space for agreement. To do this it must interpret conflicting national interests around many issues such as climate vulnerability, low carbon businesses opportunities, high carbon asset exposure, sovereignty and perceived fairness. Climate diplomacy must ensure national priorities are reflected and understood in the often abstract world of international climate change agreements. It is indeed the role of climate diplomacy to deliver the timely construction of international climate regime, ensure its effective operation, and shape its evolution to address emerging challenges.

To deal with the internal and external challenges to success, climate diplomacy must draw on the best practice of modern diplomacy and also innovate new approaches, especially as it is evolving in scope and complexity as the climate regime shifts its focus from target setting to implementation and climate risk management. This shift has prompted better integration of climate change into broader foreign policy and geopolitical discussions, a proliferation of overlapping alliances between both state and non-state actors, and new approaches to shaping a global dialogue on the consequences of, and solutions to, climate change. However, and in order to boost the evolution of climate diplomacy within this perspective, while anchoring commitment to climate change at the highest level on the international political agenda and raising the level of ambition for an efficient global climate governance, the security implications of climate change – from human, economical, environmental, and geopolitical perspectives – should be widely recognized and mainstreamed.

Based on these assumptions, this research aims to investigate the following topics:

- What is the relevance level of the 'climate security discourse', and in which areas further research and investigation should be undertaken to qualify the 'climate security paradigm' as a referential for building an effective climate regime?

- Are there any risks of linking climate change to security such as the ones which assume that framing climate change as a security issue may overshadow important social and environmental concerns and sending ironically fear-based and disturbing messages to relevant decision making processes?
- To what extent the mainstreaming of climate security as a priority in the agenda of climate diplomacy can narrow, or otherwise broaden, the scope and scale of action internationally and domestically?
- What kind of adjustments to be undertaken on all levels to make the 'climate security approach' relevant and effective in terms of climate governance?

P-4409-18

Critical Mass Governance: How Unilateral Climate Actions Create Global Impacts

L. Kemp (1)
(1) Australian National University, Fenner School of Environment and Society, Canberra, ACT, France

The current practice of UN based climate multilateralism under the UN Framework Convention on Climate Change (UNFCCC) focuses upon broad, consensus based legal treaties that cover a large number of issues. It is an approach that is creating diminishing returns over time. Despite this, it appears that the next climate agreement to be decided upon at the 21st Conference of the Parties (COP21) to the UNFCCC, will also prioritise the construction of a treaty with 'universal participation'. This paper argues that a switch towards smaller treaties which attempt to work by coalitions of the willing are a more viable approach forward. By drawing together ideas from a range of fields such as 'The Theory of Critical Mass' from sociology, 'Bandwagoning' and 'Norm Cascades' from international relations, pluritilateral proposals for both the climate and trade regimes, and practical examples from the EU and Kyoto Protocol, a theory of "Critical Mass Multilaterism" for climate change is developed. These disparate ideas and examples all deal with the notion of 'positive feedback': that a single action can cause further effects which amplify it over time. Accordingly, there is both a theoretical foundation and precedence for the mitigation actions of a few states to spread to others. This conceptual framework is then applied to case studies of both the Convention on Biological Diversity, the Kyoto Protcol and Montreal Protocol. The Theory of Critical Mass Multilateralism would suggest the the next climate agreement should focus on facilitating and linking strong unilateral and pluritlateral actions, instead of seeking a universal and consensual deal with the ratification of all major players including the US. The future of climate multilateralism, should, and most likely will, be in a number of smaller, more focused treaties, regardless of whether the Paris negotiations succeed or fail. The primary challenge of a future climate treaty is not to address free-riding and carbon leakage concerns, but to enable a critical mass of action that will generate the neccessary feedbacks in terms of market prices, norms and political will. Addressing climate change internationally is not a matter for a global deal, but simply a critical mass of progressive actors.

P-4409-19

Leadership in Climate Change Mitigation: Consequences and Incentives

U. Kornek (1) ; K. Lessmann (1) ; M. Pahle (2) ; G. Schwerhoff (3)
(1) Potsdam Institute for Climate Impact Research, Sustainable Solutions, Potsdam, Germany; (2) Potsdam Institute for Climate Impact Reserach (PIK), Potsdam, Germany; (3) Potsdam Institute for Climate Impact Research (PIK), Potsdam, Germany

So far, the UNFCCC climate negotiations have not delivered a decrease in global greenhouse gas emissions. In contrast to this lack of ambition at the global level, several local, national, and regional initiatives have emerged in the past that pursue more ambitious unilateral abatement targets – for example the European Union or California – and more initiatives can be expected to emerge in the future. This comes as a surprise in view of classical theory, which suggests that ambitious unilateral provision of a global public good is never beneficial for the actor performing the abatement. Instead, global emissions tend to increase as a consequence of unilateral action, reducing the effectiveness of the abatement and resulting in losses for the leader. Recent academic advances in climate leadership have however revealed diverse consequences of unilateral emission reductions that lead to decreases as well as increases in global emissions. Taking all negative and positive reactions into account, leadership in ambitious abatement efforts could pay off for some actors, at least in expectation. The ongoing debate on the effectiveness of climate leadership in greenhouse gas abatement among the academic, the political as well as the public sphere emphasizes the importance of a clear and comprehensive understanding of the net consequence of unilateral action.

We analyze all major channels through which countries are influenced by unilateral abatement of a climate leader and derive functions for the resulting reaction in emissions. Carbon leakage effects are included by considering that (i) countries increase their emissions because more of the public good is provided, which decreases the demand for the individual production of the public good of all other countries, (ii) the leader decreases demand for emission intensive energy carriers which decreases their global price and leads to increasing demand in other countries and hence higher emission, and (iii) emission intensive production relocates from the leading country to countries with less stringent policies and hence emissions increase abroad. The negative carbon leakage effects are counterbalanced by several positive reaction functions, in which countries decrease their emissions in response to unilateral abatement. First, the leading country will develop new technologies to decrease its emissions in the face of ambitious abatement targets. Through technological spill-overs to other countries global emissions decrease even without additional emission policies by other countries. Second, a leading country decreases abatement cost uncertainty by performing ambitious emission reductions. Risk-averse countries will in turn increase their emissions reduction targets after learning about the costs of the leader. Third, through the process of policy emulation, policies diffuse to and are adopted by other countries because of their normative and socially constructed properties instead of their objective characteristics. Fourth, countries may have an incentive to reciprocate to the ambitious actions of a leader. Lastly, a leading country may signal to other countries that it is implementing the cooperative effort, inducing other countries to adopt an analogous effort.

The common modeling framework for each of the above described effects enables us to identify the critical parameters that shape the overall reaction to unilateral emission abatement and allows us to distinguish in how far the reactions differ among following countries and for the leading actor. The analysis suggests that effective leadership in climate action is facilitated by (i) high visibility and credibility in the actions of the potential leader, (ii) a strong international connectedness, both in economic and political terms, (iii) a leader whose emitting sectors are similar to those of the main global emitters, and (iv) the capacity and infrastructure to develop technology effectively.

However, due to the number of channels of interaction between leader and others, each of which is only imperfectly known, we expect the actual reactions of countries without ambitious targets to be highly uncertain. We show that despite this, leadership may be profitable (in expectation) for the leading country if it has a high valuation for the public good or exhibits little risk aversion. Our analysis can thus produce rationales for observed ambitious abatement of current climate policy leaders and their future abatement policies, and help to identify possible future leaders in the abatement of greenhouse gases.

P-4409-20

Soft and/or Hard - What Set-Up for a Future Governance System to Implement a New Climate Deal?

M. Kuhner (1)
(1) Maastricht University, Political Science, Maastricht, Netherlands

A new climate regime is not only about the nature, reach and ambition of such an international agreement, but also about effective arrangements to ensure its implementation. This presentation will analyse the existing governance

system under the Kyoto Protocol (KP). By shedding light on how implementation of the emission reduction targets under that regime have been monitored so far, the aim is to understand what elements of the governance mechanism were useful for fostering compliance and why. In particular, the role of facilitative elements is assessed. Building on existing literature on reasons for non-compliance/ lack of implementation and ways to best achieve compliance/implementation, advantages and disadvantages of facilitative and coercive approaches are addressed both from a theoretical and practical angle.

Empirically, enforcement has often, although not always, been rather successful in achieving compliance with commitments under the KP. However, many states have shown not to be inclined to subscribe to such 'hard' measures. Therefore, knowing about the (perceived) usefulness of 'soft' elements to support and facilitate compliance of states is of high relevance, especially when discussing a new governance system for compliance/ implementation.

The presentation will start by outlining the current compliance system under the KP, focusing in particular on the interplay between facilitative and enforcement elements. Lessons learnt will be developed by drawing on empirical findings of usefulness perceptions hold by different stakeholders, in particular of the 'soft' components of compliance monitoring. These insights will be used to develop different scenarios for a future governance system. The talk will finish with an outlook of plausible and desirable governance set-ups post-2020.

P-4409-21

The Stability and Effectiveness of Climate Coalitions: A Comparative Analysis of Multiple Integrated Assessment Models

K. Lessmann (1) ; U. Kornek (2) ; V. Bosetti (3) ; R. Dellink (4) ; J. Emmerling (5) ; J. Eyckmans, (6) ; M. Nagashima (7) ; Z. Yang (8)

(1) Potsdam Institute for Climate Impact Research, Potsdam, Germany; (2) Potsdam Institute for Climate Impact Research, Sustainable Solutions, Potsdam, Germany; (3) Fondazione Eni Enrico Mattei, Milano, Italy; (4) OECD, Paris, France; (5) FEEM, Milano, Italy; (6) KU Leuven, Center for economics and corporate sustainability (cedon), Brussels, Belgium; (7) Research Institute of Innovative Technology for the Earth (RITE), Kyoto, Japan; (8) State University of New York at Binghamton, Department of economics, Binghamption, NY, United States of America

International climate policy suffers from the adverse incentive structure of public good provision, and it is well known that non-cooperative behavior results in under-provision of such goods. How much a climate coalition improves upon this dilemma depends on the costs and benefits of the individual nations. It is particularly dependent on their heterogeneity and whether nations can compensate each other, i.e. the existence of transfer schemes. In this study, we investigate coalition formation with real-world heterogeneity and various transfer schemes for the first time using an ensemble of five numerical models.

Numerical models give particularly valuable insights beyond those of their analytical counterparts, when the analysis depends on regional heterogeneity in costs and benefits, quantitative estimates, or detailed representations of reaction functions. The models in this study are diverse both in their modeling approaches and in the data sources used for calibration, representing a range of estimates for the costs and benefits of real-world regions and their dynamics. We make these differences in cost and benefit assumption comparable through two new indicators measuring the abatement potential and climate change damages for key countries and world regions. We find that the five models frequently differ in the assumed costs/benefits structure of specific countries or regions, with stronger disagreement about regional damages and better agreement about mitigation costs, which mirrors the large uncertainty in our knowledge about climate change impacts.

Consequently, the models do not necessarily agree in their assessment of the stability of specific coalitions. Remarkably, however, the models are very consistent in translating the cost/benefit information revealed by the indicators into whether or not a region supports a climate agreement, i.e. coalitions with similarly characterized signatories are stable in all models. Thus, the reason why a specific coalition is found to be stable only in a subset of models is traced back to the cost/benefit assumptions.

We also assess the potential of transfers that redistribute the surplus of cooperation to foster the stability of climate coalitions. In contrast to much of the existing analytical game theoretical literature, we find substantial scope for self-enforcing climate coalitions in most models that close much of the abatement and welfare gap between complete absence of cooperation and full cooperation. This more positive message follows from the use of appropriate transfer schemes that are designed to counteract free riding incentives. By comparison, transfers that specifically take the incentive to sign a climate agreement into account frequently differ from the transfers implicit in common normative and pragmatic burden sharing schemes, which are found to be comparatively high in volume and often to transfer payments in the wrong direction.

Using the theory of planned behaviour to understand and promote stakeholder engagement in local adaptation to climate change

S. Luís (1) ; M. Lima (1) ; C. Roseta-Palma (2) ; N. Rodrigues (3) ; F. Alves (3) ; L. Sousa (3) ; A. Lillebø (3) ; F. Freitas (3) ; C. Parrod (4) ; V. Jolivet (4) ; S. Poulos (5) ; G. Alexandrakis (6) ; T. Paramana (5)

(1) Instituto Universitário de Lisboa (ISCTE - IUL),CIS-IUL, Lisbon, Portugal; (2) Instituto Universitário de Lisboa (ISCTE - IUL),BRU-IUL, Lisbon, Portugal; (3) Universidade de Aveiro (UA), CESAM, Lisbon, Portugal; (4) Acteon, Colmar, France; (5) National and Kapodistrian University of Athens, Faculty of Geology and Geoenvironment, Laboratory of physical geography, Athens, Greece; (6) Institute of Applied and Computational Mathematics, Foundation of Research and Technology, Hellas, Greece

Most policy documents on climate change highlight the need for stakeholder engagement on policy making regarding local adaptation to climate change. There appear to different rationales for this. Engagement is promoted as way to achieve greater acceptance of policies and environmental awareness and to improve quality in decision making. In parallel, engagement ensures democratic legitimacy because citizens have a right to be included in climate-change related decisions that affect their lives (Lee et al., 2013). However, the levels of engagement in climate change issues are not typically high (e.g., Few, Brown, & Tompkins, 2006) and more research is needed to learn how engagement can be increased and improved.

The theory of planned behaviour (Ajzen, 1985) can be used to understand and promote engagement in adaptation to climate change. Even if several theories explain human behaviour and decision-making, this is one of most influential and powerful, both for its ability to predict and explain behaviour and for its contribution towards framing and evaluating behaviour change interventions (Nosek et al., 2010). Previous studies have used it to understand climate change mitigation (e.g., Tikir & Lehmann, 2011). In this study, we explored its usefulness to understand stakeholder engagement in adaptation to climate change. The theory of planned behaviour is a useful conceptual framework that incorporates central concepts in the social and behaviour sciences. It postulates that behaviour is motivated by situation-specific beliefs about the likely consequences of the behaviour (behavioural beliefs), beliefs about the normative expectations of others (normative beliefs), and beliefs about the presence of factors that may influence performance of the behaviour (control beliefs). Behavioural beliefs create a favourable or unfavourable evaluation of the behaviour (attitude toward the behaviour); normative beliefs produce the perceived social pressure regarding the behaviour (subjective norm); and control beliefs create the perceived ability to perform the behaviour (perceived behavioural control). Behavioural intention, which is the immediate antecedent of behaviour, is formed based on the attitude towards the behaviour, subjective norm, and perception of behavioural control.

Based on previous research and on a literature review, we explored different types of behavioural beliefs (e.g., costs and benefits of adaptation, attitudes towards public participation), normative beliefs (descriptive and

injunctive) and control beliefs (e.g., information on climate change and public participation, stakeholder salience). Stakeholders from different case studies in the Mediterranean were surveyed (e.g., policymakers, elected officers, researchers). Results show that the behavioural intention to engage in the process of planning adaptation to climate change was significantly predicted by particular variables of the theory of planned behaviour, depending on the characteristics of the case studies. Furthermore, descriptive results indicate which specific beliefs should be stressed in future interventions to promote stakeholder engagement.

This work has received funds from the ADAPT-MED project (CIRCLE2-MED).

Framing a post-Kyoto Climate Accord

J. Mathews (1)

(1) Macquarie University, Macquarie Graduate School of Management, Sydney NSW, France

The forthcoming Paris conference of the parties under the UNFCCC, to be staged in November 2015, is tasked with developing a global climate agreement focused on carbon reduction, as successor to the Kyoto Protocol. If this "Paris Protocol" (if such is to be its name) is to be effective it will need to go beyond a list of countries committing to make reductions in carbon emissions, to incorporate measures needed to address the promotion of green industry and its diffusion around the world. A putative Part II to the Paris Protocol could be addressed to the WTO, and list green products or processes that are agreed will lead to reduced carbon emissions – and as such provide countries with justifiable "exemption" from the rules of fair trade for a designated period. It is argued that such a bold step is needed to reduce the severity and frequency of trade disputes over green industrial policies and clear the way for the carbon reductions anticipated to come to fruition.

Who governs local climate adaptation? A comparative analysis of governance arrangements in urban areas

H. Mees, (1)

(1) Copernicus Institute of Sutainable Development, Utrecht university, Utrecht, Netherlands

The allocation of responsibilities between public and private actors has become a key urban governance issue for adaptation to the impacts of climate change. While this issue has been explored conceptually to some extent, empirical studies are scarce and have not yet been performed in a systematic manner. This paper addresses the research question of who governs urban climate adaptation, by offering a synthesis of three empirical studies in which governance arrangements between public and private actors are analysed and compared. Each study contains an in-depth comparative case-study analysis of arrangements for adaptation measures in frontrunner cities in Europe and North America: 1) green roofs for storm-water retention purposes, 2) adaptive flood risk measures for water safety purposes, and 3) a selection of measures for heat stress prevention. In total, 20 governance arrangements were analysed and compared based on data derived from over 100 policy documents; from 97 in-depth interviews; and from two multi-stakeholder workshops. The meta-analysis offers insights into emerging patterns of urban climate adaptation governance arrangements. Furthermore, it offers a first evaluation of the performance of those governance arrangements in terms of effectiveness, legitimacy and fairness. Finally, conclusions related to the types of responsibilities of local public authorities are drawn, showing how indispensable they are for both adaptation planning and action.

P-4409-25

Fostering Socio-Ecological Resilience to Climate Change by Shifting from National to Negotiated Law-Making Approach

B. Mohamed (1) ; O. Barriere (2)

(1) Head, Research Laboratory on Territorial Governance, Human Security and Sustainability (LAGOS), Public law department, faculty of law, economics and social sciences of agadir, Agadir, Morocco; (2) Researcher in Environmental Law and Anthropology, Institute of Research for Development (IRD), Umr espace-dev, Montpellier, France

International and national laws constitute a legal positivism which, by definition, excludes any form of legal pluralism. At these scales, we remain exogenous to territorialized communities since regulatory frameworks are mostly enacted on international or national levels. Face to climate change challenge, it is increasingly important to investigate how local communities can be involved in climate actions if we assume that existing top-down regulatory frameworks will not fully consider socio-ecological adaptations and resilience as highly crucial for local communities to persist and maintain their identities.

The interrelations between governance scales cannot exclude local territories. At the local level, communities tend to adapt and build their resilience to climate change by regulating the relations among groups and individuals and between social and ecological systems. Therefore, the idea of a law emerging from the bottom is becoming increasingly relevant in order to enhance the bottom-up approach as an appropriate coping strategy. In other terms, the law-making processes will no longer remain exclusively vertical but will evolve in a horizontal mode, thus abandoning the power relations to embrace the logic of negotiation.

Two examples of negotiated law-making will be presented in this research: the first pertains to the ongoing construction of a socio-ecological resilience pact in the Moroccan High Atlas involving two tribes (including four rural communities and regions); and the second case concerns the formalization of an already-implemented pastoral pact being adopted in the French Cevennes and involving sixteen counties (including one department and one region). In each case, the co-construction process is put forward and analyzed on the basis of a territorial project. The three-dimensionality aspect of the project (involvement of agro-pastoral actors, decision makers and experts) is presented as the core pillar of the design and implementation of concerned regulatory frameworks. These frameworks, materializing a territorial law perceived and formalized in a solemn text labeled «territory pact», fully integrate national laws by local deliberation.

Why establish a climate legislation to address climate change in a Latin American context?

P. Moraga (1) ; N. Kugler (2)

(1) University of Chile, Faculty of Law, Santiago, Chile; (2) Aix-Marseille Université, Faculté de droit, Aix-Marseille, France

The most ambitious Latin American countries have had a sustained political commitment with regards to the climate change actions as it can be seen in the public policies elaborated since the signature of the UNFCCC – especially in the commitment of 2009 – and the current resourceful position during international negotiations.

In this context, the initiative of a climate legislation seems

to be an adequate way for institutional strengthening and coordination of climate change at national, regional and local level. This is relevant in the current context of the national contributions' definition with regards to the Conference of the Parties (COP) in Paris in 2015.

The overall objective of this presentation is to demonstrate the necessity and viability of climate change legislation for Latin American countries and outline the recommended basic content of such a law to support the determination of the countries' Intended Nationally Determined Contributions (INDC) which are to be presented to the UNFCCC secretariat in the lead-up to the 21st COP in Paris in 2015. At a time when strengthening public policy on climate change can be a cause for concern in certain sectors of society, the results of this presentation will ground the debate on climate change legislation in objective terms and will deliver concrete inputs and tools to demonstrate the need and viability of such legislation.

Ex-post evaluation of the Kyoto Protocol: Four key lessons for the 2015 Paris Agreement

R. Morel (1) ; I. Shishlov (1)
(1) CDC Climat, PARIS, France

Agreed in 1997, following the 1992 United Nations Framework Convention on Climate Change (UNFCCC), the Kyoto Protocol (KP) is the first international tool focused on greenhouse gas (GHG) mitigation involving as many countries: in its final configuration, thirty six developed countries committed to reduce their emissions by 4% between 1990 and 2008-2012 - the first commitment period (CP1). In April 2014, the data from the CP1 was officially published. This report thus presents the first comprehensive ex-post analysis of the first period of the KP.

Based on the results of this report, it is possible to draw four key lessons from the Kyoto experience for the establishment of a new global agreement that is expected to be signed in Paris in 2015:

1. Expanding the coverage: striking a balance between overall environmental integrity and flexibility for specific circumstances
2. Removing the virtual specter of internationally legally binding commitments and limiting the focus on methods of compliance
3. Focusing on MRV processes
4. Providing flexibility in the agreement and its adoption process

P-4409-28

Medium term implications for Africa's adaptation planning in Agriculture

V. Orindi (1) ; J. Kinyangi (2) ; S. Kinguyu, (3)
(1) National Drought Management Authority, ADa consortium, Nairobi, Kenya; (2) ILRI, Ccafs east africa, Nairobi, Kenya; (3) Ministry of Environment, Water and Natural Resources, Climate change secretariat, Nairobi , Kenya

Many of the sustainable development goals to 2030 recognize the role agriculture can play in ending hunger, assuring food and nutrition security as well as promoting healthy lives with a sustained income and economic growth; thereby reducing poverty globally. For Africa, a post 2015 agreement presents the opportunity to merge a shared vision on sustainable development with that which stipulates a pathway to a low carbon transition of food systems. However, it is unlikely, given the short time available to prepare an agreement in Paris in 2015, that the United Nations Framework Convention on Climate Change (UNFCCC) subsidiary bodies and work streams will conclude discussions on agriculture to pave way for a new climate deal.

The national adaptation plan (NAP) process was established in 2010, under the Cancun Adaptation framework of the UNFCCC. It was intended as a mechanism for countries to address their vulnerability to the impacts of climate change, building their capacity to adapt to current and future climatic changes. A key focus is to integrate climate change adaptation into development planning processes and strategies across all sectors and at local to national scales. Under this framework NAPs address medium to longer term needs building on the experiences of Least Developed Countries (LDC) National Adaptation Programme of Action (NAPAs). If we examine the state of the negotiations, the subsidiary body on implementation (SBI) is currently considering guidelines for the formulation of NAPs. The LDC Expert Group (LEG) has identified the need to fast track the application of NAP guidelines emphasizing integrated development planning as a key consideration. Through the adaptation planning process, we examine how Africa is dealing with agriculture.

Since NAPA experiences are being incorporated into a new set of guidelines for NAPs, it is expected that any emerging protocol will highlight specific agriculture, fisheries and forestry actions. The result is that agriculture and food security, which is to a great extent reflected in proposed and ongoing country NAPA programmes, receives greater attention in defining the medium and long-term issues around food security and food consumption. Because these issues are not yet well understood, and are often bundled with concerns about trade and commerce and non-food products from alternative land uses such as with bio fuels, it is important to foster dialogue for the parties as they prepare for the upcoming COP21 in order to reach agreement on how to treat agriculture in a new global deal on climate.

Under the NAP process, many countries have conducted some or other form of impact assessment, usually on a sectoral basis. There exist no guidelines for initiating and completing risk and vulnerability assessments of the agriculture sector and particularly as it relates to the impacts of climate change on agriculture as well as the impacts of agriculture as a contributor to climate change. In many cases too, the economic impacts of climate related risks has not been enumerated therefore compromising the design of effective adaptation strategies and measures at the national level. The inclusion of 'national planners' is therefore critical to this process, such as from the ministries of finance and the support for LDCs under the Global Support Progamme (GSP) is crucial to advancing the NAP process. In addition, the identification and procurement of funding for adaptation is only nascent and limited to early action, therefore it is not expected that agricultural adaptation will receive significant funding commitments in the foreseeable medium term period post 2015 and pre-2020.

P-4409-29

The Road to Paris and beyond: Prospects for International Climate Policy

H. Ott (1) ; L. Hermwille (2) ; W. Obergassel, (2)
(1) Wuppertal Institute for Climate, Environment and Energy, The President's Office, Berlin, Germany; (2) Wuppertal Institute for Climate, Envrionment and Energy, Energy, Transport and Climate Policy, Wuppertal, Germany

All commentators agree that the climate conference in Lima (COP20) left a great deal of work for diplomats on the road to Paris later this year. The talks produced a quarry of language the negotiators can choose from. What was a mere annex to the "Lima Call for Climate Action" was further expanded in a first round of intersessional meetings in Geneva in February and formally adopted as a negotiating text. Narrowing down the options will be the major task for the upcoming sessions. While the progress on the post-2020 agreement (Workstream 1) was perceived as slow and tedious, somewhat surprisingly the developments in Workstream 2 (pre-2020) were rather positive and it has developed into a forum of open exchange, thus establishing a new and fruitful mode of collaboration within the UNFCCC process.

Our analysis is guided by a structurational regime model (Arts, 2000). This model assumes that the UNFCCC institutional system serves as part of the structure that guides the agency of firms and individuals within those socio-technical systems that are responsible for driving global climate change. The UNFCCC structures behaviour via the implementation of formal treaties in the respective national law of the Parties to the treaty, but also directly by providing signification and legitimation to transnational and subnational institutions to govern climate change, and immediately to corporations and consumers to develop

more sustainable behavioural routines.

Based on this model, we analyse the „Lima Call for Climate Action", the negotiating text formally adopted in Geneva in February 2015, and other developments in Lima and therafter. We look into the elements that have been tabled for the new global treaty to be agreed in Paris in 2015 and discuss their potential contributions. From this we derive recommendations for a fair and effective treaty.

Our analysis shows that the UNFCCC hitherto failed to provide an adequate impulse to act on climate change. It has become increasingly obvious that the UNFCCC institutional system as it is designed now is not delivering what it is supposed to do according to Article 2 UNFCCC: to prevent a dangerous anthropogenic interference with the climate system. This is due in large part to the consensus-based approach, which does not work well with a quantity-based system of commitments but rather calls for other forms of cooperation. The concept of Multi-Dimensional Commitments developed by the Wuppertal Institute might offer a way out of this dilemma. Furthermore, the article explores a fresh start, options to supplement the UNFCCC system with an alliance of countries that want substantial progress on climate protection – an alliance of the ambitious or a forerunner club. Such a special treaty outside of the UN framework, if appropriate feedback mechanisms are established within UNFCCC, could help injecting some of the much-needed dynamic that is required to bring our civilization on a path compatible with earth's ecological limits.

Climate Governance in two non-independent Caribbean Insular Territories: two different or similar trajectories?

J. Priam (1)
(1) Servicios Científicos y Técnicos, Doctoral student, San Juan, Puerto Rico

This contribution shows how two non-independent islands of the Caribbean reflect the multiple scales dynamics for Climate Governance. For Puerto-Rico, the adopted solutions must be understood through USA relation and for Guadeloupe, through Europe and France.

To do so, this work synthetizes the first initiatives regarding wind energy on both islands; and the recent ones/ or projects since 2009. We explore then the emerging representation of climate change issues inside those two insular territories by exploring the local press, and interviews of local population living next door wind farms in Puerto-Rico and Guadeloupe.

Both territories indeed traduce the integration of the international level conceptualization as they become "laboratories for experimentation" to demonstrate successful transformative solutions to transfer to other insular territories or even to their metropolis. We present here some international key documents or political discourses in Puerto-Rico and Guadeloupe that contribute in understanding climate governance within islands.

P-4409-31

Multilevel climate governance, between deliberative system, precaution and shared responsibilities

B. Reber (1)
(1) CNRS-Sciences Po Paris, Centre de recherche politique de Sciences po (Cevipof), PARIS, France

This paper aims at being relevant to the overarching theme of the Day 4 (themes: Climate Governance, Transforming Science to Transform Society, Information for Decision-Making, Mediating Climate Change Dialogue, Transformative Solutions, Adaptation Governance, Equity and Responsibility, Collective Action, Social Movements, SDGs and Climate Agreement). It could be relevant for Day 3 too (themes: Innovation, Technology Deployment and Policies; Climate Policies; Governance and Justice; Conflicts and Climate Change).

If climate sciences requires interdisciplinary approaches (Jeandel and Mosseri, 2011), it is the same for climate multilevel governance (Winter, 2011; Brondizio, et alii, 2009; Bache I. and Flinders M., 2004). We have to explore transformative solutions to climate change from a cross-sectorial perspective in order to reach integrated solutions especially through collaboration. This collaboration concerns different levels. 1) The actors level covering the complex and inter-related socio-political and human aspects (individuals, associations, institutions), 2) The level of different kinds of responsibilities, 3) The level of different sources of knowledge. The latter concerns scientific knowledge on the climate (description and forecast) as well as normative justifications and decisions (political, economical, legal and ethical). We have the entities, their respective responsibilities and the disciplines, more or less relevant to treat the different problems. To lead to transformative pathways to climate change challenges, we have not only to make up solutions across a range of stakeholders and sectors that encompass technological, institutional, economic and behavioural changes, but across disciplines, they are descriptive and predictive or normative and prescriptive. To be complete we have to consider multiple scales (spatial and temporal). The governance perspective of this paper is not only multi-lateral, managing different entities from a political perspective, but multi-disciplinary to explore the wide range of topics that cut across climate change issues, from physical feedbacks to social and economic impacts. Indeed to reach relevant, responsible and high quality collective decision on the international level, we need to take into account these three levels and match them carefully.

We need new concepts to match these three different levels. We have chosen here three promising ones: deliberation, precaution (precautionary principle) and responsibility.

Deliberative system is promising in the democratization of global climate governance (Stevenson, Dryzek, 2014). Precautionary Principle has the potential to combine both sides of assessment, scientific and normative in case of uncertainty (Gardiner, 2006; Reber, 2015). Moral responsibility help to make the link between mitigation and adaptation and the two kinds of justice entailed (corrective and distributive) that is not already done in UNFCCC. The common climate requires a common approach according a balanced cooperation between the three levels of governance, that can be constructed through the combination of inclusive and deep deliberation among actors (humans, publics and institutions), balanced between scientific and normative assessments, in a «conversation» among distributed responsibilities.

Unlocking deadlocked negotiations: The relevance of group pressure and policy learning in the global climate negotiations

K. Rietig (1)
(1) Department of Politics and Public Policy, De Montfort University Leicester, Leicester, United Kingdom

The UNFCCC negotiations have been deadlocked for over 20 years due to incompatible national interests. At the same time, the objective of avoiding dangerous climate change drifts out of reach as we near the end of this decade. Yet, there is increasing scope to break up this deadlock, for which mutual learning, policy diffusion and capacity building will be central. Initial evidence suggests that learning is a key-multiplying factor in accelerating policy diffusion via the international level. Learning can be a helpful factor to progress along transformative pathways

to sustainable development, in particular effective climate mitigation and adaptation. Within the UNFCCC negotiations, countries can learn from each other's successes in low carbon economic development, share knowledge on designing domestic climate legislation that is co-beneficial for sustainable development and even come to understand that addressing climate change is an opportunity to create a green industrial revolution, thus entering on transformative pathways towards sustainable development. Realizing that there are long-term benefits from acting on climate change can even influence how actors understand the issue and result in readjustments to negotiation positions based on altered national interests. In combination with group pressure, these experience, knowledge and belief-based types of learning are currently altering the negotiation dynamics within the UNFCCC. Transgovernmental city networks and non-governmental organizations are creating non-negotiation settings for governmental representatives to explore options and learn from other countries' successes. These learning platforms and networks were established by a number of actors to help countries share their experiences with low carbon economic development plans to address climate change while decoupling their economic growth from negative climate impacts. Based on interviews and participant observation at the UNFCCC negotiations between 2013 and 2015, this contribution examines the learning among government representatives about each other's low carbon economic development plans and climate legislation within (UNFCCC) non-negotiation forums and increasingly formal negotiations. Mutual learning and policy entrepreneurial strategies of key negotiators helps to create positive competition towards more ambitious climate legislation on the national level. Presenting these national climate policies in the UNFCCC creates group pressure among countries to revise their negotiation positions towards improving action on mitigating climate change to avoid being branded as 'laggards'. The key implication of this research points towards the importance of better understanding underlying learning mechanisms, which can contribute to overcoming negotiation deadlocks by helping countries shape their national interests over time towards increasing cooperation on sustainable development.

P-4409-33

Climate change governance in Small Island developing States

M. Scobie (1)
(1) The University of the West Indies, Institute of International Relations, St. Augustine, Trinidad and Tobago

Climate change governance in Small Island developing States (SIDS) is a pressing priority to preserve livelihoods, biodiversity and ecosystems for the next generations. Understanding the dynamics of climate change policy integration is becoming more crucial as we try to measure the success of environmental governance efforts and chart new goals for sustainable development. At the international level, climate change policy has evolved from single issue to integrated approaches towards achieving sustainable development. New actors, new mechanisms and institutions of governance with greater fragmentation in governance across sectors and levels make integration of policy in the area of climate change governance even more of a challenge today. What are the best frameworks to achieve successful climate change policy integration in environmental governance – especially as the complex interconnectivity of new actors, institutions and mechanisms make the process of integration even more challenging? Are the same climate change policy coherence frameworks useful or indeed applicable for environmental governance in developing states more generally and for SIDS in particular? This article reviewed the debates around policy coherence for climate change governance, creates a framework to test or measure policy coherence and examines how relevant this has been to actual regional climate change governance processes in Caribbean States. The findings fill a gap in the literature on climate change governance through policy coherence in SIDS.

P-4409-34

Review of the experience with monitoring uncertainty requirements in the Clean Development Mechanism

I. Shishlov (1) ; V. Bellassen (2)
(1) CDC Climat, Research, Paris, France; (2) INRA, Research, Dijon, France

In order to ensure the environmental integrity of carbon offset projects, emission reductions certified under the Clean Development Mechanism (CDM) have to be 'real, measurable and additional', which is ensured inter alia through the monitoring, reporting and verification (MRV) process. MRV, however, comes at a cost that ranges from several cents to EUR1.20 and above per ton of CO2e depending on the project type. This article analyzes monitoring uncertainty requirements for carbon offset projects with a particular focus on the trade-off between monitoring stringency and cost. To this end, existing literature is reviewed, overarching monitoring guidelines, as well as the 10 most-used methodologies are scrutinized, and finally three case studies are analysed. It is shown that there is indeed a trade-off between the stringency and the cost of monitoring, which if not addressed properly may become a major barrier for the implementation of offset projects in some sectors. It is then demonstrated that this trade-off has not been systematically addressed in the overarching CDM guidelines and that there are only limited incentives to reduce monitoring uncertainty. Some methodologies and calculation tools as well as some other offset standards, however, do incorporate provisions for a trade-off between monitoring costs and stringency. These provisions may take the form of discounting emissions reductions based on the level of monitoring uncertainty – or more implicitly through allowing a project developer to choose between monitoring a given parameter and using a conservative default value.

P-4409-35

Designing monitoring rules in climate policy: the uncertainty issue

I. Shishlov (1) ; V. Bellassen (2) ; F. Lecocq (3)
(1) CDC Climat, Research, Paris, France; (2) INRA, Research, Dijon, France; (3) Centre International de Recherche sur l'Environnement et le Développement, Nogent sur Marne, France

This paper assesses the environmental and economic efficiency of three different approaches to treat monitoring uncertainty in climate policy, namely no special rules, minimum certainty thresholds and discounting proportional to uncertainty. Our microeconomic model of the behavior of profit-maximizing agents demonstrates that under the simplest set of assumptions – likely representative of many practical cases – the regulator has no interest in reducing unbiased monitoring uncertainty. However, in the presence of information asymmetry monitoring uncertainty may hamper the integrity of climate policy. We find that in that case applying discounting proportional to monitoring uncertainty is preferable to setting minimum certainty thresholds or not enforcing any constraints at all, as it is currently practiced in most carbon pricing mechanisms.

P-4409-36

Forecasting the Paris Agreement

D. Sprinz (1) ; G. Bang, (2) ; J. Hovi, (3) ; S. Kallbekken, (2) ; A. Underdal, (3)
(1) PIK – Potsdam Institute for Climate Impact Research, Transdisciplinary Concepts & Methods, Potsdam, Germany; (2) CICERO, Oslo, Norway; (3) University of Oslo, Political science, Oslo, Norway

International negotiations are under way to conclude a 2020+ agreement in Paris in December 2015 within the confines of the UN Framework Convention on Climate Change (UNFCCC). Neither are the contours of such an agreement presently clear nor whether any agreement will be concluded by the end of this year. To fill this void, we undertake a prediction of select dimensions of the present negotiations with the Predictioneer's Game (Bueno de Mesquita 2009a).

The Predictioneer's Game builds on three decades of model development. In essence, it is an advanced expected utility negotiation model with incomplete information between N parties who make bilateral negotiation offers and counteroffers. Based on knowledge of who the actors (or stakeholders) are, their basic influence in world politics, the salience of the specific issue under negotiation (see

below), the actors position on the issue, as well as their flexibility on that position, the Predictioneer's Game forecasts the negotiated outcome round-by-round until no additional utility can be gained on average. The model has been used to predict outcomes on a wide range of governance and policy issue. The Predictioneer's Game correctly predicted the outcome of the 2009 Copenhagen Conference of the Parties – despite high expectations for a cooperative outcome at the time (Bueno de Mesquita 2009b).

For the conference "Our Common Future Under Climate Change," we will undertake a prediction of the likely common mitigation goal of the parties negotiating under the auspices of the UNFCCC. We will concentrate on the most important country actors and pertinent negotiations groups. In addition, we will undertake a prediction of the likely outcome of the present negotiations on "loss and damage" and its potential inclusion in a Paris agreement.

In order to calibrate our input data, we will draw, on the one hand, on the expertise provided by CICEP Norwegian Center for Excellence in Research – Strategic Challenges in International Climate and Energy Policy, which comprises CICERO, the University of Oslo, and the Fridtjof Nansen Institute, and PIK – Potsdam Institute for Climate Impact Research, on the other hand.

The analysis will be undertaken in April–June 2015 in lieu of the Intended Nationally Determined Contributions (INDCs), corroborated by a broad range of robustness checks to both reflect uncertainty about input values and external shocks on the negotiation dynamics.

Initial test calibrations of the model suggest that the common mitigation goal will not substantially differ from those discussed at Lima in late 2014, an agreement will be reached after late 2015, and an extension of the "loss and damage" negotiations towards a compensation fund will not materialize in the near future.

Transparency and Accountability in Climate Finance Governance

AS. Tabau (1)
(1) Université de La Réunion, Faculté de droit et d'économie, Saint Denis, La Réunion, France

Climate finance, to reduce greenhouse gas emissions or to adapt to the harmful effects of climate change, remains one of the central issues of current international negotiations. Progress in the fulfilment of the developed countries collective commitment, adopted in 2009 in Copenhagen and set out, the following year, in the Cancun Agreements, to provide new and additional resources to developing countries, in the range of 100 billions of dollars by 2020, may determine the conclusion of an inclusive and ambitious agreement in 2015.

However, some developed countries advanced the argument of the economic crisis to postpone the provision of public finance, to ask for the efficiency of funds provided in terms of climate change mitigation, and to consider that a major part of the climate finance will come from the private sector. Many developing countries, more preoccupied by the effectiveness of climate finance, conditioned their participation within a 2015 agreement to the actual disbursement of funding and consideration of adaptation to climate change, as well as capacity building, to estimate their needs. Finally, voices had been raised against inter alia human rights infringements resulting from previous climate projects, putting emphasis on the need for the integrity of climate finance.

These demands for efficiency, effectiveness and integrity of climate finance plea for transparency and accountability at all stage of the funding cycle, that is to say from its mobilisation to its disbursement and administration. Indeed, transparency and accountability are core democratic values, linked to the procedural rights to information, participation in decision-making and access to justice that should apply to the overall governance of climate finance. These elements, participating to public scrutiny in the field of climate finance, are particularly important to enhance developing countries' confidence by ensuring that developed countries respect their commitment and to evaluate, progressively, developing countries' needs in order to take up the challenge of dealing with climate change. They also appear crucial to adopt a holistic approach of climate action by avoiding deleterious side effects of internationally funded projects, and more broadly favouring public acceptation of the efforts needed.

Yet, the assessment of the provided and received financial support, its new and additional character or its effects on the ground raises numerous difficulties. Despite the establishment of a Green Climate Fund (GCF), meant to centralize as much as possible the financial mechanism of the international climate regime, and the setting up of a Standing Committee on Finance (SCF), intended to encourage the coordination of climate finance, governance in this domain remains highly fragmented. Different scales of decision and action are mobilized (international, regional, national and local), within the climate regime (UNFCCC) as outside. Climate funds are functioning, moreover, according to different rules and are not all managed by the same institutions. This is even truer if one takes into account private climate finance next to public climate finance.

Therefore setting up a transparency and accountability system in climate finance constitutes a major challenge, as related rules and procedures are currently incomplete and inconsistent. That is why, to elaborate such a system, the SCF and the GCF are proceeding from relatively unprecedented way, in particular by encouraging involvement of all "stakeholders". Initiatives from multilateral banks of development, the Organisation for Economic Co-operation and Development and some non-governmental organisations, like Transparency International, are also relevant in this regard. From then on, it is especially interesting to study in details this process of normative production that could apply to other fields of climate governance.

Indeed, it first favours a better understanding of the mapping of the current transparency and accountability systems relevant for climate finance, which is necessary to compare them, in order to identify their harmonisation and/or articulation potential. This presentation aims to analyse these four stages to improve the overall climate finance governance.

The Continental Approach to Climate Change: An Analysis of the European Union's Emissions Trading System

J. Wellman (1)
(1) London School of Economics and Political Science, Geography and Environment, London, United Kingdom

The European Union's Emissions Trading System stands as a model for managing a changing climate in a complicated international environment. As the international community prepares for negotiations on a post-Kyoto climate regime, an understanding of players and their performance in the EU's governance system is essential to validating the potential success of emissions markets. Concerns that wealthy countries will purchase permits, rather than reduce their real emissions, have created skepticism about emission trading's potential for success.

In this study, I examine ambition exhibited by countries in using less than maximum levels of offsets to achieve Phase II reductions. Through fuzzy-set Qualitative Comparative Analysis, I explore a number of variables including: economic growth, Green Party representation, public opinion, and renewable energy investment to construct a model explaining variety in exhibited ambition among ETS countries. Results show that renewable energy and public opinion play the most significant role in explaining a country's use of offsets. Specific case studies demonstrate wide variance in explanation for member state performance, tied closely to business group influence and early environmental action.

New norms and institutionnal practices towards radical political changes

YC. Zarka (1)
(1) Université Paris Descartes, SHS, Paris, France

The theme of my lecture will be the relationship between cosmopolitical citizenship and political citizenship faced with climate change. The questions considered will touch as much on general principles as on an examination of concrete examples of collective action in local and national contexts. In the age of the Anthropocene, the urgent and indispensable norms and modes of regulation to save our species have not yet been clearly formulated. The deep reasons for the gaps between diagnoses and action have their roots in various levels of the way in which societies function.

It is by mobilising the collective action of citizens in each state, as well as that of human beings as citizens of the world, that we shall probably find a large part of the answers. Our discussions will thus be situated on two levels: cosmopolitical and political. We are in fact living in a time when political citizenship can no longer ignore the status of every individual as a citizen of the world; that is to say, our responsibility with regard to the present and the future of the earth and of the whole living world.

K-4410-02

The political economy of decarbonisation

A. Pegels (1) ; L. Wilfried (1) ; T. Altenburg (1) ; V. Georgeta ()
(1) German Development Institute / Deutsches Institut für Entwicklungspolitik (DIE), Sustainable economic and social development, Bonn, Germany

What and how we produce and consume is largely shaped by markets. However, markets fail to solve many of the environmental challenges we are facing. Therefore, we need governments to intervene, thus reclaiming the primacy of public policy in setting and implementing societal objectives. While safeguarding the sustainability of human life on our planet makes this kind of government intervention a highly normative undertaking, its economic case is strong as well – the success stories of such 'green' frontrunners as Germany and Denmark demonstrate the competitiveness potential of the new technologies.

However, as shown by decades of discussion on industrial policy, government intervention almost invariably brings about risks of political capture and government failure. Government intervention towards sustainability is thus not only governed by ethical norms, but also by politics. The risks of failure are magnified by the urgency and scale of today's global environmental challenges, requiring particularly bold, comprehensive and well-orchestrated government intervention under high uncertainty. By highlighting lessons learned from practical cases of both success and failure, we show how these risks can be, and have been, managed. In particular, we submit that a broad-based social vision and contract need to be forged – supported by change coalitions and coupled with policy process safeguards, openness to policy learning, and an alignment of transformative policies with market mechanisms.

Urban narratives and collective mobilizations in the field of adaptation to climate change

N. Blanc (1)
(1) CNRS, LADYSS 7533, Paris, France

With the exception of climate skeptics who appreciate climate change only as a natural phenomenon to the exclusion of all human causes, climate change is not referred to nature. Climate change as a whole refers to an abstract scientific phenomena and/or a disruption of the natural order by human activities. Characterized by science, climate change involves a complex interpretative framework linked to a network of measurements, statistics and modeling, combined with scientific judgments about their relevance. It is therefore important to understand how these changes are part of the natural and built environments both in terms of representations and of social practices. We seek to address the interests of narratives regarding these issues, in particular, adaptation to climate change in urban space. Our collection of city-dwellers stories in urban situations of various constraints and resource levels as well as the CSO narratives framing their action tells us about adaptation to climate change. The capabilities require to take into account both the constraints and the resources with which people have to live and operate daily to adapt to changes of various kinds. The important thing is that it is possible to develop a reflection on the capabilities from ordinary stories. This means to explore sustainable practices in everyday life. These practices will allow us to envision social invention of new forms of action support or resistance to normative injunctions in the field of adaptation to climate change. The problematic issue is to see if the exploration of capabilities through stories can be a path to a sustainable culture.

Reinvigorating International Climate Policy: A Comprehensive Framework for Effective Non-state Action

S. Chan (1) ; H. Van Asselt (2) ; H. Thomas (3) ; K. Abbott (4) ; M. Beisheim (5) ; M. Hoffmann (6) ; B. Guy (7) ; N. Höhne (8) ; A. Hsu (9) ; P. Pattberg (10) ; P. Pauw (11) ; C. Ramstein (12) ; O. Widerberg (10)
(1) German Development Institute, Bonn, Germany; (2) Stockholm Environment Institute, Oxford, United Kingdom; (3) Blavatnik School of Government, Oxford, United Kingdom; (4) Arizona State University, Tempe, AZ, United States of America; (5) German Institute for International and Security Affairs, Berlin, Germany; (6) University of Toronto, Toronto, Canada; (7) Natural Resources Defense Council, New York, United States of America; (8) NewClimate Institute, Köln, Germany; (9) Yale Center for Environmental Law & Policy, New Haven, United States of America; (10) VU University Amsterdam, Amsterdam, Netherlands; (11) German Development Institute, DIE, Bonn, Germany; (12) Institut du développement durable et des relations internationales, Paris, France

As countries strive to negotiate a new climate agreement in time for the Paris climate summit in December 2015, a different kind of climate politics is emerging as cities, regions, businesses, and civil society groups take mitigation and adaptation actions, independently and together with each other and with national governments and international institutions. In Paris, governments have an historic opportunity to develop a framework to catalyze, support, and steer these initiatives. Social science research highlights the need for a comprehensive approach that promotes ambition, experimentation and accountability, and avoids unnecessary overlaps. This contribution specifies the functions of and design principles for a comprehensive framework for non-state climate actions that could build positive linkages and provide effective coordination.

Drawing empirical lessons learned from sustainable development governance (in particular 'Partnerships for Sustainable Development' and 'SD in Action'), we envisage a comprehensive framework as a long-term program to support, strengthen, and orchestrate non-state initiatives that contribute to international climate goals, targets and agreements.

Designing a concrete framework will not be simple, but current social science research on non-state action suggests three clear guidelines for that process. First, design and

maintenance of the framework must be collaborative, and the framework itself must be jointly 'owned' by the UNFCCC secretariat and participating non-state actors and initiatives. Second, a comprehensive framework should include a global clearinghouse, bringing together existing sources of information. The clearinghouse should build upon existing registries maintained by a network of non-state actors in partnership with the UNFCCC. Finally, as climate actions are heterogeneous, the platform should combine low thresholds for inclusion with a layered structure that would provide increased visibility - coupled with increased levels of accountability - for particularly significant actions.

The road to Paris offers a unique opportunity to ratchet up ambition, mobilize action and engage more actors in climate action. Governments and non-state actors can create a robust, capable, and long-term comprehensive framework that orchestrates and supports non-state initiatives to contribute to internationally agreed climate outcomes, and that counteracts the inefficiencies of a fragmented governance landscape. Yet inpursuing this approach we need to avoid repeating the mistakes of previous frameworks.

Community Renewable Energy in Australia – examining and comparing an emerging social movement

F. Mey (1)
(1) Institute of Environmental Studies – University of New South Wales, Sydney, School of Biological, Earth and Environmental Sciences, Sydney, NSW, Australia

Local action for global problems finds expression in the growing field of Community Renewable Energy (CRE). Community actors develop and own renewable energy projects and play an increasingly important role in the transformation of energy system providing local solutions (del Río & Burguillo, 2009; Hicks & Ison, 2011; Rogers, Simmons, Convery, & Weatherall, 2012; trend:research GmbH & Leuphana Universität Lüneburg, 2013; Walker & Cass, 2007; Walker & Devine-Wright, 2008; Walker, Hunter, Devine-Wright, & Evans, 2007).

Australia is a relative newcomer to this development, yet many communities are becoming increasingly enthusiastic about the Community Renewable Energy. However the country's communities seem to face particular challenges when it comes to implementation due to a limited support by the national government and a rather complex energy market (Hicks & Ison, 2011).

The CRE movement in Australia counts currently (as of October 2014) around 60 groups attempting to develop projects and 10 operating projects across the country (ISF, 2014).

The presentation will present results of two national surveys of community energy projects in Australia and provides insights into the "scope, scale and character" of this nascent community energy movement. The surveys were created and conducted in 2012 and 2014 by members of the Coalition for Community Energy, which included the two authors of this article.

The results of the survey have been analysed in a similar vein to that offered of the UK by Seyfang et. al. (2013). Like them, we use the STEEP (social, technical, environmental, economic, political) and SWOT (strengths, weaknesses, opportunities, threats) frameworks as the foundation of our analysis. We discuss the key issues for the further development of community energy in Australia in its socioeconomic and political context.

However, we take our analysis a step further to reflect on how this emergence in Australia has been different from other countries and what this means for different understandings of the nature and role of community energy.

For this component we employ existing concepts of community energy (Walker & Cass, 2011; Walker & Devine-Wright, 2008; Walker et al., 2007) and social movement theory (Davis et al, 2005; Schneiberg & Lounsbury, 2008; Seyfang & Smith, 2007). We draw on a literature review and historical data from other countries such as Denmark, Germany and the UK.

O-4410-03

Collective national and transnational action towards «green grabbing»

S. Vigil (1)
(1) FNRS Research Fellow, CEDEM University of Liège, Liège, Belgium

Land remains the most fundamental productive asset for the vast majority of populations in the Global South. Agriculturalists' pre-existing vulnerabilities are not only compounded by climate change impacts and lack of socio-economic assets, but also by large-scale land acquisitions that have risen since the convergence of multiple global crises (financial, environmental, energy & food) (Borras & Franco 2012). If we were to compare the phenomenon to colonial times, the fact that climate change legitimises a large part of such acquisitions is a main novelty. Since the neoliberal turn, there is a widespread belief that the market is synonymous to development leading to the commodification of the ecological commons through so called "green" market solutions such as carbon trading, emissions offsets and biofuels (McMichael 2010). Whilst the proponents refer to these transactions as "direct investment in agriculture", highlighting their potential for agricultural modernisation, employment creation, local food security and "green" energy production, the retractors point to the various threats that these deals can actually pose to the environment, to local food security and to traditional livelihoods. Furthermore, such projects stimulate the industrialization of agriculture, which is at the basis of many of our environmental problems today.

Local communities and grass root organizations have protested in several countries around the world. Yet, corruption, military intervention and landlessness are all factors which are creating obstacles for effective local collective action. Land activists are still facing considerable threats of imprisonment and murder by corrupt governments that are aligned with corporate interests. Several local and transnational NGO's and academics have been actively drawing attention to the social and environmental threats that these large scale land concessions can pose to already vulnerable communities. Despite persisting obstacles to effective local collective action, the demands of transnational grass root organizations have been key in the development of international "good governance" norms. As a result of these pressures, multilateral organizations such as the WB, the EU and the FAO have developed codes of conduct and principles for responsible agricultural investment. Transparent negociations, respect for existing land rights, sharing of benefits, environmental sustainability, and adherence to national trade policies, are the most frequently addressed challenges in order to attain "win-win" outcomes. All of them seem to suggest that good governance norms would diminish negative socio environmental impacts. Yet, despite the well-intended rationale behind such principles, they still fail to question agro-industrial development per se, as if other possible development pathways, such as smallholder agriculture and family farming, would not be better suited to address our social and environmental challenges. In a world where climate change impacts are expected to considerably reduce the resilience of already vulnerable populations, there is a need to rethink our whole model of neoliberal development and to promote other types of investment asides from corporate investment. Furthermore, the voluntary nature of such principles makes the implementation process difficult, making it arduous or impossible to track down and penalize those who fail to follow such principles. Even in cases where such guidelines are legally institutionalised at the national level, practical implementation remains scarce or inexistent. The principles are still too vague in a context where governments and elites of developing nations often take the side of investors for purposes of personal enrichment or supposedly national development. Drawing from fieldwork conducted in both Senegal and Cambodia, this presentation will shed light on the actions of citizens, NGOs and activists in pressuring governments and donors whilst shaping and contesting a model of development that has often resulted in further environmental stress and recurrent Human Rights violations. Based on field evidence this presentation will highlight cases in which collective action has resulted in positive outcomes and cases in which local demands have remained largely overlooked. The aim of this presentation will be thus to highlight the key variables that determine positive collective action

outcomes as well as to underline the obstacles that persist in the implementation of socio-environmentally sustainable agricultural development projects.

Strengthening the climate action movement: strategies from histories

L. Delina (1) ; M. Diesendorf (2)
(1) Independent Scholar, South Cotabato, Philippines; (2) Institute of Environmental Studies, Sydney, Australia

Since many governments lack the motivation to lead deep emission reduction initiatives, the climate action movement must strengthen its campaigns. This paper offers strategies for the movement derived from historical analysis of mechanisms that achieved effective social change in the past. Common elements of climate action with past social change movements, together with some differences, are identified. Although technologies, strategies and tactics vary, climate action groups can agree to support a shared common goal: effective climate mitigation, that can be accomplished not only through outward-oriented tactics, but also by forms of climate activism that are prefigurative - that is, based on action within local communities. Furthermore, the diverse campaigns that take place on a variety of scales and spaces, conducted by heterogeneous groups, should be integrated by establishing national and international hubs to facilitate coordination and communication.

P-4410-02

"Re-Imagining Radical Climate Justice for the Post-Paris World"

F. John (1)
(1) University of California, Santa Barbara, Sociology, Santa Barbara, United States of America

The science is not in question: climate change is here now, not in the future,[1] and it is already having devastating effects on people's lives. That's the bad news, of course.

Even worse, the massive social, economic, and political inequalities already generated by neoliberal capitalism would seem to set the social and natural worlds on a collision course which the elites cannot win -- even on their own terms -- without destroying the basis for all human life. To put it bluntly, the climate crisis is perilous, our 500 year-old economic system cannot see us through it safely, the window for resolving this dilemma is closing inexorably, and the forces arrayed against our common survival are strong, very strong.

The good news is that there's a global climate justice movement which is growing in numbers, reach, strength, and inventiveness. This movement is impossible to encompass easily, because it consists of literally thousands of organizations at every level - community, city, bio/region, nation, and the global - interlinked in a vast network of networks.[2]

The next few years will be the years that those of us in the climate justice movement must scale up our efforts toward the end of mounting irresistible pressure of all kinds on our governments and on the corporations, banks, and all the institutions of neoliberal capitalism that they serve. We must force them to take the decisive steps we all need and want, such as a fair and binding global climate treaty and a deeply sustainable post-capitalist society free of structured violence and run democratically by the ninety-nine percent.

Consider the following:

Parts of the radical left are turning their attention to climate change (System Change Not Climate Change in North America), while many members of the radical climate justice movement are turning their attention to anti-capitalist politics.

At the same time, the Big Green environmental organizations (the Sierra Club in the US), the mainstream global climate justice movement (CAN), and the biggest climate social movement organization (350.org) are all radicalizing.

The same can be said of climate science in general (The IPCC Fifth Assessment Report etc.) and particular climate scientists, such as Kevin Anderson, Alice Bows-Larkin, Michael Mann, James Hansen, et al.

Finally, there is an enormous push coming up from young people, and indigenous forces on all of these levels.

The question is: what are the prospects for synergy and movement building among all these forces? What is the way forward?

It appears evident that we will need to assemble the greatest social movement the world has ever seen to achieve these ends. The global climate justice movement is growing steadily, but it is still far too weak to win - at least for the moment.

This essay will trace some of what it has accomplished so far, asking where the major points of impact lie at the moment, and what strategic decisions must be faced moving forward.

Climate Change and Ebola Outbreaks: Are they connected?

D. Kassie (1) ; M. Bourgarel, (1) ; F. Roger (1)
(1) Centre de coopération internationale en recherche agronomique pour le développement (CIRAD), Environnements et Sociétés (ES) / UR AGIRs - Animal et Gestion Intégrée des Risques, Montpellier, France, France

The climate factors have an impact on pathogens (resistance, selection, etc), hosts (biology like immunity, ecology like migration movements, etc), vectors (ecological niches, vector capacity) and epidemiological dynamics. The climate can affect the rate of transmission, the way in which pathogens are dispersed, contact networks between individuals and between different species, community structures. Livestock farming methods, or biodiversity and its ambivalent role in disease emergence are also depending of climate factors. The diseases most sensitive to climate factors are parasitic diseases with external life-cycle, vector-borne diseases and infectious diseases passed on by water or micro-mammals including bats. Most of them are zoonosis.

For a zoonosis like Ebola, several potential drivers are suspected to connect climate change to ecosystems, virus transmission to Human and heath care policies:

1. Ecology and behaviour of the bat species suspected to be Ebola virus reservoir could be affected by climate change: population density, migration, habitat utilisation, reproduction, feeding behaviour, and nature or intensity of inter-specific contacts. All those parameters would have an impact on the ecology of the Ebola virus. Therefore, researches for understanding the mechanisms of virus maintenance, circulation and transmission and for identifying reservoir and bridge species need to address the correlations between Ebola foci and its environmental factors, including climatic factors.

2. Human contamination by Ebola virus can occur through close or direct contact while hunting or through eating meat from wildlife. Climate changes can for one side, favour

contact between wildlife and humans by impacting the natural habitats of the reservoir species and by influencing their movements. For other side, climate evolution may also exacerbate food insecurity, which can in turn modify human behaviour, particularly by prompting people to look for alternative food sources, such as bushmeat.

3. Low-income countries must reinforce their health systems to detect earlier infectious zoonotic diseases and control outbreaks, by taking into consideration potential impact of climate change in their sanitary strategy and policy. Indeed, health systems are structurally inadequate in the least advanced countries, where they endure rather than anticipate climatic conditions and their variations. The recent Ebola epidemic in West Africa bears witness in particular to the need to step up the early detection and management of the emergence of zoonosis taking into account accurate environmental, social and climatic data.

Research and health management regarding these 3 items should be carried out through the "One Health" concept. This holistic approach includes both animal health and human health in their shared environment. The implementation of a multidisciplinary and intersectoral approach requires above all an awareness of its benefits and greater involvement of all the scientific and policy makers. The issue of climate change and its impacts on viral diseases may be an axis of reflection on this integrated approach, and Ebola disease is a topical issue.

Our poster presents some examples of North-South collaboration between teams which are fighting together against both climate change and Ebola crisis.

P-4410-04

Localised Climate Smart Agricultural Practices from the Global Permaculture Movement: Examples from the Semi-Arid Little Karoo in the Western Cape Province of South Africa

E. Kruger (1)
(1) University of the Witwatersrand, Department of Social Anthropology, Johannesburg, Gauteng, South Africa

A growing global social movement under the banner of permaculture is aimed directly at responding to the effects of climate change and mitigating human impact on our environment, in particular the consequences of unrestrained resource extraction and consumption and non-sustainable agriculture. Permaculture, a conceptual framework that originated in Australia in the 1970s, and now practiced across the globe, provides guidelines for the design of human living environments and the activities that we carry out in those environments. The underlying aim of permaculture design is to create productive anthropogenic landscapes of benefit to both humans and the environments that we inhabit - living and non-living by reducing the negative impacts of our actions through considered design. In the process, the intention is to also have an actively beneficent impact on those environments.

A principal focus in permaculture is the localisation of resilient food production systems which mimic and integrate with local ecologies and ecosystems, and are designed in anticipation of the climatic extremes expected to occur with climate change as well as reduced access to fossil fuels.

This presentation will introduce central approaches to agriculture and food production in the permaculture framework, and draw upon case studies from anthropological fieldwork conducted at a permaculture project located in the semi-desert Succulent Karoo biome of the Western Cape province in South Africa. In particular, the discussion will consider the design methods and technologies that have been employed to provide water and food in a highly degraded landscape of climatic extremes, and in the process contribute towards improved ecological resilience and biodiversity. Examples here include the use of water harvesting earthworks such as keylines, swales and tree pan systems, as well as employing a diverse range of climate specific and resilient productive species grown together to create micro-climates more amenable to food production and human habitation.

Some points that will be considered in this oral presentation are: What is climate smart agriculture? - Some central concerns around climate change and agriculture. What agricultural practice is not smart? What is permaculture? - Case studies of permaculture food production at a semi-arid permaculture in South Africa. How does permaculture address the concerns raised in climate change debates? What lessons can we learn from the permaculture paradigm of climate smart agriculture?

P-4410-05

The Prevalence of HIV/AIDS amongst the Pastoral Communities over Kenya, Uganda, Tanzania and Ethiopia

G. Otieno (1)
(1) university of nairobi, meteorolgy, nairobi, Kenya

The Human Immune Virus (HIV) and Acquired Immune Deficiency Syndrome (AIDS) have been identified as a major threat to pastoral communities over East Africa. The regional governments have given little attention to this problem due to the perception that Pastoralisms is economically inefficient and environmentally destructive. The study was carried over Kenya, Ethiopia, Tanzania and Uganda to assess the current state of HIV/AIDS prevalence amongst the pastoral communities using desktop review and expert judgment opinion. In Kenya, about 8million people of Kenyan population depend on pastoralism. In Tanzania the livestock sector contributes about 6.1% to the national Gross Domestic Products (GDP). In Uganda 17% of GDP is accounted for by the sector and about 9% of the national GDP in Ethiopia.

In the pastoral districts the average prevalence of HIV/AIDS amongst the community is estimated at 5.7% with this figure expected to increase. The infection rates are being accelerated by factors related to human rights and gender, socio-cultural environment and lack of HIV/AIDS awareness and stigmatization. The HIV/AIDS is not recognized at policy level as a major problem facing Pastoralisms yet the statistics show increasing population of HIV/AIDS victims.

The communities refuse to admit the presence and impact of HIV/AIDS within their families with high stigma attached to the affected and infected. The number of livestock has been diminishing through sales to pay the medical expenses when the pastoralists are affected. The study recommends for budgetary support and HIV/AIDS campaign amongst the pastoral districts to reduce the stigma and curb the decreasing number of livestock.

Now You See It

L. Perrin (1)
(1) Lola Perrin, London, United Kingdom

I have spent the last year sourcing and interviewing campaigners, inventors and innovators at the frontline of climate justice and placing their words within a music composition for piano and recorded spoken words. The project is a device to drive population awareness of the issues. Interviewees range from grassroots mitigation experts in Africa to Costa Rican media agitators to campaigners in the Arctic. Please note that as of today, The Guardian newspaper is currently picking up on my work, being released end March 2015. I propose for you a Q&A, to be discussed, following a performance featuring my work - as a musician/layperson/mother of two boys/deeply concerned about our future. I will be situated at a music keyboard/acoustic piano, performing with my artistic, pre-recorded spoken word presentation created from my interviews with major international voices in the climate justice movement, delivered through PA system.

Here follows my press release. I hope to hear back from you: music is an important social device to communicate between expert witnesses and ordinary people and I would like to collaborate with you to create the perfect performance for your vital intiative. I live in London.

TITLE: 'NOW YOU SEE IT'

FOR PIANO AND AN ORCHESTRA OF WORDS RECORDED FROM ACTIVISTS & INNOVATORS AT THE FRONTLINE OF CLIMATE JUSTICE

2 min PROMO https://www.youtube.com/watch?v=EsHnQJQ1A54

Composer: Lola Perrin

Voices: recorded in interviews conducted by Christian Dymond and Lola Perrin

Voices are Marjaun van Aubel, Ben Ayliffe, Guy Battle, Helen Caldicott, Charlotte Du Cann, Seamus Garvey, Natasha Geiling, Peter Gleick, David Helvarg, Jennifer Kingsley, Andreas Mershin, Katiana Murillo, Meena Nallainathan, Margo Perin, Kate Rawles, Carl Safina, Bert Schouwenburg, Joao Talocchi, Abdel Karim Traore, Will Travers, Greg Valerio

Backgrounds of the voices

Greenpeace, Blue Frontier Campaign, Blue Ocean Institute, Pacific Institute, Board of Oceana, Chasing Ice, Smithsonian, Sustainable Business Consultancy, Born Free, If You Love This Planet, IFEX, GMB, Fairtrade, Canadian broadcasting, Latin America media, mitigation in Africa, inventors at MIT and Nottingham University Faculty of Engineering, Transition Free Press, scientists, renewables designer, outdoor philosopher.

Description

Now You See It for piano and an orchestra of words is a new contemporary classical/minimalism/imaginative piano project with a voicescape made from the specially recorded spoken words of international activists and innovators at the frontline of climate justice. The words are responses to Lola Perrin's questions designed to elicit inner meditations on cruelty, beauty, isolation, loss, overcoming difficulty and personal statement. «Such a brilliant idea» (George Monbiot).

Composer statement

«We must all work for Mother Earth right now, it is obvious.» (Nelly Brooke age 85, December 2014)

«We have to stop pressing buttons and expecting things to happen, it's ridiculous.» (Margaret Chalmers age 82, January 2015)

These comments from two elders, and my precious friends, say it better than I can.

Fiddling while the roof burns? Tales of coal, justice and grassroots opposition to energy boom in Turkey

E. Turhan (1) ; AC. Gundogan (2)
(1) Istanbul Policy Center, Sabancı University, Istanbul, Turkey; (2) King's College London, London, United Kingdom

What links a local group of activists, struggling with few resources to save their communities from the ills of coal-fired power plants to broader social movements to save the planet from burning? And what, in turn, connects global processes of climate change to local livelihoods' demands for spatial and environmental justice? Climate justice, as Pellow and Park (2009) observe, begins with an acknowledgement of climate injustice and views this problem not as an unfortunate byproduct of climate disruption but as one of its core elements, and one that must be confronted if climate crisis is to halted and reversed. Even though the notion of climate injustice implicates need, care and community, proposals for the Anthropocene remains limited to property rights and market ideas of justice. However climate justice offers a fresh approach which in practice means energy access for those who do not adequate and sustainable access to the services of energy, workplace justice and occupational health for those who produce energy sources and remediative justice those who are affected by the impacts of hydrocarbon burning. This provides a good entry point to investigate the case of Turkey, which has witnessed exacerbating ecological conflicts since 1990s. Economic growth, rapid urbanization and hydrocarbon-dominated energy policy preferences in the past 2 decades placed immense pressure on the socio-ecological systems in Turkey. These pressures often manifested themselves as ecological conflicts due to land use changes, energy production, mining and associated neoliberal legislative changes. At the peak of these conflicts, Gezi protests of 2013 became the landmark of ecological conflicts in framing climate-energy nexus as a matter of (in)justice for and by the most vulnerable communities. Yet failure of the Turkish government to take a binding emissions reduction target as the OECD country with the highest rate of emissions increase since 1990 and its ambiguous position in the global climate regime makes it a curious case. Hence in an attempt to demystify the "energy-hungry nation" idea, this paper focuses on the cases of three local movements (Aliağa, Karabiga and Yalova) against coal-fired power plants, their changing discourses and the national energy planning under climate change in stitching the gap between developmentalism, energy production and defense of rural-urban commons in Turkey.

Green Economy as a Technocratic Concept: Genealogy and Agenda

J. Foyer (1)
(1) CNRS, ISCC, Paris, France

In 1972 in Stockholm, the environment was considered as a set of constraints, imposing various biophysical limitations on economic activity. At Rio in 1992, the advent of sustainable development introduced changes in this representation: economic development or growth was considered as possibly compatible with environmental protection. In 2012 at Rio, the Green Economy was supposed to represent a further step in the environment-market reconciliation, since through this notion, the environment was no longer considered as a reality to be taken into account, and even less as a constraint, but rather as an opportunity. Thus, within 40 years, the discourse has moved from the assertion of a fundamental contradiction and the search for a balance between the environment and the economy, to that of potential synergy.

This presentation aims both at tracing a genealogy of the concept of Green Economy and a precise analysis of the moment of its international agenda setting at Rio +20. Our core hypothesis is that the concept of green economy, while conveying a very liberal and economistic worldview, is primarily a technocratic concept that did not stem from the private sector, but that emerged at the interface between academia and international institutions. We also want to analyze the role of the Rio+20 Summit in agenda setting and testing ground for the concept, as a moment of controversy and violent geopolitical confrontation over its definition and vehement criticism on the scope it should be granted.

CARBON EMISSIONS AND RESOURCE PRODUCTIVITY: Why reviving growth requires a rapid de-carbonization of the global energy system

M. Molitor (1)
(1) SciencesPo, Paris School of International Affairs, Paris, France

Most governments believe that any attempts to reduce their emissions will require giving up on some future economic growth and this has served as the principal barrier to getting global collective action on reducing

the growing risks associated with climate change. This is true despite the fact that numerous economic studies have shown that the future reductions in growth required to keep global surface temperature increases to less than 2 degrees C will be small relative to the overall increases in growth over time. What no one has questioned is whether it is possible to meet the economic growth requirements of a human population on its way to 9.5 billion people in 2050 by using fossil fuels as the primary basis of delivering both stationary and transport energy.

The global economy requires exponential growth to function properly and this, in turn, requires an exponential improvement in overall resource productivity. Resource productivity refers to the efficiency with which all forms of capital (human intellectual, hard assets, and money), energy and natural resources are deployed. There is a growing gap between the increasing levels of resource efficiency now required and the levels which we have been able to achieve. Locating, recovering, transporting, refining, and combusting fossil fuels requires increasing amounts of capital, energy and natural resources. Not only has the resource productivity of fossil fuels been declining for decades but, as energy touches every segment of the global economy, fossil fuels have had a negative impact on global resource productivity as well.

The OECD estimates that global GDP must increase from approximately US$70 trillion today to US$305 trillion by 2050 in order to meet the growing aspirations of an expanding human population. This is an unprecedented level of growth requiring extraordinary improvements in resource productivity. Many large-scale economic activities in operation today are deploying capital, energy and natural resources at levels of resource productivity that will make it nearly impossible to achieve the higher levels of growth now required. The most compelling evidence of this is the waste produced by these activities as waste is the best indicator of resource inefficiency. At 36 billion metric tonnes of carbon dioxide equivalent and growing, the waste produced through the combustion of fossil fuels is the most robust evidence of the least resource productive activity on the planet.

Getting to US$305 trillion is not possible if we continue to rely on fossil fuels as our primary source of delivering useful energy. Fortunately, there are existing and emerging energy technologies, new business models and new models for producing and distributing energy which are capable of delivering the large improvements in resource productivity now required. Furthermore, the level of capital investment required is no more than the amount that would have been deployed to continue using fossil fuels. The old narrative…

"Reducing carbon emissions requires deciding to be a little bit poorer in the future"

is not only out of date but completely inaccurate. The new narrative is…

"Reducing carbon emissions is the only pathway to restoring growth at scale and on time"

K-4411-03

Green economy and its alternatives

K. Mcafee (1)
(1) San Francisco State University, San Francisco, United States of America

Global environmental policy is increasingly framed by discourses of 'green economy'. Green economy is meant to foster economic growth while decoupling that growth from environmental decline. Its advocates hope that monetary valuation of environmental assets and deficits, economic rationality, and market mechanisms can mute the most ecologically damaging effects of unfettered, globalized capitalism. Some contend that this approach can surmount the North-South conflicts over climate-change liabilities and obligations that have bedeviled environmental negotiations.

To this end, green economy has been advanced as a successor to sustainable development. Its proponents endorse markets in nature as both a conservation strategy and a means to foster economic development in the context of resource scarcities and shrinking ecological space. In this view, international carbon trading would compensate developing countries for the costs of averting GHG emissions and ensuring conservation, while payments for ecosystem services might ease growing conflicts over land and resource rights. Advocates hope that green economy, informed by scientific expertise, can thus position environmental governance above the political fray.

Nevertheless, international climate negotiations remain highly politicized. Some G77 governments reject green economy as likely to undermine their sovereignty and reinforce longstanding patterns of global inequality. Some denounce carbon markets as 'environmental neocolonialism' yet remain dependent on extractivism and fossil-fuel-based growth. In contrast, emerging critiques 'from below' challenge the foundational assumptions of mainstream green economy, extractivism, and the growth imperative.

New peasant and indigenous social movements and their intellectual allies reject the construction of ecological limits as absolute scarcity, focusing less on the finitude of resources and carbon sinks than on the anti-entropic, life-giving relationship among human labor, water, soil, sun, and the activities of other species. They question the implicit equations of development with growth, well-being with consumption, and conservation with market rationality. Instead of growth they speak of buen vivir, sumak kawsay, lek'il kuxlejal, ubuntu, radical ecological democracy, etc. These concepts connote living well and living cooperatively both socially and ecologically.

These visionaries do not exclude trade, much less the reduction of material deprivation, but they reject narrow productivism that is blind to ecological consequences and distributive outcomes. Instead, they pursue endogenous strategies aimed at reduced dependence on external markets and capital, repeasantization, and equitable urban-rural relationships. In place of standardized scientific categories and universally commensurable values, they are informed by relational ontologies: understandings of human-nature linkages that are diverse, dynamic and specific to particular territories, times, and ecosocial systems.

Can such visions and strategies overcome the apparent conflict between the need for greater material well-being and the impoverishing, diversity-destroying results of globalized growth along current trajectories? Given the scope of the climate-change challenge in an unequal world, counter-hegemonic discourses to green economy under the broad headings of buen vivir, mainly in the global South, and degrowth, mainly in the global North, merit our attention.

Sustainable energy and development in a dichotomous economy: South Africa

A. Hughes (1) ; T. Caetano (1) ; H. Trollip (1) ; B. Merven (1)
(1) University of Cape Town, Energy research centre, Cape Town, South Africa

Currently South Africa is ranked amongst the top 20 emitters in terms of global GHG emissions. Energy consumption, which is heavily coal dependent, is expected to grow significantly in the future as the economy grows, and therefore, unless commitments to decrease GHG emissions are prioritised, GHG emissions will increase dramatically in the medium to long term. Energy modeling in the Long Term Mitigation Scenarios showed, for example, a four fold increase in GHG emissions by 2050 under a scenario of Growth Without Constraints (ERC, 2007).

In terms of Economic development and GDP, SA is considered to be an upper middle income country, with a per capita GNI in purchasing power parity terms of 12240$US (World Bank, 2015). However, society in South Africa remains very unequal. The GINI coefficient is 0.69 (StatsSA 2014) and the MDG poverty line of $1.25 (2005ppp) shows that 7.4 percent of South Africans are currently living in extreme poverty, using a poverty line at $2.5 (2005 ppp) per day, this number increases to 29.2% (StatsSA 2013). Lower income households also experience a large degree of energy poverty, despite the high levels of electrification. For example the Department of Energy found that over a third of South African households are energy poor (DOE 2013). Poverty is largely due to high levels of unemployment in the formal sector and low levels of informal sector activity. Using a broad definition of

unemployment which includes all those currently without work that would like to work, 34.6% of South Africans are currently unemployed (StatsSA 2015).

South Africa is committed to a development path which is both inclusive (reducing inequality, unemployment and poverty), and "green" (reducing greenhouse gas emissions and increasing the sustainability of both the production and consumption of energy). Impacting low carbon development aspirations is the heavy reliance of industry and electricity production on coal. Questions currently being grappled with are: how can we decouple GDP growth and coal use in the economy?, encourage more efficient and equitable use of energy and follow a growth path which promotes job creation in sectors that are less energy intensive, thereby lowering emissions. This needs to be done without negatively impacting aspirations for high GDP growth and increased employment, both of which are economic development priorities which underpin current development policies such as the National Development Plan, and the Growth, Employment and Redistribution Plan.

The question for this paper is therefore: What could a sustainable energy future under a scenario of inclusive growth look like for South Africa?

The paper uses a bottom up energy model of South Africa, SATIM, to explore possible energy pathways and deep decarbonisation, looking specifically at the energy needed for the economy and the likely fuel mix and GHG emissions associated with this until 2050. A CGE model is used to assess how close we are to meeting development objectives, and ultimately whether development and decarbonisation can be complimentary objectives.

Can "Green Growth" Guide us into a Sustainable Future?

J. Zalpyte (1) ; MS. Rhozyel, (2)

(1) Eberswalde University for Sustainable Development, Faculty of Forestry and Environment, Leipzig, Germany; (2) Eberswalde University for Sustainable Development, Faculty of forestry and environment, Berlin, Germany

Prevailing political economy is failing to maintain environmental, social, political and economic coherence. A deep changeover into a new economy is needed "where the acknowledged priority is to sustain human and natural communities" (GTI, 2011: 1). Therefore, it is widely accepted that the current linear so-called "take-make-dispose" economy is not sustainable and that solutions need to be found in order to decrease both the input of limited resources as well as the output of human waste in any form. This paper examines in how far the ideas of „green growth" are capable to cope with this problem since they promise material welfare while reducing the impacts on the environment. Even though the underlying approaches like a „circular economy", "zero-emissions economy" or „Factor x" seem to be desirable, there is reasonable scepticism in how far advances in resource efficiency can ensure a sustainable future while industrialised societies got used to constantly raising living standards. We show that there is an intrinsic contradiction within the desire for "green growth" guiding the way towards a sustainable future.

Environmental Justice and Conceptions of the Green Economy

T. Ehresman (1) ; C. Okereke (2)

(1) University of the South--Sewanee, Department of Politics, Sewanee, Tennessee, United States of America; (2) University of Reading, Reading, United Kingdom

Abstract: Green economy has become one of the most fashionable terms in globalenvironmental public policy discussions and forums. Despite this popularity, and its beingselected as one of the organizing themes of the United Nations Rio?20 Conference inBrazil, June 2012, its prospects as an effective mobilization tool for global environmentalsustainability scholarship and practice remain unclear. A major reason for this is that muchlike its precursor concepts such as environmental sustainability and sustainable development,green economy is a woolly concept, which lends itself to many interpretations. Hence, rather than resolve long-standing controversies, green economy merely reinvigoratesexisting debates over the visions, actors and policies best suited to secure a moresustainable future for all. In this review article, we aim to fill an important gap in scholarshipby suggesting various ways in which green economy may be organized and synthesizedas a concept, and especially in terms of its relationship with the idea of social andenvironmental justice. Accordingly, we offer a systemization of possible interpretations ofgreen economy mapped onto a synthesis of existing typologies of environmental justice.This classification provides the context for future analysis of which, and how, variousnotions of green economy link with various conceptions of justice.

Greenovation and Sustainable Manufacturing: A Case Study of the Chemical and Pharmaceutical Industry in Nigeria

J. Adelegan (1) ; OJ. Professor Adelegan (2)

(1) Global Network for Environment and Economic Development Research, Department of Environment and Sustainable Development, Ibadan, Oyo State, Nigeria, Federal Republic of; (2) Lead City University, Economics, Ibadan, Oyo State, Nigeria, Federal Republic of

Addressing a paucity of research about industrial adoption of green innovation in Africa and, more generally, in tropical developing countries, we examined the Nigerian chemical and pharmaceutical industry as a case study. Qualitative interviews with one hundred and forty upper echelon executives representing thirty five Nigerian firms challenge conventional expectations that energy intensive industries in developing markets operate amid highly pollution-intensive conditions, within weak or non-existent formal environmental regulatory frameworks, and with limited institutional capacity. Our findings suggest a strong positive relationship between green innovation and financial performance and positive relationship between green innovation and sustainable manufacturing of African firms.

O-4411-05

Impacts of mitigation policies on labor markets and welfare

C. Grottera (1) ; W. Wills (2)

(1) COPPE/UFRJ, Energy planning, Rio de Janeiro, Brazil; (2) COPPE/UFRJ, Energy Planning, Rio de Janeiro, RJ, Brazil

The increasing need to reduce GHG emissions gives rise to new environmental regulations and market instruments, which present the potential to transform economies over the next decades. Production and consumption patterns are about to experience major changes as the world's carbon emissions must decrease in order to meet safe carbon concentration levels in the atmosphere.

The transition to a low carbon economy offers many opportunities to create green and decent jobs in developing countries, especially in sectors related to renewable energy, sustainable agriculture, forestry and waste management. Meanwhile, sectors like oil and gas, mining and energy-intensive industry may experience significant losses.

Since sectors differ in labor skill requirements and remuneration levels, shifting to this new profile will have major implications for workers among various sectors. To the extent that this affects workers´ income, changes in inequality and poverty levels are expected. In that sense, seeking a fair transition and the preservation of decent jobs is arguably necessary.

This work uses a hybrid Computable General Equilibrium model (IMACLIM-BR) to assess the impacts of mitigation options in various sectors, ranging from AFOLU to waste management, energy and industry sectors. The model is divided in 6 energy sectors, 7 industrial sectors, apart from the agriculture and livestock, transport and services sectors, and represents the Brazilian economy for a 25-year period, from 2005 to 2030.

The household sector is divided in 3 income classes, according to the their total income measured in base-year minimum wages (2005). Household consumption and income levels were calibrated using the 2003 National Household Budget Survey (POF), undertaken by the Brazilian Institute of Geography and Statistics (IBGE). The first income class represents the 16% poorer households, the second the 60% intermediary ones, and the third class represents the 24% richest households.

The long-term scenarios depicted in the study were built through a participative process that engaged more than 70 stakeholders from different areas, including government, private sector, the scientific community and civil society agents. In order to simulate quite ambitious mitigation scenarios, a set of mitigation options was identified, contemplating possibilities in the AFOLU, industrial, transport, residential and services, energy and waste sectors. The inputs provided by the stakeholders and sectorial experts included different mitigation options, investment requirements, GHG abatement potential and marginal abatement costs, among other aspects.

After defining a set of mitigation options, stakeholders were interested in checking what would be the influence of the implementation policy over macroeconomic and social indicators. To assess those effects, two implementation policies were tested – a normative scenario (command and control) and a normative scenario plus a carbon tax (100 US$/tCO2e).

Since several of those options present low and even negative abatement costs, our results show that their implementation do not jeopardize total output and jobs, even though there are winning and losing sectors. For example, jobs in oil, coal and carbon intensive sectors decrease whilst jobs in the biomass and services sectors increase. The former usually employs high-skilled labor, while workers in the latter are usually less skilled and hence poorer. Therefore, the results indicate a greater evolution in poor workers´ income, relative to high-skilled ones, leading to a better income distribution in the long run.

O-4411-06

Low Carbon Economy versus Ecological Civilisation: Polarization and Consensus of China's environmentalism

C. Goron (1)
(1) Department of Politics and International Studies, University of Warwick, Coventry, UK, United Kingdom

China's Climate Strategy proclaims the ultimate objective to transform its economic model towards "green and low carbon development" (lvse ditan fazhan) (China Climate Strategy 2014-2020). This strategy is often equated with the concept of "green growth", which the Chinese government has supported in the UN, mirroring its success in becoming the world's largest manufacturer of green technologies (REN report 2013) and the world's largest "green market" (IGEA, 2014)[1]. Indeed, both concepts emphasise the bottom line requirement that environmental protection may never mean a "growth ban" and on the contrary can be a motor of economic growth (Pan, J. et al, 2010; Jacobs, M. 2013). However, this economic interpretation of sustainability, and the marketization policies it entails, have been challenged, not only internationally, but also within China. In my paper, I brings evidence of this domestic debate and assess the relative importance, within it, of "green growth" as enabler and inhibiter of actions against climate change. Based on an extensive review of Chinese media, NGOs and academic publications, as well as policy documents, I discuss how issues of principle have informed two "low carbon policies": the introduction of carbon markets and the promotion of "low carbon cities" in the 12th Five-Year-Plan (2011-2016). I argue that the rhetoric of "low carbon development" has served mainly to cut through a polarized debate regarding the responsibility for the provision environmental public goods in China. Amongst them, nationalists still view "Low Carbon" as a western plot to contain China's rise (Gou, 2010)[2] and blame foreign capitalists for destroying China's resources and public health for the benefit of western consumers (Wen, Dale, 2015). On the contrary, socialist interpretations of the concept of "ecological civilization" (Shengtai wenming), which was included in the Constitution of the Communist Party in November 2012, target the government as principal agent of change, and reject the focus on economic growth as corrupted and "western" (Yu, Keping, 2003; Pan, Yue, 2007,)[4]. But as implementing successful climate actions in China remains contingent on strong government support, success relies on creative accommodation of the official rhetoric of balancing economic and environmental priorities.

Co-performance: the making of ecological modernization theory and EU climate politics

S. Aykut (1) ; B. Gabrielle (2)
(1) LISIS, Université paris-est, Marne-la-Vallée, France; (2) Irstea, Cestas , France

Scholars in comparative political science generally acknowledge that the European Union took the lead in issues of environmental protection and in global climate politics in the late 1990s. They attribute the legislative and diplomatic activism of the European Union in environmental issues to the prevalence of ecological modernization beliefs within the European Commission and some Member States heralded as leaders in this domain (Weale 1992; Pridham and Cini 1994; Cini 1995; Hajer 1995; Weale, Pridham et al. 2000). Taking the EU as an example, this contribution aims at questioning the role of norms and beliefs in the development of ambitious climate policy by (supra-)state actors.

We argue that ecological modernization discourse and EU environmental politics co-evolved and co-produced a narrative of environmental performance. This occured through a twofold process: (1) ecological modernization is not only a discourse but a narrative with performative consequences; (2) the evolution of EU climate policy shaped the development of ecological modernization theory. We first explore the intellectual and political context within which the discourse on ecological modernization became an influential narrative in the EU environmental politics. We situate this context in the post-cold war history of transatlantic relations. We then relate discursive affinities between narrative and contingent features in the EU environmental politics. This enables us to disclose how EU environmental politics and the narrative on ecological modernization reinforced and shaped each other. Finally, we explore recent developments in both EU climate policy and ecological modernization theory and ask how they relate to the emergence of the concept of «Green Economy».

Why We Should Make RICE NICE: The Importance of Intragenerational Inequalities for the Economics of Climate Change

M. Fleurbaey (1) ; M. Budolfson, (2) ; F. Dennig (2) ; A. Siebert, (3) ; R. Socolow (4)
(1) Princeton University, Woodrow Wilson School, Princeton, United States of America; (2) Princeton University, Uchv/wws, Princeton, New Jersey, United States of America; (3) Princeton University, Climate futures initiative, Princeton, New Jersey, United States of America; (4) Princeton University, Mechanical engineering, climate futures initiative, Princeton, New Jersey, United States of America

RICE and leading IAMs focus on aggregate economic growth, which has the effect of downplaying important detrimental effects of climate change on the poorest populations. In this paper we introduce a variant of the RICE model in which income distributions at a sub-regional level are modeled. We call the new model NICE, for Nesting Inequalities, Climate and Economy. By reframing the model with the above income disaggregation (in our case into income quintiles), we strive to address these issues of temporal urgency and intraregional equity more thoroughly.

When the degree of inequality aversion (embodied in the elasticity of marginal utility) is increased in RICE, the prescribed mitigation effort is reduced quite significantly. The underlying reason is the Ramsey equation:

discount rate = pure time preference + inequality aversion x growth rate.

With the positive (and often significant) growth rates of such models, an increase in the elasticity simply leads to more discounting.

However, if inequality aversion is a good reason to discount future damages to wealthier individuals relative to equivalent mitigation costs to the less affluent present, it should also be a good reason to be more concerned about damages (and costs) to poorer individuals than richer individuals, regardless of the time in which they take place.

In NICE sub-regional income distributions are explicitly modeled. We combine these with several point estimates from the literature on the distribution of climate damages across income groups. Once these are incorporated, the picture of the richer future benefiting from the effort of the relatively poor present disappears. We find that for some reasonable damage distributions the poorest income groups in some regions could be worse off than their predecessors even under the low damage estimates from the IAM literature. The effect on the policy prescription is that much more aggressive mitigation is warranted to avoid damaging those vulnerable groups. Furthermore, the effort is increasing in the degree of inequality aversion in the social objective for some damage assumptions.

Explicit incorporation of distributional concerns in the evaluation of a public good such as climate change mitigation can be criticized for making an inefficient use of policy instruments. Ideally, the public good should be provided considering aggregates, and distributional concerns dealt with by more efficient redistributive policies. We consider such a possibility in NICE, and find that the redistributive policies required to substitute for the strong mitigation policy are well beyond what can be considered politically feasible. If income redistribution from rich to poor is performed within regions (with no transfers across regions), an additional 65% marginal tax rate would have to be levied and redistributed in order to alleviate the same (modeled) economic damages to the poor as might be alleviated by the welfare optimal mitigation rate. We also examine transfers between regions. "Overseas" aid from other regions would have to be particularly efficient at targeting only the poor to be an adequate substitute at all, and even so, it would have to be significantly greater than currently accepted levels.

The climate responsibilities of industrial carbon producers

P. Frumhoff (1) ; R. Heede (2) ; N. Oreskes (3)
(1) Union of Concerned Scientists, Cambridge, MA, United States of America; (2) Climate Accountability Institute, Snowmass, CO, United States of America; (3) Harvard University, Department of the history of science, Cambridge, MA, United States of America

Responsibility for climate change lies at the heart of societal debate over actions to address it. The United Nations Framework Convention on Climate Change (UNFCCC) established the principle of «common but differentiated responsibilities» among nations, suggesting that industrialized nations that had produced the greatest share of historic emissions bore particular responsibility for preventing dangerous interference with the climate system.

But climate responsibilities can be distributed in other ways as well. Here, we consider the distinctive responsibilities of the major investor-owned producers of fossil fuels, assessing the actions these companies took and could have taken to act upon the scientific evidence of climate change.

Recently published data show that just 90 entities have produced the fossil energy responsible for 63 percent of the world's industrial emissions of CO2 and methane; of these, 50 are investor-owned companies. As the scientific evidence became clear, many of these companies sought sow doubt about the science linking their products to global warming, and today are seeking new and increasingly carbon-polluting sources of fossil fuels

We conclude that major investor-owned fossil energy companies carry significant responsibility for climate change. It is still possible for these companies to effectively contribute to a solution. Significant progress in reducing emissions and limiting climate change could be achieved if companies 1) unequivocally communicate to the public, shareholders, and policymakers of the climate risks resulting from continued use of their products, and therefore the need for restrictions on greenhouse gas emissions consistent with the 2 °C global temperature target; 2) firmly reject contrary claims by industry trade associations and lobbying groups; and, 3) accelerate their transition to the production of low-carbon energy. Evidence from history strongly suggests that a heightened societal focus on their climate responsibilities may hasten such a transition.

Equity, Justice, and Security in Global Climate Governance

D. Michel (1)
(1) The Stimson Center, Environmental Security Program, Washington, DC, United States of America

Global climate change presents the international community with a seemingly intractable collective action problem. Growing greenhouse gas emissions are projected to raise global temperatures, shift precipitation patterns, and increase extreme weather events. The emerging repercussions of climate changes already underway threaten the livelihoods and security of countries and communities everywhere. Both the drivers and the impacts of transcend traditional state boundaries and governance structures. No single state can counter or avert the impacts of climate change on its own. But any country that moves to reduce its emissions shares the climate benefits with every other nation while bearing the cost of taking action alone. Those states which do nothing to combat climate change can "free ride" on the efforts of those that do. The

UNFCCC has become the global platform for international negotiations to agree and coordinate climate policies among nearly 200 sovereign states. But ongoing debates over the effectiveness and equity of mitigation measures, adaptation, technologies and funding suggest the need for re-evaluation. The future of greenhouse governance depends on innovation towards new type(s) of climate regime. Does the architecture of universal agreement constitute the way forward, or are other channels more suited for climate action? Could the emerging landscape of regional, multi-sectoral, and non-state institutional structures open fruitful potential options and practices for advancing more effective climate governance? Can new governance mechanisms simultaneously ensure climate security and justice, efficiency and accountability, technology innovation and dissemination, or must decision makers and stakeholders inevitably navigate trade-offs between these goals?

In preparation for the 70th anniversary of the United Nations in 2015, The Hague Institute for Global Justice and The Stimson Center have convened a high-level Commission on Global Security, Justice & Governance, to enhance global understanding and capacity and to advance practical recommendations for innovative collaborative action to address critical global challenges such as climate change. Co-chaired by former US Secretary of State Madeleine Albright and former Foreign Minister Ibrahim Gambari of Nigeria, commission members include Yoriko Kawaguchi, former Minister of Foreign Affairs and Minister of the Environment of Japan; Shyam Saran, former Foreign Secretary and chief climate negotiator of India; and Erna Witoelar, Founder of the Indonesian Environmental Forum. The Commission will conclude its report in June 2015. This contribution will provide the opportunity to present and discuss the Commission's analysis and recommendations.

A novel approach for analysing how equitable and ambitious countries' national policy actions and targets are in the light of the forthcoming Intended National Determined Contributions (INDCs)

MR. Rocha (1) ; N. Höhne (2) ; H. Fekete, (2) ; B. Hare (1) ; M. Schaeffer, (1) ; M. Hagemann, (2) ; ML. Jeffery (3) ; J. Gütschow (3) ; F. Sferra (1) ; Y. Deng (4) ; K. Wouters, (4) ; BP. Van (4) ; F. Comaty (4) ; K. Blok (4)

(1) Climate Analytics, Berlin, Germany; (2) NewClimate Institute, Cologne, Germany; (3) Potsdam Institute for Climate Impact Research, Potsdam, Germany; (4) Ecofys, Cologne, Germany

Countries are currently working on preparing measures to conquer climate change at many frontiers. They are developing policies that will lead to emission reductions in the short and medium term, they are considering aspirational long-term targets that provide guidance to policy-makers and stakeholders, and they are preparing submissions to the UNFCCC, in the form of Intended Nationally Determined Contributions (INDCs), committing to legally-binding targets (e.g. emissions reductions below base year) for the post-2020 period. The sum of the initially proposed national actions at a global level so far falls short of what is required to keep global warming below 2 degree above pre-industrial level. More action will be needed and major questions remaining include; which countries are doing their fair share?, which ones are not?, and by how much does each country need to increase their effort?

To answer these questions, global 2 degree-compatible emission pathways have to be broken down to country-level, fair emissions allowances. This can be achieved using effort-sharing methodologies. A wide variety of such approaches exist and their different underlying criteria and assumptions can lead to very different outcomes and a large range of emissions allowances for different countries. Here, we propose a methodology that allows the comprehensive assessment of countries' fair level of effort in a 2-degree world, which integrates the many views put forward by countries and the scientific community, without bias towards specific methodologies.

This methodology builds on previous work for the IPCC Fifth report that gathered and categorized existing effort sharing studies. The categories provided there serve as the basis for our analysis framework as they represent the broad range of possible 'principles' that could be applied to effort sharing. With the goal of extracting a unified benchmark system from the various approaches and categories for countries, we used these 'principles' to develop a framework that enables the rating of countries current level of effort against their fair level of effort. In addition the framework takes account of countries' mitigation potentials and aspects such as finance provided and the conditionality of targets on external parameters. Four categories are introduced that describe the countries' overall effort level: inadequate, medium, sufficient and role model.

Under this proposed framework, the ambition of a large number of countries that have put forward targets so far are rated as inadequate or medium according to the scale developed here. One of the major emitters, China, has pledged to peak emissions no later than 2030. The Climate Action Tracker quantifies resulting emissions of up to 15Gt in 2030, and rates this as inadequate, as only the least stringent effort sharing category is achieved at this level. The currently announced target of the USA of 26 - 28% below 2005 in 2025 results in a rating of medium, meaning that this target is within the range of a number of effort-sharing categories, but the level of ambition would only be sufficient at the global level, if other countries moved into the more ambitious end of their effort sharing ranges. The submitted INDC of the EU of reducing emissions by 40% below 1990 also receives the rating inadequate. Effort sharing approaches demand a stronger change in trends of the EU, in order for it to contribute in a fair manner to the global target.

Quantifying Development Needs: An energy centered approach to climate justice

N. Rao (1) ; W. Lamb (2)

(1) IIASA, Energy, Laxenburg, Austria; (2) Tyndall Centre for Climate Change Research, School of Mechanical, Aerospace and Civil Engineering, University of Manchester, Manchester, United Kingdom

Despite the vast literature on global climate justice, there is a surprising lack of studies that attempt to quantify the emissions impact of basic human development, even though many of these frameworks aim, either implicitly or explicitly, to shield basic human development from the costs of mitigation.[1] Broadly, the literature that frames distributive justice in terms of emissions rights neglects to relate these rights to development needs, making them susceptible as claims of 'hot air'. Proposals that aim to differentiate nations' capacity to mitigate define relatively arbitrary, universal thresholds of exemption,[2] typically in terms of income[3] or emissions, which ignore the heterogeneity in countries' energy sectors, and consequently their mitigation costs.[4] Yet, achieving climate stabilization at 450 ppm or less would significantly restrict global growth in energy, whose sufficiency for even basic development is not known.[5]

This paper presents a new basis for differentiating countries' mitigation responsibilities based neither on emissions rights nor income differences, but directly linking human development needs to greenhouse gas emissions through energy. Drawing on the well-known linkages between energy and human development, this paper presents theoretically and empirically grounded quantification of countries' energy needs for achieving basic human development. Using different indicators of human development (HD), including life expectancy and a composite (new) basic needs indicator, the historical relationship between countries' energy consumption and HD are estimated, and then projected into the future. The methodology also estimates historical decoupling between HD and energy use, so as to account for technological progress. Carbon intensities of energy are then separately projected based on different scenarios of the future, incorporating co-benefits and other future incentives for low-carbon development.

The cumulative emissions budgets for countries, so calculated, provide country-specific estimates of development needs for a universal set of HD standards, which can serve as a basis for deriving countries' mitigation responsibility. The paper discusses how the underlying analysis enables claims of basic development to be incorporated into both country-specific aggregate emissions targets, as well as into sector-specific cross-country mitigation regimes.

This work buildings on a forthcoming publication in Global Environmental Change [6] and presents preliminary ideas from research commencing shortly as part of a European Research Council (ERC) Starting Grant entitled 'Decent Living Energy: energy and emissions thresholds for providing decent living standards to all'.

Legal Strategies to Accelerate Climate Action

N. Amerasinghe (1)
(1) Center for International Environmental Law, Climate & Energy Program, Washington DC, United States of America

Climate change is occurring at a faster pace than the international negotiations to address the problem. In the absence of meaningful progress to reach an ambitious and binding global agreement on climate change, we need new strategies to accelerate climate action. Strategic legal challenges are a powerful tool in effecting transformative change, a tool that groups around the world are already starting to explore.

There are a variety of legal challenges that could be used to hold culpable actors responsible for causing climate-related harms. While the types of legal claims and corresponding evidentiary burdens will vary across jurisdictions, they typically involve a plaintiff with a particularized harm, and a defendant who is responsible and potentially liable for causing that harm. Thus, two primary hurdles in bringing these kinds of claims are identifying those responsible for climate change and connecting their actions to the harms suffered by climate-affected individuals and communities.

Scientific evidence plays a critical role in addressing these hurdles by providing the information needed to identify potential defendants and to link actions to harms (i.e. demonstrating causation). For example, in 2014, the scientific journal Climatic Change published new research that traces nearly two-thirds of all industrial emissions of greenhouse gases to only 90 carbon producing entities (including 50 investor-owned entities). This groundbreaking research provides an identifiable set of defendants whose impact can be quantified at the global level. Coupled with ongoing research to connect specific extreme weather events to the human contribution to greenhouse gas concentrations, the research adds a vital link in the causal chain essential to all successful litigation: connecting the actions of identifiable defendants to the harms suffered by identifiable plaintiffs. Scientific research can also show if climate harms can be redressed and quantify the remedy if the harms cannot be redressed.

This presentation will explore potential legal theories to hold culpable actors, particularly the major carbon producers, responsible for their contributions to climate change and its resulting harms. It will also discuss the importance of integrating scientific research into emerging legal strategies and, conversely, how legal strategies can inform and shape litigation-relevant science.

Beyond Burden-Sharing: The Potential for Peace and Reconciliation Processes in Climate Equity Debates

S. Klinsky (1)
(1) Arizona State University, School of Sustainability, Tempe, AZ, United States of America

Geopolitical changes combined with the increasing urgency of ambitious climate action have re-opened long-standing debates about equity in the international climate arena. Tensions about historical responsibility have been particularly difficult and have the potential to intensify as climate impacts and losses become more severe, and as developing countries face mounting pressure to take mitigation action. Resolving conflicts about the role of historical responsibility may be necessary to enable a global transition to a regime capable of facilitating the depth of collective action required. This paper presents an alterative to burden-sharing and suggests that a peace and reconciliation approach – in which the focus is on balancing efforts to address historically rooted injustices with a future-oriented collective direction and narrative – may have utility in the climate context.

Although substantial policy experience has been gained through efforts to address other complex conflicts at the interface of historical responsibility and imperatives for new collective futures – such as the transition from apartheid in South Africa – lessons from these processes have not been examined in the climate context. The contexts are profoundly different but international climate policy debates share three key similarities with conflicts in which peace and reconciliation processes have been pursued: a) unavoidable interdependence and mutually harmful consequences of not finding an agreement; b) limited ability to address justice concerns through existing judiciary processes; and c) profound disagreements about how the past and future should relate in a period of transition.

This paper provides an overview of insights from existing peace and reconciliation processes and focuses on the importance of negotiating a balance between addressing historical injustices and moving into a new, collective future. It then illustrates how approaching climate equity from this angle could productively refocus the discussion in particularly important areas for international negotiations, including loss and damage, financial support and capacity building.

P-4412-01

Atmospheric CO2 increase from 1990 to 2010 from emissions traced to major industrial carbon producers

B. Ekwurzel (1) ; M. Allen () ; M. Dalton (2) ; P. Frumhoff (3) ; R. Heede (4) ; R. Mera (1)
(1) Union of Concerned Scientists, Climate and Energy, Washington, United States of America; (2) Dalton Consulting, Brooklyn, United States of America; (3) Union of Concerned Scientists, Cambridge, MA, United States of America; (4) Climate Accountability Institute, Snowmass, CO, United States of America

Financial regulators and shareholders from communities around the world are calling for increased reporting of direct greenhouse gas emissions during production and manufacture by major industrial carbon producers. Requests are also growing for increased disclosure of risks to the infrastructure owned by these entities from climate change consequences. Another approach that has emerged is to account for the emissions traced to 90 major industrial carbon producers (Marland et al., 2011, Heede, 2014). Emissions traced to these producers over the period from 1854 to 2010 were incorporated into an energy-balance, carbon-cycle climate model to assess their relative contribution to atmospheric carbon dioxide and the global mean surface temperature. The UNFCCC was formed in 1988 and 1990 became the reference year for comprehensive reporting by nations for greenhouse gas inventories of emissions. Emissions traced to the 90

major carbon producers account for more than half of the atmospheric CO2 increase in 2010 relative to 1990. The emissions traced to the top major carbon producers will be discussed in terms of the consequences in atmospheric CO2 and global mean surface temperature increase. Such calculations are one factor among many other factors that can inform public discussions as to who may be held accountable to contribute to climate mitigation, adaptation, and compensation for damages.

The climate-pension deal

N. Jaakkola (1) ; F. Dennig (2) ; VB. David (3)
(1) Ifo Institut, Munich, Germany; (2) Princeton University, Uchv/wws, Princeton, New Jersey, United States of America; (3) Copenhagen Economics, Copenhagen, Denmark

'Reducing carbon emissions is costly for current generations, and only benefits people living in the far future.' Claims like this are common in the popular discourse on climate policy. However, they are mistaken: it is well known that, with overlapping generations, the beneficiaries of climate policies (future generations) can compensate those undertaking the effort (current generations). In other words, there exist climate policies which tackle the externality and leave everybody better off.

What is required for this is a 'climate-pension deal'. Such a deal involves current generations reducing emissions, while pension adjustments shift the benefits of abatement from future generations to the present, as compensation for the abatement costs. This compensation ensures that consumption of the current generations does not fall, and may even increase. In this way current generations are not made worse off, even if they don't live long enough to experience the climate benefits. The counterpart of the pension transfers is lower investment in physical capital: in effect, the portfolio of saving is allocated from (private) physical capital to (public) natural capital.

We characterise the required 'climate-debt deal' which moves society to some Pareto-efficient point. Using an overlapping-generations model, augmented with a climate externality, we assess the intergenerational distributional consequences of Pareto-improving climate policies and compare the fiscal burden due to the required transfers to existing debt and pension burdens. In this way, we assess whether intergenerational compensation is a 'big deal' or not.

We also propose a new framework to assess the distributional consequences of climate policies. Typically, Pareto-efficient points are obtained using a social welfare function. A common choice is the weighted utilitarian sum, often with discount factors as weights. These weights are an opaque device, difficult to relate to the distributional consequences.

We propose an alternative which focuses on the distributional consequences. Efficient climate policy generates a surplus: we employ the idea of intergenerational bargaining over how this surplus is divided between various generations. For example, one Nash bargain would involve the generations splitting the surplus over the business-as-usual outcome evenly amongst themselves. Alternative bargaining outcomes incorporate the effect of sunk investments and split the surplus in favour of future generations, recognizing that full compensation for past investments may not be politically achievable. We present and compare several alternative bargaining notions, all of which share the feature that all generations must benefit from the bargain. We also consider an overlapping generations economy equivalent to the standard infinitely-lived agent economy and compare the results of our intergenerational bargains with those resulting from typical assumptions in the integrated assessment literature.[1]

In addition to assessing the magnitude of the flow of intergenerational compensation involved in Pareto-efficient climate policies, our results imply that the intergenerational distributional effects of climate policy can be corrected for, and are thus a secondary issue compared to questions about the international burden-sharing.

Quantification of Effort-Sharing Principles: Policy Choices and Data Uncertainty

ML. Jeffery (1) ; Y. Robiou Du Pont (2) ; M. Meinshausen, (3) ; J. Gütschow (1)
(1) Potsdam Institute for Climate Impact Research, Potsdam, Germany; (2) Australian-German College of Climate & Energy Transitions, University of Melbourne, Melbourne, Australia; (3) University of Melbourne, Australian-german college of climate & energy transitions, school of earth sciences, Melbourne, Australia

A fundamental principle of the UNFCCC negotiations is that of Common But Differentiated Responsibilities and Respective Capabilities (CBDR-RC). Operationalizing this principle remains a core challenge in the development of a new international agreement, in part due to the nuances of national circumstances, which cannot be readily resolved without negotiation. However, the scientific and non-governmental community can contribute by providing quantitative interpretations of effort-sharing proposals in terms of emission mitigation targets and financial contributions.

Previous quantifications of burden-sharing proposals differ significantly, and a collation of existing studies identified a wide-range of targets for any individual Party or region (Höhne et al., 2014; IPCC WGIII, 2014). The ranges in reduction targets are partly due to differences in the fundamental underlying principle used to determine the fair-share distribution of emissions. For example, equal cumulative per capita emissions or a convergence toward equal per capita emissions. However, the ranges also result from different choices made in the method of quantification, global target emissions pathway, underlying data, and assumptions regarding future emissions growth and socioeconomic development. These differences in data and key assumptions complicate any comparison of results or understanding of the key factors determining fair-share allowances.

Using the PRIMAP (Potsdam Real-time Integrated Model for probabilistic Assessment of emissions Paths) Emissions Module we generate and assess a suite of effort-sharing scenarios resulting from multiple policy and data options within the Greenhouse Development Rights effort-sharing regime (Baer et al., 2008). The Greenhouse Development Rights regime requires emissions, GDP, and population data projections, and incorporates multiple policy options, thereby providing a consistent framework for comparing these factors. We generate the effort-sharing scenarios using emissions projections from the IPCC AR5 and LIMITS databases, and socioeconomic data from the Shared Socioeconomic Pathways (SSPs) developed for the IPCC 5th Assessment, all downscaled to the national level.

The generated scenarios are assessed in terms of the resulting 2025 and 2030 mitigation targets for individual countries and regions. We identify the key factors that make a quantitative difference in a countries' fair-share mitigation target. Analysis of these factors allows the identification of areas of convergence and divergence from the perspective of different policy options, and the underlying effort-sharing principles.

Using the suite of effort-sharing scenarios, we explore several key policy questions. Including: What is the difference in ambition required for a 1.5°C or 2°C limit in global temperature change? For a given country, does the start year of historical accounting, or the balance of capability and responsibility have a greater impact on the fair-share allocation? What does it mean for 2030 mitigation targets if pre-2020 ambition is not increased? From a quantitative perspective, which of these issues is the most important?

Finally, we highlight how quantification methods can be improved to minimize the impact of data and scenario projection uncertainty on the evaluation of fairly distributed emissions targets.

Global Climate Ethics: A View Based on Chinese Philosophy

X. Liu (1) ; Z. Wang (2) ; J. Wu (2)

(1) management institute of shenzhen university, shenzhen, China; (2) Institute of Policy and Management, Chinese Academy of Sciences, Beijing, China

The Ethical Factors have been recognized now in the scientific researches on the Climate Change. These researches can be more efficient and effective when studies on economic realities and ethic contexts are involved. Referring the Chinese traditional ethic values, this essay introduces a new Climate Ethic System applicable to inter-nation discussions, with pursuit of "harmony" and the practice of "operation on ranking and grouping". It probes into the assessment principles of Climate Ethics--Equity, Justice and wellbeing based on the explication of the ethic connotations of Equity and Justice in the Climate Protection, and further into the Justice in climate negotiations. As an ethic principle for the international climate negotiations, this essay suggests: all the measures against the Climate Change should keep in line with the social and economic development of all the participating countries, paving the way for the Pareto improvements in each participant while reducing the gaps among them, without depressing the social individuals, which are being poor, deeper into poverty.

P-4412-05

Intergenerational equity under catastrophic climate change

A. Méjean (1) ; S. Zuber (2) ; M. Fleurbaey (3) ; A. Pottier (1)

(1) CIRED, Nogent-sur-Marne, France; (2) Paris School of Economics, Paris, France; (3) Princeton University, Woodrow Wilson School, Princeton, United States of America

Climate change raises the issue of intergenerational equity, as catastrophes may unfairly affect some generations. As climate change threatens irreversible and dangerous impacts (IPCC, 2014), possibly leading to economic collapse, the tradeoff is no longer between present and future consumption, but between present consumption and the possible future extinction of civilization (Weitzman, 2009). This paper aims at identifying public policies that can reduce unfairness and strike a compromise between present and future generations when the potential impact of catastrophic climate change on the economy is accounted for. It explores the impact of inequality aversion and the impact of the attitudes towards population size on optimal climate policy when that catastrophic risk is accounted for.

We use an integrated assessment model which simulates the future joint evolution of the economy and the climate. The Response model is a dynamic optimization model (Pottier et al., 2015), which belongs to the tradition of compact integrated assessment models such as DICE. It combines a Ramsey-like macroeconomic module and a climate module, and can be used to determine the optimal climate objective by comparing mitigation costs and avoided climate damages. We account for the risk of extinction due to climate change, first by assuming an exogenous probability of extinction, then by assuming a probability of extinction that depends on the temperature and on the level of economic output. We assume that the states of the world where people are wealthy will show enhanced resilience to climate damages, and will therefore face a lower probability of extinction under a given level of climate damages.

Integrated assessment models can reveal the policy implications of various normative choices through the use of social welfare functions. Ideally, social welfare criteria should (i) account for inequality aversion (it should thus differ from the utilitarian criterion, which does not account for the distribution of utilities), (ii) satisfy the Pareto principle (i.e. it should account for the preferences of individuals) and (iii) be separable (i.e. the situation of past generations should not impact the evaluation). The 'Expected Prioritarian Equally Distributed Equivalent' (Fleurbaey and Zuber, 2014) accounts for the inequality aversion of the social planner and respects a weak form of Pareto, but is not separable under risky prospects (but we will not consider past generations in our analysis). This criterion includes a critical level of consumption which can be interpreted as the level of subsistence.

In order to reveal the impact of inequality aversion on optimal climate policy, we consider various isoelastic functions ϕ, which translate the inequality aversion of the social planner, and various isoelastic functions u, which translate the risk aversion of the social planner. Inequality aversion here relates to the average consumption by individual at time t. Preliminary results using Response in the certain case (with no risk of extinction), and using the standard discounted utilitarian criterion, show that the optimal policy (i.e. the timing of optimal abatement) is identical for equal discount rates $r = \rho + \eta g$, whatever the values of the pure time preference rate ρ and the degree of inequality aversion η. In the risky case, the degree of inequality aversion has a significant impact on the optimal climate policy. In order to reveal the impact of the attitudes towards population size N (which refers to the total number of individuals in all generations), welfare is weighted by the population size through αN, which is a bounded increasing sequence of N. In this case, the criterion gives priority to large populations.

Attribution of extreme heat events in the western US to emissions sourced from major industrial carbon producers

R. Mera (1) ; B. Ekwurzel (1) ; D. Rupp (2) ; P. Frumhoff (3) ; P. Mote (4) ; M. Allen () ; F. Otto (5) ; N. Massey (5) ; D. Mitchell (5)

(1) Union of Concerned Scientists, Climate and energy, Washington, United States of America; (2) Oregon State University, Oregon climate change research institute, Corvallis, United States of America; (3) Union of Concerned Scientists, Cambridge, MA, United States of America; (4) Oregon State University, Earth, ocean, & atmospheric sciences, Corvallis, Oregon, United States of America; (5) University of Oxford, Oxford, United Kingdom

There exist highly-vulnerable populations facing detrimental climate impacts within a developed nation like the United States. There is a growing need for accountability for the damages incurred as well as funding for mitigation infrastructure. The concept of responsibility for climate change impacts is central to the United Nations Framework Convention on Climate Change (UNFCCC), and calls for acknowledgement by industrialized nations for their greater share of emissions. However, it has been argued that major industrial carbon producers should recognize the impact of their activities (Heede 2014). Nearly two-thirds of carbon pollution released into the atmosphere can be traced to carbon extracted from the earth by 90 major industrial carbon producers. Recent advances in climate attribution have allowed scientists to link extreme weather events to rising levels of greenhouse gases due to human emissions. Our research uses very large ensembles of regional model simulations to explore the fractional attribution of extreme heat events in the western US to emissions traceable to 90 major industrial carbon producers. The results show that record-setting high temperatures during July in the Central Valley of California were 3 times as likely to occur in the decade of the 2000s compared to a simulated world without industrial anthropogenic greenhouse emissions. The next

phase of the project is to explore the increased risk of heat extremes attributable to major carbon producers.

P-4412-07

The contribution of emissions traced to major carbon producers to changes in meteorological and health risks during extreme events

D. Mitchell (1) ; F. Otto (1) ; S. Sparrow (1) ; M. Allen (2) ; P. Frumhoff (3)
(1) University of Oxford, Oxford, United Kingdom; (2) University of Oxford, School of Geography and Environment and Dept of Physics, Oxford, United Kingdom; (3) Union of Concerned Scientists, Cambridge, MA, United States of America

Recent studies have shown that ~63% of cumulative, world wide emissions of CO2 have come from only 90 major carbon producers (hereafter, "carbon majors"). Here, we use this result to model a hypothetical climate where the carbon majors never existed.

Specifically, we use a unique modelling capability to perform massive ensembles of climate model simulations ("climateprediction-dot-net: CPDN"), which enables assessment of any changing probabilities of particular meteorological extremes of interest. We use results from a sister study which compares scenarios representing the year 2003 (i) as it actually was (i.e. where both natural and anthropogenic conditions are used to drive the climate model; "scenario 1"), and (ii) as it could have been, if humans had not altered atmospheric gas composition (i.e. with only natural conditions; "scenario 2"). This type of scenario comparison is commonplace in probabilistic event attribution analyses. However, here, we go one step further by considering an intermediate third scenario to address the question: 'how would the frequency of a 2003-like heat wave change if the carbon majors never existed in 2003?' ("scenario 3").

A feature of CPDN is that each global simulation contains a high-resolution "nested" regional climate model centred on Europe. This high-resolution modelling capability allows us to perform much of the analysis at the city level. In our sister study we use Scenario's 1 and 2, and show how heat-related mortality changed over Paris during 2003. In this study, we then discuss the implications for such a change given our Scenario 3, which involves only the 90 carbon majors.

P-4412-08

Distributing the global RCP2.6 emissions: five versions of 'fair' country level allocations

Y. Robiou Du Pont (1) ; M. Meinshausen, (2) ; ML. Jeffery (3)
(1) Australian-German College of Climate & Energy Transitions, University of Melbourne, Melbourne, Australia; (2) University of Melbourne, Australian-german college of climate & energy transitions, school of earth sciences, Melbourne, Australia; (3) Potsdam Institute for Climate Impact Research, Potsdam, Germany

Current climate negotiations under the United Nations Framework on Climate Change Convention (UNFCCC) aim to limit global warming to 2°C. The distribution of the corresponding greenhouse gas (GHG) mitigation burden amongst countries is a major block in progress toward an international agreement on binding commitments. Scientists and national experts have proposed and quantified several equity principles to distribute the international mitigation burden (Baer, Fieldman, Athanasiou, & Kartha, 2008; BASIC experts, 2011; Jacoby, Babiker, Paltsev, & Reilly, 2008; Nabel et al., 2011). Studies modelling these principles distribute different GHG emissions of diverse global emissions pathways. However, these global emissions pathways may not achieve GHG mitigation at optimal cost and result in different temperature responses making cross-studies comparisons difficult.

The distribution of the annual GHG emissions of a global cost optimal scenario has not yet been compared across a set of approaches representative of the international equity debate. The Fifth Assessment Report of the International Panel on Climate Change (IPCC AR5) introduced the Representative Concentration Pathway 2.6 (RCP2.6), a cost optimal pathway that has a likely (greater than 66%) chance of limiting global warming to 2°C (IPCC, 2013; Meinshausen et al., 2011). The international distributions of the emissions associated with RCP2.6 following different equity principles would provide decision makers with a consistent comparison. What sets of national GHG emission pathways would reflect the proposed equity principles while matching the physical emissions of RCP2.6 at each time step? What would then be the regional and national GHG mitigation targets for 2025 and 2030 according to each effort sharing approach?

The IPCC AR5 presented regional 2030 mitigation targets collated from over forty studies and grouped into five categories according to the distributive justice concepts applied: 'equality', 'equal cumulative per capita', 'responsibility-capability-need', 'capability', and 'staged approaches' (IPCC WGIII, 2014). We model five approaches representative of these five categories using the PRIMAP (Potsdam Real-time Integrated Model for probabilistic Assessment of emissions Paths) Emissions Module (Nabel et al., 2011). Each of these approaches distributes the emissions of RCP2.6 amongst all UNFCCC parties. Consequently, the aggregation of the national emission pathways of each approach matches the emissions of RCP2.6 at each time step. For each approach, pathways are calculated for a range of parameters that account for transition period to the allocation start, historical emissions, historical and projected population data, and GDP projections.

At the next Conference of the Parties (CoP) in December 2015, the international community aims to establish a binding agreement to limit climate warming. Parties to the UNFCCC should announce their Intended Nationally Determined Contributions (INDCs) ideally by March 2015. Our analysis informs the debate on equitable mitigation burden sharing amongst the international community. In particular, it should help decision makers and the public to appreciate the consistency between INDCs and the global goal of limiting warming to 2°C according to the various concepts of equity.

A Dynamic Intepretation of the Principle of Equity in the Next Climate Change Regime-Equity as a force of gravity

M. Rosa (1)
(1) University of Oslo, PluriCourts, Oslo, Norway

Equity will play a crucial role in designing the post-2020 climate change policy. The principle of equity is intrinsically tied to sustainable development as an expression of inter and intra generations equity. The next climate agreement has to be felt as equitable in order to be signed by a majority of country states. So far Climate Equity has been interpreted through the principle of Common but Differentiated Responsibilities and Respective Capabilities as encompassed in Art.3 UNFCCC. The current interpretation has brought the so- called firewall between developed and developing countries, where the first are bound to all the emission cuts. In the latest years some developing countries have become major emitters. The current division of mitigation efforts can therefore not be regarded as equitable and should be changed.A dynamic treaty interpretation of the principle of equity could be one way to overcome this division.

This research demonstrates that the concept of equity should be interpreted dynamically because of its own intrinsic dynamism.

Since its early formulation in Art 38 of the ICJ's Statute, equity principle has played a creative role in the public international law. Indeed core international law principles like pacta sunt servanda and unjust enrichment have arisen from equity considerations. In this manner equity acts as a force of gravity, dragging new contents into a treaty. In Climate discourse a dynamic approach to equity would highlight national circumstances rather than responsibility for global warming as a criteria for designing commitments. Equity dynamism calls also for flexibility and variety. The next Climate Agreement should be shaped as a flexible agreement in its contents, settings and outcomes. Mitigation commitments should be tailored to what a country is willing and able to afford. This would bring different commitments to different countries.

This presentation will examine the main emission-reduction schemes proposed, aimed at implementing a dynamic interpretation of the equity principle. It will then analyze which of the features within the proposals the next Climate Change Agreement should include in order to be equitable. To date three approaches- the Global Carbon Budget Approach, the GDRs Framework and the Mutual Recognition Approach- have gathered momentum. Every approach has strengths and weakness from an equity perspective.

Research on Global Carbon Emission Quotas Allocation in post-Kyoto Era

Q. Zhu (1) ; Z. Wang (2) ; J. Wu (2)
(1) China university of petroleum, Beijing, China; (2) Institute of Policy and Management, Chinese Academy of Sciences, Beijing, China

Abstract□By using the bottom-up and top-down modeling methods, this paper build a global model on quotas allocation. Through simulation, we draw the following four conclusions: (1)due to the difficulties of determining abatement way, benchmark year and proportion of reduction, current global carbon reduction programs exist uncertainty. (2) single principle of quota allocation can not satisfy preferences of all regions, and may even lead to extreme result of quotas allocation. (3) the weighted principle of quota allocation based on controlling the total emissions can be adopted in the future. (4) the weighted principle of quota allocation should cover as many principles of quotas allocation as possible; meanwhile the target of emissions reduction determined by climate negotiations should be replaced by the weight of principles from voting.

Building pro-poor, low carbon innovation systems through international and indigenous efforts

A. Ely (1) ; D. Ockwell (2)
(1) STEPS Centre, SPRU – Science Policy Research Unit, Sussex, United Kingdom; (2) University of Sussex, School of global studies, Brighton, United Kingdom

Local innovation capabilities have long been recognised as a key requirement in forging new innovation trajectories and low carbon development pathways. Building on the foundational literature from innovation studies, a swathe of recent research has highlighted the processes through which these have emerged at national levels, in particular in emerging technological nations such as China and India. In most of these cases, indigenous learning processes have led to the build-up of knowledge and capabilities within a usually small subset of elite firms.

At national levels (e.g. in the Chinese and Brazilian cases) the role of central policies and investment from strong development banks has combined with more local efforts to build innovation systems in poorer regions. Relatively few scholars have investigated the governance challenges associated with centralised policies and the sometimes divergent interests of provincial/ regional actors. At international levels, scholars have investigated the potential for collaborative research and development activities as a way of facilitating technology transfer and low carbon innovation.

Informed by some of these insights, international efforts are underway through the UNFCCC to try to provide external support for low carbon innovation of a transformative nature. In particular, the Climate Technology Centre and Network, as well as the Green Climate Fund, which claims transformative ambitions, promise to enhance developing countries' low carbon innovation activities. 'New donor nations' may also play an important role (for example the BRICS bank). These efforts raise a fundamental question, echoing earlier innovation studies work that has pointed to the difficulties of purposive creation of innovation systems that have elsewhere emerged through complex indigenous interactions. How do international (donor) efforts co-ordinate with indigenous processes to foster the emergence of dynamic low carbon innovation systems?

This paper discusses some of the innovation systems literature that can inform our answers to these questions, especially the work of the Latin American school that has highlighted the challenges of implementing policies to build innovation systems that aim to emulate those that have emerged elsewhere. It will link to recent research carried out by the STEPS Centre around low carbon innovation capabilities and the role of 'system builders' in China and Sub-Saharan Africa. Linking this to the wider innovation studies literature raises questions for international processes that aim to foster innovation for alternative trajectories in low and middle-income countries.

Facilitating technological change to manage energy and climate challenges in developing countries

A. Sagar (1)
(1) Indian Institute of Technology Delhi, Humanities and Social sciences, Delhi, India

It is well understood that new and improved technologies will play a key role in efforts to address the energy and climate challenges facing developing countries. But a range of resources and capabilities – technical, financial, business, policy, etc. – needs to be marshalled to facilitate the development and/or adaptation of such technologies and their deployment at scale. Drawing examples from India, this talk will illustrate the kinds of resources and capabilities that may be needed for different technologies at different stages of their technology cycle and how these might be brought together in a systematic fashion. In doing so, I will highlight the critical role of "innovation systems operators" in this process, as entities that identify innovation gaps as well as ways to overcome them by bringing together and coordinating relevant actors and expertise, appropriate finance and policy solutions. I will also suggest that such entities are a critical element of the capabilities to manage energy and climate challenges in developing countries where innovation systems often are not well organized.

O-4413a-02

The role of partnerships in enhancing the transfer and diffusion of climate change technologies

A. Abdel-Latif (1)
(1) ICTSD, Geneva, Switzerland

The decision to establish a Technology Mechanism (TM), at the Cancun conference in 2010, was an important milestone in efforts to advance the effective implementation of the technology transfer provisions of the United Nations Framework Convention on Climate Change (UNFCCC). Since then, the two bodies of the TM – the Technology Executive Committee (TEC), more akin to a policy body, and the Climate Technology Centre and Network (CTCN), the Mechanism's operational arm –have begun to carry out their work and activities.

However, the role of partnerships in enhancing the transfer and diffusion of climate change technologies has not received significant attention in the process of the TM's operationalization or in the work programs and activities of both the TEC and CTCN. Yet the mandates of both bodies include provisions to foster such partnerships. For instance, the mandate of the CTCN states that one

of its functions is "facilitating international partnerships among public and private stakeholders to accelerate the innovation and diffusion of environmentally sound technologies to developing country Parties."

At the same time, recent years have witnessed a number of growing partnerships involving public and private entities, particularly in the context of bilateral clean energy and technology cooperation arrangements such as the US–China Renewable Energy Forum. These partnerships also address intellectual property rights (IPRs) in a pragmatic and constructive manner which could provide useful lessons for overcoming the polarized debate on this topic in the context of current climate negotiations.

The objective of this proposal would be to explore how can partnerships contribute to a strengthened TM that could be a possible basis for agreement on a technology package at COP 21 in Paris.

4413b - Environmental policies to enable innovation and transformation

Environmental policy, multinational firms and green innovation

J. Noailly (1) ; R. Smeets, (2)
(1) The Graduate Institute Geneva, Program «innovation, sustainable growth and technological change», Geneva, Switzerland; (2) Rutgers Business School, Newark, United States of America

This paper investigates the impact of environmental regulation on green innovation in a globalized world, where multinational firms locate production and R&D laboratories across several countries. Using firm-level data on multinational firms conducting green R&D both in developed and developing countries, we find that environmental regulation has a positive impact on clean innovation – in particular in countries where multinational firms face a pollution-haven motive, which is where firms locate their most dirty production processes. In other countries, other factors such as the wages of R&D workers and the country's absorptive capacity in green technologies seem to be more important triggers of clean innovation. Since multinational firms are a major channel for transfering technologies to developing countries, our results have implications for the design of policies aiming to promote the global diffusion of clean technologies.

O-4413b-01

Contextual Factors and Wind Energy Innovation Development ---- Comparing Germany, Denmark, China and India

Y. Dai (1) ; J. Nordensvard (2) ; A. Narain (3)
(1) Tsinghua University, School of Public Policy and Management, Beijing, China; (2) University of Southampton, Southampton , United Kingdom; (3) University of Maryland, Maryland, United States of America

Wind energy technology played significant role in response to climate change. Increasing academic studies tried to find the relationship between government support and the technology innovation development path. This research filled the literature gap by decomposing national contextual factors with endogenous wind policy design and implementation elements in the theoretical framework. Checking wind energy development in Denmark, Germany, China and India in the past 30 years, this research found influences coming from political context (i.e. governance structure change, governmental policy making capacity), economic context (i.e. national economic development paradigm), and social context (i.e. social legitimacy) that significantly shaped the national wind innovation path. The paper concluded that accessing wind energy policy required a through study of local context factors. One of the policy implications pointed out that policy and technology dissemination did not necessarily lead to similar innovation path. The paper also called for stable long-term support to wind sector development.

O-4413b-02

Trade flows and knowledge flows: the case of renewable energy generation

E. Verdolini (1) ; V. Bosetti (2)
(1) FEEM Fondazione Eni Enrico Mattei, CCSD, Milano, Italy; (2) Fondazione Eni Enrico Mattei, Milano, Italy

Fostering sustainable growth while addressing climate change concerns entails that energy efficient and carbon free technologies be available and diffuse widely. However, innovation and the ownership of technologies are still concentrated in developed «frontier» countries. Key issues that confront researchers and policy makers alike in both developed and developing countries are (1) understanding the dynamics of knowledge and diffusion in this sector and (2) identify the key policy levers to promote to development and green growth. This will provide insight s on the ability of technologic al progress and technology diffusion to lower the costs associated with climate mitigation while fostering sustainable energy for all. Researchers focusing on the study of diffusion and transfer of energy and climate change related technologies have increasingly resorted to patent data as a proxy of interest. This is due to the wealth of information patents include, the wide coverage in terms of countries and the possibility to classify patent s by technology through the IPC classification. Two are the core assumptions made when using patent data to this end. First, patent citations or cross country patenting informs on the flow of intangible knowledge. Second, a patent application testifies the willingness to protect an idea in a given market and exploit a temporary monopoly of power. Hence, cross country patenting is correlated to some extent with technology production, marketing or licensing. Due to the lack of technical detail in other commonly used proxies such as trade data or R&D investment statistics, patent s have represented so far the best source of information in this respect and have thus been used to study knowledge format ion(Popp 2002 and Verdolini and Galeotti 2011 among others), the role of international and inter-sectoral spillovers (see for example Mariani 2008), the diffusion of cleaner technologies across countries (Hall and Helmers 2013, Bosetti and Verdolini 2013, Dechezlepretre et al. 2011), and issues related to directed technical change from dirty to clean innovation (Aghion et al. 2012). These studies based on patent data resulted in a wealth of policy implications, which, if implement ed, will have long-lasting impacts on economic growth and sustainability. This paper contributes the literature by providing a comparative study of the diffusion of clean technologies focusing on three different proxies, namely patent data (innovation), trade data (transfer) and production of energy from reneweable sources (diffusion). We focus on the sector of renewable electricity production due to two main reasons. First, power production plays a key role for energy security, sustainable growth and climate change (IEA 2010). Due to the willingness to promote economic growth while curbing greenhouse gas emissions and climate change impacts, electricity production is currently a key to most governments' strategies for sustainable development. Second, electricity is a perfect case study because other proxies for technology diffusion and transfer can be identified. We provide two main contributions. First, a thorough description of renewable energy innovation and transfer dynamics worldwide. Second, a validation of the use of patent data as a proxy for technological change, and an analysis of whether such data can substitute or should only complement other proxies of technology transfer. Our analysis comprises both a descriptive approach and a more formal testing of the relation between patent statistics and other diffusion and transfer proxies through an

econometric model. Our contribution is hence to provide a well- rounded assessment of renewable energy knowledge and technology flows across countries. Preliminary results show that trade and patent data provide to some extent similar insights: markets in which patent protection is sought by inventors of a given country are also among the most relevant trade- partners for that country. Moreover, countries where more patents are applied for are also the countries where installed capacity is greater. However, there are cases in which such correspondence does not hold, and hence solely relying on patent statistics might provide biased policy insights.

Building fuel poverty measurement for the transport sector

A. Berry (1) ; C. Guivarch () ; Y. Jouffe (2) ; N. Coulombel (2)
(1) Centre International de Recherche sur l'Environnement et le Développement (CIRED), Paris, France; (2) Laboratoire Ville Mobilité Transport, Université Paris-Est Marne-la-Vallée, Paris, France

Because of climate change mitigation policies or depleting fossil fuels, fuel prices are expected to rise and an increasing number of households could face difficulties to afford their energy bills, adequately warm their home and achieve their required mobility. If development of fuel poverty measures are necessary to accompany fuel prices rises, their success highly depends on the capacity to identify the population at-risk. Attention has been focused on fuel poverty in the residential sector so far; however traveling by car is another essential energy service for part of the population (Sovacool, 2012). Having too high a fuel spending can induce restriction behaviours and it is particularly problematic when it becomes a barrier to access employment and when it causes social and economic exclusion (Orfeuil, 2004). If an increase in fuel prices will affect more strongly households with the highest motorized mobility needs, here we show that assessing who are those households is not straightforward, and that it calls for the development of a new multidimensional fuel poverty indicator.

Assessing who the households at-risk are is not a simple task for three reasons. First, motorized mobility needs result from multiple factors depending on the geographic, technical and socioeconomic characteristics of households. For example, living in suburban areas requires traveling longer distances to reach central business districts, or driving an old heavy car requires more energy per kilometre than a brand-new compact car. As a result, the fuel spending can vary a lot among the population. Second not only the fuel spending of a household results from a combination of factors, but these factors are often constrained in the short term, such as the residential location, the efficiency of the vehicle owned or access to public transport. As a result, households do not have the same possibilities to act on their daily lives consumption and they might be forced to restriction behaviour. Third, alternatives to car exist. Public transport, walking and cycling are sustainable substitutes to car use, but these alternatives are not equally accessible to households. Those three reasons highlight the fact that households are unequally affected by increasing fuel prices, and it raises public concerns about their impact on the most vulnerable populations.

The choice of fuel poverty indicators is essential because indicators are the basis on which to quantify the extent of the problem, to identify the affected population and to monitor progress of measures (Moore, 2012). To diagnose fuel poverty in the transport sector, the first idea would be to transpose existing indicators used in the domestic sector to the transport sector. The ratio indicator considers a household is fuel poor if its energy spending exceeds a certain share of its disposable income (Boardman, 1991). A more recent measurement approach, introduced by Hills in the UK, consists in identifying households having both high fuel spending and low income (Hills, 2012). However we find these approaches are not satisfactory because they fail to consider the three aspects described above: (1) diverse motorized mobility needs, (2) restriction behaviours, (3) variable capacities to adapt. We develop a new composite indicator that does not solely focus on budgetary aspects but also reflects conditions of mobility. Our composite indicator differentiates three levels of exposition to rising fuel prices. We test this indicator on French data and we find 4,0% of French households are identified at-risks, another 8,3% are vulnerable in their required mobility and another 6,8% are dependents to car. Using a discriminant analysis, we characterize the three identified groups and we find they show different geographic, technical and socioeconomic characteristics. Our results demonstrate using a multi-dimensional fuel poverty indicator is essential to evaluate fuel poverty in the transport sector. High fuel spending, low income but also inadequate conditions of mobility can induce difficulties to achieve one's required mobility, and a comprehensive evaluation of fuel poverty requires an assessment of each dimension. By doing so, the composite indicator brings a new light on which support measures could be developed to insure future climate change mitigation policies are fair and equitable.

P-4413-02

Sustainable energy transformations through innovation-system building

R. Byrne (1)
(1) University of Sussex, Science Policy Research Unit, Brighton, United Kingdom

National systems of innovation (NSIs) provide the contexts within which all processes of technology development, transfer and uptake occur. NSIs are characterised by networks of actors (e.g. firms, universities, research institutes, government departments, NGOs, users), the strength and nature of the links between those actors, their capabilities, and the institutional environments within which they work. Particular technologies, and other innovations, emerge from particular combinations of these elements and their evolution. For example, recent research shows that the rapid adoption of solar lanterns in Kenya can be explained as the result of an emerging solar innovation system that includes an evolving supply chain built over decades, detailed research of users' lighting practices, local - often donor-funded - experimentation with technologies and other innovations (such as finance models), and efforts to establish favourable policies. This Kenyan solar example also suggests that NSIs (including technology or sector-specific innovation systems) can be nurtured to evolve in particular directions, and so understanding how the Kenyan solar and other such cases have developed gives rise to potentially powerful exemplars for how policy interventions can encourage sustainable energy for all.

Taking this NSI perspective, the purpose of this presentation is to outline how international policy interventions such as SE4All, or the UNFCCC's Technology Mechanism, could be enhanced to successfully encourage sustainable energy transformations in developing countries. The presentation will draw on two main strands of academic literature - innovation studies and socio-technical transitions - to explain the theoretical basis for why innovation systems are so important, and what these literatures tell us about how to nurture NSI-building. Examples from the recent research on the Kenyan case noted above, and from others, will be used to illustrate these insights: i.e. how to build actor-networks, capabilities and conducive institutional environments that together can evolve into context-responsive innovation systems. In short, these literatures suggest that policy interventions should focus on achieving four overarching goals:

1. Build networks of diverse stakeholders who work together in projects, programmes and other interventions
2. Foster and share learning from research and experience
3. Promote the development of shared visions amongst stakeholders
4. Support diverse experimentation with technologies and practices

The presentation will finish with a sketch of what architecture could be established to realise these ideas in developing countries. In this regard, two - potentially complementary - proposals will be outlined. One proposal is to strengthen the capacity of national-level institutions - such as National Designated Entities under the Climate Technology Centre and Network - to act as innovation-

system builders. The other proposal is to use technology projects and programmes explicitly to build sustainable energy innovation systems.

P-4413-03

Community energy generation in the UK: the link between ownership of renewable energy developments and social acceptance

F. Chen (1)
(1) The University of Manchester, Tyndall Centre, Manchester, United Kingdom

Over the last decade, the UK government has increasingly discussed 'community energy' as a potential option to contribute towards meeting its renewable energy targets. One of the implied, and at times expressly stated, benefits of a community approach is an assumed related reduction in 'public opposition' to new renewable energy developments, which has been seen as slowing the rate of deployment and therefore threatening the realisation of related targets.

The link between ownership and social acceptance is an important research question, which has thus far lacked empirical evidence. The aim of this study is to bridge this gap by investigating three wind farm projects with three different types of ownership: fully community-owned, joint venture and fully private-owned with community benefits. The research will employ a wide range of secondary sources and in-depth interviews with key stakeholders of the wind farm projects and the local community residents.

The presentation will elucidate the impact of each ownership model on social acceptance, which will be considered in the context of other issues known to affect social acceptance e.g. the process of consultation with the community, communications and trust between developers and communities, sense of place from the community, contested impacts, processes of monitoring and perceived level of local benefits. The findings of the study will lead to recommendations for various stakeholder groups including local communities, developers and policy makers.

P-4413-04

Pacific Community Development Through Biofuel from Marine Biomass

A. De Ramon N'yeurt (1) ; S. Hemstock (2)
(1) The University of the South Pacific, Pacific Center for Environment and Sustainable Development, Suva, Fiji; (2) Secretariat of the Pacific Community, Economic development division, Suva, Fiji

This pilot project based in Fiji with ramifications in Tuvalu and Vanuatu explores the possibilities of developing for Pacific island communities a low-cost, sustainable new source of renewable energy (biogas, or biomethane) from pest marine biomass (invasive algal blooms and coral-destroying crown of thorn starfish) to develop the economy of local communities, create employment, reduce food and fossil fuel imports, reduce greenhouse gas emissions, clean up excess nutrients from sewage treatment plant discharges, and clean up beaches fouled by overabundant and invasive seaweeds. The process provides multiple products simultaneously: energy from biogas, a low-cost alternative to chemical fertilizers, plus the recyclable nutrients remaining after anaerobic digestion. The development of low-cost, efficient anaerobic digesters will empower local communities to produce their own renewable energy source while protecting the environment and improving food security. Currently research is underway at the University of the South Pacific in Fiji with two Master-level students working on the topics of biomethane from seaweeds and crown-of-thorn starfish, respectively. Pilot community-level trials on the conversion of brown seaweeds into biofuel are underway in Tuvalu.

P-4413-05

Local energy and the emergence of the pro-saver

C. Nolden (1) ; N. Fox (2) ; M. Mari (3)
(1) University of Sussex, Centre on innovation and energy demand, sussex energy group, spru, Brighton, United Kingdom; (2) University of Sussex, Sussex energy group, spru, Brighton, United Kingdom; (3) Centre on Innovation and Energy Demand, Sussex energy group, spru, Brighton, United Kingdom

The publication of the Community Energy Strategy in 2014 indicates increasing recognition of community energy within the UK. Using localised and tacit knowledge, local energy provision allows energy needs to be dealt with at the point of consumption, opening up opportunities for end-users and interest groups to engage in energy production and active consumption, 'pro-sumption', but also the potential to extend this to production and energy saving, 'pro-saving'. Local energy initiatives can combine distributed energy generation, alongside demand reduction and demand side response. The importance of localised energy governance in the UK is highlighted in the Government's recent D3 report. It specifically refers to distributed energy, demand reduction and demand side response at a local level, but also takes into account the role that local government can play in their development. A further landmark enabling more distributed approaches is the Government's Feed-in Tariffs (FiTs), available for renewable energy generation technologies below 5MW. Technological diffusion, combined with an emergence of energy related social innovation and increasing political recognition, is establishing local energy as an alternative to the incumbent energy system. Local energy provides a space for engagement with energy production and consumption at the grassroots level, as well as for local authorities to play a more proactive role in influencing the scale and rapidity of D3 deployment. Often emerging out of community-led renewable energy projects, the initiatives can address issues such as energy prices, fuel poverty and the desire of independence from existing energy utilities.

Based on three case studies, this paper traces the emergence of 'pro-suming' and 'pro-saving' in a UK context. The first case study, South East London Community Energy (SELCE) examines a community energy group that wishes to generate renewable energy "by the community, for the community", for example by installing solar PV panels on public owned buildings such as schools. Their business model is based on income derived from the FiTs and selling electricity at a reduced price. The community group's second original focus, fuel poverty alleviation, however, had to be initially scaled back due to the difficulty of establishing a viable business model based on FiT income. In the second case study Hyde Farm Climate Action Network set out to find solutions for cold and draughty houses in their neighbourhood, which were restricted by conservation area regulations while people in the area had limited funds to do expensive energy efficiency measures. The community group received support from programmes such as ECHO Action and British Gas Green Streets, which allowed them to install renewable energy installations to some of the houses. However, they proceeded to set up their own 'Draught Busting Saturdays' as a way to deal with inefficient houses, address climate change and build community coherence. The Draught Busting Saturday concept proved a popular and an affordable way to improve the energy efficiency, as well as help those who were on low incomes. The third case study provides an example of local authority engagement with fuel poverty alleviation in Southern England. In the summer of 2014, over 150 households were provided with free electricity from solar PV systems installed by their social housing provider, the local authority. The authority paid for the costs of the panels that will eventually be recouped via the FiTs. Any additional revenue generated will be used for energy efficiency work on its social housing stock. The study found that as the households engaged with free energy generation, it also encouraged demand reduction and demand-side responses.

The SELCE case study is an example of 'pro-sumption' as electricity is being used on the site of generation. Their approach provides insights into the difficulty of negotiating what may appear to be a straightforward process in light of continuous scepticism towards decentralised energy. The Hyde Farm case exhibits more 'pro-saving' behaviour emerging out of a grassroots community approach and disillusionment with established energy providers. The Southern England case provides a good example of renewable energy production, consumption and saving - 'pro-saving' - emerging out of a local authority initiative. In our discussion we explore how greater engagement

with distributed energy, demand reduction and demand side response may be fostered through a more facilitatory framework combining technological and social innovation at the local energy scale.

P-4413-06

«ENERGY HAVENS»: TOWARDS A SUSTAINABLE ECONOMIC FUTURE. A study based on the example of Iceland

J. Zalpyte (1)
(1) Eberswalde University for Sustainable Development, Faculty of Forestry and Environment, Leipzig, Germany

There are many concerns on how to enhance environmental policies through participating in the international market with opened borders. For many years already a strong cooperation with countries with lower environmental regulations developed between the United States of America and some Western European countries. This development has brought forward a raise of standards in environmental policies across the world but a big gap still prevails in the regulations between developed and developing countries. Some environmental economists claim that trade flows across countries with different environmental regulations may create the "pollution haven" effect and a "race to the bottom" in environmental standards. Globalization and international cross-border cooperation also play a vital role for international tax regimes. Different fiscal policies in one country influence the economic situation in others, even countries located far away. Companies and individual persons use the possibility of increased capital mobility and choose locations where the tax burden is lower. These locations are called "tax havens". Similar to "pollution havens", "tax havens" can create a "race to the bottom" in the collective tax base. The similarity of this terminology raises the question what makes a country a haven. Since the globalised market is being challenged by an increasing demand for energy and the energy supply is becoming one of the main cost factors in the production process for many industries, the research analysed a new definition of the term "energy havens". The term "energy havens" describes countries which have a big potential of renewable energy creation that can be provided to "power-hungry" consumers/energy-intensive enterprises. This is the aspect which differentiates them from the previously mentioned "pollution havens" because the use of traditional energy sources to offer industries a cheap energy supply would result in the "pollution haven" effect. The exploitation of renewable energy sources has to be feasible and ecologically desirable in order not to cause harm to nature and «pollute» the environment. The main target groups of this thesis are energy-intensive industries and the academic audience whose interest is the future energy market condition. The research conducted focuses on electricity, with production cost as the main factor.

4414 - Leveraging Multi-layered Climate Science-Policy Social Learning and Dialogue for Transformative Solutions: Towards A Proposal to "Decade for Accelerating Climate Dialogue for Action"

Learning for a change! The role and challenges of social learning for climate change adaptation

C. Vogel (1)
(1) University of the Witwatersrand, Global Change and Sustainability Institute, JOhannesburg, South Africa

Climate change is an additional challenge that arguably we all have to factor into our lives including in local livelihood, local and national government and other decision-making contexts. A commonly heard 'mantra' now is "behaviour change" emerging from a sense of urgency that individuals and societies must 'change' behavour so that we can both mitigate and adapt to climate change. Some seem to argue, for example, that we need well-planned 'dialogue'. But such calls for 'dialogue' and 'change' cannot be made in social vacuums. Issues of power as to 'whose behaviour should change?', 'for what and whose purposes?' and 'who is setting the dialogue agenda?' are some of the issues and questions that need careful consideration. In this paper, the background to social change and learning issues in various contexts is given focusing on developing country contexts. Examples of serious attempts to make inputs in southern Africa, using social learning approaches, are provided in various climate relevant and development areas e.g. water, food and disaster risk reduction. The challenges that arise and possible ways forward are sketched using some emerging evidence from the 'field'.

Realizing low-carbon Asia based on science-policy interaction through Low Carbon Asia Research Network (LoCARNet)

M. Kainuma (1) ; T. Masui (2)
(1) Institute for Global Environmental Strategies / National Institute for Environmental Studies, Senior research advisor / fellow, Tsukuba, Japan; (2) National Institute for Environmental Studies, Center for Social and Environmental Systems Research, Tsukuba, Ibaraki, Japan

Realizing Low Carbon Society (LCS) has become a common understanding of the global community of researchers, policymakers and citizens engaged with the concerns of climate change and sustainable development. LCS gained currency when it was realized that, on the one hand drastic GHG emission cuts necessitating major changes in energy systems and socio-economic structures are essential to prevent dangerous climate change, and on the other hand every country's domestic developmental goals must not be compromised. Attempts to achieve convergence among the multiple goals of global climate change mitigation, national economic development, poverty elimination, sustainable development and environmental protection, have led to the importance of LCS and related paradigms.

The role of Asia is becoming more and more important, considering the rapid economic growth expected in the coming decades and projected doubling of greenhouse gas emissions from 2005 to 2050 if efforts are not made toward achieving LCS. The reduction of emissions in Asia is imperative for transition by 2050 to a worldwide LCS that has halved GHG emissions from 2005 level. Transition to low carbon emissions and low-resource consumption societies, while simultaneously improving the economic standards of living is vital for sustainable development. Asia has many opportunities to realize an LCS by leapfrogging.

We have been engaged in the development of Asia-Pacific Integrated Model (AIM), which assesses policy options for stabilizing the global climate, particularly in the Asian-Pacific region, with the objectives of reducing greenhouse gas emissions and avoiding the impacts of climate change. Modeling is essential to understand the future pathways and support policy making processes for transformation to LCS.

Sustained efforts have been made to develop AIM model and transfer it to various Asian countries for developing LCS scenarios in each country over the past two decades. These include science-policy dialogues to implement LCS scenarios. One of important networking activities is Low Carbon Asia Research Network (LoCARNet) which was established in 2012 to formulate and better enable the implementation of science-based policies for low-carbon development in the region. This is expected to become an autonomous researchers' network based on south-south

cooperation in the region in the near future.

Several international research platforms of researchers have already made tremendous contribution to comparative analysis of socio-economic characteristics among different countries and stakeholders. They have developed integrated assessment models for setting de-carbonization future targets and optimal roadmaps, and shared the implementation process in designing collective solutions for national low carbon policies, infrastructure plans, eco-model city designs and industrial transformation processes. During all such collaborative research network activities, analytical methods, simulation models and evaluation indicators have been shared, investigated and refined.

The presentation will provide an overview of various analytical methods and tools used as a common scientific framework in Asia. This will include the integrated future scenario simulation system for a de-carbonization society and development roadmaps to achieve the 2 degree target. The presentation will also provide implementation examples from Asia that showcase transformative actions towards de-carbonization.

Implementing the long term transition towards Low Carbon Societies

S. Lechtenböhmer (1)
(1) Wuppertal Institut für Klima Umwelt Energie, Research Group Future Energy and Mobility Structures, Wuppertal, Germany

The work of IPCC and international governments has clearly established the global problem of climate change and identified possible solutions. It makes very clear that achieving a global climate compatible Low Carbon Society entails a «great transition» will change economies and technology and involve all societal groups to work together on coherent long term oriented strategies. This means that societies have to jointly develop long term visions that are able to guide short term oriented interests and activities. Such a venture needs engagement between all societal groups on all levels from local to global. The keynote will highlight the relevance as well as the potentials of collaboratio between sceience and society by highlighting two relevant examples on Global as well as regional levels and by this making clear, what is needed for a global LCS transition.

In 2008 the G8 environment ministers decided to contribute to the global challenge of co-evolution of Low Carbon strategies between policy science and society. Based on a proposal by Japan they decided to create the Low Carbon Scoiety Research Network. A network of science and governments of the G8 together with researchers from developing countries with a purpose to link together national discussions and strategies on LCS and to convey core LCS issues to international policy makers. The network has so far identified a clear international set of issues and was able to convey them into policymakers discussions.

Global approaches, however, need similar ones on other levels. One very intensive example is the climate law and strategy of the German state of North-Rhine Westphalia. This region hosts over 50% of German coal fired power generation and energy intensive industries, but is determined to achieve ambitious climate mitigation. In order to make progress towards the goals and to create a cross-societal movement a broad and long term oriented stakeholder process was implemented that already resulted in a policy program supported by all stakeholder groups.

A Transformative knowledge network of global youth for combating climate change: an intercultural perspective

J. Li (1) ; H. Dayan, (2)
(1) Curtin University of Technology, Perth, Australia; (2) EHESS, Centre edgar-morin, Paris, France

Understanding the societal, economic and environmental issues raised by the climate change at both global and local level calls for the synergy of disciplinary knowledge and cooperation between all stakeholders of international community. It is widely recognized that today's youth will be the first group affected by the consequences of climate change on the socio-economic-environmental biosphere tomorrow, they will and should be the engine of a collective and participatory intelligence that would contribute to concrete proposals for curtailing the accelerated global warming. This requires creating opportunities for expression and exchange between the young citizens from diverse sociocultural backgrounds and interaction with researchers on the state of the climate situation and scientific knowledge on the one hand, and enabling them to discuss possible solutions on the other hand.

The «Global Youth Climate Pact « project gather a multidisciplinary team to build a global intercultural exchange network targeting young people from several countries (e.g. Argentina, Burkina Faso, Brazil, Chile, China, Columbia, France, Guinea, Italy, Nepal, Chad, USA…), known as Transformative knowledge network of global youth (TKNGY) to bridge the knowledge gap between scientists and civil society, i.e. young people engaged in activities for securing global sustainability across the world. The TKNGY platform is established with the purposes of advancing the aggregate knowledge of civil society in particular the Youth for shaping an overall vision and defining feasible local action plan as a contribution to global climate policy.

The project seeks to leverage interdisciplinary knowledge and intercultural experience sharing between Youth in light of carving out a global climate strategy based on bottom-up approach. The network will be conceived as a new source of knowledge pool to facilitate open exchange and dialogue between diverse youth groups as well as with their interactions with global community by harnessing Information and Communications Technology (ICT) and social media. Two "crowdsourcing" tools, an online platform and offline focus groups, are dedicated to gather and share relevant data that will allow local young people to access and improve the scientific knowledge of sustainability and climate change and to develop skills of discernment regarding these issue areas.

The permanent online platform and scheduled offline meetings between young people from different parts of the world will commit to securing sustainable economic growth and to strengthen the solidarity between youth and local communities as well as taking local actions to address climate change. This platform will be constantly enriched and improved through young people's innovative thoughts and ideas within a non homogeneous economic, social and cultural context. It will also lead to the restitution of data on scientific knowledge and analysis of the perception and the proposals of the young students on climate change from an interdisciplinary research perspective. It must be emphasized that the interdisciplinary treatment of a scientific topic is concerned not only with the technological &socioeconomic aspects but also to those related to age, gender and culture.

Multi-dimensional analysis of the first results which will emerge at a meeting gathering all the actors of the project in Toulouse in May 2015 will be the aim of this scientific communication. Results are expected to mark a significant step in enhancing knowledge, training and implementation in addressing scientific questions in regard to climate sustainability. The success calls on global community to bring together knowledge of environmental scientists and social scientists as well as associating engineers and practical know-how by paying a particular attention to intercultural dialogue/understanding, from which a collective intelligence of solutions especially among young people could emerge. The project expects to deliver a «Global Youth Climate Pact « at the Paris COP-21 in Dec 2015 as a result of a series of collaborative work between young students with the support of various international institutions including academia and NGOs as well as regional governments.

O-4414-02

Doing Much More with the Same: Institutional Change and Social Learning for Sustainable Development Outcomes

W. Foerch (1) ; B. Harvey (2) ; T. Schuetz (3) ; P. Thornton (1) ; E. Le Borgne (4)
(1) CGIAR Research Programme on Climate Change,

Agriculture and Food Security (CCAFS), ILRI, Policies and institutions for climate resilient food systems, Nairobi, Kenya; (2) International Development Research Centre (IDRC), Collaborative adaptation research initiative in africa and asia (cariaa), Ottawa, Canada; (3) Consultant, Muenich, Germany; (4) International Livestock Research Institute (ILRI), Addis Abeba, Ethiopia

Climate change adds considerable uncertainties and complexities to what are already multidimensional development challenges. It is increasingly likely that we are already locked into a two-degree temperature rise, whatever happens to global greenhouse gas emissions even in the near-term. There is ample evidence that the resources needed to deal with the adaptation challenges exceed the resources currently mobilized for it. However, it is not just about resources: the approaches that many of our institutions are taking are failing to address the level of complexity and the cross-scalar nature of the challenges that are triggered by climate change in the context of development. Business as usual is, simply, not fit for purpose. This is becoming increasingly recognised at different levels, from partners on the ground right up to international funding agencies.

In response, a lot of useful practical and theoretical work is being undertaken on the value of learning and reflective practice as a way to bring together different knowledges and to address the multiple dimensions of complex problems, and to take learning beyond the local into much wider networks of practice. Social learning and similar learning based approaches are building a compelling body of evidence on their potential at more localised scales, but we know that the scale of the climate change challenge demands more than isolated community scale actions. Supported by recent scholarship in this area, we argue that the principles emerging from these local-level learning approaches are equally applicable at higher scales, and have the potential to achieve an important shift in thinking across levels. Such work is providing increasing clarity as to what kinds of research, collaboration, and disposition to problem solving are needed to address the levels of complexity and uncertainty we are facing under climate change in a development context.

This need for doing things differently, however, is not yet reflected in most organisations addressing the climate change challenge. This is in part because of the response from organisations funding research for development that place much of the onus on taking transformative change to scale on actors and initiatives working at the «last mile» of planning and practice. While work at this level is critically important, it is not sufficient, and this emphasis sometimes leads to a focus on "silver bullet" technological fixes rather than broader systemic changes.

We need to be seeing the emergence of joined-up learning-oriented models of practice, at all levels. By changing the way our own institutions think about fostering solutions to wicked problems like climate change, we can have a much longer-term impact on how knowledge and action link up in this field. However, this requires social learning or related approaches to instil institutional and organisational change. We currently have very few examples of success at these levels to guide us.

Thus, the Climate Change and Social Learning Initiative has embarked on a process to contribute to a solid evidence base concerning the costs and benefits of social learning in different contexts. This is one of a number of iterative, learning-based approaches that offer a potential avenue for significant change. Jointly with other research for development organisations we are testing a common monitoring and evaluation framework to systematically collect evidence, analyse results and share learning on when and how research initiatives may benefit from social learning-oriented approaches.

The evidence we are building should show tangible proof of the added value of these approaches towards achieving development outcomes. To take things to the required scale, the stakes need to be raised: we need nothing less than a major re-think as to how research for development is used as a vehicle for tackling one of the most complex challenges of our time. To this end, this contribution will conclude with a set of "pathways to transformation" with which we challenge institutions funding and supporting climate change research for development to pursue.

Systemic and social learning approaches for climate change adaptation: Experiences from transboundary work in Southern Africa

S. Pollard (1) ; H. Biggs (1) ; D. Du-Toit (1) ; K. Taryn (1) ; C. Vogel (2)
(1) Association for Water and Rural Development, Non governmental organisation, Hoedspruit, Limpopo, South Africa; (2) University of the Witwatersrand, Global Change and Sustainability Institute, JOhannesburg, South Africa

For climate change adaptation to be successful attention needs to be given to how people might learn to adapt. Theories of social learning enable an exploration of adaptive capacity and how people are learning to deal with climate change amidst a range of other challenges, whilst systemic approaches enable thinking about complex and often unpredictable situations. In South Africa the RESILIM-Olifants project is a multi-year learning approach that is enabling actors at various levels, from households through to catchment management agencies and transboundary organisations to build resilience to climate change in creative ways. Lying at the core of the systemic, social learning process is a collaborative scoping of context and of risk (including climate change) which, when viewed though a systemic lens, helps stakeholders understand change within complex and dynamic environments. Some of the lessons and challenges learnt in this 'creative transdisciplinary endeavor', which is being led by the Association for Water and Rural Development, will be outlined, critiqued and shared.

China's Emission Pathway towards global 2 degree target: Policies and Scientific Support

K. Jiang (1)
(1) Energy Research Institute (ERI), Beijing, China

Low carbon development in China is on the purpose for both national sustainable development and global climate change action. For the global climate change target "to hold the increase in global average temperature below 2 °C above preindustrial levels", China need to peak CO2 emission at latest at 2025, and falling into deep cut on CO2 emission, based on the IPCC report(IPCC AR5, 2014). Previous studies on emission scenario shows that it is possible for China to peak CO2 emission by 2030 if strong policies are adopted, and with a relatively high cost. Peaking CO2 emission before 2025 is a very big challenge for China. Modeling study by IPAC on the 2 degree target said it is also still possible for China to peak CO2 emission before 2025, but several pre-condition are needed, including optimazing economy development, further energy efficiency improvement, enhanced renewable energy and nuclear development, CCS etc .

In recent years, China's policy making process moved much faster tan before to tackle climate change issues. Started from 12th Five Year Plan, CO2 intensity target over GDP growth was set up for 2015. And domestic actions including emission trading, low carbon provinces and cities pilot program. The most remarkable achievement is the China-US Joint Announcement on Climate Change, it mentioned about the disire for global 2 degree target, and China set up year to peak CO2 emission, and express that to continue to work to increase ambition over time. Besides this, China's policies on low carbon energy utilization including renewbale energy and nuclear is moving very faster. By 2013, China's newly installed capacity of wind and solar power generation accounts for more then 1/3 of globale total. If put hydro and nuclear power together, China accounts for more than 40% to total newly installed capacity of the world.

In order to support the policy making process, China established a Climate Change Expert Panel for official advise. They relys on large amount of research work to make suggestion. Beside this, there are many workshops and internal meetings to discuss the possible implementation of policies on mitigation of GHG. The policy making on climate change depends much on reserch support. Our researches were adopted in the national peaking year setting, and ETS design. And now we are working on the carbon tax, which is regarded as another significant policy in China.

China also made efforts to promote south-south collaboration. China already leaded several dialog on south-south forum on climate change, and rpovided funding to help other developing countries for capacity building. This will be a direction for China to join international collaboration to help developing countries to respond to climate change.

Science-policy-stakeholder dialogues about Low Carbon Society: Lessons from the Brazilian Case

E. La Rovere (1)
(1) Instituto de Pós-Graduação e Pesquisa de Engenharia – COPPE, Centro de Estudos Integrados sobre Meio Ambiente e Mudanças Climáticas – CentroClima, Rio de Janeiro, Brazil

Science-policy-stakeholder dialogues about Low Carbon Society:

Lessons from the Brazilian Case

Achieving a Low Carbon Society entails a «great transition» of economies and technology requiring the involvement and action of different societal groups. This keynote will draw the lessons from a science-policy-stakeholder dialogue about mitigation GHG emission scenarios for Brazil.

A participatory process to discuss the economic and social implications of five mitigation scenarios for Brazil up to 2030 was held from April 2014 to March 2015, coordinated by the Brazilian Forum on Climate Change. It involved a Scenario Building Team (SBT) of 70 members from the government, business sector, non-governmental organizations (from the environmental field and trade unions) and the scientific community. A technical modelling team (TMT) coordinated by the Brazilian member of LCS-RNet (CentroClima/COPPE/UFRJ) has provided scientific support to the process. Upon draft proposals suggested by TMT, SBT selected qualitative storylines of plausible and pertinent futures based upon economic and technological assumptions. TMT has translated these inputs in quantitative projections of key variables depicting economic and GHG emissions, calculated through mathematical models representing the Brazilian economy and technical systems: IMACLIM-BR (CGE macroeconomic model especially designed for long-term GHG emission scenarios building) and sectorial models for energy, land use and forestry, IPPU and waste. The general objective was to design exploratory long-term scenarios, and not forecasts or a normative scenario: the goal was not to supply the most probable nor the most desirable scenario. A comparative analysis between the governmental plan scenario and two additional mitigation scenarios (implemented through two different sets of policy tools) helped to identify key economic and social implications of additional mitigation policies and measures, including the impacts on GDP, inflation, trade balance, employment, income distribution and household consumption across different income classes. The dissemination of the dialogue outcome has provided valuable inputs to the Brazilian society debate on the INDCs submitted to COP21.

This dialogue was part of the MAPS project (Mitigation Action Plans and Scenarios), coordinated by SouthSouthNorth (SSN). Similar participatory processes were adopted in the Long Term Mitigation Scenarios project in South Africa, and in similar dialogues around long-term mitigation scenario in Chile, Colombia and Peru.

Given the huge challenge for developing countries of achieving social and economic development goals through a environmentally sustainable and climate-compatible pathway, science-policy-stakeholder dialogues of this kind about Low Carbon Society may play a valuable role and provide a helpful contribution to a more democratic and enlightened decision-making process.

P-4414-01

Management, hazardous waste treatment and environmental □impact.□

K. Allia (1)
(1) USTHB, Chemical Engineering, Algiers, Algeria

Improvement of standard living led and will continue to generate a rather big environmental risk, given the significant amount of multiple wastes they produce and depending to the case may be landfilled or treated and recycled. According to their nature and production source, they can be medical, agricultural, municipal, industrial etc. and the protection of human health and ecosystems is much more difficult than years ago. Environmental issues are more diffuse rather than located, subtle than obvious, and involve multiple environmental media (air, water, ground, sediments and biota) rather than a single one.

According to their nature and production source, they can be medical, agricultural, municipal, industrial etc. and the protection of human health and ecosystems is much more difficult than years ago. Environmental issues are more diffuse rather than located, subtle than obvious, and involve multiple environmental media (air, water, ground, sediments and biota) rather than a single one.

Due to their composition and their properties, hazardous wastes such that expired drugs, chemicals, present a real threat to human health and the environment (consequently may have an impact on the climate even if treated), and require a set of appropriate treatments to reduce toxicity risk and contamination, particularly for gathering pathways, transportation, treatment, recycling and disposal. They are considered one of the major environmental and health concerns, and their management requires a capital interest. If untreated, they could reach the water cycle through a variety of routes. They can do after being placed in landfills, such as residues from industrial manufacturing or as unused pharmaceuticals and infiltrate groundwater. It is also possible that effluents from pharmaceutical industries contain occasionally or permanently pharmaceutical residues and can end up in surface water through wastewater treatment process. The primary interest is the risk that contaminated soils and sediments pose to human and ecological receptors, for which rigorous evaluation is essential to make informed decisions and develop effective solutions. Through potential risk they represent, their management requires capital interest. Expired pharmaceuticals and chemicals untreated, can reach the water cycle through a variety of routes and infiltrate groundwater and ending in surface water. Treatment may include production of raw and secondary materials or energy recovery and their management can lead to the valorisation of noblest fraction and treatment of polluting fractional. Recycling and regeneration lead to a recovery of materials such as metals, etc. or by incineration and finally stabilization or landfilling for residues having no more perspective.

As a practical management of hazardous waste, incineration has two attributes: permanently destroy toxic organic compounds contained in the hazardous waste by breaking their chemical bonds and transform their components by reducing or eliminating their toxicity; reduce the amount of hazardous waste by converting the solid and liquid into ashes. The products of incineration are more bottom ash, fly ash, containing toxic organic and inorganic compounds (Satnam Singh et al., 2007). The combustion gases are composed primarily of carbon dioxide and vapour water, and small amounts of carbon monoxide, nitrogen oxides, and low concentrations of organic and inorganic compounds. And like many combustion processes, incineration also produces by-products such as soot particles and other contaminants released in exhaust gases, and leave a residue (bottom ash) of incombustible and partially combusted waste that must be emptied from incinerator chambers and properly disposed. Expired or unused pharmaceuticals are now incinerated in facilities that could meet the highest environmental standards, including treatment of smokes and where releases relating thereto, are a

priori insignificant (RRCSE, 2008). However to date, there are no estimates on all of these issues. We know that climate change is a key environmental issue with major concerns with respect to the rise in global temperature and concomitant direct and indirect implications. Recently, there has been a international momentum to stay within an agreed target of a 2°C increase above the preindustrial global mean temperature, by 2050 (Erika von et al, 2013). Increasing greenhouse gases from anthropogenic activities, carbon dioxide in particular, has been well-established as the major force behind climate change and the warming of the Earth.

P-4414-02

Mind Games: Our (Un)conscious Struggle with Climate Change

H. Berry (1)
(1) The Australian National University, Climate Change Institute, Canberra, ACT, Australia

Background/purpose: Some media and academics have proposed that informing the public about the likely (harmful) impacts of climate change will increase psychiatric morbidity, querying whether such community conversations should therefore occur. This study explores whether general population 'worry' about climate change is linked to mental health and wellbeing in Australia.

Methods: Structural equations modelling, cluster analysis and geo-spatial analysis of wave 2 data from the omnibus-style Australian Wellbeing Survey (launched 2013) which includes detailed modules on mental health and wellbeing (SF-36, K10, 'happy feelings', life satisfaction, self-rated health), personality (screen for introversion, conscientiousness, creativitiy), place (e.g., geocoded database, data across the whole continent: metropolitan, rural and remote locations; different climate zones; transport; distance to services; land degradation) and socially-based determinants (e.g., employment, financial circumstances, poverty, marginalisation, household and family structure, relationship status, cultural background, education). Innovatively, the survey includes a 10-item 'climate change knowledge quiz', developed with the Australian Academy of Science, which quantifies un/certainty about climate change science. Participants in Wave 2 (2014) were N~12,000 Australian adults who completed an online or paper survey.

Results: The 2014 survey has just closed and analysis is pending. Initial results indicate that 'worrying' about climate change is not linked to any aspect of wellbeing, except trivially to distress (more distressed people were very slightly more likely than their peers to 'worry' about climate change), but is strongly linked to climate change knowledge and attitudes. In multivariate analysis, these, in turn, are linked, though only trivially, to selected predictor variables: being female, younger, creative and highly-educated. The survey will produce general population and sub-population indicators, notably including often-overlooked groups (e.g., those identifying as LGBTIQA; or living with disabilities; or experiencing marginalisation).

Discussion/conclusion: Mental health problems are the world's leading cause of disability and affect resilience and adaptive capacity. Climate change may harm mental health by, first, damaging local economies (via increased droughts, floods etc, that destroy farms, homes, businesses, infrastructure), harming livelihoods; which, in turn, can undermine social wellbeing and community functioning, key mainstays of good mental health. Uniquely, in the case of mental health and climate change, the threat may also be the solution: local-level community action could help address climate change challenges and also generate mental health co-benefits because it can promote social capital which is powerfully protective of mental health. Engaging the public responsibly in debate about climate change is unlikely to cause psychiatric morbidity and is essential in framing effective local responses.

P-4414-03

Implementing a transformative public transport project in South Africa's urban environment – the case of Cape Town's MyCiTi BRT

M. Boulle (1) ; RP. Van (2)
(1) University of Cape Town, Energy Research Centre, Cape Town, Western Cape, South Africa; (2) Hunter van Ryneveld (Pty) Ltd, Independent, Cape Town, Western Cape, South Africa

Policy implementation is a major challenge throughout the world. Implementation of mitigation projects in developing countries is particularly complex, as they have to compete with numerous other policy priorities that are perceived as more pressing than climate change mitigation.

The transformation of cities holds huge mitigation potential. In South Africa, cities currently reflect severe inequality in terms of access to opportunities, with urban form and differing levels of mobility amongst citizens, being two major contributing factors. Like other South African cities, Cape Town's urban form was significantly influenced by apartheid policies, which sought to segregate the population, based on race and placed low-income communities, in particular, far from the urban core. This was combined with a strong private car orientation from the 1960s onwards underpinned by substantial investment in roads and highways, which led to low densities and long commuting distances. Thus mobility in South African cities is associated with high emissions per passenger kilometer travelled, and entrenches the levels of inequality across income groups in cities.

The bus rapid transit (BRT) concept was presented to the South African government at a time when traffic congestion was worsening, along with the rise in private vehicle ownership associated with a growing middle class, and was forecast to increase exponentially. There was a realisation that expanding the road network would not alleviate the congestion; instead a sufficiently attractive alternative was required to entice private vehicle users away from their cars. The existing buses and trains were unlikely to induce this shift, but BRT, it was thought, could be such an alternative.

This case study investigates the implementation process of the MyCiTi BRT in Cape Town, and identifies major factors that were influential in bringing about implementation, despite significant obstacles the project had to overcome. Some of these factors include: the role of support from national government, the presence of leadership within government and with stakeholders (especially the minibus taxi industry), the role of the 2010 FIFA World Cup in driving progress at speed, a competent and dedicated project team, and the influence of the industry transition of the minibus taxi industry. Most influential was the unique combination of factors and timing that drove implementation.

It is intended that the findings from this case study will provide insights into how to bring about implementation of transformative actions in difficult circumstances, that achieve multiple objectives, amidst opposition and competing policy goals.

P-4414-04

Industrial sector inspection as a control effort on climate change impacts

M. Febianto (1)
(1) Bandung Institute of technology, Environmental engineering, Bandung, west java, Indonesia

The green economy is defined as an economy that results in reducing environmental risks and ecological scarcities and that aims for sustainable development without degrading the environment. it is closely with ecological but more politically applied focus (Lynn R. Kahle, Eda Gurel Atay Eds 2014). In Cimahi City (located in West Java - Republic of Indonesia), The local government has several facts: (1) approximately 350 industries, located in the southern region of the city, (mostly textiles), are the dominant sector of the city (15% of total area) and home for thousands of employees to earn living. (2) they have been discharged million cubic of wastewater in to a river, every day. (3) Based on the study of Cimahi river water quality, one of the result mentions that the river condition is very polluted. (3) the southern region of the city is densely populated areas (279.854 of 643.548 = 43% of total population of the city) and the lowest elevation areas. (4) rivers and drainage channels are accommodate all types of waste. All these facts lead to «silting of rivers and drainage channels. (5) In south region of the city, industrial zones coexist with densely populated settlements. So if the flood came, hazardous waste water will effect to the

people of South Regioan of Cimahi. Regarding those facts, for the government of cimahi city, green economy is about bridging or unite these two different poles. How to keep the industrial activities because they are "Economic lifeblood of the city" ; but manage their wastewater is also important. The Environment Office Of Cimahi City (KLH) as leading sector have main duty to manage environment issues, try to solve it through a routine program which has been implementing since 2010 until now, called "inspection for industrial sector". One of the output of the program is giving the industry a sanctions which are different one industry to another. Some of them be sanctioned by an obligation to fix their wastewater treatment plant (WWTP). In early 2011, The government of cimahi has issued a sanction for 60 industry. The question is how effective this sanctions improving the environment quality or is there any relation between this program with a better river water quality? Within this papers, writer try to make a simple analysis. Is there any progress? Between industrial waste water quality before and after the sanctions has imposed. Writer believe it does. For example in "X" factory, BOD (biological oxygen demand) concentration in 2013 is 250 mg/l, dropped to 178 mg/l and dropped to 160 mg/l. For another example in "Y" factory BOD concentration in 2013 is 90 mg/l then dropped to 86 mg/l and finally in 2015 dropped to 52 mg/l. Another fact mention there has been an increasing of wastewater treatment plant performance in sanctioned industry. There has been a very noticable change. Its mean that the effort has a significant result to decrease BOD number or in improving a performance of WWTP in industry. The report of inspection program also mentions that all of the sanctioned industry comply with the sanctions and began to make improvements. It means that the program is a collective action between industry and government. In the early year of 2015 the old target and the new target are on their way to be audited by KLH. Writer do believe if this program followed continuously, the environment quality will be better. The conclusion is the green economy for cimahi more than it is defined but how to keep the water in this city, just like the city's name means in the local language, "Cimahi means : a lots of water. And In the end protect and adapt people from climate change impact which is: hazardous flood.

P-4414-05

The New Story: Climate revelations and fantasies of omnipotence

J. Freund (1)
(1) Lancaster University, Dept of Marketing, Lancashire, France

This contribution concerns the fact that modern science has methodically developed a 'New Story' of how human life came to exist on the earth (Harding, 2006; Hornborg, 2009; Lovelock, 2006; Swimme & Berry, 1992; Weber et al., 1989). This new story points out that humans are an integral part of planetary bio-physical networks and flows, stretching through deep time and space; and that human existence is entirely dependent on and is co-constituted by 'dead' aspects of the Earth such as the atmosphere, the oceans, the land, magnetic fields and solar energy, inter alia.

This story clearly has far-reaching practical, organizational and economic implications (Whiteman & Cooper, 2000; Whiteman, Hope, & Wadhams, 2013), and for many people it also has spiritual implications – because it provides credible and testable (though profoundly incomplete) stories of the existence of life on the Earth (Hanh, 2013). This New Story also has psychological implications in terms of the psychodynamics of power – which is the focus of this contribution.

Why is this relevant to climate change? Progress on climate change is psychologically blocked, and may be unblocked, because of the psychology of power. In his Pulitzer Prize winning book, The Denial of Death, anthropologist Ernest Becker described how the core motivational complex of adult humans is our joy of living – and conversely our fear of death. Becker differentiated between the physical, bodily level – where we are clearly mortal – and the cultural, symbolic level where we can deny death, or at least distract ourselves from inevitable aspects of physical reality. For Becker, human organizational systems and cultures are thus selected which suggest that we are extremely powerful, invincible, or even immortal.

In recent decades a large body of quantitative scientific data has been gathered to support Becker's observation, based on experiments in the branch of psychology called 'Terror Management Theory'. This body of evidence proves that humans associate nature and the body with death, and thus we fear nature; and that symbols and artefacts of power such as money, economic growth, consumer products, technology, organizations and nations give us a deep sense of power and even immortality (Dickinson, 2009; Fritsche & Häfner, 2012).

Our attachment to these human artefacts and systems is stronger than their actual usefulness warrants, because at a deep psychological level they allow us to deny our mortality, to ignore the natural world that sustains us, and to merge in our imagination with anthropogenic systems that may appear to defy physical reality (Arndt & Vess, 2008; Kiehl, 2012). The perceived authority of these financial and cultural systems thus encourages citizens to indulge in psychological 'fantasies of omnipotence', in particular the notion that the economy contains ecology, and the idea that perpetual economic growth is a legitimate goal for countries and for globalized society (Daly, 2014; Ellman & Reppen, 1997; Lothane, 1997; Morante, 2010).

This contribution posits that the power of these salient fantasies of omnipotence is waning in favour of the New Story. As mentioned, the New Story is an evidence-based understanding of the place of humans within the living and non-living flows of the Earth and the cosmos, including the reality of deep time and space (Prigogine, Nicolis, & Babloyantz, 1972; Rifkin & Howard, 1980). This paper proposes that the New Story is more than just a collection of scientific facts and trends – in psychological terms, the New Story has transformational and revelatory potential, because it reverses the normal cultural veneration of fantasies of omnipotence. The revelation of the New Story includes an appreciation that we are not powerless and do not need to fear nature (Searles, 1972).

In a nutshell, the New Story is an encounter with the joy of physical being; and it brings with it an appreciation of the sensitive and contingent nature of human existence (Latour, 1993, 2013). This contribution will discuss the transformative power and practical implications of the New Story, with particular focus on how the New Story may help to create the context for monetary reform and the creation of a sustainable financial system (Benes & Kumhof, 2012; Fiscus, 2013; Georgescu-Roegen, 1971).

P-4414-06

Transformative Potential of the UNFCCC's New Market Mechanism

L. Hermwille (1) ; W. Obergassel, (1) ; C. Arens, (1)
(1) Wuppertal Institute for Climate, Envrionment and Energy, Energy, Transport and Climate Policy, Wuppertal, Germany

There is general agreement that preventing dangerous climate change requires a fundamental transformation of the global economy. For instance, the latest assessment report by the Intergovernmental Panel on Climate Change (IPCC) notes that "The stabilization of greenhouse gas concentrations at low levels requires a fundamental transformation of the energy supply system, including the long-term phase-out of unabated fossil fuel conversion technologies and their substitution by low-GHG alternatives".

The call for transformation has been taken up in international climate policy. The Green Climate Fund (GCF) has been given the mandate to promote a "paradigm shift" and other international funding mechanisms such as the British-German NAMA Facility also demand that activities should contribute to "transformational change". However, public finance, disbursed through the GCF or bilaterally, will not suffice to provide the means of implementation at the levels required to meet the extraordinary challenge ahead. Private funding will have to accompany these public funds in order to spur the necessary investments in sustainable infrastructures worldwide. Market-based mitigation instruments have been proposed by many to leverage such private sector engagement.

A New Market-based Mechanism (NMM) was already defined under the UNFCCC in 2011 in Durban. While further discussions on its design have stalled, it is to be guided by a set of criteria that include inter alia that the NMM should stimulate mitigation across broad segments of the economy, safe-guard environmental integrity, and ensure a net decrease of global greenhouse gas emissions. The EU has called for the NMM to "facilitate

transition towards low carbon economy and attract further international investment".

On this basis, our contribution analyses what the transformative potential of the NMM is in general and how it should be designed in order to maximize this potential? As basis for the discussion, the paper first synthesises how transformation has been defined in scientific literature and existing climate policy initiatives. Based on this synthesis the paper establishes criteria for how to determine transformational impact. Second, the paper examines the transformative potential of market-based instruments on the basis of the EU ETS, so far the largest market-based mitigation instrument in existence. Third, the paper takes stock of the current discussion on the design of the NMM and applies some of the insights from the case study analysis to the case of the NMM. We conclude by translating these insights into policy recommendations for the further consideration of the NMM under the UNFCCC.

P-4414-07

Science Policy dialogue to formulae Low carbon society blueprint of cities in developing countries – The case of Iskandar Malaysia

CS. Ho (1)

(1) University of Technology Malaysia, Built Environment, Johor bahru, Johor, Malaysia

Our common future under climate change needs knowledge sharing platform to promote low carbon societies (LCS). It is imperative in long run for developing countries "leapfrogging" to low carbon society to stabilize climate. Fast growing cities in Asia including Malaysia have large potential to leapfrog to low carbon societies by integrating mitigation and adaptation measures in managing urban development infrastructure to cater for the rapid urbanisation and industrialisation. With holistic climate resilient planning, low carbon society blueprint may achieve the co benefit of government objectives to strengthen economic competitiveness and improve quality of life, and its aspiration for promoting green economic growth and greater sustainability.

This presentation outlines the experiences gained and lessons learnt through the multidisciplinary 'Science-to-Action' (S2A) approach to drawing up and mainstreaming the Low Carbon Society Blueprint for Iskandar Malaysia 2025 (LCSBP-IM2025) for implementation in Iskandar Malaysia (IM), a rapidly developing urban region in the southernmost tip of Peninsular Malaysia. This is also in line with the commitment of Malaysian government to the voluntarily reduction pledge in COP15 of carbon emission intensity of GDP by 40% by 2020 based on the 2005 level.

The LCSBP-IM2025 is the outcome of an internationally funded joint research under the SATREPS program that brings together Universiti Teknologi Malaysia (UTM), Kyoto University, Japan's National Institute for Environmental Studies (NIES), Okayama University and the Iskandar Regional Development Authority (IRDA) in a unique 'academia-policymaker' partnership towards crafting a LCS pathway to guide and sustainably manage the projected rapid development in IM in the next 10 years. A methodology has been developed to formulate IM's future LCS scenarios; propose 12 LCS Actions to achieve the LCS scenarios; quantify the GHG emission reduction potential of the proposed LCS Actions with Asia Pacific Integrated Model (AIM models) ; and continuously engage local stakeholders for feedback and opinions in a series of Focus Group Discussions (FGDs).

To ensure effective implementation of S2A, since the Blueprint's launching, the Iskandar Malaysia Actions for a Low Carbon Future was launched, outlining 10 priority projects selected from the LCSBP-IM2025's 281 programs for implementation in IM in the 2013-2015 period; the projects are now in various stages of implementation, yielding real impacts on IM's progression towards it LCS goal.

The project offers valuable lessons especially in terms of advancing scientific research on and, importantly, into real actions LCS into policymaking. These include the importance of having strong highest-level government support; aligning LCS Actions and programs to higher-level development priorities; taking policymakers on-board the research team as active researchers; continuously actively engaging local communities and stakeholders through FGDs; and overcoming 'science-policy gaps' and 'disciplinary gaps' that are bound to arise. Most importantly, the methodology can also be disseminated to other developing countries where implementation of low carbon society policies that will eventually contribute to mitigating global climate change through real cuts in GHG emissions while still achieving a desired level of economic growth.

P-4414-08

A study on the Korean model for greenhouse gas mitigation of livestock industries

HU. Kim (1)

(1) National Academy of Science, Korea, Natural Science, Div. 5(Agriculture)., Seoul, Republic of Korea

GGIRC of Korea reported Korean agriculture emitted 22 million tons of CO2 eq., which is 0.6% of total emission, 688.7 million ton CO2 eq. in 2012. Korean livestock industries are characterized by the intensified production system and the heavy dependency on the grain imports. Recently Korean livestock industries have been suffering from many problems like feed price increase, animal pandemics, increasing meat imports, and harder control on the environmental problems including GHG emission. In 2010, average Korean consumed about 110 grams of animal meat daily (excluding dairy products, fish, and soybeans), and they love to eat grilled-beef ribs and bacon high in fat. The population of the obese people and the death toll from the circulatory problems have been rising steadily in recent years, which raised the national medical expenses and the import budget of the meat and feed grains. They should tackle on many GHG-related problems of Korean livestock industries collectively, including the obesity, the residue utilization, the clean energy supply, the animal disease control, and the grain import, all of which are inter-related and caused by the human activities.

For GHG mitigation of livestock industries, they should start from the nutrition education programs, which could persuade the people to cut down the fatty meat intake to a recommended level to control the urgent obesity problems, and they have to renew the animal production system urgently to a renewable one, which they could manage the feed supply, and control the animal pandemics and the pollution problems. Korean meat grading system giving the top grade to the heavily marbled meat must be amended to a healthier meat grading system. The import of bacon meat must be taxed on the basis of fat content. The fattening practices of cattle before marketing and the high-grain feeding must be abandoned. Recently probiotic lactic acid bacteria have shown to decrease the intestinal and the rumen gas production as well as the noxious smell of the man and animal feces. More researches are needed for the ruminant yogurt which could decrease GHG emission and enhance the feed efficiencies, which will provide a natural tool to solve the GHG problems of animal industries. The organic residues from livestock operations, food industries, and residences must be collected and digested anaerobically for the production of clean biogas as well as organic fertilizer, which could help the GHG problems, the pollution problems, and the clean energy demands. This concepts for GHG mitigation is hoped to help the nation to decrease the GHG emission from livestock industries and to solve other related problems, like the grain import budget and the national medical expenses. When we consider our history of meat-eating, the dependency on grain import, the obesity problems, and many difficulties of Korean livestock industries, this model for GHG mitigation could be a probable one especially in Korea, which might serve the nation as well as the world then. The methane fermentation is ancient, prevalent, and natural, but I believe we could manage to control GHG problems from livestock operations for our common future.

P-4414-09

Shifting the Epistemology of Gender and Climate Change

C. Jost (1) ; N. Ferdous, (1) ; A. Otzelberger (2) ; P. Kristjanson (3)

(1) World Agroforestry Centre (ICRAF), Climate Change Science Domain, Nairobi, Kenya; (2) Independent Consultant,

London, United Kingdom; (3) World Agroforestry Centre (ICRAF), Climate change science domain, Washington D.C., United States of America

To move the discourse related to gender and climate change beyond the conceptualization of women as a homogenously vulnerable group, we engaged in a social learning experiment that led to the creation of the Gender and Inclusion Toolbox jointly produced by CCAFS, ICRAF and CARE. By documenting the processes used, we were able to observe how changing research power and norms, and shifting incentives through partnerships, were possible despite the complexity of actors and interests involved. We achieved triple-loop-learning, as feedback from scientists and field-testing looped back to re-evaluating and changing modules, methods and practices. Joint learning can happen in planned or unplanned ways, and research interests shifted too autonomously to involve all planned partners, while opportunities to work with others arose. In this sense, the triple-loop-learning that lead to the decision to orient the Toolbox as a development practitioner's resource rather than a purely research resource also led to changes in our partnership needs. As we moved away from expert knowledge and technical language, the assumption that communities have the capacity to shape discourse and also their own development visions took better hold. In this way, the role and sensitization of development practitioners in doing participatory research and social differentiation analysis became of upmost importance in promoting social learning across diverse groups. Shifting the research process to be more participatory and investing in downstream actors can be a critical intervention to improve gender and social differentiation analysis. If development practitioners are not expected to share in responsibility over research outputs, and in many cases have no idea what research objectives and approaches in a study are, conducting gender-sensitive research in particular becomes highly problematic.

P-4414-10

Integrated Assessment Modelling to Enhance Climate Policy Design in Thailand

B. Limmeechokchai (1)
(1) THAMMASAT University, Sirindhorn International Institute of Technology, Pathumthani, Thailand

In the climate change framework, there is a gap between modeling analyses and policy development. The adoption of national climate policy from modeling analyses depends on several factors. Through policy dialogue on pathways to low emission development, Thailand succeeded to reflect the modeling analysis into actual policy development in its Nationally Appropriate Mitigation Action (NAMA) in 2014. Thailand's scenario studies on NAMA and NAMA roadmap development in the country have been very successful. In COP20, Thailand communicated its mitigation pledge for greenhouse gases (GHG) reduction potential in 2020 to UNFCCC. Thailand experienced in Integrated assessment modelling (IAM) in the climate policy design. In addition, presently Thailand is also employing IAM in designing its Intended Nationally Determined Contribution (INDC) for its GHG reduction potential in 2030. It is clear that the IAM is an effective catalytic role to enhance the policy dialogue. This lesson learnt can be applicable to other regions as a "good practice" of climate policy design; though adaptation is needed to fit local conditions.

P-4414-11

Cross-Cultural Dialogue for Sustainable Develoment ethics

JE. Marcos (1)
(1) RSE&Interculturalité – Elan Interculturel, Training and Cross-Cultural Communication, Paris, France

After investigating Climate Change from a sociological and a cross-cultural perspective, I realized that the problem and the subsequent ecological crisis in which we find ourselves today is, above all, an ethical crisis. My work and research has no higher aspiration than to recapitulate some of the prima facie thoughts on sustainable development ethics to better address the cross-cultural Climate Change Dialogue and negotiations. No doubt the subject is vast, complex, and almost incomprehensible. However, I assume the risk of a disorderly exhibition of ideas because I believe that it better reflects the current state of ethical thinking towards climate change crisis.

The motley collection of ideas presented may seem broad, heterogeneous and little detailed; it is just a hint that obviously is neither finished nor exhaustive. Its purpose is to delineate some of the regulatory requirements, cognitive preconditions and political preconceptions that may be needed for an ecological reorientation of activities and social practices. I am convinced that there is much to think and a lot to work with: it is essential not to fear ridicule and to make continuous proposals, like bottles thrown into the sea.

Along my presentation, the aim of my research and work will not be to make a specialized proposal. On the contrary, after establishing the technical state of the question on climate change, I will devote a few paragraphs to the explanation of a fundamental principle for understanding why we reached this ecological crisis. Thereupon, I will try to demonstrate a central point: the importance of recovering the cross-cultural notion of planning. Finally, and after having presented some past ethical principles that guide present time, I will summarize the central problems and some of the main contributions that ethics can provide on the sustainable development question.

The problem that I will first address in my presentation is simple: to what extent climate change and sustainable development is a social challenge that requires an ethical approach? The fact is that international climate change negotiations are complex, especially because we are talking about different cultures sharing the same problems, but not necessarily sharing the same perspective about its solutions. A first clue is that socially, politically and ethically, we must act on the one factor that multiplies the emission: population. In other words, it's not about «the way» we do things, but about what we do. We will have to expose the cultural roots and understand the cross-cultural idea that mankind is to seek best performances, efficiency and good results.

Whence, we can ask: is there another way of conceiving cross-cultural Climate Change dialogue?

There are no doubts: the problems of climate change comes from the current harmful development program, initiated with the Industrial Revolution. This is when it was born what Tim Jackson (among many others) calls the myth of unlimited growth. Climate change leads this problem to the ethical question of how we have to conduct ourselves with respect to future generations (which, according to the UN, are also a part of humanity). Under the aegis of the idea that we will be able to solve everything in the future, it's been a long time since we are running forward, en "fuite en avant".

To expect that a new cross-cultural conscientiousness is led by the current state of political representation seems nonsense. The present dynamics of representative democracy is limited to meet demands of orthodox economics and a false conception of prosperity -linked most of the time to the myth of unlimited growth and a conception of men as a free consumer-. But prosperity can not be reduced to the accumulation of material goods. A new ethic of sustainable development must favour a humanistic and cross-cultural approach on progress that encourages work culture, happiness, health, education, long-term planning and that helps to build a renewed confidence on society based on an ideal of diversity and common destiny.

Development of scientific tools and their application to Asian countries toward low carbon society

T. Masui (1) ; M. Kainuma (2) ; F. Tsuyoshi (1)
(1) National Institute for Environmental Studies, Center for Social and Environmental Systems Research, Tsukuba, Ibaraki, Japan; (2) Institute for Global Environmental Strategies / National Institute for Environmental Studies, Senior research advisor / fellow, Tsukuba, Japan

Asia will play an important role to achieve the 2 degree target because the region is expected to witness rapid economic growth during the 21st century. Resulting greenhouse gas emissions are likely to grow rapidly as well if appropriate countermeasures are not taken. In Asia, researchers have been increasingly working together with

a common goal in the development of future scenarios and collective solutions for realizing a low carbon society. Together with several Asian researchers we have been carrying out analyses of the various initiatives with a focus on low carbon society. Based on our integrated assessment model, the Asia-Pacific Integrated Model (AIM), as a common tool of analysis, quantitative visions and roadmaps to achieve the 2 degree target have been investigated, and results shared among researchers in Asia. The researchers in Asian countries have been applying the AIM to analyse low carbon future targets and optimal roadmaps for their countries. They have been sharing results and the implementation process in order to design collective solutions for national low carbon policies, infrastructure plans, eco-model city designs, and industrial transformation characteristics. During all these collaborative research network activities, scientific methods such as analytical techniques, simulation models and evaluation indicators have been shared, investigated and refined. Moreover, these international research platforms have already made tremendous contribution to comparative analysis of socio-economic characteristics among different countries, and to actual policy making process through dialogues between stakeholders and researchers. The purpose of our presentation is to demonstrate, firstly, the structure of the AIM as the integrated future scenario simulation system toward analyzing low carbon society and developing roadmap to achieve 2 degree target. Secondly, we will showcase examples of transformative actions towards low carbon society in some countries. The examples include project designs that lead to green city such as low carbon new city development plan. Thirdly, from our experiences of the interaction between researchers and policymakers, we will show the importance of scientific analysis based policy discussions. Fourth, we will demonstrate the use of monitoring and observation system in order to validate future scenarios for low carbon society and develop roadmap to achieve 2 degree target. Finally, by combining all these efforts, the presentation will highlight Asian example as a reference for rest of the world in regional cooperation, collaborative process of developing integrated tools and common solutions to realize low carbon society.

P-4414-13

Vulnerabilities and threat models on smart grid cyber security: A survey

KD. Muthavhine (1)

(1) tshwane university of technology, engineering, Pretoria , South Africa

When smart grid was inverted, two out of many main purposes were to have self-immune on vulnerabilities and threats posed on it. Lot of thread models have been developed to achieve these purposes on smart grid but up-to-date there is no better achievement [1]. These vulnerabilities and threads are posed by attackers on the building blocks of smart grid like, meters, communication media, billings, electrical transmission, power generators etc [2]. When these components are being maintained, they give loop whole to pose vulnerabilities and threats [2]. These attackers want to analyze plan inadequacy, poor design in components or building block in order to steal identity of end user, conduct deception and divulge sensitive information and data [3]. Most of these vulnerabilities are not clearly known by many researchers, some of them are not listed anywhere [2]. These leads the question that do we have enough threat models to mitigate these vulnerabilities [1]? To answer these questions is to first conduct a survey. Albeit there is no other project that encompasses on vulnerabilities and threat models on smart grid cyber security: A survey.

In this project proposal we will survey, discuss and summarize new threats and vulnerabilities on smart grids cyber security, after that we will survey the current developed threat models or solutions on smart grids cyber security and compare their strengths and weakness. These will be measured by checking if one threat model can mitigate more than three vulnerabilities, table of vulnerabilities and thread models will be provided. After that indication of where improvement will be done in all models is going to be indicated in the conclusion of the paper.

Definition of threat modeling

This is a solution that recognizes a set of vulnerabilities (potential attacks) on a specific product or system and precise how these attacks might be inflicted and the best technique of blocking potential attacks. Threat models are used as input to the creation of test plans and cases [1].

Biosphere to Noosphere: Creating People with Planetary Mindset

JR. Nair (1) ; U. Aarathy. (2) ; NP. Sooraj (2)

(1) IIITM-K, Ecological Informatics, Trivandrum, Kerala, India; (2) IIITM-K, Ecological informatics, Trivandrum, India

More than three decades of collective action towards securing our common future reveals that efforts primarily pegged on scientific stubs alone are inherently incapable of transforming human society into sustainable trajectory. The centrality of social sciences in this endeavor has dawned on mankind. It is unequivocally acknowledged that value enriched education is a non-negotiable prerequisite for sustainable development.

Three out of the five pillars of education (to know, to be and to do), as defined by UNESCO, (Anonymous, 2012) are physical and social embodiments in the Biosphere. They are easy to comprehend, define and achieve. The remaining two pillars (of living together and to transform) are embodiments within Noosphere. They are abstract, difficult to comprehend, express and realize.

Achievements of modern education, based on the former set of pillars are informative, but not transformative. Drawing from the Freudian ice berg analogy of human mind, the authors state that modern education; despite its remarkable achievements in physical and social planes, is deficient in its ability to transform human attitude. It is limited to the conscious part of human mind - tip of the ice berg. Sub conscious interventions transform human attitudes and social behavior.

This paper reaffirms preliminary findings reported previously by the authors on human attitude to sustainable development. Attitude of 750 respondents in Trivandrum, India, spread across all strata of society, towards the notion of sustainable development was evaluated using semantic differential technique (Osgood et al. 1957). It involved asking respondents to independently rate a set of statements on sustainable development using a set of bipolar adjectives on a seven point scale.

Semantic differential analysis reveals information on three dimensions of Evaluation, Potency and Activity. Evaluation assesses whether the respondents' perceive the notion positively or negatively. Potency is concerned with how powerful the topic is for the respondent and activity expresses the respondents' approach to the notion.

Whilst three quarters of respondents evaluated sustainable development positively, hardly two-fifth of them felt the notion had any power and reported any active approach. Both the potency and activity of the notion of sustainable development showed an inverse relation to level of education. This was more pronounced in working women in nuclear family. The results reaffirm the sub-criticality and exposes perceptional flaws of modern education in fostering transformative changes. Figure 1 depicts the threshold required to ensure transformation of human attitude. A numerical solution to the surface plot will provide us a quantitative estimate of efforts needed to make education transformative.

«Warming and Greening»: An assessment of farmers' capability to curbing water disasters in Muooni Catchment, Kenya

C. Ngonzo Luwesi (1)
(1) Kenyatta University, Geography, Nairobi, Kenya

In the 16th century B.C. Moses the prophet saw «a burning thornbush» that was not consumed. This account has thrilled many of us for centuries beyond any imagination. Thanks to recent scientific knowledge, which has unveiled similar adaptation to the global warming. Yes, climate change is a threat to life supporting ecosystems, and particularly to forests and freshwater resources. This study puts in motion Moses' account of the "burning thornbush" in an ecosystem similar to that of Mount Hored: the semi-arid and hilly Muooni Catchment of Kenya. The research used rigorous scientific methods and tools to assess vulnerability and capability to curb exposure to hydro-meteorological hazards, social risks and economic misfortunes facing farmers in the course of climate change. The study used innovative and integrated Vulnerability-Capability Assessment (VCA+) techniques for agricultural water adaptation to climate change. Results from the study show without any contradiction that farmers living in Muooni Catchment are mostly vulnerable to drought than flood. This can only be attributed to the high risks of changing hydro-climatic conditions triggered by ill-planned land-use activities and subsequent environmental changes, which are likely linked to the global warming, to sea surface temperature rise, high ocean currents and atmospheric wind pressure occurring in the southern hemisphere, and which are commonly known as El Niño (flood) and La Niña (drought). These factors are well known to impact on the farmland productivity and the sedimentation of water channels. However, it comes out from the analysis that individual farmers' capability to adapt to future disasters will largely depend, not on their endowed capacity (or resources) but on the integration and preparedness of their community to disasters. These factors combined with high investments in water infrastructure, operations and maintenance may lead to water and food security. Farmers hence need to incorporate these drivers, risks and impacts in their decision-making for their future investments and adaptation to environmental changes. This may enhance their capability to manage water resources, land and subsequent institutions thus decreasing their vulnerability to water shortages. Moreover, a green economy has been propounded to be a true paradigm shift from "Business-As-Usual" (BAU) to behaviour change and climate adaptation. This may contribute to preserving our forest and freshwater reserves under the threat of greenhouse gases emission and increasing surface temperatures. All stakeholders are invited to cooperate in environmental conservation through adjustment of their lifestyles and land use activities, owing to uncertain climatic vulnerabilities. Whether acting independently ("autonomous" adaptation programme) or collectively ("planned" adaptation programme), farmers are called to increase their adaptive capacity and ability as a community to respond to climate risks and impacts and take advantage of the benefits arising from a green water economy under «Warming and Greening».

Obstetrics Risk of HIV infection among women attending antenatal clinic in General Hospital Suleja, Niger State, Nigeria

MU. Okojie (1)
(1) FCT COLLEGE OF EDUCATION ZUBA, ABUJA, NIGERIA., REPRODUCTIVE HEALTH EDUCATION, ABUJA, FEDERAL CAPITAL TERRITORY, Nigeria, Federal Republic of

Background: Obstetrics risk and practices can lead to the spread of HIV/AIDS. Identifications of such obstetrics risk of HIV infection is a useful step in the prevention of transmission of the virus. Objective: The research sort to determine obstetrics risk of HIV infection in pregnant women attending antenatal clinic in General Hospital Suleja, Niger State. Methods: The researcher conducted a cross-sectional descriptive study of pregnant women attending antenatal clinic in General Hospital Suleja, Niger State between August and December, 2014. Data were collected using structured questionnaire. HIV screening and confirmation was carried out on pregnant women after voluntary counseling. Results: 350 pregnant women were enrolled with a mean age (+or-SD) of 26.8+or-6.4 years. The highest number of HIV infected women was observed in those who had their first coitus between 16 and 20 years. The age at first coitus was significantly related to the HIV infection (P=0.41). Neither parity (P=0.13) nor past history of abortion (P=0.42) was associated with HIV infection. Non of the 41 women who had their last delivery at home had HIV infection compared with 9.8% of the 194 women who delivered in the hospital clinic (P==0.008). 40% of those who had their last delivery in primary health care centre had HIV infection while 22.2% of those who delivered under the care of traditional traditional birth attendant had HIV infection. Conclution: Obstetrics practices mayencourage transmission of HIV infection. This calls for re-examination of the obstetrics practices especially in our primary health care centres in order to prevent transmission of HIV infection.

P-4414-17

Effectuating Humane Societal Transformation through Effective Collaborative Governance - A Holistic System-Cybernetic Model

J. Ostergaard (1)
(1) Malik, Global Transformation Initiatives, St. Gallen, Switzerland

In order to ensure reliable governance and control of the Great Transfromation21 (The paradigm for the special kind of change called substitution or creative destruction) Malik is providing the most advanced systems, tools and methods for mastering complexity and ensuring effectiveness.

While in earlier times, societal revolutions were induced by groundbreaking technological innovations, today social technology of system-cybernetic management will revolutionize the functioning of companies, societal organizations and whole countries.

The Malik Governance Systems® - Management operating systems of a new era Management for people and management for organizations are the fields of application of Malik's holistic management and governance systems. These systems create the conditions in which people can effectively transform their own strengths into performance, thus achieve their goals, see meaning in what they are doing and find fulfillment.

The Malik Governance Systems® have unique characteristics that enable people and organizations to overcome any management challenge. The Syntegration® methodology is at the heart of the transformative power - a highly innovative social technology for profound change. It increases the performance of any organization immensely.

During a Syntegration the knowledge of a large group of people is effectively combined. Executives around the world apply it for developing solutions to their most complex challenges and for simultaneously achieving strong commitment and fast implementation. The basic model for the functioning of Syntegrations is the most complex platonic solid, the icosahedron and its geometrical-mathematical properties. These determine the logic of the communication linkage of large groups of people.

The Syntegration approach allows highly complex challenges, often interlinked across the whole organization or even across sectors of society to be mastered quickly, effectively, cheaply and holistically. This requires the simultaneous collaboration of all the specialists who, when networked together, have the necessary knowledge to find solutions for the problems.

The results of the Syntegration include the following two effects: on the one hand, it leads to innovative solutions by releasing the existing creative intelligence in the system, and by making full use of all available knowledge. On the other hand, the hierarchy-free participation of all those involved mobilizes the social engagement required

for efficient, accurate and speedy implementation. The effectiveness and speed of this method are much higher than with conventional methods. It works without the periods of inactivity, which usually occur at big events, and with a precision hitherto regarded as impossible in change management.

The Syntegration method proved its high level of efficiency and reliability in more than six hundred applications across society in Businesses (e.g. Food, Energy and Automotive), Science (e.g. Helmholtz-Institute and German Cancer Research Center), GOV (e.g. Cities, Higher Education and HealthCare) and clusters of same (e.g. SolarValley, an internationally established cluster of photovoltaics (PV)).

The Economics of Mitigating Climate Change: Factors Usually Neglected

R. Rosen (1)
(1) Tellus Institute, Boston, MA, United States of America

There are many problems with the traditional use of integrated assessment models for the purpose of quantifying the net economic impacts in the very long run of mitigating climate change. First, the modeling teams almost completely ignore uncertainty both as it affects the models, the estimation of parameters, and the input assumptions. Second, reasonably broad ranges of sensitivity analyses are never performed. Third, the discount rates assumed are very high. Fourth, the role of enhanced energy and resource efficiency is usually underestimated. Fifth, the models do not typically allow for transformative scenarios whereby past trends can be radically altered. Sixth, live style changes are typically ignored which could facilitate mitigation efforts and policies. Seventh, new laws and regulations for mitigation are usually ignored. Eighth, policies such a increasing the role of mass transportation are usually ignored, in part because most integrated assessment models can not model changes in transportation modes for either passengers or freight. Ninth, the impact of reducing income inequality between and within nations on the potential for mitigating climate change is ignored. Finally, the absolute amount of investment needed to mitigate climate change is usually dramatically underestimated, and issues related to how such large investments could be financed on a sustainable basis are often excluded from research papers on the long-run economics of mitigating climate change.

P-4414-19

The Sustainable Energy Utility as a transformative solution to 'utility 2.0'

J. Taminiau (1) ; J. Byrne, (1)
(1) University of Delaware, Center for Energy and Environmental Policy, Newark, Delaware, United States of America

Economic development decision-making criteria throughout the 20th century relied heavily on economic optimality as a chief guiding principle in the design of energy, technology, markets, and policy. Proposals to redefine energy progress on sustainability principles gives rise to an emerging 21st century sustainability paradigm revolving around commons-based economics and long-term ecological viability. An existing operational expression of the new paradigm – the Sustainable Energy Utility (SEU) [1],[2] – is analyzed as a practical means to arrive at the New Economics and New Policy which might guide the energy sector under a 21st century sustainability paradigm. The SEU is compared and tested against other candidates for 'utility 2.0', most notably the Energy Service Utility in order to establish the transformative potential of the SEU application.

Strengthening Nomadic Herders' Traditional User Groups for Sustainable rangeland management in Mongolia

EA. Tseelei (1) ; D. Maselli (1)
(1) Swiss Agency for Development and Cooperation in Mongolia, Green Gold Project, Ulaanbaatar, Mongolia

Nomadic livestock herding has been the livelihood of many Mongolians for centuries. For countless generations, herders have lived in harmony with the fragile and sensitive ecological systems of the semi- arid and arid rangelands which make up 80 per cent of the country's total land area. Rotational grazing between four seasonal rangelands and water access combined with the balancing of livestock numbers to suit the carrying capacity enabled rangelands to regenerate, as did the setting aside of reserve areas for use during emergencies and natural disasters. These have been the core practices of nomadic herding that have ensured long-term environmental sustainability.

At the start of the transition period, there was a rapid increase in the number of "new herders" – many of whom were former State employees who had lost their jobs and turned to herding as a means to support themselves and their families. Since then, the number of herder families has doubled, as has the number of livestock. The use of public rangelands, however, has remained unregulated and they can be used by anyone. This has had a number of negative consequences: Chaotic and opportunistic behaviour in rangeland use at the expense of traditional herding norms and practices, encouraging herders to increase animal numbers without regard for quality; and discouraging an ownership mentality and impeding the initiatives of herders and local governments, providing opportunities for local elites to secure exclusive rights to productive rangelands, which generates inequality and endangers the sustainable foundation of herders' livelihoods.

In the mid-2000s, the Mongolian government began to take measures to address the problem and to ensure the proper use of public rangelands, with the first Land Law enacted in 2006. Under the Land Law, herder families with shared access to seasonal rangelands and organised on a voluntary basis to collectively manage the land are able to negotiate Land Use Agreements with local authorities. To ensure more effective implementation of the Land Law, the government adopted an annual local land-management planning methodology in which local governments are required each year to draft rangeland use plans, to be implemented and monitored with the participation of the herding community. Despite this initiative, the implementation of the Land Law and the planning methodology has proved to be insufficient, largely due to poor capacity at the local government level and inconsistent government policy resulting from increasing conflicts of interest that favour the issuing of mining licences on former rangelands. In addition, raising awareness and capacity development at the level of herder households is a time-consuming task.

Since 2008, the Green Gold Project, in cooperation with local governments, has supported herders' traditional user groups – Pasture User Groups (PUGs) – in order to develop the capacities needed to collectively develop and implement grazing plans and regulate the use of common seasonal rangelands. In the intervening years, about 1000 PUGs have been supported. By September 2014, about 400 of those PUGs had negotiated land-use agreements with local authorities based on collective rangeland use plans and the adoption of internal regulations. In those soums where herder families have become organised and have adopted collective rangeland use plans and regulations, the implementation of annual soum land-management planning has become more feasible. The division of responsibilities between herders and local governments in managing rotational grazing, stocking rates and the management of hay-making and reserve areas has become clearer and is thus better implemented and monitored. At present, PUG Land Use Agreements are the only legal documents assuring herders of their traditional user rights to their rangelands.

Our Common Future, Our Common Global. Approaches from an educational experience towards collective action

MB. Wehbe (1) ; M. Juarez (2)
(1) Economic Science, Economy, Rio Cuarto, Cordoba, Argentina; (2) Humanities, Psycopedagogy, Rio Cuarto, Cordoba, Argentina

"…When we understand how much we depend on nature then we will start this huge cultural change we need to be more sustainable…" Antonio Tironi Silva, Young Scientists Network Conference, Villa Vigoni, Italy, 2014 (Video available at www.icsu.org)

A common future under climate change will need deep behavioural changes. We need to learn more about threats and risks, to reduce vulnerabilities, to increase our capacities to adapt to global environmental changes, and to reduce our pressure on the environment. We need to sustainably live under uncertainty within a complex human-nature world.

We can think about climate change as a major threat to humans and nature, a threat to our common future, a tragedy of our global commons. Despite quite strong, short term global actions are required if we are to avoid this and other threats to and from global environmental changes, equally strong but long term individual and collective behavioural changes will be necessary.

This presentation is about an educational experience aimed at fostering behavioural changes at the individual level and towards collective action. We present results from a local experience through formal education at the National University of Rio Cuarto in Argentina. An ongoing Project (PRODEC*) which aims at introducing environmental issues within all discipline curricula at our University based on the premise that most of our students are those future professionals and educators that at different levels and within different spaces will have the opportunity and hard challenge to foster that huge cultural change we need to sustain life on Earth.

The Project started in 2013 with the integration of professors from different disciplines, within the social and natural sciences, interested in an interdisciplinary approach to global environmental changes and challenges through formal education. The Project has been associated to a request from the Humanities school at our University and nurtured from the demand of a Secondary school with a trajectory in "education for the environment". To date, four workshops have taken place: one with undergraduate students from our University; one with students for primary education; and the other two, with students from first years of secondary school. In all cases, each workshop was structured in three phases: a) an oral presentation accompanied by allusive photographs, pictures and diagrams to the presented global environmental threats and challenges; b) the development of competitive and cooperative games; and, c) a space for creativity from group productions (posters made by students) related to what has been experienced, followed by a fifteen minutes presentation by group. Each workshop started with an impersonal individual written inquiry about their expectations for the workshop and ended with another individual appreciation on what has been experienced, in a written form.

Main results from these participative dynamic experiences may be summarized as follows: a) all students show themselves eager to learn more about what is going on at Planetary scale concerning the relationship human-environment; b) there is a widespread willingness to reconnect to nature -i.e. through different activities within and outside the University; and, c) there is a kind of widespread happiness when discovering the possibilities to solve problems through collective action.

To date, these experiences have allowed our working team to increase our expectations on introducing environmental issues within all discipline curricula at our University through this type of workshop activities, even we have not been able to assess the extent to which these activities may have transformed students behaviour yet.

Dynamic of agricultural innovations diffusion in Burkina Faso

B. Zongo (1) ; D. Abdoulaye, (2) ; B. Barbier (3) ; D. Thomas, (4)
(1) International Institute for Water and Environmental Engineering (2iE), Ouagadougou, Burkina Faso; (2) International Institute for Water and Environmental Engineering (2iE), Laboratoire d'hydraulogie et des ressources en eau, Ouagadougou, Burkina Faso; (3) CIRAD , Umr geau, Dakar , Senegal; (4) Univesrité de Liège, Department of rural economic and development, Gembloux, Belgium

This study highlights the factors determining the spread of agricultural innovations for water harvesting since the drastic effects of drought 70s in Burkina Faso. These innovations include zaï, stone bunds, bunds land, half-moons, mulching and grass strips. A survey of 629 farmers revealed that farmers fall into five categories which are the pioneer, early, latecomer, late and non-adopters. After four decades of diffusion (1974-2013) the rate is estimated at 69.3% for stone bunds, 49.1% for zaï, 26.2% for grass strips and less than 10% for half-moons, bunds land and mulching. The multinomial logit model showed that the climatic conditions in the Sahel zone, age and perception of increased dry spells of farm households promoted the spread of these innovations. However, the low level of organization and access to agricultural services were the major constraints to their adoption.

Urban form, mobility and greenhouse gas emission in African cities: the case of Yaoundé

V. Ongolo Zogo (1)
(1) Univerisity of Yaoundé, Public Economics, Yaoundé, Cameroon

Short summary: (max 15 lines)

This contribution using the city of Yaoundé with a mono centric spatial form, as a case study, aims to show how accessibility is created through the link between urban form and transport services.

The main finding of the estimation is that CO2 emissions is linked to mobility practices associated to distance covered. Consequently, urban form and mobility planning in Yaoundé are not CO2 neutral. The mono centric spatial form of the city of Yaoundé with a spatial concentration of services and economic activities, low residential density likely induces high level of travel demand. Associated with high emission of greenhouse gas services, induces high level of CO2 emissions. The main policy herald should be the necessity to insist on putting in place an integrated land used and mobility plan with a specific focus on non-motorized facilities and mass transit solutions.

Full abstract: (max 34 lines)

Urban sprawl and mobility are currently becoming an important concern in developed countries with the principal challenge being the reduction of greenhouse gas emissions. Nonetheless, in sub-Saharan Africa where household's motorization rate is still weak, the main issue appears to be adequate transportation. This communication aims at shading light on integrated land use and mobility planning actions with a focus on reducing vehicle emissions, introducing clean fuel and clean vehicle technologies, improving fuel economy and reducing CO2 emissions.

Estimates by Godard (2002) for some cities in Africa indicate that CO2 emissions rate is weaker than certain capital cities in Europe. However, studies by CERTU and STC (2002), redone by Duprez (2002), highlight the interest of this question by comparing greenhouse gas pollution between buses and business associated with small size low cost vehicles in Abidjan. Results indicate that, those taxis reject more CO2 emissions than minibuses and buses.

This contribution using the city of Yaoundé with a mono centric spatial form, as a case study, aims to show how accessibility is created through the link between urban form and transport services. The aim of the paper is to evaluate accessibility policies by measuring the consequences of urban sprawl on the production of greenhouse gas emission, within the context of an African cities experiencing growth, where mass transit has not been adopted as a pertinent solution for urban displacement. Using data from the third Cameroon household consumption survey (2007) and the urban displacement Plan for Yaoundé (2010) describing mobility is realized by individuals on a daily and weekly basis, the study estimates the rate of CO2 emission according to characteristics associated to displacement as well as urban form.

The main finding of the estimation is that CO2 emissions is linked to mobility practices associated to distance covered. Consequently, urban form and mobility planning in Yaoundé are not CO2 neutral. The mono centric spatial form of the city of Yaoundé with a spatial concentration of services and economic activities, low residential density likely induces high level of travel demand. Associated with high emission of greenhouse gas services, induces high level of CO2 emissions. The main policy herald should be the necessity to insist on putting in place an integrated land used and mobility plan with a specific focus on non-motorized facilities and mass transit solutions.

The EASI (Enable, Avoid, Shift, Improve) concept: a climate-friendly policy framework to ensure accessibility and sustainable mobility in urban areas of developing countries

JC. Crochet (1)
(1) CODATU, Angers, France

The objective of this presentation is to discuss the results of a major study recently carried out under the aegis of the SSATP on the basis of which a new approach to sustainable urban transport in developping countries, the EASI (Enable, Avoid, Shift, Improve) concept, was developed. The SSATP is the Africa Transport Program, administered by the World Bank and funded by various bilateral and multilateral donors. The SSATP is the main donor supported African fund dedicated to knowledge creation and capacity building in the transport sector.

The study took place in 2013-14 and focused on African cities. Although specific to the African context, the study's findings and recommendations apply to most developing countries particularly those with low to medium GDP per capita. The study's goal was, first, to identify through a bottom-up approach the key constraints to the efficiency of urban mobility systems and accessibility in Africa, including the cities' ability to reduce green house gas (GHG) emissions and to adapt to potential extreme climatic events, and, second, to present priority policy measures needed to address these constraints. The study is based on a systematic and thorough data collection effort of a scope never carried out before. Twenty cities (metropolitan areas in fact) were selected for the data collection. A detailed set of information in eleven domains was collected for each city in the same format.

The key weaknesses that were identified were the following: (i) inadequate governance systems, although there was a lot of variability in this among the cities; (ii) little progress with respect to land-use planning and control and their integration with the development of mobility systems; (iii) insufficient system optimization of the various transport modes; (iv) unplanned development of informal, environmentally unsound, small public transport providers; (v) serious deficiencies in the design of infrastructure and in its operation and maintenance; (vi) high level of traffic accidents; and (vii) neglect for the environmental impact of transport and the resilience of cities. A major consequence of these weaknesses is that urban growth produces much greater GHG emissions in the transport sector in Africa than it needs to do. The presentation will examine in particular the relationships between two indices developed during the study to assess the level of governance achieved by the cities as well as their performance vis à vis mobility and accessibility, and, indirectly climate change.

The presentation will then discuss the key elements of the policy framework needed to address the above issues. It will show that the ASI (Avoid, Shift, Improve) conceptual framework formulated about ten years ago to structure public action mostly in developed countries is fully relevant to African and developing world cities as long as it is adapted to the particular context of these cities. This requires that special emphasis be given to the future urban form and future infrastructure networks (including their resilience) in the "Avoid" actions, to an integrated and inclusive multimodal mobility strategy focused on non motorized transport and low cost public transport in the "Shift" actions, and to more efficient traffic and vehicles in the "Improve" actions.

The presentation will also emphasize that, for public action to take place and be effective, it is essential to establish a competent and responsible governance framework for urban transport in Africa, which will lead the transformation effort in conjunction with all stakeholders, therefore to add a set of "Enable" actions. This framework should be capable of anticipating needs, guiding action, and ensuring integrated management and development of urban transport systems. It would include the adoption of a national urban transport strategy, the adequate allocation of public responsibilities at the metropolitan level, the setting up of metropolitan transport agencies in the large cities, the fast development of human resources, the sustainable increase of financing flows to urban transport, the continuous participation of civil society in the development of urban transport systems, and the involvement of the private sector in the provision of transport infrastructure and services.

K-4415a-03

Urban Agenda for Climate Change- Meeting the mobility needs of urban poor

R. Sharma (1)
(1) Housing and Urban Development Corporation Ltd., Human Settlement Management Institute, Delhi, India

India is at the doorstep of rapid urbanisation. The process of urbanisation is contributed by migration of population, with diverse socio-economic and cultural backgrounds, to cities. One common aspiration they all come with is- quality of life. Although cities contribute to more than two-third of total GDP, the flow back for city improvement is very meagre. City infrastructure is getting overstressed with the added burden of migrants. City is unable to meet the demand of migrants for housing, urban services, employment and social security.The result is islands of disparity and social divide between different segments of population on the basis of origin, socio-economic fabric and religion.

Ove the years, many attempts have been made to integrate population living in various clusters of the city. Inclusive planning is a tool, which provides opportunities for the residents to plan for their social, physical, cultural and socio-economic needs. Urban transport is an improtant entry point towards acheiving the objective of inclusive planning, for the simple reason that it cuts across all the sectors and population. Mobility is directly linked to interaction of various stakeholders, which is a precondition for generation of GDP. Mobility also consumes large resources and leads to high levels of carbon footprints.

This session would look into various planning imperatives pertaining to urban transport, with an objective of making a city 'inclusive' and environment friendly. Discussions

would focus on formulating strategies to make transport accessible to the urban poor, with an objective of reducing carbon footprints. Tools like integrated transport network, last mile connectivity, transport demand management, transport oriented development, transport pricing etc would be illustrated to demonstrate their adaptability in meeting the needs of urban poor in the making of inclusive and carbon neutral cities.

O-4415a-01

Sustainable Urban Mobility Plans: a local approach for national mitigation actions

J. Allaire (1) ; T. May, (2)
(1) CODATU, Lyon, France; (2) Institute for Transport Studies, Leeds, United Kingdom

In European countries, Sustainable Urban Mobility Plans (SUMP) have shown how much they could be a powerfull approach to define urban transport policies that combine the multiplicity of transport modes and their actors.

In its international review, the European Conference of Ministers of Transport (ECMT, 2002) highlighted the principal barriers to effective SUMP development as poor policy integration and coordination, counterproductive institutional roles, unsupportive regulatory frameworks, weaknesses in pricing, poor data quality and quantity, limited public support and lack of political resolve.

Thanks to Nationally Appropriate Mitigation Actions (NAMA) there is an interesting potential to develop mitigation policies in developing countries by combining local urban transport planning and national policies.

The concept of the NAMA – Nationally Appropriate Mitigation Action – emerged in December 2007 during the 13th session of the Conference of the Parties in Bali (COP13) and it was detailed in the Cancun agreement in 2010. NAMAs are voluntary measures taken by developing countries – and registered by the UNFCCC – to reduce their GHG emissions. Not only do they cover investments that directly reduce GHG emissions, they also cover investment projects and programmes, as well as sector-based or national policies to reduce emissions in the medium and long term.

They must refer to a real-time situation and show the expected reductions in GHG emissions using MRV methodology (Measure, Report, Verify) to quantify the impact of the measures taken. But they have also to report on co-benefices such as accessibility improvments, congestion reduction, air quality, road safety, public health, etc.

By using a national MRV (Measure, Report, Verify) methodology, the local authorities could monitor and evaluate the impact of their mobility policies within a SUMP process, but their effort could also be encouraged at the national level, by national support and appropriated legislative framework before being submitted to the UNFCCC secretariat.

Such Vertical NAMAs in the urban transport sector could certainly facilitate sustainable urban developpement in developping countries and give to urban transport a transformational role for cities.

O-4415a-02

Transforming a Megacity: Climate Change Adaptation and Mitigation in Jakarta

EB. Kurniawan (1)
(1) Ministry of Public Works and Housing, Jakarta, Indonesia

Recently, Jakarta has been selected as a city with the worst traffic jam in the world. As among the largest urban areas in the world, the city suffers various urban problems on extreme levels. In 2010, it has 771 traffic congestion points and 11,185 l/s water supply deficit. It is also struck by flood every year. Flood does not only come from the upstream areas but also from the sea. Some of its northern coastal areas experience rapid land subsidence with 7.5 cm/year on average. It is predicted that if nothing be done, water from the sea will go up into the heart of the city in less than 50 years. The rapid urban population growth in Indonesia, especially in Greater Jakarta, makes the problems in the future worsening.

The 5th Assessment Report describes how urban areas are strongly related to the climate change. It contributes significantly to CO2 emissions. Urban form and transport infrastructure, as well as density and mixed use of land use are strongly related to GHG emissions. They also have a strong link to the level of efficiency in the use of energy.

This paper explains how the Indonesian government addresses those problems, their strategies and to what extent they already implement such efforts. Do they handle it in a comprehensive manner? Wich efforts can be considered as climate change mitigation, adaptation and both? Such questions will be answered here.

The central government of Indonesia comes up with the concept of Green City, not only for Jakarta but also for other Indonesian big cities. The concept requires that a city in Indonesia needs to focus in improving the condition of its eight elements, namely Green Planning, Green Open Space, Green Waste, Green Energy, Green Water, Green Transportation, Green Building and Green Community.

In the case of applying the concept, the government is on the way of mainstreaming climate change into spatial planning. In the case of Jakarta, it tries to cope with the increasing number of motorized vehicles on the roads and the worsening traffic congestion by improving the public transport condition through the development of Bus Rapid Transit (BRT) and Mass Rapid Transit (MRT). The government also tries to connect the improvement of that public transport network with the densification of land use and the application of mixed use by implementing the transit oriented development (TOD) concept.

As for the problem of land subsidence and the sea level rise, the government has a plan to build the so called Giant Sea Wall, which can protect the coast of Jakarta and to be functioned as raw water storage. In addition, Jakarta is also increasing the size of its green open space. It may reduce the flood and at the same time cooling the city's temperature. Therefore, Jakarta is and will be experiencing a big transformation in order to overcome its problems as well as ways of climate change mitigation and adaptation.

O-4415a-03

Comparative resilience process of Asian river / coastal cities faced with hydraulic crisis

C. Pierdet (1)
(1) Université de Technologie de Compiègne – COMUE SORBONNE-UNIVERSITES, Umr 8591 lgp (meudon), FRANCE, France

The Asian coastal or river cities are already subject to very high stresses in their urban development. They have most often expanded behind the bank of the rivers or on the coastal areas with dikes and embankments on the river floodplains. So they are very vulnerable to natural disasters such as flooding and sea level rise.

For example, in Phnom Penh, infrastructures of protection against flooding (i.e. drainage network in the city center and large peripheral dikes) have been rebuilt only after the great flood of 1996. They have been badly damaged during the Khmer rouge regime.

In Bangkok Metropolitan Area (BMA), despite the many evacuation canals and pumping stations, major floods occur almost every year. The floods of 2011 have caused new developments in order to protect the inner city and industrial areas north of the capital.

Recently, in Phnom Penh and Bangkok, speculative projects to private investors reject in the outskirts of cities the poorest populations. The consequences are social, but also environmental. Firstly the peripheral areas, in contrast to the city center, having no embankments, are prone to flooding, with no proper drainage systems. Secondly the proliferation of high-rise towers worsens the process of subsidence and flooding vulnerability of cities. How to be resilient without being sustainable?

So we propose to compare the resilience to hydraulic crises of these river/coastal Asian cities, as well as actors and tools used in each case for the implementation of priority actions identified at the conference of Hyogo in 2005 (HFA 2005-2015). They gradually incorporate into their planning instructions to promote risk reduction, under pressure guidelines and international actors such as United Nations, the World Bank and NGO.

4415b - Transformative solutions for urban sustainability governance: Multi-level government and cross-sectoral collaboration for efficient climate action

ORAL PRESENTATIONS

K-4415b-01

Transformative solutions for urban sustainability governance: Multi-level government and cross-sectoral collaboration for effective and efficient climate action

T. Elmqvist (1)
(1) Stockholm University, Stockholm resilience centre, Stockholm, Sweden

In this session we will focus on transformative solutions for urban sustainability governance. After more than two decades of attempting to address climate change and broader sustainability challenges through a global regime, progress has been largely incremental and piecemeal. Despite a rich theoretical tradition that increasingly addresses the normative issues in global environmental governance, and considers the crucial role of non-state actors, the application of this theory to practice often retains a biophysical or managerial lens rather than a deeply normative or socio-political one. Transformative actions are emerging, however, that may deepen resilience and trigger effective climate change adaptation and mitigation. These actions are particularly abundant at the urban scale, drawing upon novel constellations of actors, resources, and engagement strategies.

Responding to the global environmental challenge requires a deepened understanding of how urban areas relate with the environment and how they transform it. New areas of research are needed that explore the dynamics of urbanization, including the globalization of urban lifestyles and diets, which must take into account urban complexities and urban resilience for refurbished governance and urban transformations.

Collaborative engagement that includes non-state actors, non-governmental networks and civil society provides a deeper and better understanding of the complexity that comes with bridging human and biophysical dimensions of environmental policy, including social-ecological dynamics, in order to bring about sustainable development in urban contexts. This requires a shift in thinking within governance that embodies transformative pathways – with the international tools in hand (i.e., MRV regulation, transparent reporting of climate action), as well as deeper engagement with a variety of stakeholders to help build a meaningful, legitimate, and ultimately effective mode of "urban sustainability governance."

To this end, this panel brings together key scholars and leading experts on local government climate action to propose new insights into participatory, inclusive action that engages non-state actors.

The session proposed will be focused on urban environments (cities) and their climate action transformations. Examples of successful transformative dynamics and solutions tested in and demonstrated by cities will be highlighted. The session includes new insights into community-based action research on climate change; guiding principles in governance at multiple scales for efficient urban transformations; the drivers of unsustainable development paths; collective action with involvement of diverse knowledge-and-power domains and multi-stakeholder engagement towards creating transformative pathways at the local level; and approaches to standardized, transparent emissions reporting.

O-4415b-01

Urbanisation, sustainability and transformation - from local decisions to global goals

B. Webb (1) ; X. Bai (2) ; M. Stafford-Smith (3)
(1) Australian National University, Fenner School of Enviornment and Society, Canberra, Australia; (2) Australian National University, Canberra, Australia; (3) Climate Adaptation Flagship – CSIRO, Black Mountain, Australia

Urbanisation with its attendant resource and social pressures is an increasingly dominant feature of development. Substantial research addresses sustainable urban development. However, whilst there are important attempts at integration, from a 'whole of systems' perspective much of the research has been partial and fragmented. Understandably public and private sector decision makers find it difficult to encompass the full range of issues, whilst also facing a range of risks and uncertainties (including, but not only, climate change).

With much of the growth in urbanisation still to come, there is a window of opportunity to address the complex and multi-level issues from the local, regional and national decision-makers perspective. At the same time development of the UN Sustainable Development Goals, many directly relevant to urban directions, provide an overall context to address the many trade-offs and synergies faced in practice by urban decision-makers.

The presentation describes an initiative currently under development to use a wide range of Asian and Australasian urban case studies to systematically investigate:

- the extent of two-way interactions between urbanisation and sustainable development goals at local, regional and global levels
- identification and analysis of the most critical trade-offs and synergies that need to be addressed by urban decision makers at local, regional and national levels if they are to achieve sustainable, equitable, inclusive and resilient development
- the preconditions and mechanisms for cities to achieve the transitional and transformational change necessary to address the above issues
- the extent to which the key choices, trade-offs and synergies, and the transformational preconditions identified, can be related to various urban characteristics and typologies; this to better understand the potential for (and limitations in) transferability of insights, learning, practices and strategies.

It is crucial to reveal and understand these key inter-linkages, which are not always apparent, but can present both challenges (unintended outcomes or even derailment of an intervention) and opportunities (identifying the leverage points for generating and realising co-benefits). The initiative will aim to provide practical integrated cross-sector guidance to urban decision-makers at various levels, on the key strategic issues and choices they face, and relevant to their context. It also aims to develop underpinning scientific insights including a robust set of frameworks that will facilitate understanding and analysis of the impacts of various urbanisation choices and futures, at multiple levels of analysis, and so contribute more generally to future research methodology and practice.

The approach to be taken to the initiative includes analysis through research and stakeholder partnerships and collaborations with a diversity of case study cities and scales to be included; trans/inter-disciplinary approaches including knowledge co-design/development with stakeholders, recognising that multiple decision makers and other stakeholders need to be engaged to reflect the initiative's decision-centred approach; viewing cities as

complex emergent socio-ecological systems with many possible future urban pathways which need to encompass incremental and transitional as well as transformational change.

Whilst the initial case study focus is on Asia and Australasia the approaches and findings will draw on and contribute to broader international initiatives, including Future Earth.

O-4415b-02

Urban transitions

D. Loorbach (1)
(1) Dutch Research Institute for Transitions, Rotterdam, Netherlands

Urban transformati¬ons are complex and shockwise processes of change cocreated by formal and informal types of governance. This presentati¬ons draws from the experiences with urban transi¬tion labs to reflect upon the dynamics of urban sustainability transi¬tions, its inherent poli-cal dimension and their governance. Ci¬ties are the breeding ground for transformati¬ve changes. Not only are ci¬ties confronted directly with the impacts of unsustainability, they are also the contexts in which the high density of actors, technologies, capital and knowledge leads to experimentati¬on and social innovati¬on. This presentati¬on will build upon transiti¬on studies to reflect on the mechanisms, dynamics and patterns underlying the complex and shockwise process of urban sustainability transi¬tions. One of the features of such urban transi¬tions is that they are inherently poli¬tical: new forms of agency and governance challenge mainstream thoughts, structures and cultures to create space for transforma¬tion. It will introduce the idea of governance panarchy in this contexts: the emerging contexts in which different actors at different levels develop informal and formal governance structures to address specific complex problems. These range from local coopera¬ves to public-private partnerships, ci¬zen juries, par¬cipatory planning and social entrepreneurship. Urban transiti¬on management takes this emerging context as the basis for developing the meta-governance framework of urban transiti¬on labs.

O-4415b-03

Driving change through effective local climate action, collaboration and integrated solutions

A. Marques (1) ; A. Pickens (2) ; Y. Arikan (2) ; M. Van Staden (1)
(1) ICLEI – Local Governments for Sustainability, Low carbon cities / carbonn climate registry center, Bonn, Germany; (2) ICLEI – Local Governments for Sustainability, Global policy and advocacy, Bonn, Germany

Setting the scene for inclusive and decisive global climate regime is not done in an isolated manner. Transformative climate action requires multi-level government and cross-sectoral collaboration for ensuring low-emission, climate-resilient development in the urban world.

Local Governments can have significant impacts on local markets and on the large-scale delivery of low emission development technologies and practices, through their mandates and different roles as policy maker, regulator, service provider and consumer (procurement processes).

This presentation focuses on the change system which is being implemented by ICLEI – Local Governments for Sustainability* and other local government networks, from the definition of a common global vision and strategy that enables the recognition, engagement, and empowerment of local and subnational governments, to the main methodologies and tools used for the collaborative identification of transformative pathways at local level. Results are presented and key barriers and opportunities are identified and discussed.

This presentation also explores the different processes, methodologies and tools ICLEI uses to identify the local unique context and priorities, and catalyze broader engagement from different actors, including the business community, to foster the development of long-term Low Emissions development Strategies (LEDS) and design and implementation of low-carbon projects and programs which are adequate to the local needs. A Measurement, Reporting and Verification framework of local climate action is also addressed, by using globally-recognized methodologies for consistency, comparison and aggregation across different entities and initiatives. Transparent reporting of local climate data is essential to ensure the credibility and empowerment of local governments as partners in the global climate regime.

As conclusion from the multiple initiatives analyzed, collaborative engagement emerges as enabler for the sharing of best practices, vertical-integration of policies and investment plans across multi- levels of government, mainstreaming low-carbon strategies into all sectors of urban planning and development, and fast-tracking climate action.

(*ICLEI – Local Governments for Sustainability is an international association of Local Governments which has more than 1000 members in 86 countries.)

Sustainability governance: the role of entrepreneurs in triggering transformative development pathway shifts

S. Burch (1)
(1) University of Waterloo, Geography and Environmental Management, Waterloo, Ontario, Canada

Sustainability transitions are fluid and multi-faceted phenomena, and may be characterized by multiple 'false starts,' punctuated equilibria, and contradictory pressures (such as a shifting political landscape and economic stressors). Many of these transitions are taking place at very small, community-based scales, and are driven by grassroots or bottom-up initiatives. While the idiosyncrasies of a particular urban context may strain our capacity to garner lessons that apply to other cities, social learning is a crucial dimension of accelerated sustainability transitions. In particular, cases of established leadership and innovative responses to sustainability challenges provide important insights into the roots, enabling factors, and various pathways that sustainability transitions might follow.

Despite increasingly frequent engagement with large corporate partners, cities rarely have the capacity to meaningfully engage with the abundant variety of small businesses that contribute much of the innovation necessary for a transition to low carbon, resilient communities. These entrepreneurs are often characterized by the ability to rapidly take advantage of opportunities that others might view as risks, and create the 'radical novelties' that are central to sustainability transitions. In this talk, I explore the role that entrepreneurs in general, but small businesses in particular, can play in sustainability transitions. I investigate novel mechanisms that are emerging that might contribute to more effective governance of this group of non-state actors, and the potential that a multi-level governance approach might have to accelerate innovation.

Mitigating Climate Change Through Managing Urban Mobility and Urban Form

R. Agustina (1)
(1) National Institute of Technology (Itenas), Urban and Regional Planning, Bandung, West Java, Indonesia

Some researches have emphasized that travel patterns and their impacts on the environment are strongly related to the urban form. It is also believed that the private automobile has been the primary cause of the expansion of cities. However, in fact, they affect each other. The urban form affects the travel pattern, and the suburbanisation is also the cause of the changes in the socio-economic context of urban life that are also responsible for the growth in car ownership.

The high-energy consumption of transport in low-density cities has become a matter of growing concern. The threat of long-term climate changes due to greenhouse gases have sharpened the awareness that present energy prices

do not nearly cover the environmental and social costs of energy use. However, there have been some suggestions to respond to this challenge. The majority of them follow the hypothesis that the energy use of urban transport is a direct function of population density and suggest a return to mixed-use, compact urban form.

Nevertheless, such researches on developing countries are still limited. Do they bring a similar conclusion? Using Bandung Metropolitan Area (BMA) as the case study, this paper tries to investigate how the urban form affects travel patterns in Indonesia's metropolitan areas. BMA is the second largest metropolitan area in Indonesia, it has more than 7 millions inhabitants in which about 67,7% of them live in the urban area. Thus, it can be predicted that it generates a significant level of urban mobility, which in turn may lower the environment condition.

This paper discovers the impacts of the urban form on the travel pattern. It tries to explain to what extent the urban form affects the travel pattern and how it is strongly related to urban environment especially through the air pollution factor.

Integration of adaptation to climate change within the design process of urban planning projects : new tool(s) and new methodology(ies)

M. Colombert (1) ; M. Gantois, (2) ; L. Jacquet, (3) ; A. Leseur, (4) ; G. Meunier, (3) ; H. Nassopoulos, (1) ; JL. Salagnac, (5)
(1) Ecole des Ingénieurs de la Ville de Paris, Paris, France; (2) City of paris, Paris, France; (3) EGIS Concept / ELIOTH, Montreuil, France; (4) CDC Climat, Paris, France; (5) CSTB, Desh, Champs-sur-Marne, France

During the ADAPTATIO project, partners have reflected on the means available to address in the design of development projects the issue of adaptation to climate change in relation with mitigation. For this, the adaptation has been defined in terms of two key resources for tomorrow – water and energy – and on the economic evaluation of these two intakes. Exploring contrasted possible futures was privileged to show the consequences, including economic, of those choices. Solutions to act on the building envelope, on equipment and on the immediate environment of the buildings were identified. Each solution has an investment cost, operating and maintenance costs, and a very specific lifetime.

Thereafter, the reflections in common with professional urban development have led to two conclusions. Firstly, the adaptation does not appear to the specifications of ongoing and planned projects. The project and the daily monitoring are already very complex. The consideration of climate change during project is not easy due to the uncertainty regarding the intensity of future climate change. Secondly, this relative lack of interest on adaptation, due to the significance of the operational aspects of the conduct of operations, however, is accompanied by a curiosity to have elements of appreciation regarding the magnitude and urgency to set up adaptation measures.

Premièrement, l'adaptation ne figure pas au cahier des charges des projets en cours ou projetés à court terme, dont le déroulé et le suivi au quotidien se révèlent déjà très complexes. L'incertitude autour de l'intensité des futurs changements climatiques ne facilitent pas leur prise en considération lors des projets.

The tools developed within the project ADAPTATIO, including the «toolbox», intend to propose an answer to the needs of professionals. This toolbox processes the results of simulation software to the scale of the building on the one hand (CLIM'ELIOTH. Ecodesign tool developed by Egis Concept and addressing energy issues and comfort of buildings), to the neighborhood level on the other hand (ENVI-MET: simulation tool on urban comfort particularly taking into account the evapotranspiration of vegetation phenomena). This software uses meteorological data for 2050-2100 provided by Meteonorm. The toolbox also includes economic data regarding the costs of energy and water to the same time periods as for the climate. This tool enables meeting the wishes of professionals to have synthetic indicators on the qualification of indoor and outdoor comfort at the neighborhood level. The associated costs are also accessible. ADAPTATIO toolbox is able to raise awareness of professionals regarding the issues due to a new climate. Particular attention has been paid to the interface that further tests will lead to improvement. Its current limits are to require a complete new data entry (geometry and description of buildings and their environment) to analyze a new neighborhood.

The ADAPTATIO objective was however achieved: to make possible an exploration by professionals on the incidence of future climate on water consumption and energy of a group of buildings actually made in the ZAC Tolbiac. It is all about creating the conditions for an exchange without pretending to replace the detailed study and simulation tools operationally mobilized by the actors of urban development. The maturity of the concept of adaptation and reflections on its close ties with mitigation still seems inadequate given the analysis of research on these topics. It seems therefore necessary to continue the maturation and ADAPTATIO toolbox may help. The project has also attracted the rich exchanges at workshops and public meetings about the economic aspects of adaptation. Some steps have been taken in connection with the professional practices to facilitate the exchange between economists and practitioners about the economic and financial implications of adaptation. However the long-term outlook for costs (energy and water) is difficult to understand.

P-4415-03

CLIMATE CHANGE ADAPTATION AND RESILIENCE IN CITIES: An Analysis of the Living Community Challenge Certification

J. Glowacki (1)
(1) Université Laval, Québec, QC, France

Adaptation and resilience are emerging as key components to the paradigm shift needed in urban planning to deal with the super wicked problems of climate change and resource depletion that characterize the urban reality of the early XXIst century. However, the lack of emphasis on the examination of governance from a practical perspective is stunting the transfer of academic ideas to actual interventions and hindering the timely implementation of solutions. My presentation addresses these issues by analyzing the newly released Living Community Challenge (LCC) certification system as a conceptual framework in guiding interventions for adaptation and resilience in cities.

The presentation will be separated into four sections: 1- characterization of principal parameters in resilience and adaptation, 2- synthesis of currently applied methodologies, 3- identification of recognized barriers in adaptation interventions 4- and analysis of the LCC certification as a regulatory tool. Specifically, in the first section, I will be performing an epistemological analysis of the fundamental concepts of climate change adaptation within the context of urban planning processes. Second, I will provide a summary of current methodologies used in adaptation experiments, as well as, juxtaposing these methodologies against theoretical processes proposed by many leading thinkers in the field of adaptation planning. I will discuss the involvement of these processes in strategic program development, especially as pertaining to the importance of the multi-level governance frameworks and the transmission of information in institutional learning. The use of innovative ideas such as experimentation, market-based approaches and maintenance management will be addressed. An examination of the obstacles encountered in applying climate change sensitive modifications to regulatory aspects in cities and their related projects will examine the prevailing barriers accompanying legitimacy/power struggles and the characteristics of policy development coupled with super wicked problems.

Finally, the LCC certification system will be juxtaposed against the theoretical groundwork identified in the first three sections to establish connections between the processes described in adaptation management and the potential for real-life application in order to meet adaptation and resilience goals. The presentation will answer the following questions: Does the LCC certification meet adaptation and resilience parameters in its scope and implementation? How does the certification system measure against current methodologies applied in existing experimentation? Does the tool provide a structure which enables well-recognized barriers to be surmounted more easily or does it create potential negative feedbacks hampering its use?

As the urgency for climate change adaptation in cities increases, the need for tools which can guide practitioners in uncharted waters will become pressing. This analysis of the Living Community Challenge (LCC) examines the system within the framework of academic theory on adaptation and resilience, in order to facilitate community approaches to sustainability and resilience.

P-4415-04

Livable Urban Futures - Process and Way Forward for Urban within Future Earth

C. Griffith (1) ; P. Romero Lankao (2) ; D. Simon (3)
(1) UGEC Project, ASU GIOS, Tempe, United States of America; (2) University of Colorado, Boulder, United States of America; (3) Chalmers University of Technology, Mistra urban futures, Gothenburg, Sweden

The complexity of urban systems and the global sustainability challenges that we face require inter- and transdisciplinary research that combines context sensitive regional and global approaches to inform and challenge solutions. Although traditions of addressing urban complexities have long existed in the social sciences, humanities, engineering, and natural sciences, we have barely scratched the surface in our efforts to understand many crosscutting issues. A lack of interdisciplinary and co-produced research on the interactions and feedbacks between urbanization, urban areas and global environmental change (GEC) profoundly limits the potential to intentionally shift development pathways through planned governmental and nongovernmental actions.

Sponsored by the Science and Technology Alliance for Global Sustainability, the global research platform, Future Earth represents a new opportunity to rethink how GEC research is organized to encourage interdisciplinarity, and how it can better connect science with policy in order to offer solutions to today's grand sustainability challenges. Future Earth recently published its 2014 Strategic Research Agenda naming 'urban' as one of its priority research areas. With this changing global research landscape, a number of urban research and practice communities are currently interested in new opportunities for enriched collaboration and for expanding and enhancing the 'urban' research agenda under the Future Earth framework. There is a lot of fertile ground for innovative research to promote linkages across established or rapidly emerging areas of urban and environmental research and the Future Earth research themes.

In February 2014 and March 2015, Scoping Meetings were held in London, UK and Boulder, CO, USA that brought together representatives of different regions, disciplinary backgrounds and inter- and non-governmental organizations to begin conversations on the gaps and future needs for urban research as well as the necessary components for the design of a new urban interdisciplinary initiative.

The purpose of this presentation is to share the outcomes of the two workshops and the overall process that has been set in motion by the Urbanization and Global Environmental Change (UGEC) Project along with many other partners known as the Future Earth Urban Platform (FEUP) Working Group. This Working Group is leading the transition of the urban agenda within Future Earth through: a) the establishment of urban flagship activities and b) the design of an urban platform for facilitating interdisciplinary research coordination and co-design with urban stakeholders and practitioners. The goals for this session is to openly communicate this process of the urban transition into Future Earth and how it can better facilitate research and practice related to urban options for and limits to the transformation towards global sustainability; to offer pathways for the engagement of new communities of urban researchers, practitioners, and others; and receive input and feedback from the session participants on the process and platform design.

P-4415-05

Qualitative Scenario Building for Post-carbon Cities

K. Johnson (1) ; M. Breil, (1) ; A. Bigano (2) ; C. Cattaneo (3)
(1) FEEM, Climate change and sustainable development, Venice, Italy; (2) FEEM, Climate change and sustainable development, energy resources and markets, Milan, Italy; (3) FEEM, Climate change and sustainable development, Milan, Italy

This contribution presents the results from interactions with representatives in 10 cities of different sizes, located across Europe, aimed at the development of local visions and scenarios for transitioning to become post-carbon by 2050. Findings are based on experiences from the European Union funded project Post-Carbon Cities of Tomorrow (POCACITO), which aims at the development of an evidence-based roadmap for post-carbon European cities in 2050.

By means of holding local workshops in a participatory case study approach, the foresight exercise is conducted using a two-step methodology, consisting of vision building and back casting exercises. Both exercises have a strong focus on the inclusion of stakeholders. The use of a participatory approach, where the people whose futures are being discussed are the key actors of the process, can improve the relevance, consistency, and hence usefulness of scenarios. Creative brainstorming is employed to induce stakeholders to first envision the future of their city, and then develop qualitative scenarios describing how the transition to reach their post-carbon vision might be possible. Obstacles and opportunities that might be encountered along the way are identified, and actions needed to meet future goals are highlighted. The case study cities include Barcelona, Copenhagen/Malmö, Istanbul, Lisbon, Litoměřice, Milan/Turin, Rostock, and Zagreb.

Initial results from 6 out of 10 case study cities show similar elements in the local strategies that have been proposed by local stakeholders, focusing primarily on urban projects for energy efficiency and the transition to non- fossil energy resources. The specific mix of strategies envisaged in these fields for each city depends both on different points of departure with regards to local governance (greater or smaller financial autonomy, extension of the municipal jurisdiction, etc.), and in part on specific local economic issues (development of economic sectors and/or generic aims of development). Under the prospect of urban sustainability, consideration is also given to thematic areas like consumption, as most visions contain "circular economy" as an aim, related to waste but also to energy generation. Further to "classic" urban issues in the transition to become a post-carbon city, some visions contain, for instance, a more or less generic prospective on local economic development and social inclusion. Additional analysis will be conducted to identify if the different city characteristics influence the set of actions, obstacles, opportunities, and milestones proposed during the workshops. Moreover, the actions proposed during the participatory exercise will be compared to the existing urban plans for carbon reduction. The objective of this analysis is to identify if the participatory approach provides tangible advantages.

The great homogeneity of the initial results and the high rate of correspondence to issues considered in the international debate on post-carbon transitions can be interpreted as a sort of bottom-up confirmation for these arguments. However, it can also be seen as a result of a relatively high-level of uniformity in the composition of stakeholder groups across the local case study workshops, raising the question of how visions and scenarios might be described in a forum not composed mainly by "educated middle-class representatives".

P-4415-06

Reimagining Civic Technologies for the Urban Poor in Indian Cities

S. Kesavan (1) ; S. Kainur, (1)
(1) Crosslinks Foundation, Bangalore, Karnataka, India

Introduction: People-centred economic transformation will play an important role in realizing inclusive and sustainable development in an increasingly urbanizing world. UN member states have therefore accorded a central place to "Make cities and human settlements inclusive, safe, resilient and sustainable" as Goal 11 on the "road to dignity" in the December Synthesis report of the Secretary-General on the post-2015 sustainable development agenda. According to UN-Habitat, the UN agency for human settlements, around 33% of the urban population in the developing world in 2012 were living in slums. Urbanization in India, like in other low and middle-income developing countries, has been characterized by

environmental degradation, deepening economic divide and rampant proliferation of slum settlements that house close to 100 million urban poor in 640 cities and towns. Slum dwellers have a poor quality of life as they are deprived of access to basic services in the area of water and sanitation, electric power, street lights, healthcare and education. Slum settlements have also been reported to have become breeding grounds for criminal incidents and other unlawful activities thus jeopardizing public safety in the neighbourhood. Moreover, greater exposure to adverse environmental conditions in the form of polluted water and air, makes the slum inhabitants particularly vulnerable to the adverse impacts of climate change.

Problem: The poor and disadvantaged slum dwellers suffer from a persistent digital and financial exclusion that prevents the fruits of Indian's economic growth from truly percolating to them. However, in spite of the rapidly deteriorating living standards of the urban poor, most government programs have paid little attention to their plight. For example, Government of India has recently embarked on an ambitious multi-year program to create 100 smart cities with an investment of over USD 1 Billion every year. The proposed initiative aims to harness the power of technology to create profound changes in how cities operate and to deliver more effective governance to their residents. While the smart city program has a strong focus on increased competitiveness and economic growth through technology-driven urban improvements, the challenges faced by slum settlements are not sufficiently emphasized. The National Optical Fiber Network (NOFN), is Government of India's largest nation-wide optical network initiative that aims to extend broadband connectivity to 600 million rural citizens of India across 2.5 lakh village offices in the country by 2017. Once again, the initiative fails to address the needs of the urban poor in slum communities since it's primarily focused on the empowerment of rural masses through broadband Internet.

Uni-Fi Architecture: In this paper, we present and discuss a universal and cost-effective broadband network architecture called "Uni-Fi" that is geared towards advancing the needs of slum dwellers in Indian cities through superior service provisioning, improved governance and a better quality of life. Each Uni-Fi node in a slum community comprises three key components: i) Wireless Streetlights with integrated cameras for public lighting, broadband delivery and remote surveillance by public safety agencies, ii) Community Kiosks that serve as broadband training centres and single-window facilitation units for government welfare schemes for low-income slum dwellers, iii) eCommerce/Deals platforms that list and sell daily-use items and other services at deep discounts to them. Uni-Fi nodes in a city are networked and managed centrally with an easy-to-use, drag-and-drop interface for transferring relevant municipal content to these devices.

Methodology and Results: A detailed techno-economic analysis was carried out to quantify and compare direct and indirect benefits of the Uni-Fi approach with competing multi-layer overlay options for varying network scales, ranging from 100 to 1000-node networks. The study observed a reduction in total cost of network ownership in the range of 30-60% for Uni-Fi over 5 years, besides accruing multiple socio-economic benefits to the state. Uni-Fi is being currently rolled out as a six-month pilot across 5 slum areas in Bangalore city in Karnataka state for proof-of-concept testing and further architectural refinements prior to scale-up.

Adapting cities to climate change : a systemic modelling approach

V. Masson (1) ; A. Lemonsu (1) ; C. Marchadier (1) ; M. Bonhomme (2) ; G. Bretagne (3) ; J. Hidalgo (4) ; T. Houet (5) ; N. Long (6) ; MP. Moine (7) ; C. Demunck (1) ; G. Pigeon (1) ; JL. Salagnac, (8) ; V. Viguie (9) ; K. Zibouche (10) ; L. Nolorgues (11) ; S. Hallegatte (12)

(1) CNRS/Météo-France, Toulouse, France; (2) ENSA, Toulouse, France; (3) AUAT, Toulouse, France; (4) LISST, Toulouse, France; (5) GEODE, Toulouse, France; (6) LIENSs, La Rochelle, France; (7) CERFACS, Toulouse, France; (8) CSTB, Desh, Champs-sur-Marne, France; (9) CIRED, Ecole des Ponts ParisTech, Paris, France; (10) CSTB, Champs-sur-Marne, France; (11) IAU Ile de France, Paris, France; (12) The World Bank (WB), Washington, United States of America

To answer the climate change challenge, all states have to reduce their greenhouse gas emissions, but also to adopt adaptation measures to limit the negative impacts of global warming on the population, the economy and the environment. The question arises especially for cities.

Because of complex interactions between climate change, the evolution of cities and its inhabitants, studying adaptation strategies for cities requires a strong interdisciplinary approach involving urban planners, building engineers, and researchers in architecture, meteorology, climate, economy, and social sciences.

Our four-step methodology consists firstly of defining interdisciplinary scenarios at several scales influencing the city evolution; secondly of simulating long term city evolution based on socio-economic and land-use models; thirdly of calculating impacts with physical models, and finally of calculating the indicators quantifying the impacts and evaluating the adaptation strategies.

Interdisciplinary systemic modelling performs well to evaluate several adaptation strategies for a very broad range of topics. Some of the results obtained for the agglomeration of Paris through our interdisciplinary research projects VURCA and MUSCADE will be discussed:

A finding is that urban planning strategies may have unexpected influence on city expansion when considered on the very long term of the climate change. Another is that the combine effect of global warming and UHI can lead in the future to larger energy consumption in summer than in winter.

Indeed, air-conditioning will probably be necessary in 2100, because of expected stronger, and longer, heat waves. Limiting the UHI intensity allows for energy savings, and hence contributes to climate change mitigation. Adaptation strategies exist to limit air-conditioning use, both in time and intensity.

Analysis of several vegetation strategies, at several spatial and planning scales (from agricultural practices in the city surroundings to urban trees and green-roofs) have been performed and evaluated. Architectural choices also allow to reduce the UHI. Finally, inhabitants' use and practices seem to be an efficient lever to reduce energy consumption in buildings and its impact on the urban climate.

P-4415-08

How do we Create and Build Knowledge Partnerships for Cities?: The Urban Climate Change Research Network (UCCRN) ARC3-2

C. Rosenzweig (1) ; S. Ali Ibrahim (2)

(1) NASA Goddard Institute for Space Studies, New York, United States of America; (2) Urban Climate Change Research Network (UCCRN), Columbia University, New York, United States of America

The objective of this presentation is to introduce the Urban Climate Change Research Network (UCCRN), and to foster a dialogue between global experts and local policy leaders regarding latest scientific findings and action areas on cities and climate change.

Climate change mitigation and adaptation are areas of high priority action in the urban context. These are often dealt with as separate issues in academic research, international climate talks, as well as national and local policy-making -- leading to a situation where these focus areas often compete for funding and for decision-makers' attention. The session will discuss the main challenges and potential of cities to integrate climate change adaptation and mitigation actions.

This presentation will introduce the UCCRN and present initial findings from the Second UCCRN Assessment Report on Climate Change and Cities (ARC3-2), concerning interelationships between adaptation and mitigation in cities. Synergies, conflicts and trade-offs between adaptation and mitigation will be analyzed and discussed across scales. The session will illustrate the need and importance of building a robust climate knowledge base in cities to support them in developing climate change actions strategies to address both climate adaptation and mitigation in an integrated manner.

The objective of the UCCRN is to bring together experts

working on global-scale, climate change and cities assessments in order to simultaneously present state-of-the-art knowledge on how cities are responding to climate change and to define emerging opportunities and challenges to the effective placement of this knowledge in the hands of local stakeholders and decision-makers.

The First UCCRN Assessment Report on Climate Change and Cities (ARC3) was published in 2011 by Cambridge University Press, and articulates urban climate risk frameworks, climate science for cities, and derives policy implications for key urban sectors — water and sanitation, energy, transportation, public health — and cross-cutting issues through land use and governance. The ARC3 report, containing 46 city adaptation and mitigation case studies, represents a four-year effort by 100+ scholars from over 50 cities in both developing and developed countries, and is the first-ever global, interdisciplinary, cross-regional, science-based assessment to address climate risks, adaptation, mitigation, and policy mechanisms relevant to cities.

The UCCRN is now working towards launching the next installment in this ongoing series, the Second UCCRN Assessment Report on Climate Change and Cities (ARC3-2). This session will present a 'First Look' at the ARC3-2 Report, which has been submitted to Cambridge University Press. The ARC3-2 Report is scheduled to be launched at COP21 in Paris.

The content and format of the ARC3-2 report has been based on several scoping session dialogues held at international conferences, inviting thoughts and reflections from urban and climate change scholars, city practitioners, and stakeholders. It has also taken into account survey feedback from ARC3 users and city officials. This discussion will highlight UCCRN's approach to knowledge creation and the status and next steps for ARC3-2.

The presentation will comprise of an introduction by the Co-Editors of the ARC3-2, its new topics and novel perspectives. It will present the main thrust of the Report and the analytical challenges of the main sections of ARC3-2, and will outline the content, analytical breath and anticipated challenges in building the main sections of the report, including: Interdisciplinary methods and tools to analyze cross-cutting processes driving climate change and sustainable development; climate science and disaster risk management; urban infrastructure; urban ecosystems; and governance, policy and finance. It will also include details on the UCCRN Regional Hubs in Paris, Rio, and Durban, to be launched at COP21. Through this regional participation, the audience will be able to grasp key regional priorities addressed in ARC3-2, with concrete examples of relevant analytical and policy cases. It will also discuss innovations for analyzing, reporting and communicating scientific progress in this field. This includes a short briefing on how ARC3-2 is building a storing communication platform (i.e., a Case Study Docking Station) to improve access to information by policy makers, academics and practioners.

P-4415-09

Transforming the Urban Fabric to a Solar City: Market, Finance, and Policy Factors for Infrastructure-Scale PV Deployment in Amsterdam, London, Munich, New York, Seoul, and Tokyo

J. Taminiau (1) ; J. Byrne, (1)
(1) University of Delaware, Center for Energy and Environmental Policy, Newark, Delaware, United States of America

A significant and sustained transition to a renewable energy future required to avoid further climate change continues to elude societies. Meanwhile, cities play an increasingly important role as they have propelled themselves onto the global climate change stage and have engaged in polycentric networks. To achieve substantial energy transformation while capturing the dynamic and important role reserved for the world's cities, this article reconsiders finance-policy-market interactions by positioning the build-out of a particular renewable energy technology, photovoltaic (PV) energy, as a commitment to infrastructure-scale development. The concept of the so-called 'solar city' [1] is analyzed where large-scale deployment of urban PV essentially transforms the urban fabric into an urban renewable energy power plant as the strategy utilizes the vast rooftop real estate available in all cities. More specifically, a capital market strategy to finance the infrastructure-scale implementation of urban PV is evaluated for six case study cities that have taken up active global roles - Amsterdam, London, Munich, New York City, Seoul, and Tokyo. The paper makes clear the substantial potential of the solar city concept in each location and outlines a practical financing strategy to realize the potential.

[1] Byrne, J., Taminiau, J., Kurdgelashvili, L., & Kim, K. (2015). A review of the solar city concept and methods to assess rooftop solar electric potential, with an illustrative application to the city of Seoul. Renewable and Sustainable Energy Reviews, 830-844. doi:http://dx.doi.org/10.1016/j.rser.2014.08.023

4417 - Transforming Society and Science for Sustainability – Addressing Challenges in Transdisciplinary Research

ORAL PRESENTATIONS

K-4417-01

Social Transformations towards Sustainability – needs and opportunities for transformative, transdisciplinary science

H. Hackmann (1)
(1) International Council for Science (ICSU), Paris, France

Research on global environmental change and sustainability increasingly goes hand-in-hand with calls for deep social change, and yet we know very little about how real and enduring social transformation comes about and how – if at all – it can or should be initiated, fostered or steered. 'Transformations towards Sustainability' is one of the three major thematic lines of activity of Future Earth, the new international hub coordinating research on global environmental change and sustainability, along with 'Dynamic Planet' and 'Global Sustainable Development'. As a direct contribution to this initiative, the International Social Science Council recently launched a research programme on Transformations to Sustainability in the first significant global effort to address knowledge gaps around social transformation.

Both Future Earth and the Transformations to Sustainability Programme are committed to a new approach to research for sustainability. Science as usual is not going to be successful in addressing climate change or other environmental challenges. Change is needed, and urgently, in how we do science, if we want to help accelerate transitions to a sustainable and just world. A transformations approach to sustainability research demands integrated, solutions-oriented science that takes account of the complexity of the challenges: research that involves the appropriate scientific disciplines, from social sciences and humanities to natural sciences and engineering; which focuses on specific problems in specific places; and crucially, which engages with society in its many dimensions in identifying the challenges, framing the research questions, designing and implementing the research, interpreting the findings and disseminating and using the results.

However, integrated, transdisciplinary research involving multiple stakeholders and places is difficult and done in various ways with varying results by different communities of practice. We need now to go beyond enumerating the challenges, obstacles or even successes, to pull together and learn from what we know about transdisciplinary research to enhance its quality and usefulness more generally.

O-4417-01

Stakeholder based science in transition research – challenges and opportunities

J. Mielke (1) ; H. Vermaßen (2) ; S. Ellenbeck (3) ; B. Fernandez Milan (4)
(1) Global Climate Forum (GCF), Green Growth, Berlin, Germany; (2) Center for Political Practices and Orders Universität Erfurt, Erfurt, Germany; (3) Potsdam Institute for Climate Impact Research, Potsdam, Germany; (4) Mercator Research Institute on Global Commons and Climate Change, Berlin, Berlin, Germany

The clean energy transition – based on the findings of the IPCC and others– is a highly political issue. It touches the way how society and especially the economy is organized, but also requires change on a personal and community level. Powerful interests of all status quo advocates are at stake and there exists not at all a consensus on how to transform and where to transform to. Hence, research on possible decarbonization pathways is a tricky issue that led researchers to involve stakeholders more strongly in the scientific process. Reasons behind this are (at least) twofold: First, engaging stakeholders more actively can facilitate access to issue-specific insider information that helps tackle scientific uncertainty and consequently improve the research process. Second, such involvement is perceived by the scientific community as a way to increase the influence of research on decision-making in political and economic arenas. However, these developments challenge the classical way scientific research is carried out and raise the question of "objectiveness" and value- and interest-driven research results.

We use the case of clean energy transition in Germany and Europe to systematize and discuss arguments for and against stakeholder based science and put them in a meta-scientific context. By doing so, we tackle the following questions: What kind of knowledge can be generated from stakeholder dialogues involving actors with varying degrees of influence in society and how can it be used? Which are the limitations of the so called co-production of knowledge? How can researchers coordinate and evaluate the influence that stakeholders have on their research process? What kind of trade-offs exist in the way research involves stakeholders and what implications do different approaches have for the science-policy interface? Our discussion paper thus investigates the influence of stakeholder based science on research «validity» and «objectivity», and its effects on research processes.

O-4417-02

Transforming Science to meet Society's Needs - The Social Footprint Laboratory

D. Mcbain (1) ; M. Joy (1)
(1) University of Sydney, Integrated Sustainability Analysis, Sydney, Australia

A quiet revolution is taking place that began a decade ago on a small Pacific island. A group of trans disciplinary academics had gathered to enjoy the sun, great company and discuss the how they could share data in a way that would be scalable and replicable. The data would be based on the trade in the world economy, and have detailed sets of environmental accounts for countries globally. When these data sets were all used together, the impact could be transformational. Complex global problems, such as understanding indicators of climate change, could be modelled and scenario tested. Academics from across the world could contribute and upload environmental and economic data, to be used with a multi-regional input-output database. The database and user friendly interface has now been uploaded to a cloud based platform. In 2014 this idyll dream came to fruition in the form of the Australian Industrial Ecology Virtual Laboratory (IELab). The IELab is transformational in bringing together academics, early career researchers, and users to better understand the environmental impacts of consumption, production and trade.

Now that the lessons have been learned for environmental data using economic modelling, researchers are developing a network to establish the global Social Footprint Laboratory (SFL). Where the IELab can be used to model carbon, energy and water footprints, the SFL will model social footprints such as labour or inequality. Social footprints are already being used to demonstrate the inequality in trade between countries, the 'Master/Servant' relationships between producing and consuming nations, and the embedded social impacts such as accidents and even workplace deaths associated with production. The development of indicators in the SFL will provide a focus on basic needs and the capacity to engage local stakeholders to define and model relevant indicators for transformational change for social sustainability, as well as develop networks for data collection, sharing and use. The power and innovation of the project is to enhance and extend the existing economic and environmental data and structures of the IELab, with the critical social data and indicators required to identify, guide and monitor changes towards sustainability.

The development of these cloud based tools will bring together users such as governments, businesses, non-government organisations (NGO's), academic research institutions and international institutions worldwide to start to understand the drivers of globally and locally complex problems such as climate change and inequality. The SFL, when developed, will also help to monitor multidimensional progress against social, environmental and economic goals such as the UN Post 2015 Sustainable Development goals. An important part of the process of developing the SFL will be bringing together users to form a network and creating the knowledge links essential for transformational change. This network will complement the existing Asia-Pacific Research and Training Network on Trade (ARTNeT), which is an open network of research and academic institutions and think-tanks in the Asia-Pacific region, currently coordinated through UN ESCAP in Bangkok. Even without the virtual laboratory, the establishment of such a global network concerned with the collection, use and dissemination of social impact data will be transformational. The case studies developed as part of this project will also add to the transformational change through demonstration to the different user groups of how the data in the SFL can be applied.

Existing data sets on social indicators such as employment, income, poverty and child labour have already been used with the multi-regional input-output databases, in both the IELab and the Social Hotspots Database, proving viability of this project. A transformational aspect of this project will be in bringing together early career researchers in developing countries to gather the data and involving end users with the development of the tool.

This paper will present the transformational work on the IE Lab, giving examples of studies this work has enabled early career researchers to conduct and publish and share practical experiences of building a virtual laboratory in Australia and scaling it to a global capacity. It will also outline the proposed SFL project and network as part of the Transformation to Sustainability Programme, and showcase some of the social footprinting studies conducted to date and how this multidisciplinary work can contribute to solutions oriented research on climate change.

O-4417-03

FEAST (Food: Engaging in Action for Sustainable Transformation): Building a Transformative Knowledge Network

E. Nelson (1) ; R. Garcia, (2) ; B. Rault, (3) ; N. Castillo (4) ; A. Blay-Palmer, (5)
(1) Wilfrid Laurier University, Waterloo, France; (2) Benemerita Universidad Autonoma de Puebla, Puebla, Mexico; (3) Desarrollo y Aprendizaje, A.C., Puebla, Mexico; (4) Desarrollo y Aprendizaje, Puebla, Mexico; (5) Wilfrid Laurier University, Waterloo, Canada

With academic and community partners in Mexico, Brazil, Kenya, Canada, the United States, and the European Union, the FEAST (Food: Engaging in Action for Sustainable Transformation) social economy of food network focuses on co-creating and sharing knowledge about innovative, community-scale solutions to the interrelated challenges of climate change, poverty, and food insecurity. We take as our starting point practical initiatives that have demonstrated potential to improve access to healthy food, build resilient communities, and contribute to transformation to more sustainable food production and consumption practices. These include: promoting new as well as traditional climate-smart production techniques; building community capacity to engage in agroecology and

agroforestry; facilitating increased access to traditional foods, particularly in Indigenous communities; developing appropriate alternative markets for ecological products; and, implementing participatory governance systems, for example for organic certification.

By analyzing and developing connectivity amongst projects such as these, our transdisciplinary network of scholars and practitioners aims to increase the scope of their transformative potential. Specifically, our objectives are to: 1) Use a social economy of food as a lever to explore socially just, economically robust, and ecologically regenerative sustainable opportunities for communities in the Global South that would increase their ability to address the interrelated challenges of climate change, poverty, and food insecurity; 2) Build direct person-to-person (or community-to-community) knowledge flows that enable citizens in the Global North to better understand the impacts of climate change, poverty and food insecurity in communities of the Global South, and also build solidarity amongst communities in the Global South that are confronting these challenges; 3) Create a networked learning community to facilitate the exchange of knowledge regarding concrete examples of innovative, community-scale solutions to the problems of climate change, poverty and food insecurity; and 4) Use this knowledge-network as a platform to extend knowledge sharing to other communities. This learning community would highlight the co-creation of knowledge between South and North and between academic and community partners, and be facilitated in a way that empowers traditionally marginalized communities. It would also enhance the capacity of researchers/scientists – particularly emerging scholars – to analyze household and community-level adaptation strategies, and inform climate-smart policies.

The proposed paper will highlight some of the advances that have been made to date by FEAST network partners working at the regional scale to address climate change, poverty, and food insecurity, particularly for marginalized populations including women, youth, Indigenous communities, and smallholder farmers. It will also outline how the development of a robust transdisciplinary knowledge network creates opportunities to increase the transformative potential of existing regional work.

O-4417-04

Strengthening collaboration for transformation to sustainability in research and education at universities

P. Adam (1) ; H. Kromp-Kolb (1) ; T. Lindenthal (1)
(1) Centre for Global Change & Sustainability, University of Natural Resources and Life Sciences, Vienna, Austria

To be able to respond to grand societal challenges such as climate change, it is necessary for universities and other research organisations to recognise and act upon their responsibility as both educators and generators of knowledge. An effective contribution of science to societal transformation requires an adaptation of teaching and research activities and intensified collaboration and networking. Equally important is that science opens up to civil society and improves interactions with decision makers. Inter- and trans-disciplinary approaches can help expedite the necessary dialog on all levels. "Responsible Science" is the catch word used to address these changes – but what needs to be done? What are best practice examples from different academic cultures? How can universities and other research institutions cooperate to speed up the necessary change?

Increasingly science is becoming aware of and acting upon this responsibility. In Austria e.g. over 240 scientists have collaborated to jointly create the first Austrian Panel on Climate Change (APCC) report, mimicking in form, structure and process the assessment reports of the Intergovernmental Panel on Climate Change. The leading climate research institutions have founded the Climate Change Centre Austria (CCCA), which coordinates activities of and facilitates exchange between the climate science community. Recently a number of major universities created the Alliance of Sustainable Universities in Austria that is working on implementing the necessary transformation in teaching, research, on-campus and in societal outreach and exchange activities. In 2014, this alliance e.g. completed a research project on climate friendly research and managed to implement sustainability strategies on the regulatory level as part of mandatory performance agreements with the Austrian Ministry of Science and Research.

In this contribution we will discuss experiences, particularly on barriers and leverage points and potentially transferable "catalysing mechanisms" for "science and research in transition".

Although these activities have many positive effects, a fundamental issue still persists: Currently the academic system is geared towards achievements within the scientific community such as e.g. SCI publications, disciplinary oriented research and education, scientific oriented third-party funding, etc. However, responsibility toward society means dealing with the challenges society faces rather than investigating issues which promise to be lucrative either financially or in terms of scientific 'standing'. Sustainability science and education with its inter and trans-disciplinary research, exchange and dissemination of knowledge and engagement in collaboration and networking activities of the kinds mentioned above are often not rewarded and hence are difficult to prioritise in a publish-or-perish system.

Universities and the scientific system at large can play and must play a leading and visionary role toward the solution of the climate crisis and other grand societal challenges. However this will mean considerable changes to the current academic system, supplementing systems of evaluation and rewards in order to enable science to answer the pressing questions of our times and engage in the type of education, collaboration, networking and exchange, which is so crucial if we are to achieve the necessary transformation to a post-carbon, sustainable society.

O-4417-05

Networked co-design for trans-national sustainability-oriented innovation systems

A. Ely (1)
(1) STEPS Centre, SPRU – Science Policy Research Unit, Sussex, United Kingdom

This paper presents initial findings from a co-design process involving 'transformation platforms' in six different high, middle and low-income countries as part of the 'Constructing Pathways to Sustainability' network. In each case, co-design workshops were hosted in order to bring stakeholders together around challenges that linked to climate change, including sustainable cities, sustainable agricultural and food systems and low carbon energy. In all cases the host institution convened a mix of academic scientists and knowledge partners in order to analyse the locally-defined problem and explore alternative pathways serving environmental sustainability and social justice objectives.

The paper will focus in particular on the examples from China and Africa, which primarily address the challenge of low carbon transitions that serve the needs of the poor. In each case, local innovations were identified that related to solar photovoltaic technologies, and participants discussed the problem of enabling access among poorer communities. Whilst innovation policies in China are clearly succeeding in the competitive production of low-cost PV panels, primarily for export, the uptake of PV in poor rural areas remains relatively slow. Participants identified the need to move away from technology-focused approaches to expanding energy access towards bottom-up approaches that also integrate concerns embodied in a new central government focus on poverty reduction, seen for example in the State Council's new policies on rural participation.

In the African case, participants discussed the utility of solar home systems (SHSs) and biomass in providing energy services to off-grid communities. Of particular interest to this paper is the development of novel payment mechanisms for solar energy, utilising mobile phone systems, that have been pioneered in Kenya. Interestingly, these are being recombined with solar PV hardware imported from China to produce a (socio-technical) system with potential to enable low carbon transitions that serve the needs of the poor.

The networked approach to co-design enabled the pairing of the China and Africa cases, offering opportunities to explore linkages and mutual learning across continents

that can – together – contribute to transnational (low carbon) sustainability-oriented innovation systems. The paper ends with a proposal to take forward these initial findings through continued work at the levels of the local transformation platforms and across the international transformative knowledge network.

O-4417-06

Collaborative political ecology: Mapping movements to leave oil in the soil with and for Environmental Justice Organizations

L. Temper (1)
(1) Institute of Environmental Sciences and Technology (ICTA)– Autonomous University of Barcelona, Barcelona, Spain

This paper presents the results of the collaborative work on climate justice undertaken in the EJOLT (Environmental Justice Organizations Liabilities and Trade) EU fp7 project through the presentation and analysis of over 300 cases of conflicts over fossil fuel extraction and infrastructure as documented in the Atlas of Environmental Justice (www.ejatlas.org).

The Global Atlas of Environmental Justice (www.ejatlas.org) is a collaborative project that draws on activist knowledge to document social conflict over the environment. Ecological conflicts are defined as: "mobilizations by local communities, social movements and EJOs against particular economic activities (or state policies), in which concerns about current or future negative environmental impacts are an important part of the grievances, along with social, psychological and political impacts."

The Global Atlas of Environmental Justice currently documents over 1400 such ecological conflicts displayed on an online interactive map. Each conflict contains around 100 fields including activity type and commodity, actors, quantitative data, degree of violence, forms of action, outcomes and perception of success, among others. Over 250,000 users have opened over 1 million pages of the atlas in the last year since it has been public.

The atlas one one hand serves to document, making visible, and support the struggle for environmental justice (EJ), with the ultimate goal of empowering movements and activists, and increasing the recognition and legitimacy of research done by environmental justice organizations. It also serves as an important activist resource for information sharing and networking.

Scientifically it contributes to a form of 'statistical political ecology', and the development of a system whereby a large number of environmental conflicts can be described, analyzed, and compared across geographies and thematic issues and across spatial and temporal scales. The global nature of the atlas enhances the study of transnational spatial patterns of environmental and economic risks and impacts and their connections through commodity and financial flows that cannot be gained except at broader geographic and political scales.

The EJatlas is part of a new wave of initiatives that use geo-spatial information and new spatial media to advance, legitimate and secure political claims (Elwood and Leszcynski 2012). Through these "knowledge politics" individuals and institutions leverage digital spatial data and spatial technologies in negotiating social, political, and economic processes. The process of co-production of knowledge in producing the EJatlas is thus a contribution to transcending the expert/amateur or expert/grassroot activist dichotomy, while creating a new spatial knowledge politics and contributing to a collaborative political ecology.

After an explaination of the methodology of the EJatlas process the paper will present results from a comparative survey of the 300+ cases related to climate justice and fossil fuel extraction in the EJatlas with an emphasis on the following lines of enquiry: 1) The increasingly interlinked nature of place-based mobilizations over fossil fuel extraction and their articulation with global climate activist movements 2) The growth in conflicts over new technologies such as hydraulic fracturing and how citizen science is created and knowledge difused and transmitted between locations 3) the use of increasingly contentious and disruptive forms of resistance to fossil fuel expansion such as blockades in some regions 3) Transformative cases in the atlas that demonstrate how communities resisting fossil fuel extraction are presenting innovative governance mechanisms to leave oil in the soil and move towards energy sovereignty and post-extractivism.

O-4417-07

The Role of Young Scientists in Advancing Knowledge and Informing Decisions in a Changing Climate

J. Baum (1)
(1) University of Victoria, Biology, Victoria, BC, Canada

Young scientists are passionate about addressing the climate challenge, and this community is increasingly being recognized for its leadership and contributions to international climate science and policy efforts. Processes such as the Intergovernmental Panel on Climate Change and the U.S. National Climate Assessment are making explicit efforts to include early-career scientists. Young scientists play critical roles in advancing the understanding of climate change, developing mitigation and adaptation solutions, and informing societal decisions that enhance sustainability in the face of climate change. Doing so often requires early-career researchers to work across traditional disciplinary boundaries throughout the process of discovery. In addition, many young scientists regularly engage with the public and with decision makers, such as resource managers, local officials, urban planners, and stakeholders, through their work. For such emerging leaders, metrics of professional success should therefore reflect not only new contributions to knowledge but also the tangible benefits that those insights bring to society. Despite progress in meaningfully integrating young scientists as leaders in the climate-science community, institutional barriers often hinder early-career researcher engagement both with the scientific community and with stakeholders. This talk will discuss opportunities and challenges facing young scientists working on transdisciplinary projects to inform sustainability solutions in a changing climate. In particular, organizations such as the Global Young Academy provide critical opportunities for mobilizing and empowering early-career scientists to become the leaders of tomorrow's climate science and policy efforts.

Three perspectives on global energy transitions and the promise of inter-disciplinary dialogue

A. Cherp (1)
(1) Central European University, Department of Environmental Sciences and Policy, Budapest, Hungary

Human's use of energy in the 21st century could result in the collapse of the global climate, persistent poverty, and international conflicts over access to increasingly scarce resources. Alternative energy scenarios portray climate stabilization, universal access to modern energy, and strong global cooperation. Yet our knowledge of what political forces could trigger sustainable global energy pathways is still scarce and fragmented. Three distinct scientific disciplines strive to explain the driving forces behind the evolution of energy systems. Energy-economy models base their explanations on equilibrium between growing energy demand and supply constrained by resource scarcity and cost-optimization by rational actors. Technology studies analyze emergence and diffusion of energy technologies across socio-technical systems stressing innovation, performance and non-linearity. Political economy focuses on interests, ideas and institutions that impede or promote certain types of energy systems. Due to their diverse historic origins and different disciplinary roots, these scientific fields rarely communicate or cooperate. This paper outlines a transdisciplinary research agenda involving the three perspectives on energy transitions. It subsequently uses several examples from developing, developed and emerging countries to illustrate how a meaningful scientific dialogue between these fields could help to understand and guide sustainable energy transformations.

"¿Post-normal research networks?: Rethinking the production of interdisciplinary and transectorial knowledge"

MF. Fossa Riglos (1) ; V. Hernandez (2)
(1) Instituto de Altos Estudios Sociales/UNSAM-CONICET, Ciencias Sociales, San Martin, Buenos Aires, Argentina; (2) Institut de recherche pour le developpement, Paris, France

This presentation aims to reflect about the epistemological implications of knowledge production in the frame of international collaborative research networks on climate and its social impacts. The way in which climate change knowledge is produced in the frame of international interdisciplinary networks and integrated into social actor's´practices is a complex process where a numerous of factors intervene: knowledge production conditions, sociopolitical, environmental and socio-structural settings (macroeconomics, social structure, etc.), among others. An effective appropriation of expert knowledge by social actors and politicians requires not only methodological tools with the ability to integrate these factors within a dynamic of knowledge co-production, but also an analysis of the social field concerned in order to understand in which historic- political thread is this trying to get involved. This analysis is not related to a techno-methodologic matter but it summons to a political economy of knowledge. The challenges this epistemological perspective opens express both in the social as the scientific field and on the design of public policies. Basing in our own experience as social sciences researchers in two different climate research networks of this kind, our objective is not to present a social network analysis but to analyze the dynamics of this research networks as an apparatus (Foucault, 1977), whose ambition is to produce a "governance" response to climate change problem. These apparatuss are generally organized in a three-part logic: pluridisciplinary (diverse interdisciplinary interactions inside network´s working groups), multilocation (interaction among diverse academic institutions and countries) and transectoriality (interaction between researchers and society actors).

This work is organized in five sections. In the first one, we introduce and describe our networks of interest, as well as the ethnographic approach we have applied to study this research apparatuss. In second section, we present a brief description of the historic construction and management dynamics of scientific production on the extensive areas of post-normal concern, and we analyze the structure and logics of these networking research apparatus. Then, interdisciplinary dynamics is analyzed in the third section, showing how different disciplinary approaches, theoretical frameworks and concepts are engaged with the aim of legitimizing this network apparatus three-part logic. In the fourth section we analyze transectorial collaboration, describing its dynamics, the way stakeholders, policy makers and local communities are conceived by researchers, and discuss the possibilities of climate knowledge appropriation. Finally, we present our conclusions reflecting on the epistemological implications of these apparatus considering the role of global political-scientific agenda in the construction of climate change problematic, the hegemony of the techno scientific logic, and the relevance of political dimension for the creation of alternative responses facing the challenges and interests of our globalized world.

P-4417-03

Artisticc: An Art and Science Integration Project to Enquire into Community Level Adaptation to Climate Change

JP. Vanderlinden (1) ; J. Baztan, (1)
(1) University of Versailles-Saint-Quentin-en-Yvelines, Observatory of versailles-saint-quentin-en-yvelines/cearc, Guyancourt, France

The purpose of this paper is to present the Belmon Forum «Adaptation Research a Transdisciplinary community and policy centered appoach» (ARTisticc) project. ARTisticc's goal is to apply innovative standardized transdisciplinary art and science integrative approaches to foster robust, socially, culturally and scientifically, community centred adaptation to climate change. The approach used in the project is based on the strong understanding that adaptation is: (a) still «a concept of uncertain form"; (b) a concept dealing with uncertainty; (c) a concept that calls for an analysis that goes beyond the traditional disciplinary organization of science, and; (d) an unconventional process in the realm of science and policy integration.

The project is centered on case studies in France, Greenland, Russia, India, Canada, Alaska, and Senegal. In every site we jointly develop artwork while we analyzie how natural science, essentially climate sciences can be used in order to better adapt in the future, how society adapt to current changes and how memories of past adaptations frames current and future processes.

Artforms are mobilized in order to share scientific results with local communities and policy makers, this in a way that respects cultural specificities while empowering stakeholders, ARTISTICC translates these "real life experiments" into stories and artwork that are meaningful to those aff ected by climate change.

The scientific results and the culturally mediated productions will thereafter be used in order to co-construct, with NGOs and policy makers, policy briefs, i.e. robust and scientifically legitimate policy recommendations regarding coastal adaptation. This co-construction process will be in itself analysed with the goal of increasing arts and science's performative functions in the universe of evidence-based policy making.

The project involves scientists from natural sciences, the social sciences and the humanities, as well as artists from the performing arts (playwriters, film directors) as well as the visual arts (photographs, designers, sculptor) working in France, Senegal, India, Russia, Greenland, Alaska, and Canada.

P-4417-04

Science and art together

C. Villegas Ivich (1)
(1) ArNaMe International, Paris, France

For decades worldwide scientists rely considerable efforts to bring to the world and particularly to decision makers of the planet, all the knowledge that allow us to understand the causes of global warming, and its predictable and irreversible consequences on the environment and on the balance of the world. In other words, thanks to science, we have for a long time and especially today, sufficient dates to take necessary decisions and measures. Despite this, greenhouse gas emissions have risen, and on the contrary, nothing has been done to effectively fight against global warming. It seems that knowledge is not enough to raise awareness, create responsibility and encourage ethical behavior in front of the current climate crisis. Would it be because conscience, responsibility and ethics are not only forged with scientific or rational considerations? It is undoubtedly an urgent need to enrich and strengthen the contribution of science with other forms of perception and understanding of the world in order to go further in this thought. To understand and internalize what is at stake in environmental and climate issues, we should perhaps call upon our sensitivity and our emotional intelligence. This could probably help us to understand better what science tells us, because what we live and experience don't just have a rational explanation. This would bring us, among other things, to develop our empathy, carry us to change the way we see and understand our relationship to life, to ourselves and to someone other than Me. This Other than me is plural and singular, he surrounds us and expects from us another way to coexist and live on this planet. We must be able to pass to the other side of the mirror, to go beyond the immediacy of things, to really understand what is our place and responsibility in the community of the livings. Among the possibilities that are available in order to succeed in this passage, the better of them is probably art. Indeed, it could best go along with science to bring us further in the process of evolution of our awareness, our understanding of reality and our way of being in the world. In the creative process of art, logos and sensitivity merge together and the result offers to our senses stimulates our mind, sharpens our perception, our vision widens and expands our critical and analytical skills. In this paper we try to show, with ongoing experiments, how this collaboration between science and art can happen. How, while working together, they can create a new perception and a new understanding of environmental and climate issues and in the end, how this alliance and this merger can contribute to the development of awareness and willingness into order to act in responsible ways.

Decision-relevant science for water security: An iterative process for targeting and evaluating impacts of watershed investments

AL. Vogl (1) ; J. Goldstein (2) ; R. Mcdonald (3) ; P. Hamel (4) ; M. Ruckelshaus (5)
(1) The Natural Capital Project, Stanford Woods Institute for the Environment, Stanford, CA, United States of America; (2) The Nature Conservancy, Fort Collins, CO, United States of America; (3) The Nature Conservancy, Washington, D.C., United States of America; (4) The Natural Capital Project, Stanford Woods Institute for the Environement, Stanford, CA, United States of America; (5) The Natural Capital Project, Stanford woods institute for the environment, Stanford, United States of America

Nature-based solutions are increasingly recognized as viable strategies to address major challenges for human development in areas such as water security, disaster risk mitigation, infrastructure development, and sustainable agriculture. Such strategies have the potential to provide adaptive solutions to changing climate conditions by encouraging ecosystem-based adaptive management and community participation. In the realm of water security, protecting and restoring nature to regulate the quantity and quality of water flows is increasingly viewed as a cost-effective and complementary strategy to engineered approaches. Broadly termed Investments in Watershed Services (IWS), these projects typically invest in the conservation of source watersheds to secure clean water for downstream communities. Recent studies show the potential for IWS to provide a positive return-on-investment for water resource goals, to generate additional environmental and social co-benefits, and to be a strategy that can adapt, potentially more so than engineered solutions, as climate conditions change. In 2013, there were an estimated 345 active IWS programs globally and an annual investment totaling $12.3 billion (www.forest-trends.org/dir/sowi_2014/). Yet, despite its exponential growth over the past two decades, IWS remains a relatively small-scale, often one-off strategy in particular locations, which contrasts with the widespread use of engineered solutions.

We argue that a key barrier limiting the scope of IWS is that tools and guidance to bridge the science-to-practice gap are less well developed - tools to help practitioners understand if, where, and how well IWS will work. A recent plethora of reports and decision support tools highlight for cities, regional authorities, and corporate actors the risks that they face due to dependence on water resources (e.g., Ecolab and Trucost's Water Risk Monetizer and WWF's Water Risk Filter). However these tools largely focus on the "risk" component of the water security equation. To effectively mainstream IWS, decision makers need science that addresses the "opportunity" component of the equation - the degree to which improved watershed management activities can mitigate risk. Combining risk and opportunity information enables decision makers to quantify the scope for IWS and to identify actionable solutions that are specific to the decision context. Such decision support would allow policymakers to target natural capital investments towards programs (at global/regional scales) or projects (at local scales) that promote IWS where it has the highest potential to be a cost-effective intervention. We will showcase several tools and methods developed by The Natural Capital Project - in collaboration with various NGO, academic and policy partners - in support of IWS programs in 7 countries across Latin America, India and Kenya. Our experiences illustrate the importance of co-producing ecosystem services information as part of an iterative research-application process, for 1) targeting investments based on ecosystem services outcomes, 2) addressing uncertainties around drivers of change (including climate change), and 3) monitoring and impact evaluation. Delivering more resource-efficient and transferable science will allow decision-makers to evaluate where IWS is, and critically is not, likely to be an effective and robust institutional mechanism to achieve water security goals in the face of climate change.

K-4418a-02

School Earth Care Centre: A Communication and Decision Support System for Community Level Weather, Climate, and Environmental Services

PK. Sengupta (1)
(1) Jadavpur Centre for Study of Earth Science, Hydrology, Kolkata, West Bengal, India

Development of a weather, climate and environment service system requires scientific and technological development including development of understanding and knowledge regarding enhanced observational needs. To create an "intelligent and wise" rural community secondary schools can do a lot. Schools have the scope for fostering scientific, human and technological resources required for making people aware and resilient to threats and impacts of climate change through appropriate science and technology communication.

School Earth Care Centres (ECC) catalyzed by the Natural Resource Data Management System (NRDMS) of Department of Science and Technology (DST), Government of India is an approach to establish a bridge between the community and educational institutes for catering community level climate and weather services through generating water & weather related data, preparing maps and sharing it with the stake holders.

In 2007-12 ECC have been established in 75 schools of West Bengal, India representing each geoclimatic, socio economic and demographic situations. A state level NGO had been engaged to act as the central resource agency and a communication link between the expert community and the rural institutions. The ECC schools have been provided with weather instruments, soil and water monitoring kit and a kit for map making. Necessary orientation, hands on training workshops were held in each ECC school involving stake holders from the teachers, students, farmers and the community. Development of methods for efficiently making use of weather and water databases and implementation of user-relevant approaches for evaluating the quality and benefits of products and services are considered to be the end product.

This paper discusses the model in terms of formation process, tasks and results that have been measured in terms of development of awareness, knowledge, motivation, sharing and participation. While analyzing the overall success indicators of the model it is observed that rural schools in backward and disaster prone areas showed a higher level of competency and motivation. It has also been observed that development of ownership of the data and making wise use of it resulted into a more resilient society in those areas.

This paper argues that the scientific effort is reliant on extensive sharing of capabilities and knowledge where educational institutions and other stakeholders can play as a key factor for comprehensive services system development. Such a framework is essential in developing countries, allowing weather and environmental data generated and provided by the local institutions to the service of the local community at the grass root level.

O-4418a-01

Personal adaptation: discussions, decisions and planning

L. Coulter (1)
(1) Griffith University, Urban Research Program, Nathan, Queensland, Australia

Decisions that will be effective to manage the impacts

of climate change that are now unavoidable will need to account for ongoing instability in social, economic and environmental systems. Commonly examined barriers in accounting for progressive climate impacts include: disbelief in aspects of climate change processes; lack of understanding of the impacts; poor access to relevant and credible information; and a felt need for greater certainty. Professionals who exchange climate change knowledge in research, policy, and practice will have overcome many, if not most, of these barriers through training and experience. Barriers that affect even these professionals are personal reactions to envisioning the future such as: emotive responses; lack of facility in future thinking; and subjective assessments of perceived risks and capacity. This paper draws on interviews that inquire into personal adaptation discussions and planning by Canadians and Australians. Participants have professional expertise and regular high-level communications regarding climate change with colleagues and the public. The interviews and this paper focus on a different sphere: discussions by these same professionals with family and friends. Key improvements in interpersonal discussions of climate change adaptation decisions and planning identified in the research include the need to: connect concern for mitigation of climate change to adaptation to climate impacts; think beyond unpleasant possibilities and envision future life affected by climate change; and foster skills for greater cooperation in education and planning. Even among this highly educated group there was difficulty in imagining changes in society in the climate of the future, especially among those who do not tend to engage in future thinking or plan for the long term. This has implications for our understanding of individual factors in climate adaptation decision processes that may affect the wider society over time. Further study with people from other nations, professions and culture groups would broaden understanding of personal factors in adaptation decision-making.

Synthesis centers: an essential tool in our complex, data-rich future

A. Specht (1) ; J. Baron (2) ; M. Winter (3) ; P. Bishop, (4) ; J. Boyd, (5) ; A. Campbell, (6) ; F. Davis, (7) ; D. Hawthorne, (5) ; C. Jonsson, (4) ; J. Kramer, (5) ; T. Meagher, (8) ; M. Palmer, (5) ; C. Salomon, (9) ; D. Steinaker, (10) ; T. Vision, (11)

(1) School of Geography, Planning and Environmental Management, University of queensland, St Lucia, Queensland, Australia; (2) John Wesley Powell Center for Analysis and Synthesis, Fort Collins, CO, United States of America; (3) DFG German Research Foundation, German centre for integrative biodiversity research, Leipzig, Germany; (4) National Institute for Mathematical and Biological Synthesis, University of tennessee, Knoxville, Tennessee, United States of America; (5) National Socio-Environmental Synthesis Center, University of maryland, Annapolis, Maryland, United States of America; (6) Research Institute for Environment and Livelihoods, Charles darwin university, Darwin, Northern Territory, Australia; (7) National Center for Ecological Analysis and Synthesis, University of california, Santa Barbara, California, United States of America; (8) Environmental Omics Synthesis Centre, University of st andrews, St Andrews, Scotland, United Kingdom; (9) Centre for the Synthesis and Analysis of Biodiversity, Fondation for research into biodiversity, Aix en Provence, France; (10) Canadian Institute of Ecology and Evolution, University of regina, Regina, Saskatchewan, Canada; (11) University of North Carolina, Biology, Chapel Hill, United States of America

Climate change presents a challenge to traditional scientific practices of disciplinary focus and the well-established research pathway. Understanding and responding to global climate change requires the integration of an abundance of information over many disciplinary fields and from many different organisations, with the added urgency of needing rapid answers and applications. Synthesis centers provide a unique environment for harnessing knowledge and expertise to catalyse discovery through cross-disciplinary working collaborations. Supported scientific synthesis—the integration of disparate theories, methods, and data across disciplines, professional sectors, and scales—has been proved to provide general, robust scientific explanations and evidence-based solutions across the social, economic and scientific realms. We contend that providing a synthesis intervention is a necessary, even mandatory, requirement for humanity to properly address critical climate change challenges.

More than a dozen synthesis centers now exist across Europe, North America, Asia and Australia. These centers bring discipline-specific experts together for blocks of time to stimulate cross-sectoral creative thinking and insight. The synthesis center approach is a vital tool to achieve collective action and transformative solutions. It offers something rare: participation based on a collective interest to deliver outcomes, and distraction-free, supported time and space for groups to totally immerse themselves in a question. A common tool provided by all synthesis centers is the technological support to analyse and synthesise diverse and disparate datasets.

Each synthesis center reflects the imperatives uppermost in its own country, and has developed a unique approach and expertise relevant to its mandate. Some centers emphasise the earth sciences, some the application of mathematics to biology, some natural resource management, social science and science policy, some the dynamics of marine and terrestrial ecosystems, inter alia. Conservatively, the Centers together have been instrumental in bringing more than 25 singular disciplines together to work in unique trans-disciplinary combinations to address complex problems. The Centers have amassed large networks of people and provide the necessary infrastructure and skills to support them to collaborate. As a group, newly formed into the International Synthesis Consortium (www.synthesis-consortium.org), these centers provide a powerful tool across the whole range of disciplines and geographies needed for innovative solution-oriented thinking around the effects of climate change.

4418b - Information for decision making - Improve availability, access and use of information

ORAL PRESENTATIONS

K-4418b-01

Enhancing National Climate Services for Development in Africa

T. Dinku (1) ; M. Thomson (1) ; S. Connor (2)

(1) The International Research Institute for Climate and Society, Palisades, NY, United States of America; (2) Liverpool University, Geography, Liverpool, United Kingdom

Timely and appropriate climate information could play a critical role in national development planning; helping policy and decision makers to better manage climate risks and maximize opportunities. Available and decision-relevant climate information on the past climate, recent trends, likely future trajectories, anomalies and associated impacts is a prerequisite for climate-informed decision making. Unfortunately, climate information is not widely used in Africa to make development decisions. This is mainly because useful information is often not available or, if it does exist, is inaccessible to those that need it most.

The ENACTS (Enhancing National Climate Services) initiative is an ambitious effort to simultaneously improve the availability, access and use of climate information by working directly with National Meteorological and Hydrological Services (NMHS). It enables the NMHS to provide enhanced services by overcoming the challenges of data quality, availability and access - while at the same time fostering stakeholder engagement and use. The new spatially and temporally complete ENACTS data products allow for characterization of climate risks at a local scale, and potentially offer a low-cost, high impact opportunity to support applications and research. ENACTS has so far been implemented in Ethiopia, Madagascar, Tanzania, Rwanda and The Gambia at national levels, and at regional level for the CILSS countries (West African Sahel).

For effective climate change adaptation planning, conservation practitioners must consider how their areas and species of concern are likely to be impacted by climate change. At present, however, they face a burgeoning scientific literature describing a wide variety of methods for assessing species' vulnerability to climate change, each with its own strengths and limitations. Based on inputs spanning the conservation science and practitioner communities, along with broad literature review, the IUCN Species Survival Commission's Climate Change Specialist Group has developed guidance for selecting and applying methods for assessing species' vulnerability to climate change.

The best practice guidelines outline commonly used approaches for assessing species' climate change vulnerability namely correlative (niche-based), mechanistic and trait-based approaches. They guide users to clearly define the scope and objectives of their assessments, and to identify and evaluate their available data, technical, expertise, time and financial resources. With the aid of a decision framework, users match their objectives with appropriate methods, and then identify those for which they have sufficient resources. The guidelines also include sections on selection and appropriate use of climate and biological data, selecting temporal and spatial scales, and working with uncertainty, knowledge gaps and indirect climate change impacts. They present overarching principles, ideas for communicating assessment results, and a broad range of case studies demonstrating how the guidelines can be applied.

This presentation provides an overview of the new best practice guidelines for assessing species' vulnerability to climate change and familiarizes attendees with steps for making sound and defensible decisions on method choice. Through the guidelines we hope to make climate change vulnerability assessment more accessible to the conservation practitioner community, thereby providing the best possible foundation for climate change adaptation planning.

The experience of the Brazilian Climate and Health Observatory

R. Gracie (1) ; C. Barcellos, (2) ; D. Silva, (3) ; H. Barros, (4) ; V. Matos, (5)

(1) Fundação Oswaldo Cruz, Instituto de Comunicação e Informação Científica e Tecnológica, Laboratório de informação em saúde, Rio de Janeiro, RJ, Brazil; (2) Fundação Oswaldo Cruz, Centro de Informação Científica e Tecnológica, Laboratório de informação em saúde, Rio de Janeiro, RJ, Brazil; (3) Fundação Oswaldo Cruz, Centro de Informações Científicas e Tecnológicas, , Laboratorio de informação em saúde, Rio de Janeiro, Brazil; (4) Fundação Oswaldo Cruz, Instituto de Comunicação e Informação Científica e Tecnológica, Laboratorio de informação em saúde, Rio de Janeiro, Brazil; (5) Fundação Oswaldo Cruz, Instituto de Comunicação e Informação Científica e Tecnológica, , Laboratorio de informação em saúde, Rio de Janeiro, RJ, Brazil

Gathering and analyzing data on climate and health, as well as information on socioeconomic and environmental factors, is essential for planning actions to adapt to and mitigate climate change. In view of the complexity of the processes involved between global environmental and climate change and its effects on health, it is essential to bring together and analyze data in such a way as to provide society, government agencies and the media with information on these changes. To achieve this follow-up, a set of data on the dimensions of the climate, environment, population and health is required. The Brazilian Climate and Health Observatory project is making information on climate and health available through an internet page (www.climasaude.icict.fiocruz.br) where data from different origins can be accessed on a common platform. This technology is innovative in that it allows users to make consultations that simultaneously use distributed data, i.e. data generated and maintained by different institutions. The Information Technology and the information content were agreed between the participating institutions, researchers and representatives of government and civil society in workshops during which a consensual platform was agreed among data producers and data users.An initial assessment of the possible impacts of climate changes on health was made by a group of public health researchers, resulting on a list of climate-sensitive diseases (Barcellos, 2009). Vector-borne diseases, respiratory and cardiovascular diseases, water-borne diseases and a variety of health problems resulting from prolonged drought or floods, such as hunger and infant mortality, were selected to be monitored by the Observatory.The debate on climate change drivers, its impact on public health and adaptation actions needs to be a democratic process that allows participation by different social actors, with guidance towards motivating present-day changes with short, medium and long-term repercussions. In the Observatory project, participation is proposed as a path leading to integration between citizens, researchers and public health administrators so as to enable manifestations towards and interactions with other individuals within the community, develop reflective discussions and propose new ways of comprehending the process of climate change. Citizens, even if without links to any institution, can feed the Observatory with information on extreme climatic events and new data giving warnings about the population's health conditions, by means of the "Live Database". The intention with this database is to allow insertion and publication of georeferenced information in the formats of text, images or external links. In addition, comments on news items or research conducted under coordination from the Observatory are encouraged. The Observatory's various workshops held in different regions of the country have included participation from organizations within local and national civil society.Furthermore, the project has acted as a means of assembling researchers interested in the debate on the effects of climate change on health. Recent occurrences of extreme events, such as the torrential rainfall on the coastal mountain range of the state of Rio de Janeiro, the fluctuations in river levels in the Amazon region and the intensification of vegetation burning in the arc of deforestation, have raised awareness among researchers and citizens regarding the need for preventive action to reduce the impact of climate-related natural disasters. On the other hand, the long-term and indirect effects of climate change on health, such as expansion of the incidence of vector-borne diseases, remain little studied by researchers. This makes it difficult to bring citizens into the debate on the long-term effects of climate change and the possible measures to adapt to these changes. The results from studies under development at the sentinel sites have shown how climatic factors influence the transmission of water-borne diseases in Manaus; how atmospheric pollution associated with vegetation burning influences respiratory diseases in the states of Rondônia and Mato Grosso (Carmo, 2010); and how rainfall and temperatures affect vector-borne diseases like dengue (Lowe, 2012). These studies may promote of debate on the effects of climate change on health, and on the role of the healthcare services, within the Brazilian National Health System, in reducing these impacts.

The Global Island Database as a strategic asset for island biodiversity issues

C. Depraetere (1) ; AL. Dahl (2) ; J. Hutton (3)
(1) IRD, UMR ESPACE/DEV, Montpellier, France; (2) International Environment Forum, Geneva, Switzerland; (3) World Conservation Monitoring Centre, Cambridge, United Kingdom

The Global Island Database (GID) targets the five themes important for islands, as identified by the Convention on Biological Diversity (CBD/UNEP), namely biodiversity, climate change, invasive species, pollution and sustainability. It aims to provide a geographical and environmental strategic tool to define priority in island biodiversity issues, including assessment and protection, at a global scale. As such, it does not replace regional, national or local GIS databases but it comes in synergy with them in a macrobiological perspective. GID aims to be a GIS networking platform for international collaboration, noticeably for the Global Islands Partnership (GLISPA).

Some pioneering works were initiated in the 90ies in the scope of providing global information on islands before GIS and the WEB became available [1] [2]. The initiative of making available an online version of GID was supported by GLISPA, the UNEP/WCMC and the Italian Government during the CBD CoP9 2008 in Bonn. The first version of Global Island Database (GID) was officially announced at the UN Commission on Sustainable Development SIDS Special Day of celebrations on 10 May 2010 in New York. The further versions were updated at the initiative of the WCMC and includes specific tools for interactive functionalities to users, as for instance the GID validation tools [3]. It allows edition and validation of spatial and attribute information for any islands including those not referenced in GID. It is an example of on-line participative science whose purpose is to improve and update the spatial accuracy and associated information relating to islands or islets whatever the size.

The GID present version takes account of more than 180,000 islands including all the 116,103 islands greater than 0.06 km² from New-Guinea (783,408 km²) down to the islet of Gemini close to the shore of Elba (0.06 km²). Each island received a specific international island coding (IIC) and refers to attributes on geographical names, location, planimetry, human occupations, climatology, and topography (Table 1).

This GIS asset is not only allows the visualisation of data relevant for islands but also provides added value through contextual information, data analyses and potential biodiversity indicators for the various stakeholders requiring homogenous information for comparison purposes and prioritizing funding and actions. It is one of the tools which is urgently required to get over the present «island data gap» facing SIDS and countries with islands, as stated by macro ecologists: «We found that environmental characteristics were harder to determine for islands because they are not well represented in most global environmental data sets" [4]. It is also worth noting that the UN Under-Secretary General and UNEP Executive Director, Achim Steiner said: "High quality databases are crucial for addressing both the threats to biodiversity and economically important ecosystems. The importance of GID for island nations cannot be over stated, and is long overdue"[5].

Quantifying the changing shape of local climate

DA. Stainforth (1) ; S. Chapman, (2) ; N. Watkins, (3)
(1) London School of Economics, Grantham Research Institute, London, United Kingdom; (2) Centre for Fusion, Space and Astrophysics,, Department of physics, Warwick, United Kingdom; (3) London School of Economics, Centre for the analysis of timeseries, London, United Kingdom

Climate is intrinsically a distribution and changing climate a change in distribution. Adaptation decisions and individual's perceptions of climate change are influenced by changes in thresholds in these distributions. Different decisions are impacted by different thresholds but in most cases the relevant distributions are those experienced at local scales. To understand the impact of climate change on practical decisions requires us to quantify how local climatic distributions are changing shape. Such information also substantially affects how climate change can be communicated and made relevant.

Changes in the shape of local climatic distributions are influenced by global and large scale (synoptic) changes in the earth system but are mediated by local / meso-scale circumstances. It is not clear to what extent it is possible given current technology and model limitations, to predict such changes multiple decades in the future. However, it is now beginning to be possible to identify changes in the shape of local climate from observational timeseries in some locations. Such changes provide crucial information which can help decision makers optimise decisions for the climate of today by putting them in the context of the fine detail (geographic and distributional) information from recent decades. It also provides a baseline of climate change against which future projections can be put into context.

Here we will present such analyses showing the changing shape of European climatic distributions in terms of changing probabilities and changing decision-relevant thresholds. The process could be automated by climate services providers to generate output tailored to the needs and vulnerabilities of individuals and organisations. Challenges in the statistical interpretation of the data will be highlighted and a means of identifying robust aspects will be presented. Results will be shown from two recent papers which address local temperature distributions, and work-in-progress on changes in precipitation distributions. The analytical process can be seen as transforming direct weather observations into observations of climate change.

Outlook for Integration between some African Countries (Egypt, Libya, Sudan and South Sudan as Case Study)

EHM. Ahmed (1)
(1) Lead Author, WG III, IPCC, climate change and sustainable development, Cairo, Egypt

Often considered by developed countries to developing countries as the countries lagging behind in everything, and deal with it as representing store of natural resources, which you can get from the developed countries to their raw materials cheaply and then send to the factories to

return as producers full industrialization of the African market with densities high population to sell at very high prices, which has purchased raw materials.

In spite of the financial aid provided by the developed countries of the African countries are often consumed to feed those poor people and African countries remain waiting for food aid from rich countries, which give barely enough to eat.

In spite of the large number of economic programs and development provided by developed countries to developing countries and least developed countries, we did not find programs that seek to technology transfer, albeit a relative, so that they can African countries to adopt serious programs aimed at building an industrial base, economic and promising those countries, and did not seek the developed countries to Technology Settling in African countries, but all their quest to remain African countries representing the trunk filled with raw materials needed by developed countries as well as Africa remains the most hungry market for the purchase of products from European countries and the United States.

Therefore, the integration between African countries all or some of a director and the sanctuary of the problem, which is no way to solve it, but by African-African cooperation between the countries of the African continent, and here we are trying to shed some light on the possibility of integration between some African countries which are similar in many circumstances and can of through integration together to build an economic base is good, and I've dealt with here, the possibility of integration in the future, between Egypt and Libya, Sudan and South Sudan, as we talked about earlier attempt (1969/70-1971), to build this integration between the same countries before the secession of Sudan and the announcement of the south as an independent state, but that attempt has failed, and call on the African parties and leaders of those countries free to study the reasons for the failure of the previous attempt integration, and looking to the new leadership at these countries to try again and get rid of all the challenges and barriers to get success of the next attempt.

P-4418-02

Population Vulnerability and Adaptation to Climate Change in Large Metropolitan Areas: a Brazilian Perspective

A. Barbieri (1) ; G. Guedes (2)
(1) Universidade Federal de Minas Gerais (UFMG), Demography, Belo Horizonte, MG, Brazil; (2) Federal University of Minas Gerais, Department of Demography, Belo Horizonte, Minas Gerais, Brazil

The rapid urbanization process in Brazil and the consolidation of large metropolitan areas have created important challenges for public policies. This process has been "incomplete" in the sense that population and urban growth have occurred without the corresponding investments in urban infrastructure and reduction of poverty and inequality. These problems assume a new momentum with the potential impacts of climate changes in Brazil regarding, in particular, extreme rainy and dry seasons, health endemics (such as dengue fever and respiratory diseases), urban disasters and water scarcity. The main purpose of this paper is to discuss a pilot research project and its corresponding conceptual and methodological framework to identify and assess population vulnerability to climate change in large Brazilian cities in the next decades. This pilot project is being developed as a key activity of the Rede Clima - the Brazilian Network for Research on Global Climate Changes from the Brazilian Ministry of Science, Technology, and Innovation. The main mission of Rede Clima is to generate and disseminate knowledge about the causes, effects, and adaptation mechanisms related to climate change in Brazil and consequently inform public policies. We will discuss the key features of the pilot research which will focus on the three largest metropolitan areas of Brazil - São Paulo, Rio de Janeiro, and Belo Horizonte. The main methodological feature involves the use of a mixed methods evaluation (MME), which combines primary data collection on perceptions and attitudes of population towards potential climate impacts, as well as other primary and secondary data, which allow measuring intra-urban population vulnerability. This information will help us to assess profiles of population vulnerability at finer urban scales and develop alternative scenarios for adaptation policies in Brazil, as well as to improve tools for the dissemination of information and knowledge on adaptation to climate change to urban population and stakeholders. Finally, we will discuss how the research project will provide us a base for the creation of a monitoring system of the human dimensions of vulnerability and adaptation to climate change in the large Brazilian cities.

Observatories for Climate Change monitoring : Local vs Global approaches

M. Fargette (1) ; M. Loireau (2) ; T. Libourel (3) ; N. Ben Katra (4)
(1) IRD, UMR Espace-Dev, Montpellier cedex 5, France; (2) IRD, Umr espace-dev, Montpellier, France; (3) Université Montpellier, Umr espace-dev, Montpellier, France; (4) Observatoire du Sahara et du Sahel, Tunis, Tunisia

Introduction: Eco-sociosystems are all impacted by Climate Change. The future of humanity depends upon the adequacy of analyses related to such systems. Several views prevail, some within a local approach and others which take a more global view. These views are used in ascending or descending approaches. The aim of the article is to show a) how «local» and «global» are inseparable to preserve both the stability of the system as a whole and global equity ; b) and how the two methods should be continuously confronted to each other. We capitalize here on the conceptual expertise built during programmes aimed at the implementation of specific devices (scientific observatories for the acquisition and monitoring of socio-environmental phenomena).

System: Facing Climate Change, we will first assume a) that we consider the system emerging from «Earth-human interactions» (further on named System Earth) as an integrated (eco-socio)system, even though we are quite aware that some kind of ecosystem would further exist, regardless of climate change, while this may not be the case for mankind ; b) that System Earth is a complex system, where natural and anthropogenic processes occur ; c) that humanity (all of mankind) should aim, for a sustainable future, at maintaining a relatively steady state (holocen like) for Earth System. As a system, System Earth has a structure with biophysical and human components and a functioning, the output of which may (partly or as a whole) be considered as adequate to social expectations. More generally, this may result in the concept of sustainable services. System Earth is a whole, consisting of elements, organized altogether in some more or less connected subsystems. Climate is one of these subsystems, which in turn consists of biophysical components. In addition, human interactions with this subsystem are key-points for studies and discussions : «How and to what extent do anthropogenic processes interfere with the climate subsystem ?». The impacts of these interactions (in either ways) and relevant management measures for control / regulation represent the core problem. Hence the importance of the choice of disaggregation (choice of categories and scales*) of System Earth into subsystems and the taking into account of existing connections between these subsystems. The spatial projection of the disaggregation of System Earth should help to better assess the proposed management measures with respect to their ratio efficiency / equity in populations involved in efforts for a better management of System Earth.

Observatory: For several years, we have built expertise on long-term environmental monitoring observatories for «Desertification» (ROSELT/OSS and REPSAHEL/OSS). This leads us to define the concept of «Scientific Observatory», which relies on a rigorous and scientific approach in order to observe the dynamics of systems. Because, even in science, work is often sectorial, the challenge in such observatories is to develop interdisciplinarity so that it becomes possible to share the best definition of theoretical models (of the observed system(s)) as well as methods for observation and analysis. If the observatory is to answer the question «How and to what extent do anthropogenic processes interfere with climate subsystem ?», it has to comply with two objectives in its local observation devices: a) gather information for power the global climate model, b) gain information on the local territorial system and measure its viability, especially when management measures related to Climate Change have been incorporated. Assuming that, as regards the climate system, the theoretical model is at the global level**, one of the challenges is to translate the question of society in a scientific issue and in local models consistent, with respect

to the given holistic ontology, with the global model. Such a network of observatories should be the tool of decision support for governance at both global and local scales.

Conclusion: Let's stop trying to save the planet (it does not care) and save humanity instead. Our proposal makes a Plea for the implementation of a network of perennial observatories ; as a part of governance processes, this would provide a powerful support for decision making, both at a global and local scale.

Vulnerability Sourcebook: Integrated and participatory vulnerability assessments support adaptation planning and evaluation

C. Bollin (1)
(1) adelphi consult, climate adaptation, Berlin, Germany

Decision making on effective adaptation policies and actions depends on a sound assessment of adaptation needs and the identification of the most promising approaches. This requires information on types and extents of climate change impacts, existing vulnerability patterns, related adaptive capacities and already implemented measures. The assessment, in addition, has to be realized in a participatory manner in order to take into account all existing knowledge (technical, scientific, local experiences), allow common decision making on key factors and needs, and achieve the sensitization and political will that are later on needed for the planning, financing and implementation of adaptation activities.

A tool that has been explicitly put forward at international level for this purpose are vulnerability assessments. Due to the variety of vulnerability definitions and methodologies to assess it, German International Cooperation GIZ commissioned the development of standardized methods and tools allowing a better comparability of results across sectors and regions. The Vulnerability Sourcebook, published in 2014, is a practical guideline that can be applied to support cross-sectoral, integrated and collaborative adaptation planning across different levels, especially in the context of the National Adaptation Plan processes (NAPs). Moreover, it is conceived for the Monitoring and Evaluation of adaptation as well.

The Vulnerability Sourcebook comprises eight modules and an annex that provide practical guidance on how to conduct standardized vulnerability assessments. Its application in in Bolivia, Pakistan, Burundi and Mozambique demonstrated that it can make a valuable contribution to collaborative and integrated adaptation planning and the M&E of adaptation. It combines outcome- and process-oriented perspectives and provides very detailed decision support.

The presentation will outline the tool itself and describe the results of the various application experiences, which concern national level as well as decentralized and community-based processes. The presentation will then stress how the different results have been used for concrete adaptation planning and implementation. These experiences serve also to discuss the different perspectives of various stakeholders and the demand-side aspects on decision support in climate adaptation.

P-4418-05

Ethno-malacology in mangrove ecosystems: integrating local and scientific knowledge to assess socio-ecological variability and coastal change

A. Burgos (1) ; M. Despinoy, (2) ; C. Sabinot, (2)
(1) Muséum National d'Histoire Naturelle, «hommes, natures, sociétés» umr 7206 ecoanthropologie et ethnobiologie, Paris, France; (2) IRD, Umr 228 " espace pour le développement", Nouméa, New Caledonia

Ecosystems and societies face major emerging challenges as climate change and ecological services degradation. Nowadays, linking local knowledge and global science in multi-scale assessments is at the heart of international debates. Although, ecological monitoring approaches to assess coastal change have improved considerably during the last decade, many projects still fail at incorporating local knowledge on the conception of the master plan and the analysis of the collected data. Participatory monitoring methods and assessments protocols of coastal change, especially relative to climate change, are generally based on informing the local community what to observe and how to do it, rather than understanding their own perception of ecosystem change and integrating it to the analysis. For providing a strong interface between science-policy-society on climate change issues, these local perceptions and actions for adaptation cannot be overlooked. There is a real need to develop an in-depth reflection on local knowledge and know-how and on interdisciplinary methods to integrate them in the pool of data information for decision-making.

In the search for indicators to monitor and assess coastal change while combining local and scientific knowledge, mollusks appear to be particularly interesting for setting a constructive and interactive dialogue between scientists and local villagers. In the one hand, the cumulative and complex bodies of knowledge of shellfish gathers include accurate knowledge of mollusks diversity, habitat and distribution, as well as, detail knowledge on marine environment characteristics and coastal socio-ecological change. In the other hand, for scientists, mollusks are considered to be performant indicators of ecosystem quality and physico-chemical change. Furthermore, their ubiquitous nature and broad distribution make mollusks particularly suitable for geographical large scale surveys.

Shell harvesting was found to be an important subsistence activity in Indonesia and Papua New Guinea. Though, shellfish might be considered to be of secondary importance in the overall diet of coastal societies, it plays a crucial role supplying proteins when faced with environmental fluctuation and seasonal inequalities. In the current context of global and rapid coastal change, shell gatherers can provide thus valuable views, knowledge and observations related to the dynamics of mollusks assemblages and population change within highly sensitive and productive ecosystems as mangroves are coral reefs.

By combining anthropological, geographical (human geography and remote sensing) and ecological approaches, the aim of this communication is 1) to describe the development of ethno-malacological research - considering ecological, cultural and scientific representations - in two different contexts, 2) to examine the applicability of local knowledge in climate and coastal change monitoring and assessment, and 3) to propose participatory ethno-ecological methods and criteria for enhancing local participation in coastal and climate change assessment. Our presentation will be based on research program and fieldworks that are at different steps of realization in Asia and Oceania and will present potential sites for undertaking further comparative research.

P-4418-06

The IRI Data Library: Decision-Making Tool for Climate and Health

P. Ceccato (1) ; M. Thomson (1) ; B. Blumenthal (1) ; T. Dinku (1) ; M. Bell (1) ; J. Del Corral (1)
(1) The International Research Institute for Climate and Society, Palisades, NY, United States of America

Public health professionals are increasingly concerned about the potential impact of climate variability and change on health outcomes. Protecting public health from climate requires new working relationships between the public health sector and the providers of climate data and information. The Climate Information for Public Health Action initiative at the International Research Institute for Climate and Society (IRI) is designed to increase the public health community's capacity to understand, use and demand appropriate climate data and climate information to mitigate the public health impacts of the climate. Significant challenges to building the capacity of health professionals to use climate information in research and decision-making include the difficulties experienced by many in accessing relevant and timely quality controlled data and information in formats that can be readily incorporated into specific analysis with other data sources. We present here the capacities of the IRI climate and

health map room and show how we have used it to build an integrated knowledge system in the support of the use of climate and environmental information in climate-sensitive decision-making with respect to vector-borne diseases.

P-4418-07

The application of multi-criteria decision analysis in exploring the co-benefits of climate mitigation technologies and scenarios

B. Cohen (1)
(1) University of Cape Town, Energy Research Centre, Rondebosch, South Africa

The MAPS Programme (www.mapsprogramme.org) supports developing countries in long term planning to reduce greenhouse gas emissions. The Programme combines an extensive stakeholder consultation process with deep quantitative research to provide defensible results that have buy-in from a wide range of stakeholders. These results are then used for long-term greenhouse mitigation planning and policy setting. The Programme is currently active in Peru, Brazil, Colombia and Chile, with preliminary planning activities already having been conducted in a number of African countries.

What has become evident through the projects already implemented in Latin America, as well as ongoing related work in India, is that mitigation planning cannot be conducted in isolation of the consideration to trade-offs related to co-benefits for and negative impacts of mitigation actions on society and the environment. Such co-benefits and impacts include those relating to poverty alleviation, human health, water demand, employment and air quality. In some countries, such as India, the co-benefits concept is inverted, with the salient issue being the mitigation co-benefits of development actions, leading to a formulation of "multiple objectives". However conceptualized, however, there is limited knowledge and experience in how broader development considerations can be incorporated into mitigation planning or vice versa. A particular challenge is the long time horizons that need to be considered in this context, as well as giving due weighting to the multiple developmental challenges facing the target countries.

The discipline of multi-criteria decision analysis (MCDA) has developed a wide range of tools and methodologies that are well suited to problems that require concurrent consideration of a range of impacts. These include tools that allow for identification of a suitable set of criteria for measuring impacts, quantifying performance of alternatives which do not have natural measurement scales, and for exploring trade-offs in situations with multiple decision makers and sometimes conflicting priorities.

This paper provides a taxonomy of the types of problems and challenges in the climate mitigation space that may be approached using MCDA. These include assessing the co-benefits of individual mitigation options, combining of mitigation options into scenarios, and interpreting the results of modeling of following particular emission trajectories. It then goes on to describe the key components that underpin analysis of problems using an MCDA framework, which fall broadly into the areas of problem structuring and problem analysis. The paper will then highlight two examples of the key errors that are often made in co-benefits analysis – notably use of rating scales and weighting, using relevant examples. Finally, the key limitations of MCDA will be described – notably the time required to conduct a proper engagement exercise and the complexity of the analysis (and hence challenges with communication of results).

Acknowledgements:

This work has been conducted under the MAPS Programme (www.mapsprogramme.org) with funding for Children's Investment Fund Foundation (www.ciff.org). Some of the thinking that underpins this work was developed during a 3 day workshop on the use of MCDA in co-benefits analysis and hence was informed by participants at this workshop. Individuals who participated were: Hernan Blanco, Navroz Dubash, Matthias Ehrgott, Jose Rui Figueira, Marta Torres-Gunfaus, Radhika Kosla, Francisco Molina, Ana María Rojas Méndez, Britta Rennkamp, Serban Scrieciu, Ashok Sreenivas, Theodor Stewart, Tanya Visser and Harald Winkler

Foreseeing the evolution of the expertise on climate: some thoughts from the French Association on Disaster Risk Reduction

M. Deves (1) ; M. Lang (2) ; PH. Bourrelier (3)
(1) Sciences Po Paris & Institut de Physique du Globe de Paris – Sorbonne Paris Cité, Scientific committee of the french association on disaster risk reduction (afpcn), Paris, France; (2) IRSTEA, Scientific committee of the french association on disaster risk reduction (afpcn), Lyon, France; (3) AFPCN, Scientific committee of the french association on disaster risk reduction, Paris, France

The French Association for Disaster Risk Reduction (AFPCN), formerly the French Committee for the International Decade for Natural Disaster Risk Reduction (UN-IDNDR), is a multidisciplinary platform that aims to strengthen the coherency of public policies on disaster risk reduction. One of AFPCN working groups focuses on the risks associated with climate change. At the occasion of the release of the fifth IPCC report, the group re-examined the organisation of IPCC expertise and brainstormed on how it could evolve in the future. This thinking process was based on a review of the existing academic literature and on interviews undertaken with top climate scientists (with the support of the French Academy of Science, IPSL, LEGOS or CEA) and the IPCC focal point (former and actual) in France. A preliminary report was written, sent off to the public authorities and disseminated to the wider public at the occasion of a study day on July, 9th 2014. Since then, the team has continued to follow up on AR5 results and several study days are scheduled in 2015, aimed at further discussing, enlarging and strengthening its views.

In this contribution, we propose to communicate the results of this integrative thinking process with the willing of nourishing the science-policy dialogue on what could be a more efficient articulation between research, expertise and decision regarding to climatic issues. IPCC is a unique experience: first, because of its international dimension; second, because it occupies a specific position at the crossroad between science and policy. Evaluating the advantages and the limits of its organisation is key to foresee the evolution of the climatic expertise in the future.

Our analysis focuses on the difficulty to transfer the disparate knowledge of fundamental research, which is organised in specialised disciplines, to build a coherent expert narrative. Today, each of the three working groups of IPCC has a relatively wide field of knowledge to cover and build on a variety of research communities from atmospheric to solid earth sciences, from socio-economy to political science. Each discipline is confronted to different constraints in terms of observational, modelling or conceptual thinking – differences that are not anecdotic but are heritages of different cultural scientific background as well as of the complexity of the real world. The question is whether and how these differences can be accounted for while building a relevant expert narrative. We propose to explore three key steps: 1) the articulation of the working groups, 2) the treatment and communication of uncertainty, 3) the process of successive summarization done from the report to the technical summaries to the Summary for Policy Makers. On that basis we propose leads for amelioration and adaptation for compliance to the needs of the new agreement that is emerging from Copenhagen, Cancun, Lima and will be adopted in Paris.

As we are particularly interested in public policies on adaptation and mitigation, we tend to suggest bigger changes than the ones adopted by IPCC last February. The idea of transferring the expertise on impacts from WGII to WGI seems particularly relevant to us. Additionally, we would suggest developing more works combining adaptation and mitigation. The trend that has led IPCC to produce ever-bigger reports corresponds to a somewhat inductive view of science. In addition to a large expertise on climate change, it would be important to allow for more focussed works to be undertaken at a variety of scales, involving a greater variety of scientific disciplines and with the contributions from a greater variety of stakeholders (notably the civil society). Workshops and seminars could be organised at the level of the United Nation that could help identifying the research questions to be covered up

in order to answer to the future expertise needs. The scale at which climatic risks, adaptation and mitigation solutions can be thought together in an applicable manner is the scale at which decisions can be taken and applied. Working at a well-thought scale on well-designed questions, and with relevant groups of stakeholders, could allow approaching the challenges associated by climate change in a more readable manner. On the side of public policies, it also seems important to explicit more clearly the interplay between science and policy while going from the large expert reports to the short SPMs.

Towards a scalable architecture for climate adaptation services: illustration of challenges through future coastal flooding assessments

F. Dupros (1) ; A. Tellez-Arenas (1) ; G. Le Cozannet (1) ; R. Quique (1) ; F. Paris (1) ; F. Boulahya (1) ; S. Leroy (1) ; F. Robida (1)

(1) BRGM, Orléans, France

As climate is changing, more applied information on its impacts is required to inform adaptation planning. It is a fact that during the last decade, the amount of information relevant for climate change impact assessment has grown drastically. This can be particularly illustrated in coastal areas, where a most important recent development has been the delivery of precise and accurate topography obtained by LiDAR at regional to national scales. However, these developments have not led to easier assessment of coastal climate change impacts. This is due to (1) the complexity of coastal models that also depend on local natural changes and anthropogenic actions and (2) the difficulty to actually use such large and complex datasets. This raises the following questions: can such complex and heterogeneous datasets be used for an efficient communication of future flooding affected by sea-level rise and climate change? How to communicate the related uncertainties? What infrastructure is needed to support the development of such services?

One of the major challenges in the design of this class of information system is to tackle both the volume and the heterogeneity of the data required to build relevant climate services. Contributions from wingspan projects (Copernicus, EarthCube, EPOS), have demonstrated the feasibility of such architecture. The scalability of the components lying at the heart of these global systems is therefore critical in order to handle large data sets, to integrate complex coastal models and also to deliver near real-time quantitative flooding scenarios. We will therefore discuss several issues related to data architecture at large scale, on-the-fly (geo)-processing capabilities, management of asynchronous workflows and data diffusion strategies in the context of international standards such as INSPIRE (Infrastructure for Spatial Information in Europe).

We finally describe a prototype of web service to quickly communicate spatial information on future flooding along the French coastal zones that takes into account the related uncertainties. We believe that our flexible architecture, mainly reusing off-the-shelf components is able to improve both complex scenarios analysis for experts and dissemination of these future coastal changes to the general public.

P-4418-10

Science-policy interfaces for climate change adaptation in Vietnam: A Case Study of Quy Nhon City

J. Ghimire (1)

(1) University of Hawaii at Manoa, Department of Urban and Regional Planning, Honolulu, Hawaii, United States of America

Climate science has improved more than ever in the human history. With continuous research at national and international levels, more accurate knowledge of climate change – scenarios, models, data and case studies – is being produced. This body of knowledge has crucial role to resolve challenges raised by climate change – sea level rise, severe weather events, extreme temperature, etc. – through mitigation and adaptation measures in policies and plans. But in reality, it is almost impossible to reach on common consensus on use of these scientific knowledge in policy process because the policy choices are so context dependent (Prewitt, Schwandt, & Straf, 2012). Therefore, the role of climate science research is not straightforward on addressing challenges of climate change in plans and policies. In case of climate change adaptation, the use of this knowledge is even more complex because adaptation bears more pragmatic and immediate values than mitigation in the policy processes. But it is quite pressing to improve interfaces between science and policy to effectively adapt with current and future problems posed by climate change; especially among rapidly developing countries where the urbanization and economic growth is surmount. There is very little research exploring science-policy interfaces for effective climate change adaptation in plans and policies in the context of developing countries. This research tries to address this gap using case study of Quy Nhon city of Central Vietnam; where almost all effects of climate change – sea level rise, temperature change, change in precipitation, drought events – are predicted. Studies have shown that Vietnam is 5th most exposed nation to the impacts of climate change where 7 – 12 typhoons make landfall annually. It is also one of the most rapidly transforming countries – economically and socially – in Asia. It has strong institutional and bureaucratic set up for policy formation and implementation as well as for scientific research of climate change. Using more than 30 interviews at Central and at Provincial level among policy makers, climate scientists, policy implementing agencies, and local political as well as community representatives; this research attempts to identify a pragmatic approach of science-policy interface for climate change adaptation. Major contribution of this research is methodological – to propose an appropriate approach of better interaction between scientific researches and policy processes to adapt with climate change among vulnerable communities in developing nations; where the formal mechanism of policy implementation are not adequate.

P-4418-11

Sharing skills and needs between providers and users of climate information to enable decision making based on science: lessons from the Northern Adriatic case study

V. Giannini (1) ; A. Bellucci, (2) ; S. Torresan (3) ; S. Caparelli, (4)

(1) Centro Euro-Mediterraneo sui Cambiamenti Climatici, Venezia, Italy; (2) Centro Euro-Mediterraneo sui Cambiamenti Climatici, Bologna, Italy; (3) Centro Euro-Mediterraneo sui Cambiamenti Climatici, Venice, Italy; (4) Comune di Venezia, U.o.c. sostenibilità urbana, Venice, Italy

The growing evidence in support of an anthropogenic influence on Earth's climate, and the need to cope with the expected impacts of climate change on socio-ecological systems call for a closer dialogue between climate scientists, and the large community of climate information users.

The research described here is focused on an interactive process designed to bridge the gap between climate information providers (i.e. climate scientists) and climate information users (i.e. decision makers belonging to public institutions). Bridging this gap means designing a two-way communication, so that mutual learning occurs. Main objective of this research is to analyse the need of climate information for the integrated assessment of climate change impacts on the coastal zone of the Northern Adriatic Sea. The Northern Adriatic coastal zone is considered to be particularly vulnerable to several climate-related phenomena, including, among others, heavy rainfall events, pluvial flood, sea-level rise, causing potentially high damages to coastal eco-systems and urban areas (e.g., acqua alta in the Venice Lagoon). The work reported in this article (conducted within the framework of the EU-funded CLIM-RUN project) focuses on the set up of a participatory process designed to understand end-users' needs, engaging representatives from both the scientific and local stakeholders communities. The process was facilitated by the Centro Euro-Mediterraneo sui Cambiamenti Climatici (CMCC) acting as a "boundary organization".

End-users of climate information were selected among representatives of those public institutions having a

specific mandate for Integrated Coastal Zone Management (ICZM). End-users' involvement and discussion allowed, since the preliminary phases of the iterative process, to identify which were the end-users' needs: (1) data to support land-use planning, (2) data with greater resolution and longer time series, (3) data on climate impacts and risks, (4) precipitation patterns to improve irrigation, (5) sea level rise and tides to plan ahead both agriculture and Venice defences, (6) climate variations and extreme events, (7) seasonal trend for tidal waves, and (8) hydraulic risk. End-users selected extreme events as the most important climate variables needed, because they are necessary for the development of flood early warning systems, for urban planning, and for Integrated Coastal Zone Management. Based on all needs expressed climate variables were listed in a table and climate products were designed.

Three climate products addressing some of the highest priority needs identified by local end-users were selected. Specifically, climate experts decided to focus on 1) short-term (2020-205) projections of sea-level rise; 2) seasonal predictions of extreme rainfall events; 3) long-term regional projections of climate extremes (including heat waves, dry spells and heavy rainfall events). Additionally, two risk products were developed: 4) Sea level rise inundation risk maps for the low-lying coastal areas of Veneto and Friuli-Venezia Giulia regions; and 5) Pluvial flood risk maps for the urban territory of the municipality of Venice.

We can conclude that the dialogue between end-users and climate scientists is still at an early stage, and there are objective difficulties in clearly identifying a common ground where scientifically robust climate information can be effectively translated into a usable product by the end-users community. However, more than lack of information the problem seems to be, nowadays, lack of integration of climate information into the decision making process.

Transforming Science: The Process and Performance of Scientific Synthesis

EJ. Hackett, (1) ; J. Parker, (2) ; SR. Hespanha, (3) ; E. Cardenas, (1) ; A. Dorr, (1) ; S. Hampton, (4) ; E. Leahey, (5) ; C. Mcclain, (6) ; I. Rafols, (7) ; L. Sheble, (8) ; T. Vision, (9)

(1) Arizona State University, Shesc, Tempe, United States of America; (2) Arizona State University, Barrett honors college, Tempe, United States of America; (3) University of California, Santa Barbara, Nceas, Santa Barbara, United States of America; (4) Washington State University, Pullman, United States of America; (5) University of Arizona, Sociology, Tucson, United States of America; (6) NESCENT, Nescent, Durham, United States of America; (7) Polytechnic University of Valencia, Valencia, Spain; (8) University of North Carolina, Chapel Hill, United States of America; (9) University of North Carolina, Biology, Chapel Hill, United States of America

Transforming science is a term meant to be understood in two senses. In one sense it means changing the way science is organized and done; in another sense it means producing science that may transform what we know and can do. Achieving transformative solutions to sustainability challenges will require transforming science in both senses of the term: we will need new forms of scientific knowledge and inquiry, and will need scientists to organize and collaborate in new ways to produce such knowledge. Synthesis centers offer promising possibilities for transformations of both sorts, achieved through intense and focused collaboration across academic fields and across the sectors of science and public policy. This talk describes the inner workings of two organizations that promote scientific synthesis, analyzing their structures and consequent patterns of interaction to understand why they work well and to draw lessons for the design and operation of other such centers. To do so we measure collaborative process in new ways - using sociometric sensors - and analyze substantive output using a topic models of publications from synthesis centers and a reference corpus of articles from cognate fields. We summarize our findings in a model of intellectual fusion that captures the principal dynamics of the process.

P-4418-13

Towards more consistent assessments of country-level impacts of climate change

L. Horrocks (1) ; G. Wilkins (1) ; S. Winne (1) ; J. Lowe (2) ; H. Mcgray (3) ; J. Cook (4)

(1) Ricardo-AEA, Adaptation and climate resilience, Didcot, Oxfordshire, United Kingdom; (2) Met Office Hadley Centre, Climate knowledge integration, Exeter, United Kingdom; (3) World Resources Institute, Vulnerability & adaptation initiative, Washington DC, United States of America; (4) UK Department of Energy and Climate Change, Climate science and international, London, United Kingdom

Vulnerability and impacts assessments contribute evidence to shape and support action to tackle climate change at various levels. However, there is currently no international process for presenting information about climate impacts consistently at the national level. The lack of consistency means it is hard to compare results from different assessments and different countries, and it can be challenging to attempt a synthesis at the country level, given absences of common approaches, preferred timescales, descriptions of sectors, etc. International cooperation on cross-border impacts can be especially challenging when assessments in different countries lack consistency or transparency in respect of assumptions and methods.

The level of ambition for national assessments is constrained by multiple factors within countries, including research budgets, technical capacity, data availability at appropriate spatial and temporal scales, political priorities, and uncertainty over best practice methods. Approaches to country-level climate impacts, vulnerability and risk assessments span a spectrum including top-down modelling of impacts in sectors, expert synthesis, and bottom-up stakeholder-led risk aggregation and prioritisation. Even within individual countries, preferred approaches for national assessments have evolved over time.

Previous studies have shown that greater consistency in the assessment and communication of climate impacts and vulnerabilities at a country level is both possible and desirable. The UNEP-UK Country level impacts of climate change (CLICC) project is now addressing this. It is facilitating the co-creation of a common process with a range of countries to enable them to present their own climate change impacts and risks in a more standardised way. The CLICC initiative aims to establish a long-term process supported and coordinated at the international level, rather than simply to deliver a one-off suite of information products.

Participating countries represent a range of economic development and geographies. Some of the benefits identified by countries during consultations include: (1) more effective information-sharing on climate impacts, leading to enhanced collaborative research and action, especially in relation to trans-boundary impacts; (2) expansion of common capabilities in scientific assessment and building capacity of national systems for climate assessment; (3) generation of good practice and collective learning, through improved transparency around methods, assumptions, data sources and limitations in assessing impacts; (4) consolidation of existing studies and findings within countries, also contributing to a more detailed picture of the global risks from climate change; (5) country-led contributions to the evidence base for provision of support to countries lacking in technical or financial capacity, or approaching their limits of adaptation.

This conference presentation will provide an overview of the achievements of the CLICC project so far, including the results of consultation with more than 30 countries. It will explain the principles that CLICC has established to engage successfully with the needs of multiple countries addressing multiple impacts in distinctive contexts. These include:

- Maintaining country control over content and communication of their impacts information
- Maximising inclusivity regardless of countries' current capacities
- Minimising the burden and avoiding parallel institutions or obligations
- Promoting good practice, enabling quality control and signposting research needs

CLICC has considered both qualitative and quantitative formats to achieve greater consistency in the communication of results, and the importance of metadata has been underlined. We will present the CLICC options

currently in development, showing how they fit with other common approaches and requirements on countries. We will explain how the outcomes from CLICC support better decision-making at national and international levels. Finally, we will foster discussion around CLICC's longer-term aspirations, exploring how the sustainability of this initiative may be achieved through international support and coordination, leading up to COP21 negotiations and beyond.

P-4418-14

Multi-model, multi-method, information for decision making

C. Jack (1)
(1) University of Cape Town, Environmental and Geographical Science, Cape Town, South Africa

Despite continual advances in our understanding of the climate system and climate change, continual increases in complexity of earth system models, and continual developments in both dynamical and statistical downscaling methods, decision makers continue to be presented with a diversity of contradicting and often highly uncertain information regarding potential changes in climate with respect to their decision context. Added to this is the increasing complexity of the information needs of decision makers as they consider a range of time scales, spatial scales, and complex system interactions in their day to day and long term strategic decision making. Urban centers, particularly in developing nations face severe resource constraints, and yet stand out at key points of risk and vulnerability under future climate due to rapid urbanisation, pressure of natural resources, and critical limitations on governance and administration.

It is therefore crtiical that the most robust and, critically, defensible, information is available to decision makers and that this information is made available that facilitate co-production of knowlege, rather than just supply of knowledge. This is a significant challenge. This paper presents some initial work being done at the University of Cape Town, South Africa. The focus drawing out defensible scale and context appropriate information from a diversity of global climate models (CMIP5), regional dynamical downscaling (CORDEX) and regional statistical downscaling (CORDEX-ESD). The method presented allows for rapid and continual exploration of the diversity of information and so facilitates co-production. The approach allows for the specification of certain characteristics of the information required (variables, and multi-variate characteristcs, spatial scales, temporal scales and time horizons, etc.) and uses these requirements to interrogate the diversity of source data and signals in such a way as to extract the most defensible messages.

It is explicitely acknkowleged that the resultant messages may still contain contradicitons, and that some levels of uncertainty due to natural variability or model inadquecy is irruducible given the available data.

P-4418-15

Climate induced environmental domain change: informing conservation decision making in KwaZulu-Natal, South Africa

D. Jewitt (1)
(1) University of the Witwatersrand, School of Animal, Plant and Environmental Sciences, Johannesburg, South Africa

Climate change is having marked influences on species range distributions, ecosystem composition and phenology. This raises questions as to the effectiveness of current conservation strategies and conservation planning, the central tenets of which are representivity and persistence of species. Conservation planning is currently based on static spatial plans which do not adequately account for dynamic threats such as climate change and thus cannot ensure the persistence of species. KwaZulu-Natal, a province occurring on the eastern seaboard of South Africa, occurs in one of the biodiversity hotspots of the world. This high diversity and the paucity of species specific information make it impracticable to develop individual climate adaptation responses for all species. We propose a method to incorporate climate-dynamic environmental domains into conservation strategies. The environmental domains are identified using specific environmental correlates of floristic composition in the province, which were temperature, soil base status and precipitation variables. The environmental domains represent the metaphorical stage of the province whilst recognising that species constituting the diversity may change through time. This offers an approach to conserve diversity under current and future climates. Current domain locations were mapped by identifying their positions in a multi-dimensional environmental space using a non-hierarchical, iterative k-means clustering algorithm. Their future locations were explored using an ensemble of six different dynamically downscaled Coupled Global Climate Models based on the A2 emission scenario. The HadCM2 and GFDL2.1 models represented the extreme ranges of the models. Domains occurring in savanna biomes increase at the expense of domains occurring in the grassland biomes. This has significant negative consequences for the species rich grasslands. Euclidean distances were used to determine the magnitude of change in each environmental domain. The magnitude of change models identify areas of greatest and least stability for each future climate projection, and represent areas of changed climatic conditions or edaphic disjunctions. Species with specific soil requirements may not be able to track changing climatic conditions. Using the identified environmental domain and magnitude of change maps, a vulnerability framework was developed to inform appropriate conservation actions to mitigate climate change impacts on biodiversity. The framework incorporated climatic stability and habitat loss which is another major global change factor in the province. The mean magnitude of change expected in each domain formed the third dimension of the framework which indicates the potential velocity of change in each domain. The study explicitly links floristic pattern and climate variability and provides useful insights to facilitate conservation decision making for climate change.

P-4418-16

Building a Climate Information Platform for Europe

M. Juckes (1) ; R. Swart (2) ; P. Thysse, (3) ; DCW. Som (4) ; A. Groot, (2) ; V. Bennett, (1) ; L. Costa, (5) ; L. Bärring, (6) ; J. Lückenkötter, (7) ; S. Callaghan, (1)
(1) STFC, RalSpace, Chilton, United Kingdom; (2) Alterra, ESS-CALM, Wageningen, Netherlands; (3) MARIS, Voorburg, Netherlands; (4) KNMI, De Bilt, Netherlands; (5) PIK, Potsdam, Germany; (6) SMHI, Norrköping, Sweden; (7) TU Dortmund University, Faculty of Spatial Planning, Dortmund, Germany

In association with the new European space programme (Copernicus), the European Commission is promoting the development of a climate information platform which should supply comprehensive, reliable and consistent information for stakeholders.

The FP7 project "Climate Information Portal for Copernicus" (CLIPC) is developing a demonstration portal for the Copernicus Climate Change Service (C3S). This project is one of a suite of FP7 research activities which are administratively independent of Copernicus, focussed on creating the technical and scientific building blocks needed for the service. There are dozens, if not hundreds, of climate portals already offering a variety of products to a confused user community. It would be unwise to seek to replace all this creative activity with a single portal - instead CLIPC is designing a portal to make distributed resources more accessible through flexible discovery systems. CLIPC needs to deliver more than a directory of resources: resources need to be presented in common protocols so that users can access multiple datasets.

More information about the project objectives is available at www.clipc.eu. The gulf between the climate science communities and the end user communities is a central challenge being addressed in the project. It is important to understand that there is significant diversity and multiple communication barriers within these two sets of communities as well as between them. The CLIPC services must presentation will provide a review of progress towards this ambitious goal, through a discussion of user requirements activities, an overview of the proposed architecture, work on assessing and adjusting model biasses, and a discussion of the climate impact indicators which will be provided through the portal. When looking at the usability of data for the various users, CLIPC will implement a set of services functioning as a "knowledge base" supplying information to users about the data, including definitions of terminology used, quality of datasets, versioning, and user annotations.

P-4418-17

Cooperation on climate change under economic linkages - How the inclusion of macroeconomic effects affects stability of a global climate coalition

J. Kersting (1) ; M. Weitzel (2) ; V. Duscha (1)
(1) Fraunhofer Institute for Systems and Innovation Research, Karlsruhe, Germany; (2) National Center for Atmospheric Research, Boulder, CO, United States of America

Game-theoretic models of international cooperation on climate change come to very different results regarding the stability of the grand coalition of all countries, depending on the stability concept used. In particular, the core stability concept produces an encouraging result that does not seem to be supported by reality. However, current implementations of this model are based on the assumption that a country's consumption loss due to emission abatement measures only depends on the country's domestic emissions. This approach neglects international macroeconomic effects of emission reduction measures, such as technology spillovers or changes in fossil fuel prices. We extend the game-theoretic model based on the core stability concept by introducing these effects into the model. The computable general equilibrium model DART and damage functions from the RICE model are used to quantify the theoretical model. Contrary to the classical model, we find that the core of the resulting cooperative game is empty and no stable global agreement exists. This is mainly due to fossil fuel exporting countries, which are negatively affected by lower fossil fuel prices resulting from global emission reduction measures. Also, other countries do not have a sufficient incentive to compensate fossil fuel exporters for their participation in a global agreement, because the gains of further cooperation are small. We also find that, if damages from climate change are assumed to be high, countries with comparatively low projected damages are a hindrance to global cooperation. Our results point to two alternative ways forward in the climate negotiations. The first option calls for a «coalition of the willing» to compensate blocking countries, mainly fossil fuel exporters, for participation in a global agreement. As we found that no stable global agreement exists, such compensation would not be rational, if the decision is based purely on a benefit-cost analysis of GHG abatement. However, if other arguments such as fairness principles are taken into account, the necessary compensation might be justifiable. The second option calls for the «coalition of the willing» to abandon the UNFCCC process and to try to consummate an agreement among this coalition. This option could come close to the environmental effectiveness of the grand coalition.

P-4418-18

Development of an interactive, multi-objective decision support system in South Africa

T. Lane-Visser (1)
(1) Energy Research Centre, Cape Town, South Africa

Climate change, and the decisions to be made regarding the management thereof, is inherently complex and multi-faceted. However, in the complex world we live in, it is but one of many complexities - there are many other essential systems and pivotal issues with which it interacts. Going forward, decisions will not be based on the traditional decision criterion of cost alone, nor should it be based on a single criterion (which ignores the knock-on impacts of a decision in terms of other criteria). To be defensible and responsible, decision makers need to be cognisant of the full extent of their decision's impacts before making a final decision. Myopic decision support systems often, inadvertently, do more harm than good in the long run. Multi-objective decision support has been developed to try and overcome this problem.

Generally, a country's energy generation and consumption is a key driver of its greenhouse gas emissions. The TIMES model generator, a widely used country-wide energy planning tool, was developed as part of the IEA Energy Technology Systems Analysis Program, an international community which uses long term energy scenarios to conduct in-depth energy and environmental analyses. The TIMES model generator combines two different, but complementary, systematic approaches to modelling energy: a technical engineering approach and an economic approach. It is a technology rich, bottom-up model generator, which uses linear-programming to produce a least-cost energy system, optimised according to a number of user constraints, over medium to long-term time horizons. In a nutshell, TIMES is used for the exploration of possible energy futures based on contrasted scenarios. The model makes equipment investment decisions and operating, primary energy supply, and energy trade decisions, by region. This outputs an optimal mix of technologies and fuels at each period, together with the associated emissions to meet the demand. The model uses scenarios to do what if analysis, and does not optimise for anything other than costs.

The first part of this presentation chronicles the conversion of SATIM, a South African calibrated version of TIMES, from a cost only to a bi-objective (initially) and multi-objective (ultimately) optimisation model. The practicalities of such a conversion, along with the obstacles encountered and ways to surmount said obstacles, are discussed. This conversion was part of a MAPS South Africa initiative to create a multi-objective energy sector planning model for South Africa. The benefit of having such a model is the ability to study trade-offs and to provide more rich data for decision makers. The second part of the presentation will demonstrate and elaborate on the enrichment of data outputs thanks to the expanded model.

The end goal of this modelling work is to convert the South African linked energy and economic model (a combination of SATIM and a South African economic (CGE) model) into a multi-objective optimisation framework. Adding the economic framework opens the scope for a wealth of economic and social considerations to be included in the objectives, broadening the reach of the model in terms of decision support and stakeholder representation. Further to this, true multi-objective decision support cannot happen in isolation from decision makers, who have insight into the problem and are able to specify preference information related to the objectives considered and the different solution alternatives. It is, thus, proposed to incorporate interactive modelling techniques in the model formulation. Interactive modelling is a constructive process where, while learning, the decision maker is building a conviction of what is possible and confronting this knowledge with his or her preferences, which are also evolving. The presentation will conclude with an overview of the proposed methodology for the development and implementation of such a large scale, complex model. Ideally, advice and constructive feedback on this proposed plan will be elicited during or after this presentation.

P-4418-19

Communicating uncertainties of future coastal impacts for decision making

G. Le Cozannet (1) ; J. Rohmer (2) ; A. Cazenave (3) ; D. Idier (4) ; F. Lavigne (5) ; C. Oliveros (2)
(1) BRGM / CNRS, BRGM-DRP-R3C / CNRS-LGP (UMR-8591), Orleans, France; (2) BRGM, Orleans, France; (3) CNRS-CNES, Laboratoire d'études en géophysique et océanographie spatiales, Toulouse, France; (4) BRGM, Orléans, France; (5) LGP, Orleans, France

As sea-level rises, coastal hazards and risks such as extreme flooding or erosion are changing. For accurate assessments, several factors must be considered, such as the variability of sea-level rise and storm surge patterns. We proceed to a global sensitivity analysis of future coastal impacts of sea-level rise, in order to provide quantitative insight into the relative importance of contributing uncertainties over the coming decades. The method is applied for typical coastal settings of high- and low-energy coasts. Storm surge propagation processes, then sea-level variability, and, later, global sea-level rise scenarios become successively important source of uncertainties over the 21st century. This defines research priorities that depend on the target period of interest. On the long term, scenarios RCP 6.0 and 8.0 challenge local capacities of adaptation for the considered sites. For decision makers concerned with adaptation to climate change in coastal areas, this approach provides quantitative insight into three key issues related to: (1) the timeliness of coastal adaptation planning (2) the identification of periods by which rising sea-levels cause rapid obsolescence of regular adaptation measures (3) the constraints imposed by different future climate change scenarios for long-term adaptation planning.

P-4418-20

Climate services for adaptation to climate change in a developing country: case studies from South Africa and Burkina Faso

M. Lugen (1)
(1) Université Libre de Bruxelles, Centre d'études du développement durable (cedd), Brussels, Belgium

Background and objectives: Adaptation to climate change (CC) is an issue growing rapidly, one reason being the observation and projection of negative impacts highly challenging human societies and ecosystems. Amongst barriers to adaptation, the lack of useful and understandable climate information is regularly emphasized. Many initiatives to implement climate services have emerged in recent years to respond to this need, especially in developing countries. According to the World Meteorological Organization, climate services aim to « provide climate information in a way that assists decision making by individuals and organizations ». My PhD project has a multidisciplinary nature and aims to understand whether, and if so in what ways, climate services may represent a first step towards the development of adaptation strategies at the local level. This research is based on a bottom-up approach, and has for main hypothesis that using climate services for the development of adaptation strategies requires to meet certain criteria (as relevance, access, legitimacy, equity, integration) associated with a participatory approach for the construction of information, taking into account contextual aspects of vulnerability to CC. More specifically, the focus is on the interactions between climate services providers, users and final beneficiaries for one part; and the communication tools used to broadcast the information for the other part. I pursue this way the goal to analyze the degree of consistency between the "supply" and "demand" in terms of climate information, both for content and communication structures, and therefore understand whether CS can be a first step towards adaptation to CC. This may serve to formulate recommendations or alternatives in order to improve the reconciliation between the bottom and the top on that matter.

Methods: The methodology (that will be described in more details in the poster) will be applied to two case studies. The first one is South Africa (1), in the province of Western Cap, where a multidisciplinary research center at the University of Cap Town acts as climate service and collaborates with public local stakeholders. The second one is Burkina Faso (2), where two climate services projects are currently being implemented targetting adaptation in rural communities. Both countries present a high degree of vulnerability to climate change, although different internal contexts influence the distribution of adaptive capacities and social vulnerability. I first want to highlight internal logics coming from the building of climate services at the level of suppliers (scientists) and users (administration and technical agents involved) of climate services; then identify demands from final beneficiaries (local public stakeholders and rural farmers in our case studies) through qualitative investigations carried out locally. Data will be collected by means of semi-structured interviews (for all actors) and participatory workshop (for beneficiaries). The selection of those key stakeholders will be a crucial point of the research, and particular attention will be given to what some authors have called « weak » or « absent » stakeholders, traditionnaly excluded from participating in consultation/decision making processes. The understanding of contextual factors forging social vulnerability to CC, as well as interactions between all actors involved in building climate services, will be two major points of attention in this project.

Results : I will present early results from the analysis of a field research planned for April 2015 in South Africa (case study 1) as well as highlights about adaptation to climate change in Burkina Faso (case study 2) on the basis of a previous field research conducted in this country in 2012. I also intend to present a simplified typology of climate adaptation services in Africa. This PhD project is in its first year, research is then on-going and new points may be included later on.

P-4418-21

Land use changes and emissions from deforestation in Guatemala: advances and challenges to prepare this Central American country for REDD+

E. Castellanos (1) ; D. Fernandez (1) ; G. Fuentes, (1)
(1) Universidad del Valle de Guatemala, Centro de Estudios Ambientales y de Biodiversidad, Guatemala, Guatemala

In spite of the fact that Guatemala is consistently listed as one of the most vulnerable countries to climate change, adaptation needs and gaps have not been the focus of governmental and non-governmental organizations dealing with climate change issues. Rather, most of the work on climate change for the last 15 years has focused on capitalizing on the potential for income from international sources derived from carbon-offset projects, first as part of the Clean Develop Mechanism CDM and more recently as part of avoided deforestation initiatives.

Our research group has accompanied this process for the last 15 years and this paper will present the most important advances in terms of producing the hard data needed to show recent deforestation and reforestation trends in the country, as well as advances in defining the governance system required to implement the National Strategy Against Deforestation which is the basis for REDD+ initiatives in the country.

We first discuss forest cover change information for Guatemala, where we observe a steady drop in the net deforestation rate from a high value of 1.7% measured for the period 1991-2001, to 1.3% for 2001-2006, to 1.0% for 2006-2010. This drop is not a result of a drop in the gross amount of cleared forest. Rather, it is a result of an increase in the forest regenerated, which includes new plantations and forest regenerating after disturbances such as fires and as secondary growth in abandoned agricultural fields. This is in part the result of a successful incentive program by the central government both for large and small holders (PINFOR and PINPEP), which provides monetary incentives for people and communities who plant new forests or preserve existing forest cover. Ironically, these programs have not been able to generate a single carbon credit because of problems demonstrating additionality.

In terms of the governance needed to reduce deforestation and to generate marketable carbon credits, this paper describes various significant advances in recent years. A climate change law was passed in 2013, which mandates the implementation of a series of policies to reduce and compensate emissions from sectors such as energy, industry and transportation. It includes some provisions to create a national registry for carbon-offset projects, which could set the basis for the development of an internal carbon trading system.

Beyond these national initiatives, many sectors within the country, including several government offices, are very actively pursuing the development and implementation of REDD+ initiatives to attract international investments. We will describe some of the governing issues under discussion, particularly the intergovernmental coordination needed to implement a proper Monitoring, Reporting and Verification (MRV) system and the discussions around the fair distribution of potential income from avoided deforestation projects in protected areas between the communities implementing the activities to reduce deforestation and the central government who is the legal owner of the land and therefore of the carbon credits to be generated. This of course has been a difficult issue to negotiate, which has resulted in tension between the communities and the central government.

Many of these issues and challenges are typical of situations encountered in developing countries around the world that have been pursuing the elusive goal of bringing in enough funding to reduce or stop their deforestation problems. Unfortunately, even after many years of work, international markets for carbon credits appear to be unreachable to communities in need of funds to improve their adapting capacites. National carbon markets may prove to be a more feasible solution.

Controlling environmentally-related diseases outbreaks: support of remote sensing, modeling and knowledge integration

M. Mangeas (1) ; C. Barcellos, (2) ; N. Dessay, (1) ; L. Durieux (1) ; F. Girond (3) ; V. Herbreteau (4) ; T. Libourel (5) ; C. Menkes (6) ; P. Piola (3) ; E. Roux (1) ; M. Teurlai (7) ; JC. Desconnets (1) ; JF. Faure (1) ; I. Mougenot (5) ; C. Révillion (4)

(1) Institut de recherche pour le développement, Umr espace-dev, Montpellier, France; (2) Fundação Oswaldo Cruz, Centro de Informação Científica e Tecnológica, Departamento de informação em saúde, Manguinhos, Brazil; (3) Institut Pasteur, Unité d'epidémiologie, Antananarivo, Madagascar; (4) Institut de recherche pour le développement, Umr espace-dev, St Pierre La Réunion, France; (5) Université de Montpellier, Umr espace-dev, Montpellier, France; (6) IRD, LOCEAN, Noumea, New Caledonia; (7) Institut Pasteur, Unité d'épidémiologie, Noumea, New Caledonia

Recently, in their fifth report on the impacts of climate change (CC), IPCC experts highlight 6 major challenges that will face humanity (IPCC, 2014). The fifth one concerns the impact of global warming on health with a modification of the geography of diseases due to changes in climate. Indeed, in certain areas, CC is going to deeply modify the environment (for example land use, water accessibility, natural habitats) and the links between environment and human health are multiple, complex and multiscale. For example, environment plays an important role on the dynamic of vector-borne diseases since it can modify the distribution of the vectors, and affects interactions between human-vector and vector-pathogen.

In addition to environmental changes, health inequalities are determined by unequal health provision, unequal access (health care coverage, travelling time) and unequal use (related to: socio-economic difficulties, risk perception, risk behaviors). These complex relationships between a changing environment, societies and health are major issues for policy makers.

In this context, gathering and analysing data on climate and health, as well as information on socioeconomic and environmental factors, is essential for planning actions. For this purpose, remotely-sensed data are increasingly available in a very short time (few days) at high spectral (from radar to blue), spatial (<5m) and temporal (daily or weekly) resolutions. The access to such data is promising to improve models and response. Recent advances in information and communication sciences and knowledge engineering could advantageously assist the implementation of spatial data infrastructures. Such infrastructures should handle highly heterogeneous and distributed data while allowing to formalize multidisciplinary knowledge.

In this contribution we propose an integrated solution for assessing the impacts of the CC on Environmentally-Related Infectious Diseases that can be broken up into four sub topics:

- aggregation of high quality multidisciplinary in-situ and permanent monitoring spatial information related to environment (including climate), human (socio-economics...), diseases (blurred georeferenced cases to respect anonymity);
- formalization of knowledge and reasoning to facilitate contextual interpretation, data integration and dissemination;
- use of mathematical models to investigate epidemiological dynamics and associated risks linking diseases occurrences with factors related to environment and human activities at different scales (regional to local);
- production of indicators for assessing social and environmental changes and predicting the spatio-temporal evolution of the epidemiological patterns.

These transformative solutions are useful to mitigate the effects of CC (vector spread control, epidemics forecast and control), to target appropriate actions, to reduce the costs related to improvement in people's health and to facilitate the dissemination of information to health stakeholders, society, government agencies and media.

We describe several ongoing works which partly contribute to reach these objectives: i) New-Caledonia: --spatial risk modelling, 6 months ahead forecast of dengue epidemics and evolution of dengue dynamics up to year 2100--, ii) French Guiana/Brazil: catalog of multi-thematic spatialized data related to the transborder area between French Guiana and Brazil, portal of a future malaria sentinel site of the Brazilian observatory on climate and health, iii) Mayotte and La Réunion: surveys to investigate the inequalities and choices that drive the use of health care; development of a method to spatially anonymize georeferenced individual data, and iv) Madagascar: early warning system for forecasting malaria outbreaks. We also situate this project within the worldwide initiatives context.

We analyse the benefits of such an approach but also the related obstacles (e.g. data sharing) and technical issues (e.g. multiscaling, complex modelling).

P-4418-23

Robust technological and emission trajectories for long-term stabilization targets with an energy-environment model

C. Nicolas (1) ; S. Tchung-Ming (1) ; E. Delage (2) ; O. Bahn (2)

(1) IFPEN, Economics, Rueil, France; (2) HEC Montreal, Decision sciences, Montreal, Canada

In order to inform decision makers and to evaluate climate policies, the use of integrated assessment models (IAMs) is now widespread and common. These models are in particular used to identify promising technological pathways (Labriet et al., 2009), to evaluate various climate policies (Hu et al., 2012) or to assess the impact of policy measures on resource exhaustion (McGlade & Ekins, 2015).

Climate change being a recent and complicated field of research, the last decade brings multiple answers regarding the climate system evolution but raises also a lot of new questions that still need to be addressed by physicists and climate scientists. The imperfect knowledge of global warming mechanisms and the large variety of IAMs lead the model users to reach conclusions sometimes very different.

This lack of robustness across models leads some economists to disregard the use of IAMs. Pyndick (2013) states that considering the numerous uncertainties surrounding the climate system behavior or the impacts of climate change on economic aspects and the inability of IAMs to consider very low probability/catastrophic outcomes events, the IAM-based analysis of climate policy creates "a perception of knowledge and precision that is illusory and misleading". Hence, it seems absolutely necessary to make uncertainty a core feature of long-term, climate related policy analysis and to identify relevant techniques to solve large-scale problems contaminated with "massive data uncertainty".

Motivation Stochastic optimization (SO), sensitivity analysis and deterministic multi-scenario analysis have been applied to tackle this uncertainty issue. SO allows to endogenize uncertainty and to provide an explicit hedging strategy while the other methods stay deterministic. One drawback of SO is that it requires to know the probability distribution of the uncertain parameter which is not always possible. Another drawback of all these methods is that they become rapidly intractable as problems grow in size.

In this work, we introduce an alternative way to tackle uncertainty in energy system models. We rely on robust optimization (Ben-Tal et al, 2009) to make many model parameters simultaneously uncertain. So far, this technique has been scarcely used in energy modeling (Babonneau et al, 2012). We focus on the climate system modeling because of it is large uncertainties and the numerous criticisms it faces.

Methodology In this study, we use the TIAM-World model (Loulou, 2008) that relies on the TIMES paradigm. Often used to analyse climate change policies or objectives, this model contains a climate module inspired by the DICE model. Using robust optimization techniques, we assess the impact of the climate system parameter uncertainty on energy transition pathways under climate constraints. Unlike other studies (Syri et al., 2008, Labriet et al., 2015); we consider all the climate system parameters. This is of primary importance since (i) parameters and outcomes of climate models are all inherently uncertain (parametric uncertainty) and (ii) the simplified models at stake summarize in a (sometimes linear) few equations phenomena that are by nature complex and non linear, so that structural uncertainty is also a major issue.

Given the non linearity of the climate module in the parameters, we had to implement a two-level master-subproblem algorithm in order to solve the non-linear problem apart from the classical Times one. We run this constraint-generation algorithm for various values of the uncertainty budget (which represents the number of climate parameters allowed to deviate from theirnominal values) and for several levels of the temperature constraint.

Results and discussion The use of robust optimization techniques allows us to identify economic energy transition pathways under climate constraints for which the outcome scenarios remain relevant for any realization of the climate parameters. In this sense, scenarios/transition pathways are made robust. In particular, we show that adverse combinations of climate parameters include not only the expected climate sensitivity, but also carbon cycle parameters, which directly impact the quantity of atmospheric carbon. Moreover, we compute robust emissions trajectories, and examine how the strategies are spread across regions - especially between oil producing and non-producing regions.

P-4418-24

Information Technology in management of social-economical estimation of the flood affects and water quality in the Central Asia

P. Normatov (1)

(1) Tajik National University, Water resources, Dushanbe, Tajikistan

The aspects of water allocation between the countries of Central Asia are considered from the point of view of river drain ecology. For the decision of ecological problems, the creation of Interstate Water Quality Control Commission of Transboundary Rivers is offered in the region.

Water relations between Central Asia republics during the Soviet Union time were regulated by "Complex Use and Protection of Water Resources Schemes" in Amudarya and Syrdarya basins. The main purpose of working out basin "Schemes" was to define real volumes situated within the Amudarya and Syrdarya basins and available for using water resources. It was also providing their fair allocation among region republics, meeting all the water users' interests. It should be noticed, that the number of important aspects were not considered and included in "Schemes", for the situation has greatly changed after 1980 (years of the last "Schemes" specification and completion of hydraulic range composition). Mainly it concerns the ecologic acquirements and sanitarian clears thrown into rivers and channels. Overusing basin water in irrigational lands planned as maximum use by "Scheme" resulted in exhausting water resources and appearing new problems. They are:

- Deterioration of ecological condition sometimes leading to ecological disaster in downstream of rivers of Aral Sea Basin;

- Great pollution of river water with pesticides, herbicides, other harmful elements and increasing of water mineralization.

Among all the regions of Tajikistan 93 % of territory that borrow mountains in the Zarafshon River Basin the formation of floods is observed most often (almost 7% of the total across Tajikistan) and their average number in a year reaches 150. More than 300 thousand inhabitants live in the Zarafshon River Basin located in the Ajni and Penjikent regional centers. The local population is affected almost annually with great economic losses.Nowadays one of the most polluted rivers of Central Asia is Zarafshon River. The capacity of this water is changed under the influence of collector drainage water of irrigating basin zone and wastewater of Samarqand, Kattakurgan, Navoy, and Bukhara cities. Mineralization of water exceeds from origin to estuary from 0.27-0.30g/l to 1.5-1.6 g/l.

It gives the ground to hope, that the problem of contamination and ascending of a degree of water arteries mineralization can be solved with the same success by creating (similar ICWC) Interstate Coordination Water Quality Commission (ICWQC). Structural subdividing "The interstate experts" unite the leading technicians in evaluating the quality and composition of waters from all five states of Central Asia. The main function of this body is to compare the republican experts' information about water composition and to solve disputable questions by carrying out the independent expert appraisals of water quality of Transboundary Rivers. ICWQC Secretary appoints the stuff and sets terms of power of the interstate experts. In Information Center established in each country of Central Asia the water quality control statistics in industrial, agricultural, municipal sectors and Hydroposts are gathered, generalized and systematized. Thus, the data concerning water arteries quality from each country come to Analytical Center of ICWQC.

It should be noted that after reaching the complete transparence of relative composition and quality of all water arteries in Central Asia the next stage is the development of mechanisms to encourage and take measures to the states polluting water environment. These problems together with other questions should be studied in ICWQC Secretariat for considering at Meeting of Central Asia Heads of Governments.

P-4418-25

Balancing Short- and Long-lived Climate Pollutant Mitigation: Clearer Metrics are Critical

I. Ocko (1) ; S. Hamburg, (2) ; S. Pacala (3)

(1) Environmental Defense Fund, Office of Chief Scientist, New York, NY, France; (2) Environmental Defense Fund, Office of chief scientist, Boston, NY, United States of America; (3) Princeton University, Ecology and evolutionary biology, Princeton, NJ, United States of America

Any effective program to address climate change must reflect a well-balanced effort to reduce emissions among a suite of climate pollutants, including carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), various fluorocarbons (e.g. HFCs), and black carbon, as their radiative effects and atmospheric longevities vary by orders of magnitude. However, confusion among policy makers about how to attain the optimum balance required to achieve the desired climate benefits has increased dramatically in recent years, in large part because of the way in which climate metrics, Global Warming Potentials (GWPs), are reported in the scientific literature. This confusion is particularly evident in the public and political debate over the expansion of natural gas production in the United States and its use to replace coal in the generation of electricity. Understanding the climate impacts associated with this fuel switching over time is an important and unnecessary source of acrimony. We propose a simple change in the convention used in reporting GWPs that we believe would significantly reduce confusion about the implications of a host of policy decisions. Rather than picking a single time period over which to report the cumulative radiative forcing caused by an emission, typically 20 years (GWP20) or 100 years (GWP100), we propose that the scientific community adopt the convention of reporting climate impacts as a slashed pair: GWP20/GWP100, much the way systolic and diastolic blood pressures are reported together. This framing will help to clarify short- and long-term temporal tradeoffs that are at the heart of much of the confusion.

P-4418-26

Surpassing cognitive barriers for an international climate agreement: Communication matters

C. Pillay (1)

(1) Universidad Autónoma de Barcelona, Institute of Science and Technology, Barcelona, Spain

Individual perceptions of climate change should matter for the design of an international climate agreement and domestic climate policy. Especially responses to uncertainty will determine whether one can gain support for climate policy, let alone for an agreement. Communication of its magnificence is vital to garner just this. This paper addresses the individual mind and how it reflects the interests of various actors, be it governments, businesses or international organizations, by focusing on similar cognitive barriers. Using the existing literature on behavioural decision-making, two cognitive barriers that seem to get in the way of a desired climate agreement are highlighted: positive illusion and interpreting behaviour in a self-serving manner. Positive illusions serve as a necessary buffer for human beings in dealing with

negative information about potentially disastrous future developments. In the context of climate change, unrealistic optimism and the illusion of control stand in the way of climate policy. This can explain an array of behavioural responses between various actors. For instance, the reason for climate scepticism; or the overreliance on technological solutions without needing to change individual behaviour. With regard to the second cognitive feature, it is in human nature to behave in a self-interested manner, more so when facing limited resources such as food security, oil and clean air. The agreement should be communicated in a way that does not instill such perceptions but instead should focus on the numerous co-benefits of climate mitigation policy. For example, the results of the 2015 agreement are designed to go into effect well into the future with many possible co-benefits. This gives time for preparation and advancement of domestic climate policy. The United Nations Framework Convention on Climate Change (UNFCCC) has even launched a pre-2020 workplan to raise mitigation ambition by highlighting the benefits of action. Nevertheless, the agreement/climate policy is frequently viewed as costly whilst inflicting unwanted immediate self-anxieties that end up blocking such imperative policies unnecessarily. Thus communication which pays attention to words used influences expectations and information processed cognitively by a person.

The paper ends with solutions and tentative proposals on steering such biases so as to foster support for an agreement. Key questions from the behavioural decision-making perspective are elaborated along with its contribution and important implications to the ever evolving trans-disciplinary framework in tackling barriers towards an international climate agreement.

P-4418-27

An integrated framework for climate vulnerability, and natural hazards & risks assessment at the local scale - and its potential for regional upscaling

N. Salzmann (1) ; S. Allen, (2) ; K. Awasthi, (3) ; C. Huggel (4) ; M. Ali Khan (3) ; A. Linsbauer (1) ; M. Rohrer (5) ; M. Stoffel (6) ; A. Gupta (7) ; N. Mendiratta (7) ; J. Kuriger (8)

(1) University of Fribourg, Department of Geosciences, Fribourg, Switzerland; (2) University of Zurich, Department of geography, Zurich, Switzerland; (3) Indian Himalayas Climate Change Adaptation Programme, New Delhi, India; (4) University of Zürich, Department of geography, Zürich, Switzerland; (5) Meteodat GmbH, Zürich, Switzerland; (6) University of Geneva, Institute for environmental sciences, Geneva, Switzerland; (7) Department of Science & Technology, New Delhi, India; (8) Swiss Agency for Development and Cooperation SDC, New Delhi, India

The Indian Himalayan Region (IHR) as many other (mountain) regions worldwide, is facing important challenges in view of coping with adverse effects of climatic changes. In order to address adaptation needs and reduce the vulnerability of the communities living in potentially affected regions, the Indian Government under its National Mission on Sustaining Himalayan Ecosystem (NMSHE) is targeting an integrated vulnerability and risk & hazards assessment encompassing the 12 Indian Himalayan States. The assessment will serve as an important basis for prioritizing, planning and implementing adaptation measures at State/ sub-national level.

The Indian Himalayas Climate Adaptation Programme (IHCAP) of the Swiss Agency for Development and Cooperation SDC, being implemented in partnership with Department of Science and Technology (DST), Government of India is actively supporting these efforts through scientific and technical knowledge cooperation between Swiss and Indian scientific institutions. A first step includes the development and implementation of an integrated and comprehensive framework for climate vulnerability and natural hazard and risk assessment in a pilot region of the IHR. Kullu district in Himachal Pradesh, India, has been identified as climate hotspot and as such represents an ideal pilot region.

The framework for Kullu is based on the latest concept of vulnerability, hazards and disaster risks from the Intergovernmental Panel on Climate Change (IPCC; AR5, SREX). Specific joint Indo-Swiss collaborative studies are in progress in Kullu covering thematic themes such as climate, cryosphere, floods, agriculture, perception, tourism, forestry and biodiversity. Fundamental for integrated vulnerability assessments is a common baseline and thus particular care was addressed to the definition and agreement for a common time window and homogenous datasets (climate, socio-economic, environmental) for all studies conducted within the framework. With regard to the time window, the baseline refers ideally to a relevant time horizon of their livelihood and must span a climatological period of preferably 30 years (WMO standard). For Kullu, the time window 1981-2010 was chosen.

In this contribution, we present the framework for the Kullu region, related results from specific thematic studies and discuss in particular the potential and limitations of the upscaling processes towards a common framework for integrated vulnerability and risks & hazards assessment for the IHR.

P-4418-28

Integrating Research and Practice - What Climate Service can learn from other Fields

S. Schuck-Zöller (1) ; M. Bergmann, (2) ; C. Brinkmann, (3) ; JT. Huang-Lachmann, (3) ; S. Rödder, (4)

(1) Helmholtz-Center Geesthacht, Climate service center 2.0, Hamburg, Germany; (2) ISOE – Institute for Social-Ecological Research, Frankfurt, Germany; (3) working for: Helmholtz-Center Geesthacht, Climate service center 2.0, Hamburg, Germany; (4) University of Hamburg, Centre for globalisation and governance & center for earth system research and sustainability, Hamburg, Germany

Climate change and its widespread impacts are a challenge for both science and society. To find sustainable solutions and develop adaptation strategies, a transdisciplinary approach to this challenge is needed. Climate service is bridging the gap between climate research and practice. This integrated research relies on intense communication between various players in science, politics, economics and administration. So – by nature – climate service is transdisciplinary.

Some fields now have a tradition of integrating practice partners, but so far, there is hardly any integration of knowledge and experiences on the meta-level. Rather, the terminology, concepts and references that are used are very divers. Neither theoretical insights nor empirical case studies on transdisciplinary communication in different fields have so far been systematically reviewed.

To evaluate in how far climate service can benefit from existing approaches to transdisciplinarity, a literature review has been carried out. Its aim was to better understand definitions, approaches, methods, and barriers over the different fields of context. Following Stauffacher et al. (2008), different levels of practitioners' involvement were identified. The presentation will both, sum up the results of the literature review and the outcomes of a recent conference, which collected experiences from scientists and practitioners from a wide range of disciplines and practice fields. From this experiences and good-practice-examples the workshop, held in November 2014, aimed to deduce success factors and quality criteria in transdisciplinary dialogues.

On the basis of both review and conference data, the integration of research and practice is looked at in a range of contexts, such as public health, environment protection, sustainability, and climate change. A special focus lies on aspects of social-ecological research and stakeholder engagement in climate change adaptation.

P-4418-29

Maning Risks? Early Warning Systems for Climate Related Hazards

A. Sitati (1) ; Z. Zommers (1) ; M. Habilov (1) ; A. Vanzanten (1) ; E. Vogel (1)

(1) United Nations Environment Programme, Division of Early Warning and Assessment, Nairobi, Kenya

Early warning systems are a tool with which to minimize risks posed by climate related hazards. Although great strides have been made in developing early warning systems most deal with one hazard, only provide short-term warnings and do not reach the most vulnerable. This presentation will review research results of the United Nations Environment Programme (UNEP)'s CLIM-WARN project. The project has sought to identify how

governments can better communicate risks by designing multi-hazard early warning systems that deliver actionable warnings across timescales. Household surveys and focus group discussions were conducted in 36 communities in Kenya, Ghana and Burkina Faso in order to identify relevant climate related hazards and early warning communication options. Preliminary results show significant variability in risks and needs within countries. Here there is critical need for advanced warning so that adaptive measures can be taken. Some regions have limited access to information through TV or SMS. Here traditional institutions, such as chiefs and meteorological extension officers, will be critical for warning delivery. In contrast, in urban areas mobile phones may be an effective way to deliver warnings and spread information about risks. Communities should be involved in early warning system design so appropriate communication channels, and trusted groups, are used to deliver warnings. There is a need for flexible early warning systems that address community specific needs and deliver broad information about risks. Information disseminated through early warning systems should not only include details of hazards, but also short -term response options and long-term adaptation options, thus increasing both capabilities and response options.

P-4418-30

Water Related Disaster Risk Reduction (DRR) Management Strategies in the United States: Climate Adaptation to Floods and Storm Surges

EZ. Stakhiv (1)
(1) Institute for Water resources, Johns Hopkins University, Baltimore, MD, United States of America

Water resources planning and management has evolved in the United States through several distinct stages over the past two centuries, transitioning from a concern for inland waterways transportation to single purpose flood control and finally to multiple purpose large reservoirs. Disaster risk reduction (DRR) – both economic and loss of life – were always the main goals of these strategies, as an integral part of a US Federal system that presents major challenges to coordinating water resources development and DRR, at both the watershed level and metropolitan area scales. Equally, the underlying and inherent climate-based components of risk and uncertainty comprised the scientific basis of assessment and evaluation of management strategies.

The relative performance of existing flood protection systems of three recent disasters are presented; Hurricane Katrina (2005), Superstorm Sandy (2012) and the Mississippi River flood (2011). The cases revealed new vulnerabilities and weaknesses in the US DRR responses and planning, while contrasting the relative successes of long term, strategic DRR planning and investments in the case of the Mississippi River and Tributaries system.

Today, the underpinning of DRR in the US is risk-based decision making, which is distinct from traditional water resources multi-objective decision making. This new paradigm maximizes social well-being, public safety and risk-reduction strategies for the local populace, subject to numerous environmental constraints (and preferred solutions), leading to what could be termed 'sustainable development'.

The new 'risk-informed decision making' culture is far more complex. It is based on risk-cost comparisons and tradeoffs among various options. It engages the affected public. This evaluation approach requires a great deal more complex and technically sophisticated information and attention of the public – not just the analysts and decision makers. As a consequence, the public is also asked to bear more of the residual risks and costs, without often fully understanding the consequences.

OVERALL LESSONS LEARNED FROM THE THREE RECENT MEGA-DISASTERS

a. Disaster risk reduction comprises a special category of flood management, as it connotes extremely large events, with catastrophic human consequences and national level economic impacts.

b. Conceptually, federal systems should be able to deal effectively with such events, but a series of recent disastrous floods and storm surges in the US has exposed some of the weaknesses in the response of federally-based disaster management systems.

c. Risk-based decision making at the local level is neither replicable nor uniform. It is not at all clear, whether a collection of loosely connected local solutions, with varying degrees of risk and uncertainty, can guarantee either robustness or resilience. The recent responses to Katrina and Superstorm Sandy reinforce that public confusion.

d. Residual risk is almost always underestimated because it is difficult to quantify a cascading series of highly interdependent measures, each of which has its own reliability characteristics and risk of failure.

e. A flood protection system is a collection of fragmented measures, including new building codes, zoning ordinances, and structural measures that are implemented over a long period of time and loosely coordinated by multiple authorities. This comprises the definition of a 'brittle system'.

f. Because people bear the risks, their involvement in choosing risk and participation in the tough operational decisions made during the process of planning for mitigation of potential events is critical to the health of a democratic system

P-4418-31

Climaps.eu an Online Platform for Informing Decision-Making

T. Venturini (1) ; A. Meunier (1) ; A. Munk (1)
(1) Sciences Po, médialab, Paris, France

In our contribution we will present the platform Climaps.eu: a digital atlas providing data, visualizations and commentaries about climate adaptation debate.

This atlas is addressed to climate experts (negotiators, NGOs and companies concerned by global warming, journalists...) and engaged citizens. It employs advanced digital methods to deploy the complexity of adaptation discussions and information design to make such complexity legible.

Climaps contains 33 issue-maps, each focusing on one adaptation issue and providing:

- an interactive visualization;
- a discussion of the map and the findings that it discloses;
- a description of the protocol through which the map has been created;
- the data on which the map is based and the code employed to treat them.

Climaps.eu has been produced by the EU-funded project EMAPS (www.emapsproject.com) as the largest experiment tempted so far with the method of 'controversy mapping'. Controversy mapping is a research technique developed in the field of Sciences and Technology Studies to deal with the growing intricacy of socio-technical debates. Instead of mourning such complexity, it aims to equip engaged citizens with tools to navigate through expert disagreement. Instead of lamenting the fragmentation of society, it aims to facilitate the emergence of heterogeneous discussion forums.

A few examples of the Climaps.eu findings that we will discuss in our presentation:

Adaptation and mitigation in the UNFCCC

Analyzing the Earth Negotiation Bulletin, we identified the main discussion in the UN Convention on Climate Change, traced their visibility over time and the countries engaged with them. Adaptation and mitigation, we concluded, have different places in the UNFCCC. Mitigation constitutes the main object of the convention, is present everywhere in its conversation and structures the articulation of the debate. Adaptation, on the contrary, appears as a group of specific discussions and has a limited though central place in the negotiations. Although, adaptation is present from the beginning in UN conferences (in particular the question of its funding), an 'adaptation turn' is visible from 2004 with

the rise of the questions of vulnerability and of climate change impacts.

cfr: http://climaps.eu/#!/narrative/mitigation-and-adaptation-in-the-unfccc-debates

The geopolitics of adaptation expenditure

Using RioMarkers coding we extracted from the OECD Official Development Assistance the bilateral adaptation funding and visualized it in a way that allows comparing how the distribution of aid varies between these countries. We compared not only the amounts committed by donor countries, but also their preferred policy areas, the concentration of their aid, their favored recipient countries and closest UNFCCC recipient groupings. Some donors appear to specialize in particular policy areas: for example, Japan is best at funding disaster reduction; France water management; Spain government and civil society; UK biodiversity and Germany agriculture. Some countries concentrate their aid more among policy areas and recipient countries (EU, Denmark) than others (Spain, Italy, Ireland), which could suggest a more planned approach to adaptation aid.

cfr. http://climaps.eu/#!/narrative/the-geopolitics-of-adaptation-expenditure

Who deserve to be funded

We have compared the priorities of bilateral and multilateral adaptation funders with different ways of assessing vulnerability. Using Germanwatch, DARA and Gain vulnerability indices, as well as the Human Development index, we explored possible correlations between the amount of money allocated to a country and the degree to which it could be said to be climate vulnerable. We found both positive and negative correlations. In general, development oriented indices correlate more with adaptation funding, providing evidence that adaptation and development are closely connected. We have also tried to find out, where vulnerability indices are mentioned and we found that climate specific vulnerability indices are rarely used by actors in the UNFCCC process, but widely cited in the new media.

cfr. http://climaps.eu/#!/narrative/who-deserves-to-be-funded

P-4418-32

An Integrated GIS-Based Climate Change Model to Assess Sustainable Development Scenarios

AM. Yadghar (1)
(1) CIRAIG, Environmental Engineering, Montreal, Canada

Climate change and its impact are serious issues that scientist and engineers are involving with. It is believed that human activities contribute to the Earth's climate change significantly and the change is tremendously rapid. A reliable methodology to predict the climate change is modeling. Climate change models aim to improve the understanding of Earth's climate by focusing on scientific analysis of the governing sets of processes that describe the climate over different conditions; evaluate strong methods to obtain higher spatial resolution for projections of climate change; and detect uncertainties in climate predications by real simulating.

On the other hand, sustainable development needs a bright image of the future. Sustainability cannot be achieved without regulating and controlling human activities. Regulations and policies come within different scenarios that are acceptable internationally. Models can predict the future conditions based on various scenarios.

This research proposes an integrated GIS-based climate change modeling methodology than can use different climate scenarios. Its easy-to-use method helps the policy makers and decision support systems to see what will happen in the future by applying a certain scenario in a short time. It also helps the users to visualize the results with a good spatial resolution in order to choose the best policy. The proposed methodology is believed to be first of its kind as it is run very fast and has a simple interface, yet with powerful background.

4419 - Climate science in the public sphere. Media coverage and communication devices analysis for effective policy implementation

Climate change journalism - communicating the science

E. Eide (1) ; J. Painter (2) ; R. Kunelius (3)
(1) Akershus University College for Applied Sciences, Department for journalism and media studies, Oslo, Norway; (2) University of Oxford, Reuters school of journalism, Oxford, United Kingdom; (3) School of Social Sciences and Humanities, Tampere, Finland

The MediaClimate network presents the results of TV and newspaper representation of the IPCC AR5 reports in a large number of countries, analyzing the differing levels of attention and frames emerging when journalists in a variety of national contexts report on the latest results from climate scientists. To what extent are the carefully formulated scientific concepts, such as uncertainty, probability and degrees of likelihood present in the journalistic texts? Which voices are quoted, which genres are salient, and which recommendations are made by editors and journalists? To what extent are the IPCC results and recommendations related to peoples' everyday experiences investigated in the media? Which challenges in reporting on a global scientific endeavour may be traced, and what are the perspectives for a more cosmopolitan (globally oriented) journalism?

O-4419-02

Advancing climate mitigation efforts through dialogue with the Australian Public

P. Ashworth (1)
(1) University of Queensland,, School of Social Sciences, Brisbane, Australia

There is no doubt the politicisation of climate change discussions in Australia have severely impacted the coordination of Australia's mitigation actions. Despite the lack of proactive action at the political level, many of the Australian public are concerned about climate change and its impact, but are at a loss as to what might be the best actions for them to take as part of the response to climate change. To help facilitate greater understanding of the portfolio of mitigation options, and raise awareness of actions that can be taken at the individual and community level, a number of engagement and dialogue opportunities have been undertaken. This paper will present the research findings from a range of activities that have been utilised to engaged with lay publics across Australia. As a result of this work we have been able to inform policy makers of public preferences, bring about a reduction in participant footprints and understand in more detail the Australian public's preferences for engagement on the topic. Processes used vary from kitchen table discussions; to large group processes – of up to 100 people in the room; citizens' panels and interactive survey tools. The results

generally confirm that the Australian public are concerned about action on climate change, tend to have a preference for renewable energy, but lack in-depth knowledge on the range of low carbon energy technologies.

Building a vision for a low carbon society in France with non-violent communication methods, result from the R&Dialogue european project

M. Ha Duong (1) ; M. Cherbib (2)
(1) CNRS, CIRED, Nogent sur Marne, France; (2) CIRED (International Research Center on Environment and Development), Nogent sur Marne, France

As organisations and governments working towards the energy transition broaden their focus to include a large spectrum of society, they need processes capable of building deep understanding out of the diverse backgrounds, perspectives, and judgements oftheir stakeholders. Several countries have initiated large-scale social dialogues on the energy transition, demonstrating the difficulties inherent in implementing a genuinedialogue and integrating it into the democratic process.

This communication presents the results of the R&Dialogue project in France, a research-action to implement dialogue at the regional, the national and local levels using renewed tools to improve the practice of democracy.

O-4419-04

How to rethink the Science-Societies debate about climate change?

P. Maugis (1) ; L. Scotto D'apollonia (2) ; S. Blangy (3)
(1) UMR CEA-CNRS-UVSQ (UMR 8212), IPSL, Laboratoire des sciences du climat et de l'environnement, Gif-sur-Yvette , France; (2) UM2, Liderf, Montepellier, France; (3) CEFE-CNRS-UMR 5175, Dynamique des Systémes socio-écologiques, Montpellier, France

The question of climate change is increasingly drawing consensus among the scientific community. However, there is an obvious and continuous lack of dialog between scientists and stakeholders (institutions and civil society). How can we foster debate on climate issues between academics, decision-makers and the citizens of the World?

Such a dialog is impaired in different ways. We will focus on some of those that are particularly pregnant and will propose mechanisms to address them. The first one lies in polemics and controversies related to uncertainties in the scientific knowledge and the way they are accounted for and communicated. Pascal Maugis will show how uncertainties should be reported in order to go beyond them and eventually make them an opportunity for enlighted and shared decision making for the management of the risks induced by climate change.

Second, «citizen science» about the climate issues remain isolated, weakly coordinated and for the most part unknown to the general public. Moreover, social demands vary a lot, addressing for example educational issues, adaptation measures or public debates. Because the climatologists who intervene in the public space are at the frontier between science, expertise for territorial policies and political strategies, they bear contradictory constrains. This may result in uneffective – or even counter-productive – discourses. Lionel Scotto d'Appolonia will analyse such situations using the example of climate controversies. This suggests to strenghten the path towards participatory science : A new form of the «Palaver Tree» (L'Arbres à Palabres in french). Inspired by African tradition, the palaver tree is a meeting place where villagers « freely » discuss social and political problems. Its modernized form, scientifically enriched by Human and Social Sciences, will be explained.

Finally, participatory citizen expertize and science have met several success. Sylvie Blangy will present one such success story on tourism adaptation in Québec.

This presentation is set-up and facilitated by the PARCS (Participatory Action Research and Citizen Sciences) research working group: a group including 50 scientists and NGO members from diverse research fields. The objective of PARCS is to synchronize various initiatives of «citizen science» about the climate issues. The PARCS group is conceived as a field-laboratory to explore new ways to question Science-Society relationships, by putting into synergy all demands and initiatives from citizens and institutions. The «palaver tree» is one of its three research axes.

Dialogue among stakeholders for climate risk management strategies

E. Aoki (1) ; S. Emori (2) ; T. Kiyoshi (2) ; K. Fukushi (1)
(1) The University of Tokyo, Integrated Research System for Sustainability Science, Tokyo, Japan; (2) National Institute for Environmental Studies, Tsukuba, Japan

Climate risk management in long-term and in global scale is a key topic in this century to achieve global sustainability. Therefore, we need to develop risk management strategy to encounter problems caused by climate change. However, climate risk management is still controversial and complicated issue especially in developed countries. One reason is that there are various issues and stakeholders (SHs) play various roles in the society and relationship among them are very complicated. In order to provide arena of discussion for SHs, it is extremely important to provide appropriate scientific knowledge for all SHs in an easy-to-use manner with an understanding of the actual social context.

"ICA-RUS", Integrated Climate Analysis - Risks, Uncertainties and Society, a research project funded by the Ministry of the Environment, Japan, in order to deliver scientific findings to SHs and to develop climate risk management strategy for various sectors in Japan. From this project, we organized SH dialogue for communicating and developing a framework of climate risk management. We set two objectives; framing climate risk management problems and understanding SHs' needs. Framing problems is expected to extract agenda, to develop a framework of relationships among perspectives and values, and to understand key factors to influence on problems. Understanding SHs' needs is to know these three points; what kinds of information sources they would like to use for judgment, how scientists should deliver information for the society and what they expected scientists and different SHs to do for contributing to the better consequences of climate risk management in the future.

This SH dialogue can contribute to develop global strategy and stimulate comprehensive and active discussion in the society. However, conventional methods of interview and discussion are not effective for uncertainty relationship with SHs and issues. In addition, people are not familiar with expressing their opinions to others in public in Japan and many Asian countries. People also feel non-experts should not talk about issues. In Asian culture, we need to reform and integrate methods for supporting participants to express their views even in front of experts. Thus, we have designed a triangulation approach for the dialogue and its analysis.

The SH dialogue contains three steps: information sharing from experts, in-depth interview, and focus group discussion. This step by step approach encourage participants to join dialogue actively gradually. We also collected relatively small number of people (4-5 people in a group) as focus group than conventional manner. This helps everyone get opportunity and reason to utter in a group. We chose SHs from those who are involved in global climate talks and related activities. The structure of dialogue is divided in two sections; current perspectives in a semi-structured group interview and long-term strategy in an interactive focus group discussion. In the dialogue, we observed group dynamism became active gradually.

From the dialogue records, we made verbatim transcriptions. We analyzed it by the qualitative research method for understanding key categories or points. To utilize all utterance and to integrate the quantitative research methods, content analysis was also adopted to

transcriptions. We give attention to "real voice" deeply but also to comparison analysis and integration in an easy-to-understand manner. Therefore, we can share findings from a multilateral perspectives.

From these triangulation approach, we discussed key categories and related SHs of climate risk management, like international governance, mechanism of decision-making, communication, future vision and so on.

Multiple research design seems to be an effective way for framing complicated issues and setting agenda from it. This diversity of choices in findings is expected to invigorate discussions in the society.

A linguistic analysis of IPCC Summaries and its coverage in scientific and popular media

R. Barkemeyer (1) ; G. Napolitano, (2) ; S. Dessai (3) ; B. Monge-Sanz, (4) ; BG. Renzi, (5)
(1) Kedge Business School, Bordeaux, France; (2) University of Bonn, Institute for medical biometry, informatics, and epidemiology, Bonn, Germany; (3) University of Leeds, Leeds, United Kingdom; (4) European Centre for Medium-Range Weather Forecasts (ECMWF), Reading, United Kingdom; (5) Rome 3 University, School of education, Rome, Italy

The Intergovernmental Panel on Climate Change (IPCC) Summary for Policymakers (SPM) is the most widely read section of IPCC reports and the main springboard for the communication of its assessment reports. Its findings should be communicated in a way that can be understood by a non-scientific audience. Existing studies have focused on the way in which IPCC probabilistic statements are interpreted, and on the discursive construction of the IPCC in national newspapers, including the influence of grammatical and word choices. We have undertaken a linguistic analysis of SPMs and related scientific and popular media coverage on the launch of each IPCC assessment report from 1990 to 2014. We employ widely-established sentiment analysis tools and readability metrics to explore the extent to which information published by the IPCC differs from the presentation of respective findings in the popular and scientific media within this time-frame. IPCC SPMs clearly stand out in terms of low readability, which has remained relatively constant despite the IPCC's efforts to consolidate and readjust its communications policy. In contrast, scientific and broadsheet newspaper coverage has become increasingly readable and emotive. Our findings reveal easy gains that could be achieved in making SPMs more accessible for non-scientific audiences.

P-4419-03

Young Voices: Developing narratives for engaging young people on climate change

A. Corner (1) ; J. Clarke, (1)
(1) Climate Outreach and Information Network (COIN), Oxford, United Kingdom

Young people are in a unique position as they face the reality of a changing climate:

potentially they are best-placed to push for and define the long-term societal response to climate change, yet they are also the most vulnerable to the legacy of decisions made by older generations. Young voices are not prominent in the climate change discourse, and engagement with climate change among this crucial demographic is in many ways limited.

In this presentation, we will report the findings from a series of qualitative 'narrative workshops' involving 36 young adults in the UK during May/June 2014. The research found that young people see climate change as a problem for the here and now and respond positively to messages that frame climate change as a contemporary concern requiring an immediate response. However, young people sometimes find it difficult to talk about climate change with their peers because of a perception that it comes with a certain stigma and is 'uncool', or preachy to do so.

Most participants were either unaware or uninterested in the idea of organised climate change scepticism, suggesting that campaigns to counteract science-based scepticism will not be particularly useful for this audience. Debating solutions – rather than the science – was identified as a much higher priority. Some commonly used climate advocacy phrases (such as '2 degrees' or 'managing climate risks') were either unfamiliar or unpopular with the young people we engaged. Participants were receptive to the idea of protecting the 'things they love' from climate change, but to avoid trivialising the issue, felt that it was important to always make the link between the 'everyday' and the 'bigger picture', joining the dots between the personal and the political.

We will present and discuss these and other key findings, and explore the implications for developing narratives to engage young people more effectively in future initiatives.

P-4419-04

Communicating Climate Change to the General Public and Policy Makers

H. Cutting (1)
(1) Climate Nexus, Strategic Communications, San Francisco, California, United States of America

The results of polling surveys, academic literature, and practitioner field work in communications suggest that the work of communicating climate science should be calibrated in a strategic manner against the mind-set and experience of audiences, the larger landscape of communications by all voices that construct the public narrative, a clear theory of change, and a clear understanding of the goal of science communicators. Scientists are highly sought after communicators in pubic discussion on climate change – but that dynamic is driven more by the high regard and trust the public places in scientists when discussing a controversial issue than any public interest in taking a deep dive into the science. Polling in the context of climate change communications is best used as a road map, illustrating audience mindset, not as a compass heading indicating direction of travel. Support for climate protection in the general public is often a mile wide but only an inch deep. One barrier is the impression of climate change as a distant and future threat. Extreme weather offers a teachable moment addressing a key misperceptions regarding climate change. Another issue is the analog of smog that audiences bring to their understanding of carbon pollution. Another compounding problem is the self-identification by the audience of bad actors. The experience of science communications on tobacco control offers a helpful soltution here. Action on climate change requires what sociologists call «hot cognition,» a story element that goes beyond the physical science of climate change. Principles for effective climate science communication include: tell us what you know (not what you don't know) and choose metaphors that not only illustrate the science but highlight the signifiance of the situation. The bathtub metaphor for carbon sinks and sources is one example of a techically correct metaphor that often sends the wrong message. Scientists can leverage their validating authority to affirm the basic climate science narrative that speaks to the interests of the general public and policy makers, a narrative that centers on the salience of the science for public policy, not on the physics or chemistry of the science. The narrative is centered on five key points:

- Climate change is happening, right here, right now.
- We're causing it.
- Scientists agree about this.
- We can fix it.
- We can't wait, the problem is locking in now.

P-4419-05

Climate Communication: Bringing It All Together

R. Mccarthy (1)
(1) Met Office, Exeter, United Kingdom

When it comes to matters of global importance a wide view is needed.

This talk brings together independent studies in the fields of communication, media, phsychology, lingustics

and the physical sciences to identify the optimum way forward for climate communication. Recommendations as to how climate communications could be improved have been made by various institutions, but as of yet no multi-disciplanary, or multiple-institution strategy has been unveiled. This talk is designed to bridge that gap and work to bring disciplines together.

An analysis of opinion polls and the reporting of the detail of climate matters primarilly in European and American newsapers — including the provision of renewable energy generation— indicate equallly a 'will' to address climate issues and a 'dis-satisfaction' at current action.

The talk specialises in analysing these divides but with a particular and focused experience in lingustics. The scientific language uses words in a different way to 'regular' english. This talk asks what we can learn from a very proficient use of the english language. The issues of conveying clear messages around climate variabilty and change transcends these boundaries.

This lecture looks at these lingustic, societal, and scientific issues, drawing them togther to make a cohesive way forward.

P-4419-06

Has Political Action On Global Warming in the United States Been Forestalled by Gangsters? A Historical Analysis

M. Roddy (1)
(1) independent, Yucca Valley Ca, United States of America

Action behind the scenes to hide and sabotage climate change awareness is pervasive, especially in English speaking countries such as the United States, Australia, and Canada. Causes include fossil fuel influence on mainstream media, as well as educational institutions and government agencies.

This fossil fuel campaign, abetted by corporate sectors such as banking and construction, is well organized and financed. Global warming activists are relatively underfunded and poorly represented in American media. We propose a historical analysis employing biting satire in order to correct this situation.

The author achieved prior success in this regard through his Climate Villains series, published in Alternet and Buffalo Beast, and republished in over 40 internet magazines. Actors such as the Koch Brothers and media puppets like George Will and Lord Moncton were portrayed in biting satirical fashion. The author has also published serious research pieces in Energy Future and Climate Progress.

The proposed article for Paris is being written at present, and will employ the gangster metaphor, along with examples from European history. Examples will come from the 14th and 17th centuries, periods of difficult climactic conditions that led to large areas of Europe being controlled by armed bands of mercenaries. Consequences included disregard for any laws or social norms, as these «companies» of armed thugs sacked towns, raped and pillaged, and sold their services to the highest bidder. These companies were often employed by heads of state, or religious leaders such as Cardinal Richilieu.

We are seeing gangsters take control of the United States, using political leaders as proxies. Included are control of media messaging via corporate advertisers, and placing puppets on courts and in local political offices. Violence is routinely employed, as in American bombing campaigns in the Middle East, assassination of reporters, and intimidation of political opponents. These actions are mostly employed by Republican Party political operatives, acting on instructions from fossil fuel and banking firms, but Democrats are also often complicit. Evidence can be seen in the majority support of the Keystone Pipeline in the US Senate, where 63 Senators insist on allowing a pipeline that could devastate aquifers, will increase GHG emissions, and provide no significant job growth or increase in US oil supply. The end products, too dirty to meet US standards, will be shipped to the Latin American market.

The beneficiaries of the pipeline are the Koch Brothers, the largest owners of Tar Sands operations, and the owners of the refineries in Texas where the Tar Sands oil will be shipped. Their net worth of approximately $100 billion US has enabled this level of political control. Estimates of their reported cash contributions to political puppets have exceeded $1 billion US, with dark money contributions possible.

I propose to use historical analogies, and make recent comparisons to American gangsters of Sicilian origin. This portrayal will be illustrated by Ian Murphy of Buffalo Beast, whose satirical art work is among the best in the world. Koch, Tillerson of Exxon, and Boyce of Peabody Energy (a coal company) will be drawn in expensive Italian suits, similar to what is worn by actors in shows such as Boardwalk Empire and The Godfather series. Along with the satirical drawings will be detailed summaries of their criminal activities. These fossil fuel executives have killed far more people through pollution and greenhouse gas emissions than any Sicilian mob ever did, and evidence will be cited to support this assertion.

The analogy is based on evidence, but somewhat imperfect. The goal is to reach a wide popular audience, establishing the gangster meme and illustrating how it plays out in considerable detail. By illustrating financial ties, including degradation of education and media reporting, we propose to put pressure on bad actors in the United States and elsewhere.

4420a - How to price carbon for industry?

ORAL PRESENTATIONS

O-4420a-01

Session Number 4402b - Carbon Pricing

M. Muuls (1) ; R. Martin (2) ; A. Dechezleprêtre (3)
(1) Grantham Institute, Imperial College London, Business School, London, United Kingdom; (2) Imperial College London, Business school, London, United Kingdom; (3) London School of Economics, Grantham institute on climate change and the environment/centre for economic performance, London, United Kingdom

The EU Emissions Trading System is the EUs flagship climate policy, establishing since 2005 a carbon market across Europe with more than 12,000 plants in 31 countries regulated at present. With industry responsible for a large share of global carbon emissions, carbon pricing is seen as a central policy instrument for industry's transformation towards more energy and material efficiency and for unleashing innovation processes. We will discuss what effect the carbon price had to date on industry.

We discuss the results of a research paper that uses comprehensive firm and plant level data for more than 4,500 French manufacturing firms. It examines the economic and environmental impact of the EU ETS. Our results suggest that ETS regulated manufacturing plants in France reduced emissions by an average of 15-20%, a significant amount. The most marked reduction in emissions occurs following Phase II of the EU ETS in 2008, though there is some evidence of emissions reductions occurring during Phase I (2005-2007). Further investigation provides evidence that while these emission reductions do not arise from reallocation within the firm there is some evidence that these reductions are, at least in part, the result of outsourcing carbon-intensive production.

We also discuss recent research investigating the relative intensity of knowledge spillovers in clean and dirty technologies. In addition, a recently published paper by one of the co-contributors and his coauthor shows that the EU ETS has increased low-carbon innovation among regulated firms by as much as 10%, while not crowding out patenting for other technologies.

Together, these provide a robust basis for discussion of the impacts of carbon pricing, on emissions, economic performance and innovation by firms.

O-4420a-02

Assessment of Allowance Mechanism in China's Carbon Trading Pilots

L. Xiong (1)
(1) Wuhan University, Institute for International Studies, Wuhan, Hubei, China

Due to its rapid economic expansion over the last decade, China has become the world's largest energy consumer and greenhouse gases (GHGs) emitter. With growing resources and environmental constrains domestically and the need for meeting international commitment to GHGs abatement, China's National Development and Reform Commission (NDRC)launched a series of local carbon cap-and-trade pilots in seven provinces and cities including Shenzhen, Beijing, Tianjin, Shanghai, Chongqing, Guangdong, and Hubei, each of which has started its operation between 2013 and 2014.

In this paper, we examines the allowance mechanism of China's pilots from two aspects, one is the allowance allocation, and the other is the allowance distribution and make comparisons in the two aspects with EU Emissions Trading System (EU ETS) and CA CAT. Allocation determines how the carbon emission cap on the total number of emission allowances is set and how emission allowances are allocated among covered entities within the cap. Allowance distribution deals with distribution of allocated allowances to all covered entities as well as dynamic allowance management in post-distribution.

China's carbon trading pilots formed its unique allocation mechanism, which includes the following four characteristics: rigid cap combined with elastic structure, historical emissions method combined with benchmarking, free distribution combined with the auction, pre allocation combined with post adjustment. However, due to the short preparation time and lack of sufficient emissions data, there are many problems in the pilot design of the allocation mechanism, such as the loose cap, whipping the fast ox, double counting, and too small proportion of benchmarking and auction.

O-4420a-03

Emission Trading Scheme and competiveness:the tricky equation of free allocation for the EU ETS through to 2030

E. Alberola (1) ; M. Jalard (1)
(1) CDC Climat, Research, Paris , France

One of the central debates surrounding the design of the European Union Emissions Trading Scheme is the approach to address carbon leakage concerns. In preparation of its phase 4, new design settings proposals of the European Commission in January 2014 have revived the debate. Based on the European Commission's communication on the 2030 Energy and Climate framework, in October 2014, the European Council approved a new target to reduce CO2 emissions by 43% in EU ETS sectors by 2030 in addition to the implementation of a market instrument for stability. These two measures are likely to induce the emergence of a more robust carbon price signal, and the Council committed to the continuation of free allocation for industry after 2020.

From 2005 to 2012, all installations were eligible for free allowances which were allocated using installations' historical CO2 emissions data. Since 2013, free allowances have been allocated according to EU harmonized rules on the basis of benchmarks (carbon intensity target) and historical production levels. These have been adjusted by a coefficient of exposure to the risk of carbon leakage and finally adjusted to the free allocation cap by a Cross Sectorial Correction Factor (CSCF). In this new context, the paper assesses the robustness of the expansion of the 2020 mechanism to define free allocations by 2030 regarding three criteria. Firstly, free allocations are assumed to mitigate carbon leakage risks efficiently and sustainably; secondly to minimize sectorial distortions; and thirdly to maintain the environmental and economic efficiency.

In a first section, based on a literature review and on estimations from industry data, the paper examines the phase III experiences which provide useful insight into the necessary considerations for phase IV of the EU ETS. Then, in the second section, the paper presents three modeling scenario to define the amount of free allocation for the European industry: a scenario of the expansion of the 2020 mechanism by 2030, a scenario with the output based mechanism and three alternative scenarios based on the output based mechanism with additional measures to mitigate the uncertainty of an ex-post adjustment.

We conclude that, by extending the current mechanism, the amount of free allowances remains higher than the free allowance cap, which should mechanically decrease from roughly 800 million in 2013 to 500 million by 2030. It would thus be necessary to gradually reduce the amount of freely allocated allowances using a Cross Sectorial Correction Factor (CSCF) from 94% in 2013 to 82% by 2020 and 66% by 2030. The implementation of the output based allocation, based on actual industrial production (rather than historical), using up to date benchmarks in line with technological progress, would induce an annual correction coefficient of 71% in 2030. However, depending on the annual aggregate activity level, a new uncertainty would arise concerning the value of the CSCF coefficient. According to our estimates, this coefficient would be comprised between 62% and 82% in 2030, which would imply an uncertainty on the net carbon cost of the magnitude of 10% of the added value in the cement sector and 6% for in the steel sector, under the assumption of a 30€/tCO2 price.

There are three potential avenues which can be explored to mitigate this uncertainty and facilitate investment in low carbon technologies. Firstly, a reserve of free allowances could be established to offset yearly deficit / surplus between free allowances cap and the quantity of freely allocated allowances. Secondly, by removing the free allowances cap, the need to apply the correction factor is eliminated. However, this may reduce the amount of auctioned allowances, which was already decreased by the market stability reserve (MSR). Finally, the definition of a more targeted list of sectors at risk of carbon leakages could reduce the number of free allowances by identifying and gradually allocating allowances according to sectors exposure. This would deem it unnecessary to apply the correction factor, and therefore eliminate all associated uncertainty. The method of dynamic allocation combined with a more targeted list would thus be an adequate solution to the tricky equation of free allocation through to 2030.

O-4420a-04

Energy market regulation and leakage: implications for industry

S. Weishaar (1)
(1) University of Groningen, Law and Economics, Groningen, Netherlands

Electricity markets are crucial for addressing climate change. Electricity generation accounts for vast amounts of greenhouse gas emissions and electricity costs are an important concern for industries and thus a prominent topic in leakage discussions. This contribution focuses on electricity leakage (the avoidance of emission costs when generating electricity through relocation or importation) and its implications for industry. Following a comparative economic and a legal analysis it highlights 1) the carbon pricing implications for industry in terms of incentives for innovation and investments and 2) compare different regulatory approaches in various emissions trading systems such as e.g. the EU ETS, RGGI, and Korea.

O-4420a-05

Inclusion of Consumption in Carbon Pricing Systems

K. Neuhoff (1)
(1) German Institute for Economic Research (DIW Berlin), Berlin, Germany

Climate protection is a global challenge that all countries have a common but differentiated responsibility to address. The UNFCCC Lima outcome reconfirmed that pricing carbon remains important. However, not all governments are willing to commit to targets of equal stringency. Moreover, countries may have different views on the choice of policy mix. Some countries may put a stronger emphasis on the carbon price and see a higher

carbon price in the policy mix whereas other countries may make more use of other regulatory instruments. Carbon prices may thus continue to differ over longer time horizons. Without additional measures, this difference in the carbon price threatens a shift in production volumes to regions with lower carbon prices, which would undermine the effectiveness of carbon pricing.

Carbon leakage protection measures have therefore been and most likely will continue to be taken that complement carbon pricing in the production of carbon intensive materials. As leakage protection measures , all emission trading mechanisms thus offer free allowance allocation and all carbon tax schemes have implemented some exemptions for materials production. As a result, the carbon price signal is largely eliminated for mitigation opportunities in the materials sector other than efficiency improvements within the primary production process. In our studies of the cement and steel sector we found that only 10 to 20% of emission reduction potential exists through further efficiency improvements. The majority of future mitigation opportunities are linked to break-through technologies, the use of higher value products and thus lower weight and carbon intensity, alternative materials and more tailored use of materials. Thus the current approach to leakage protection cannot support the realization of the majority of mitigation options in these sectors. The reform options for leakage protection currently discussed for the European Union Emissions Trading System (EU ETS), dynamic allocation and abandoning the linear adjustment factor, would further reinforce this effect and undermine incentives for mitigation along the value chain. This puts at risk the low-carbon transformation of our economies because materials production comprises the largest share of industrial emissions.

Hence for post 2020 a new philosophy for leakage protection is necessary. We therefore propose to introduce a scheme (Inclusion of Consumption) for high-carbon commodities that:

1. continues to ensure leakage protection by (benchmark based) free allowance allocation or corresponding tax exemptions
2. includes the domestic consumption of selected carbon intensive materials in carbon pricing schemes.

The scheme, which would replicate systems that are already in place for the consumption of electricity in emission trading mechanisms of Chinese provinces and the Republic of Korea, would thereby restore the carbon price signal for the value chain which is broken where leakage protection motivates free allocation or tax exemptions. Thus the carbon price could contribute to set the incentives necessary for a low-carbon transformation of production and use of carbon intensive commodities.

4420b - What role of carbon pricing in a post Paris world?

ORAL PRESENTATIONS

K-4420b-01

Carbon price in a long-term, normative perspective

C. Hope (1)
(1) University of Cambridge, Judge Business School, Cambridge, France

This paper describes the use of an integrated assessment model to derive a (shadow) carbon price for government policymaking, including the current status of the SCCO2, ways that governments should periodically revise the SCCO2, potential improvements to the SCCO2 to encompass impacts by sectors, and the potential diffusion of standard SCCO2-type measures around the world.

K-4420b-02

"Carbon pricing in the United States: Markets and prices in the new national and international regimes"

J. Wiener (1)
(1) Duke University, Nicholas School of the Environment, Durham, United States of America

This presentation will be part of Session 000110 - «What role of carbon pricing» (A Creti), which will itself be part of the Topic on «Emissions Trading» as a form of «Collective Action toward Transformative Solutions,» featuring several related presentations on the evolving carbon markets in Europe, the United States, and elsewhere, as they build toward an effective and efficient new international regime.

This presentation will focus on the United States and Canada. First, it will assess the development of sub-national carbon markets among key US member states, including the «RGGI» emissions trading program among northeastern states and the California emissions trading program, and the links from some of these sub-national programs to carbon markets in other jurisdictions such as Quebec and Ontario, Canada. Second, the presentation will explain the new national program («Clean Power Plan») being advanced by the US Environmental Protection Agency (EPA) under the US Clean Air Act, section 111(d), including its current status (scheduled to be issued in final form during the summer of 2015), its legal basis, its economic efficiency, and the legal and policy challenges it may face. Third, the presentation will discuss how these North American carbon markets -- especially the EPA 111(d) national «Clean Power Plan» -- may contribute to action at the international level, including the Intended Nationally Determined Contribution (INDC) of the United States, along with other countries' INDCs to be presented at COP 21 in Paris in December 2015. It will discuss the potential for linking the evolving carbon markets in the US to those in Europe, China, and others, and it will consider the role of these developing carbon markets in the longer-term evolution of an effective and efficient international climate change regime. Fourth, the presentation will address the development of a carbon price for government policymaking through the US government's «Social Cost of Carbon» (SCC) measure, including the current status of the SCC, ways that governments should periodically revise the SCC, potential improvements to the SCC to encompass a broader array of impacts, and potential diffusion of SCC-type measures around the world.

This presentation will draw on the author's prior work in publications such as IPCC 2014, 5th Assessment Report, Working Group III, chapter on «International Cooperation» (of which J.B. Wiener was a co-author); W.A. Pizer et al., «Using and Improving the Social Cost of Carbon,» in Science (5 December 2014) (J.B. Wiener is a co-author); J. B. Wiener, «Property and Prices to Protect the Planet,» in Duke Journal of Comparative & International Law (2009); R.B. Stewart & J.B. Wiener, Reconstructing Climate Policy (2003); J.B. Wiener, «Global Environmental Regulation,» in Yale Law Journal (1999); and the author's experience helping to negotiate the UN Framework Convention on Climate Change (FCCC) in 1989-92.

Contours of carbon pricing: factors influencing 'optimal' developments over space and time

M. Grubb (1) ; K. Neuhoff (2) ; JC. Hourcade (3) ; JF. Mercure (4) ; P. Salas, (4)
(1) University College London, Institute of Sustainable Resources, London, United Kingdom; (2) German Institute for Economic Research (DIW Berlin), Berlin, Germany; (3) International Research Center on Environment and Development (CIRED), Paris, France; (4) University of Cambridge, Land Economy, Cambridge, United Kingdom

This paper summarises the main economic reasons why carbon prices are likely to, and should, differ between regions, and key factors that would affect the optimal trajectory over time in ways that diverge from a simple formulation based on an estimated social cost of carbon. We illustrate the generic discussion of some issues in space and time variance of carbon pricing with reference to key earlier works respectively on international welfare dimensions of carbon pricing, and the results of models with different dynamic specifications.

It is widely assumed in economic studies that the optimal approach to carbon pricing is a single global carbon price, reflecting the 'social cost of carbon', which should rise over time to reflect the assume cost or constraint. We first detail the assumptions under which this would be true and show these to be highly restrictive (and indeed implausible), which is one of the reasons why nothing like this is observed in practice. At the same time, industrial expectations of long-run carbon price trajectory are crucial to efficient investment, so developing a common understanding of desirable contours of carbon pricing over space and time is central.

Reasons why a common global carbon price is not welfare-efficient include those articulated by Chichilnisky and Heal in the 1990s, with reference to international inequalities; we add some specific real-world illustrations. We then analyse reasons why even in an equal world, factors of expectations, inertia, uncertainty and evolutionary economic considerations (including the combination of innovation and infrastructure in different sectors) may all create reasons why the locally optimal carbon price may be larger than the estimated SCC, illustrating with respect to varied published models with different dynamics specifications.

We build upon this work in three ways. First, conceptually, we link some of the existing modelling literature to the framework of different domains of economics processes in Grubb, Hourcade and Neuhoff (2014), notably the Second and Third domain processes of markets and innovation respectively, and highlight implications in terms of the relationship between these economic processes and corresponding policies. Second, we present results from a simplified model which to illustrate some aggregate influences and potential magnitudes of these effects, comparing results from other aggregate global models.

Finally, we discuss how interactions between the various factors should inform understanding of the desirable "contours" of carbon price development over space and time. In particular we illustrate some implications for the debate on linking emissions trading systems, in terms of the need for exchange rate mechanisms which can help to both support equitable development of investment and returns, and help to foster the processes of regional transformations.

Price formation in the EU ETS: politics or abatment-related fundamentals? Policy implications

G. Grosjean (1) ; N. Koch, (2) ; O. Edenhofer (1) ; S. Fuss (2)
(1) Potsdam Institute for Climate Impact Research, Potsdam, Germany; (2) Mercator Research Institute on Global Commons and Climate Change (MCC), Resources and international trade, Berlin, Germany

First, we analyze empirically the drivers of the carbon price between 2008 and 2013 in the world's largest cap-and-trade system - the EU ETS. We provide evidence that the market fundamentals such as the economic crisis, the development of renewables and the use of international credits explain only a small share of price variation during the period.

Secondly, we investigate how and to what extent allowance prices respond to regulatory news. Capitalizing on an event study method that incorporates a highly flexible econometric technique, we isolate and quantify the news-implied price response to 28 hand-collected announcements about the time profile of EU ETS supply schedules that took place between 2008 and 2014. The induced price reaction gives an instantaneous feedback onhow market participants view the evolution of cap stringency in the light of a particular policy announcement. Our findings suggest a high responsiveness of the cap-and-trade market to political events. We provide strong evidence that the backloading decision process caused substantial pricedeclines. The event-induced negative drifts evolve gradually as market participant's faith in the political support for backloading is shaken in the light of severe decisional bottlenecks in the lengthy legislativeprocess. In addition, we document positive price reactions to the announcement of the 2020 and 2030 policy packages, while news related to the 2050 roadmap either did not affect allowance prices orinduced negative price drifts. These results point to an underappreciated feature of cap-and-tradeprograms: with temporarily non-binding periodic cap, market perceptions will dominate priceformation. If a relaxation of cap schedules in the future is expected, the current allowance price drops significantly, irrespective of whether the contemplated change actually happens.

Thirdly and following our findings, regulatory instruments to stabilize expectations in the market and induce sufficient investment in low-carbon technologies are compared. This includes both price and quantity adjustment mechanisms as well as institutional reform such as delegation to an independent carbon central bank.

O-4420b-03

Extending carbon pricing with the expansion of the ETS scope: the road transport sector moving towards the EU ETS?

E. Alberola (1) ; P. Coussy (2) ; P. Portenart (2) ; M. Afriat (1)
(1) CDC Climat, Research, Paris , France; (2) IFPEN, Economy, Paris, France

One of the central debates surrounding the design of Emissions Trading Scheme is the question of its sectorial scope and its potential progressive expansion. In the context of the increasing development of emissions trading schemes all around the world beyond 2015, sharing the experience of implemented emissions trading schemes could be useful for other governments which should involve or would like to be involved in the implementation of this carbon policy.

In Europe, the Emissions Trading Scheme (EU ETS) covers energy and industry sectors. However, Since 2005, there have been several extensions of the EU ETS: new states, sector (domestic aviation) and gases. In the context of the EU ETS reform and in its first report on the EU ETS functioning in November 2012, the European Commissions suggested to constraint energy related CO2 emissions in sectors currently outside the EU ETS by for instance including fuel consumption in other sectors. In the 2030 Energy and Climate framework, the European Commission introduced namely the potential avenue beyond 2020 to introduce new sectors in the coverage such as road transport or buildings sectors. Beyond the overall revision of the EU ETS directive, the road transport sector can be included in the EU ETS via the opt-in provision which gives Member States the option of introducing, voluntarily and unilaterally, new GHG or new sectors. Denmark is the first European State to express, in September 2014, its wish to include the road transport sector in its national Emissions Trading scheme (ETS) target.

Based on this policy context, the paper deals with the introduction of the road transport in the EU ETS. In a first section, the paper examines the future trends of CO2 emissions from road transport in Europe by 2030 by modeling technology deployment in passenger and heavy duty car parks in two main regions in Europe (EU15 and EU13).

In a second section, the paper investigates what lessons could be drawn for the European Union from the experience of others ETS. Since the implementation of the EU ETS in 2005, other emissions trading schemes have been developed but only a small number include or envisage including road transport within their scope. The New Zealand includes the road transport in 2008 and California and Quebec's emissions trading schemes cover transport fuels suppliers and importers since 2015. The analysis reveals two main design lessons: in all cases, the emission trading scheme is a complementary measure adding to other sectorial policies and credit offsets play a key role to mitigate compliance costs.

Then, the third section analyses what would be institutional and economic impacts of the introduction of the European road transport in the EU ETS. Based on modeling results from three different general equilibrium models, the paper reveals that the EU road transport sector is not likely to be included in the EU ETS by 2030. First, we conclude that the new burden sharing after the road transport inclusion would be supported mainly by the power sector. Secondly, the CO2 price would increase sharply revealing higher compliance costs without the potential opportunity to use offsets credits. Thirdly, the new higher carbon price with the road transport in the EU ETS would be too low to trigger structural changes in the sector towards the deployment of low-carbon technologies or behaviors.

O-4420b-04

Linked domestic CDM: A proposed climate architecture

K. Pillay (1)
(1) Environmental Resource Management, Sustainability and Climate Change, Johannesburg, Gauteng, South Africa

Three dominant issues have historically plagued climate negotiations: how to bypass issues of sovereignty, generate sufficient climate finance, and establish an agreement that is inclusive of the current major polluters. Despite the highly contested nature of the Clean Development Mechanism (CDM) under the Kyoto Protocol, it provides policy makers with a starting point for the formation of new climate policy architecture. This research proposes the integration of CDM, as hosted by each state and therefore under their jurisdiction, into a linked climate policy architecture. A linked domestic CDM system would allow for Certifiable Emission Reductions to be earned through the implementation of domestic projects or projects hosted in other states. These Certifiable Emission Reductions can act as a unique climate currency for each state. This research questions how a linked domestic CDM system would be structured in a climate finance context, specifically analysing how Certifiable Emission Reductions would operate and interact as a climate currency. From this research, we conclude that fixed exchange rates are more stable than flexible exchange rates in a climate currency framework. Fixed Exchange Rates reduce losses of capital (owing to uncertainty in the markets) and the prominence of asymmetric spatial price transmission associated with fiat Certifiable Emission Reductions prices. To encourage co-operation between developing and developed countries, it is recommended that a combination of currency area theory and trade blocs be implemented as opposed to a currency union. Currency areas are the most viable option as they maintain that the CDM is under the control of the state and retains a level of stability as individual state Certifiable Emission Reductions prices are fixed to the same price. Even though this research forms the basis for a new climate policy architecture, the overall effectiveness of the policy will be determined by the selection of appropriate discount schemes, increased participation and agreement by states, and most significantly, political will.

Linking Up Emissions Trading Schemes: Lessons, Risks and Challenges

S. Quemin (1) ; R. Trotignon (2) ; B. Solier (2)
(1) Climate Economics Chair & Paris-Dauphine University, Paris, France; (2) Climate Economics Chair, Paris, France

This presentation will come after contributions about design and functioning issues of carbon markets in Europe, the U.S. and China.

Following these presentations, it's appear clearly that the fragmentation of carbon markets in the world is reflected by the wide range of regional designs, among which discrepancies regarding flexibility rules and dynamic price management mechanisms are particularly salient.

Although on the face of it inter-ETS linkage looks appealing, impediments to linking could arise from these discrepancies. This raises the twofold issue of whether to engage in linkage given the risks and challenges involved; and of how to link up ETSs given such discrepancies and how these could be overcome by gradual alignment.

Regarding the why-link side of the question, much can be gained by flipping it upside down and rather addressing the potential sacrifice from not linking. We identify determinants and key convening features of past linkages and investigate the question of how to make linkage more attractive and induce further cooperation.

On the how-to-link side of the question, we discuss what we identify as impediments to linkage and how these can be remedied. Such relative concepts as linkability or compatibility are discussed in light of a comparative analysis of schemes' design features (whom would it be better/easier to link with). Different linking path scenarios are then reviewed, namely case-by-case or bilateral regulation, definition of model rules for regional partnership, globally networked ETS, etc.

This discussion draws on current experience, that is determinants of observed linkage agreements.

P-4420-01

An analysis of climate policies which include compensation mechanisms to preserve the competitiveness of the French industry

G. Le Treut (1)
(1) Centre International de Recherche sur l'Environnement et le Développement, Paris, France

The aim of this presentation is to explore tax arrangements that can help to reduce the negative aspects of the application of carbon tax through objectives comprising equity, competitiveness and better efficiency.

This will be done by comparing the impacts of different strategies on various macroeconomic indicators, and through analysis of the corresponding distributive effects on energy-intensive sectors, as well as on households with different levels of income.

Each strategy offers different options to recycle the carbon tax revenue, in situations when it is applied unilaterally to the French economy.

We use the IMACLIM-S France computable general equilibrium model designed for comparative static exercises. It represents an open-French economy, distinguishing four categories of agents (households, businesses, government and «the rest-of-world»). The description of the production system distinguishes the energy sectors, as well as energy-intensive sectors, and a composite remainder of the economy.

IMACLIM is a «hybrid» model. It is based on input-output tables of the national accounts previously harmonized with the energy statistic information to obtain a consistent framework for the study of environmental issues. This harmonization effort between energy balance and national accounts provides an accurate description of energy volumes traded directly through their physical flow. Furthermore, the distribution of income and the structure of public finances are detailed without disrupting the overall consistency, reconciling the microeconomic data from household surveys with macroeconomic statistics.

The model is based on a set of economic parameters on which «various beliefs» are expressed, and from which we must conduct systematic sensitivity tests: (i) the adjustment of energy consumption levels in response to signal prices, (ii) the response of wages to changes in unemployment, (iii) the effectiveness of alternative methods on public finance management, (iv) the effects of price competitiveness, by observing the response of changes in production costs in France with the rest-of-world, exogenous to the model.

The version of the model is calibrated by data of the year 2010.

The critical point of a carbon tax reform is to contain the spread of a higher energy costs on production costs, increases that ultimately affect the purchasing power of households and affects the international competitiveness of firms.

The combination of a carbon tax with structural policies to support growth (lower social contributions) does not reduce the unequal effects of taxes. To reconcile equity, employment and activity level, it seems essential to combine these policies with specific compensation mechanisms according to household income levels, and to the exposure of energy-intensive sectors to international competitiveness.

Thanks to the sectorial and household disaggregation described by the latest version of the model, we consider various revenue-recycling schemes that better preserve altogether economic efficiency, equity and competitiveness.

The joint analysis of the distributive impacts across sectors,

the distributive impacts between households, and their macroeconomic feedbacks on the rest of the economy, and of several environmental policy proposals highlight possible trade-offs for maximizing global consumption, reducing unemployment, reducing inequalities, and protecting exposed sectors.

The analysis framework allows the design of a reform resulting from inevitable trade-offs between redistribution, competitiveness and aggregate impacts on activity and employment.

P-4420-02

How carbon pricing can foster collective solutions

S. Qi (1)
(1) Wuhan University, Economica and Management School, Wuhan, China

China made great decision to reduce its carbon emission based on Cap and trade mechanism.China began its ETS pilots in five cities and two provinces which controls 20 percent of China's carbon emission since 2011 and will start its national carbon market in 2016 based on the experiences of the seven ETS pilots. As the current biggest emitter, China's ambitious action to reduce its emission by market oriented policy will influence our globle emission reduction heavily and will be one of the important driver to getting the internatinoal climate agreement in the COP in Paris in this year. Therefore, we will firstly compare the policy features and the effect of the seven ETS pilots in China. Then,we will forecast how to step into a united national carbon market based on the seven ETS pilots. Finally,we will analyse the significance of China's ETS pilots to China, emerging economies and even the globle carbon market and emission reduction.

P-4420-03

«Carbon pricing and markets in the United States: Constructing the new national and international regimes»

J. Wiener (1)
(1) Duke University, Nicholas School of the Environment, Durham, United States of America

This presentation will be part of the Session on «Emissions Trading» as a form of «Collective Action toward Transformative Solutions,» featuring several related presentations on the evolving carbon markets in Europe, the United States, and elsewhere, as they build toward an effective and efficient new international regime. This presentation will focus on the United States and Canada. First, it will assess the development of sub-national carbon markets among key US member states, including the «RGGI» emissions trading program among northeastern states and the California emissions trading program, and the links from some of these sub-national programs to carbon markets in other jurisdictions such as Quebec and Ontario, Canada. Second, the presentation will explain the new national program («Clean Power Plan») being advanced by the US Environmental Protection Agency (EPA) under the US Clean Air Act, section 111(d), including its current status (scheduled to be issued in final form during the summer of 2015), its legal basis, its economic efficiency, and the challenges it may face. Third, the presentation will discuss how these North American carbon markets -- especially the EPA 111(d) national «Clean Power Plan» -- may contribute to action at the international level, including the Intended Nationally Determined Contribution (INDC) of the United States along with other countries' INDCs to be presented at COP 21 in Paris in December 2015. It will discuss the potential for linking the evolving carbon markets in the US to those in Europe, China, and others, and it will consider the role of these developing carbon markets in the longer-term evolution of an effective and efficient international climate change regime. Fourth, the presentation will address the development of a carbon price for government policymaking through the US government's «Social Cost of Carbon» (SCC) measure, including the current status of the SCC, ways that governments should periodically revise the SCC, potential improvements to the SCC to encompass a broader array of impacts, and potential diffusion of SCC-type measures around the world. This presentation will draw on the author's prior work in publications such as IPCC 2014, 5th Assessment Report, Working Group III, chapter on «International Cooperation» (of which J.B. Wiener was a co-author); W.A. Pizer et al., «Using and Improving the Social Cost of Carbon,» in Science (5 December 2014) (J.B. Wiener is a co-author); J. B. Wiener, «Property and Prices to Protect the Planet,» in Duke Journal of Comparative & International Law (2009); R.B. Stewart & J.B. Wiener, Reconstructing Climate Policy (2003); J.B. Wiener, «Global Environmental Regulation,» in Yale Law Journal (1999); and the author's experience helping to negotiate the UN Framework Convention on Climate Change (FCCC) in 1989-92.
