

The GPML Toolbox version 3.5

Carl Edward Rasmussen & Hannes Nickisch

December 8, 2014

Abstract

The GPML toolbox is an Octave 3.2.x and Matlab 7.x implementation of inference and prediction in Gaussian process (GP) models. It implements algorithms discussed in Rasmussen & Williams: *Gaussian Processes for Machine Learning*, the MIT press, 2006 and Nickisch & Rasmussen: *Approximations for Binary Gaussian Process Classification*, JMLR, 2008.

The strength of the function lies in its flexibility, simplicity and extensibility. The function is flexible as firstly it allows specification of the properties of the GP through definition of mean function and covariance functions. Secondly, it allows specification of different inference procedures, such as e.g. exact inference and Expectation Propagation (EP). Thirdly it allows specification of likelihood functions e.g. Gaussian or Laplace (for regression) and e.g. cumulative Logistic (for classification). Simplicity is achieved through a single function and compact code. Extensibility is ensured by modular design allowing for easy addition of extension for the already fairly extensive libraries for inference methods, mean functions, covariance functions and likelihood functions.

This document is a technical manual for a developer containing many details. If you are not yet familiar with the GPML toolbox, the *user documentation* and examples therein are a better way to get started.

1 Gaussian Process Training and Prediction

The `gpm1` toolbox contains a single user function `gp` described in section 2. In addition there are a number of supporting structures and functions which the user needs to know about, as well as an internal convention for representing the posterior distribution, which may not be of direct interest to the casual user.

Inference Methods: An inference method is a function which computes the (approximate) posterior, the (approximate) negative log marginal likelihood and its partial derivatives w.r.t.. the hyperparameters, given a model specification (i.e., GP mean and covariance functions and a likelihood function) and a data set. Inference methods are discussed in section 3. New inference methods require a function providing the desired inference functionality and possibly extra functionality in the likelihood functions applicable.

Hyperparameters: The hyperparameters is a struct controlling the properties of the model, i.e.. the GP mean and covariance function and the likelihood function. The hyperparameters is a struct with the three fields `mean`, `cov` and `lik`, each of which is a vector. The number of elements in each field must agree with number of hyperparameters in the specification of the three functions they control (below). If a field is either empty or non-existent it represents zero hyperparameters. When working with FITC approximate inference, the inducing inputs `xu` can also be treated as hyperparameters for some common stationary covariances.

Hyperparameter Prior Distributions: When optimising the marginal likelihood w.r.t. hyperparameters, it is sometimes useful to softly constrain the hyperparameters by means of prior knowledge. A prior is a probability distribution over individual or a group of hyperparameters, section 7.

Likelihood Functions: The likelihood function specifies the form of the likelihood of the GP model and computes terms needed for prediction and inference. For inference, the required properties of the likelihood depend on the inference method, including properties necessary for hyperparameter learning, section 4.

Mean Functions: The mean function is a cell array specifying the GP mean. It computes the mean and its derivatives w.r.t.. the part of the hyperparameters pertaining to the mean. The cell array allows flexible specification and composition of mean functions, discussed in section 5. The default is the zero function.

Covariance Functions: The covariance function is a cell array specifying the GP covariance function. It computes the covariance and its derivatives w.r.t.. the part of the hyperparameters pertaining to the covariance function. The cell array allows flexible specification and composition of covariance functions, discussed in section 6.

Inference methods, see section 3, compute (among other things) an approximation to the posterior distribution of the latent variables f_i associated with the training cases, $i = 1, \dots, n$. This approximate posterior is assumed to be Gaussian, and is communicated via a struct `post` with the fields `post.alpha`, `post.sW` and `post.L`. Often, starting from the Gaussian prior $p(f) = \mathcal{N}(f|m, K)$ the approximate posterior admits the form

$$q(f|\mathcal{D}) = \mathcal{N}(f|\mu = m + K\alpha, V = (K^{-1} + W)^{-1}), \text{ where } W \text{ diagonal with } W_{ii} = s_i^2. \quad (1)$$

In such cases, the entire posterior can be computed from the two vectors `post.alpha` and `post.sW`; the inference method may optionally also return $L = \text{chol}(\text{diag}(s)\text{diag}(s)K + I)$.

If on the other hand the posterior doesn't admit the above form, then `post.L` returns the matrix

$L = -(K + W^{-1})^{-1}$ (and `post.sw` is unused). In addition, a sparse representation of the posterior may be used, in which case the non-zero elements of the `post.alpha` vector indicate the active entries.

2 The gp Function

The gp function is typically the only function the user would directly call.

```
5a <gp.m 5a>≡
1 function [varargout] = gp(hyp, inf, mean, cov, lik, x, y, xs, ys)
2 <gp function help 5b>
3 <initializations 6b>
4 <inference 7b>
5 if nargin==7                                     % if no test cases are provided
6     varargout = {nlZ, dnlZ, post};                % report -log marg lik, derivatives and post
7 else
8     <compute test predictions 8a>
9 end
```

It offers facilities for training the hyperparameters of a GP model as well as predictions at unseen inputs as detailed in the following help.

```
5b <gp function help 5b>≡ (5a)
1 % Gaussian Process inference and prediction. The gp function provides a
2 % flexible framework for Bayesian inference and prediction with Gaussian
3 % processes for scalar targets, i.e. both regression and binary
4 % classification. The prior is Gaussian process, defined through specification
5 % of its mean and covariance function. The likelihood function is also
6 % specified. Both the prior and the likelihood may have hyperparameters
7 % associated with them.
8 %
9 % Two modes are possible: training or prediction: if no test cases are
10 % supplied, then the negative log marginal likelihood and its partial
11 % derivatives w.r.t. the hyperparameters is computed; this mode is used to fit
12 % the hyperparameters. If test cases are given, then the test set predictive
13 % probabilities are returned. Usage:
14 %

```

Depending on the number of input parameters, gp knows whether it is operated in training or in prediction mode. The highlevel structure of the code is as follows. After some initialisations, we perform inference and decide whether test set predictions are needed or only the result of the inference is demanded.

```

6b <initializations 6b>≡ (5a)
1 <minimalist usage 6c>
2 <process input arguments 6d>
3 <check hyperparameters 7a>

```

If the number of input arguments is incorrect, we echo a minimalist usage and return.

```

6c <minimalist usage 6c>≡ (6b)
1 if nargin<7 || nargin>9
2     disp('Usage: [n1Z dn1Z          ] = gp(hyp, inf, mean, cov, lik, x, y);')
3     disp('      or: [ymu ys2 fmu fs2   ] = gp(hyp, inf, mean, cov, lik, x, y, xs);')
4     disp('      or: [ymu ys2 fmu fs2 lp] = gp(hyp, inf, mean, cov, lik, x, y, xs, ys);')
5     return
6 end

```

Set some useful default values for empty arguments, and convert inf and lik to function handles and mean and cov to cell arrays if necessary. Initialize variables.

```

6d <process input arguments 6d>≡ (6b)
1 if isempty(mean), mean = {@meanZero}; end % set default mean
2 if ischar(mean) || isa(mean, 'function_handle'), mean = {mean}; end % make cell
3 if isempty(cov), error('Covariance function cannot be empty'); end % no default
4 if ischar(cov) || isa(cov, 'function_handle'), cov = {cov}; end % make cell
5 cstr = cov{1}; if isa(cstr, 'function_handle'), cstr = func2str(cstr); end
6 if strcmp(cstr, 'covFITC') && isfield(hyp, 'xu'), cov{3} = hyp.xu; end %use hyp.xu
7 if isempty(inf) % set default inference method
8     if strcmp(cstr, 'covFITC'), inf = {@infFITC}; else inf = {@infExact}; end
9 end
10 if ischar(inf), inf = str2func(inf); end % convert into function handle
11 if ischar(inf) || isa(inf, 'function_handle'), inf = {inf}; end % make cell
12 istr = inf{1}; if isa(istr, 'function_handle'), istr = func2str(istr); end
13 if strcmp(cstr, 'covFITC') % only infFITC* are possible
14     if isempty(strfind(istr, 'infFITC')==1)
15         error('Only infFITC* are possible inference algorithms')
16     end
17 end % only one possible class of inference algorithms
18 if isempty(lik), lik = {@likGauss}; end % set default lik
19 if ischar(lik) || isa(lik, 'function_handle'), lik = {lik}; end % make cell
20 lstr = lik{1}; if isa(lstr, 'function_handle'), lstr = func2str(lstr); end
21
22 D = size(x,2);

```

Check that the sizes of the hyperparameters supplied in `hyp` match the sizes expected. The three parts `hyp.mean`, `hyp.cov` and `hyp.lik` are checked separately, and define empty entries if they don't exist.

```

7a <check hyperparameters 7a>≡ (6b)
1 if ~isfield(hyp,'mean'), hyp.mean = []; end % check the hyp specification
2 if eval(feval(mean{:})) ~= numel(hyp.mean)
3     error('Number of mean function hyperparameters disagree with mean function')
4 end
5 if ~isfield(hyp,'cov'), hyp.cov = []; end
6 if eval(feval(cov{:})) ~= numel(hyp.cov)
7     error('Number of cov function hyperparameters disagree with cov function')
8 end
9 if ~isfield(hyp,'lik'), hyp.lik = []; end
10 if eval(feval(lik{:})) ~= numel(hyp.lik)
11     error('Number of lik function hyperparameters disagree with lik function')
12 end

```

Inference is performed by calling the desired inference method `inf`. In training mode, we accept a failure of the inference method (and issue a warning), since during hyperparameter learning, hyperparameters causing a numerical failure may be attempted, but the minimize function may gracefully recover from this. During prediction, failure of the inference method is an error.

```

7b <inference 7b>≡ (5a)
1 try % call the inference method
2     % issue a warning if a classification likelihood is used in conjunction with
3     % labels different from +1 and -1
4     if strcmp(lstr,'likErf') || strcmp(lstr,'likLogistic')
5         if ~isstruct(y)
6             uy = unique(y);
7             if any( uy~=+1 & uy~=-1 )
8                 warning('You try classification with labels different from {+1,-1}')
9             end
10        end
11    end
12    if nargin>7 % compute marginal likelihood and its derivatives only if needed
13        if isstruct(y)
14            post = y; % reuse a previously computed posterior approximation
15        else
16            post = feval(inf{:}, hyp, mean, cov, lik, x, y);
17        end
18    else
19        if nargin<=1

21        else
22            [post nlZ dnlZ] = feval(inf{:}, hyp, mean, cov, lik, x, y);
23        end
24    end
25 catch
26    msgstr = lasterr;
27    if nargin>7, error('Inference method failed [%s]', msgstr); else
28        warning('Inference method failed [%s] .. attempting to continue',msgstr)
29        dnlZ = struct('cov',0*hyp.cov, 'mean',0*hyp.mean, 'lik',0*hyp.lik);
30        varargout = {NaN, dnlZ}; return % continue with a warning
31    end
32 end

```

We copy the already computed negative log marginal likelihood to the first output argument, and if desired report its partial derivatives w.r.t. the hyperparameters if running in inference mode.

Predictions are computed in a loop over small batches to avoid memory problems for very large test sets.

8a $\langle \text{compute test predictions } 8a \rangle \equiv$ (5a)

```

1 alpha = post.alpha; L = post.L; sW = post.sW;
2 if issparse(alpha) % handle things for sparse representations
3   nz = alpha ~= 0; % determine nonzero indices
4   if issparse(L), L = full(L(nz,nz)); end % convert L and sW if necessary
5   if issparse(sW), sW = full(sW(nz)); end
6 else nz = true(size(alpha,1),1); end % non-sparse representation
7 if isempty(L) % in case L is not provided, we compute it
8   K = feval(cov{:,}, hyp.cov, x(nz,:));
9   L = chol(eye(sum(nz))+sW*sW'.*K);
10 end
11 %verify whether L contains valid Cholesky decomposition or something different
12 Lchol = isnumeric(L) && all(all(tril(L,-1)==0)&diag(L)'>0&isreal(diag(L)));

28 ys2(id) = sum(reshape(Ys2, [],N),2)/N; % .. variance

```

3 Inference Methods

Inference methods are responsible for computing the (approximate) posterior `post`, the (approximate) negative log marginal likelihood `nlZ` and its partial derivatives `dnlZ` w.r.t. the hyperparameters `hyp`. The arguments to the function are hyperparameters `hyp`, mean function `mean`, covariance function `cov`, likelihood function `lik` and training data `x` and `y`. Several inference methods are implemented and described this section.

```
10 <infMethods.m 10>≡
1 % Inference methods: Compute the (approximate) posterior for a Gaussian process.

21 %   infPrior      Perform inference with hyperparameter prior.
22 %
23 % The interface to the approximation methods is the following:
24 %
25 %   function [post nlZ dnlZ] = inf..(hyp, cov, lik, x, y)
26 %
27 % where:
28 %
29 %   hyp      is a struct of hyperparameters
30 %   cov      is the name of the covariance function (see covFunctions.m)
31 %   lik      is the name of the likelihood function (see likFunctions.m)
32 %   x        is a n by D matrix of training inputs
33 %   y        is a (column) vector (of size n) of targets
34 %
35 %   nlZ      is the returned value of the negative log marginal likelihood
36 %   dnlZ     is a (column) vector of partial derivatives of the negative
37 %            log marginal likelihood w.r.t. each hyperparameter
38 %   post     struct representation of the (approximate) posterior containing
39 %     alpha  is a (sparse or full column vector) containing  $\text{inv}(K) \cdot (\mu - m)$ ,
40 %            where  $K$  is the prior covariance matrix,  $m$  the prior mean,
41 %            and  $\mu$  the approx posterior mean
42 %     sW     is a (sparse or full column) vector containing diagonal of  $\text{sqrt}(W)$ 
43 %            the approximate posterior covariance matrix is  $\text{inv}(\text{inv}(K) + W)$ 
44 %     L      is a (sparse or full) matrix,  $L = \text{chol}(sW * K * sW + \text{eye}(n))$ 
45 %
46 % Usually, the approximate posterior to be returned admits the form
47 %  $N(\mu = m + K * \alpha, V = \text{inv}(\text{inv}(K) + W))$ , where  $\alpha$  is a vector and  $W$  is diagonal;
48 % if not, then  $L$  contains instead  $-\text{inv}(K + \text{inv}(W))$ , and  $sW$  is unused.
```

```

49 %
50 % For more information on the individual approximation methods and their
51 % implementations, see the separate inf??.m files. See also gp.m
52 %
53 <gpml copyright 6a>

```

Not all inference methods are compatible with all likelihood functions, e.g.. exact inference is only possible with Gaussian likelihood. In order to perform inference, each method needs various properties of the likelihood functions, section 4.

3.1 Exact Inference

For Gaussian likelihoods, GP inference reduces to computing mean and covariance of a multivariate Gaussian which can be done exactly by simple matrix algebra. The program `inf/infExact.m` does exactly this. If it is called with a likelihood function other than the Gaussian, it issues an error. The Gaussian posterior $q(f|\mathcal{D}) = \mathcal{N}(f|\mu, V)$ is exact.

```

11 <inf/infExact.m 11>≡
1  function [post nlZ dn1Z] = infExact(hyp, mean, cov, lik, x, y)
2
3  % Exact inference for a GP with Gaussian likelihood. Compute a parametrization
4  % of the posterior, the negative log marginal likelihood and its derivatives
5  % w.r.t. the hyperparameters. See also "help infMethods".

3.2 Laplace's Approximation

For differentiable likelihoods, Laplace's approximation, approximates the posterior by a Gaussian centered at its mode and matching its curvature `inf/infLaplace.m`.

More concretely, the mean of the posterior $q(\mathbf{f}|\mathcal{D}) = \mathcal{N}(\mathbf{f}|\boldsymbol{\mu}, \mathbf{V})$ is – defining $\ell_i(\mathbf{f}_i) = \ln p(\mathbf{y}_i|\mathbf{f}_i)$ and $\ell(\mathbf{f}) = \sum_{i=1}^n \ell_i(\mathbf{f}_i)$ – given by

$$\boldsymbol{\mu} = \arg \min_{\mathbf{f}} \phi(\mathbf{f}), \text{ where } \phi(\mathbf{f}) = \frac{1}{2}(\mathbf{f} - \mathbf{m})^\top \mathbf{K}^{-1}(\mathbf{f} - \mathbf{m}) - \ell(\mathbf{f}) \stackrel{\text{c}}{=} -\ln[p(\mathbf{f})p(\mathbf{y}|\mathbf{f})], \quad (2)$$

which we abbreviate by $\boldsymbol{\mu} \leftarrow \mathcal{L}(\ell)$. The curvature $\frac{\partial^2 \phi}{\partial \mathbf{f} \partial \mathbf{f}^\top} = \mathbf{K}^{-1} + \mathbf{W}$ with $W_{ii} = -\frac{\partial^2}{\partial f_i^2} \ln p(\mathbf{y}_i|\mathbf{f}_i)$ serves as precision for the Gaussian posterior approximation $\mathbf{V} = (\mathbf{K}^{-1} + \mathbf{W})^{-1}$ and the marginal likelihood $Z = \int p(\mathbf{f})p(\mathbf{y}|\mathbf{f})d\mathbf{f}$ is approximated by $Z \approx Z_{LA} = \int \tilde{\phi}(\mathbf{f})d\mathbf{f}$ where we use the 2nd order Taylor expansion at the mode $\boldsymbol{\mu}$ given by $\tilde{\phi}(\mathbf{f}) = \phi(\boldsymbol{\mu}) + \frac{1}{2}(\mathbf{f} - \boldsymbol{\mu})^\top \mathbf{V}^{-1}(\mathbf{f} - \boldsymbol{\mu}) \approx \phi(\mathbf{f})$.

Laplace's approximation needs derivatives up to third order for the mode fitting procedure (Newton method)

$$d_k = \frac{\partial^k}{\partial f^k} \log p(\mathbf{y}|\mathbf{f}), \quad k = 0, 1, 2, 3$$

and

$$d_k = \frac{\partial}{\partial \rho_i} \frac{\partial^k}{\partial f^k} \log p(\mathbf{y}|\mathbf{f}), \quad k = 0, 1, 2$$

evaluated at the latent location \mathbf{f} and observed value \mathbf{y} . The likelihood calls (see section 4)

- `[d0, d1, d2, d3] = lik(hyp, y, f, [], 'infLaplace')`

and

- `[d0, d1, d2] = lik(hyp, y, f, [], 'infLaplace', i)`

return exactly these values.

3.3 Expectation Propagation

The basic idea of Expectation Propagation (EP) as implemented in `inf/infEP.m` is to replace the non-Gaussian likelihood terms $p(\mathbf{y}_i|\mathbf{f}_i)$ by Gaussian functions $t(\mathbf{f}_i; \nu_i, \tau_i) = \exp(\nu_i \mathbf{f}_i - \frac{1}{2} \tau_i \mathbf{f}_i^2)$ and to adjust the natural parameters ν_i, τ_i such that the following identity holds:

$$\frac{1}{Z_{t,i}} \int \mathbf{f}^k q_{-i}(\mathbf{f}) \cdot t(\mathbf{f}; \nu_i, \tau_i) d\mathbf{f} = \frac{1}{Z_{p,i}} \int \mathbf{f}^k q_{-i}(\mathbf{f}) \cdot p(\mathbf{y}_i|\mathbf{f}) d\mathbf{f}, \quad k = 1, 2$$

with the so-called cavity distributions $q_{-i}(f) = \mathcal{N}(f|\mathbf{m}, \mathbf{K}) \prod_{j \neq i} t(f_j; \nu_j, \tau_j) \propto \mathcal{N}(f|\boldsymbol{\mu}, \mathbf{V})/t(f_i; \nu_i, \tau_i)$ equal to the posterior divided by the i th Gaussian approximation function and the two normalisers $Z_{t,i} = \int q_{-i}(f) \cdot t(f_i; \nu_i, \tau_i) df$ and $Z_{p,i} = \int q_{-i}(f) \cdot p(y_i|f_i) df$. The moment matching corresponds to minimising the following local KL-divergence

$$\nu_i, \tau_i = \arg \min_{\nu, \tau} \text{KL}[q_{-i}(f)p(y_i|f_i)/Z_{p,i} \| q_{-i}(f)t(f_i; \nu, \tau)/Z_{t,i}].$$

In order to apply the moment matching steps in a numerically safe way, EP requires the derivatives of the expectations w.r.t. the Gaussian mean parameter μ

$$d_k = \frac{\partial^k}{\partial \mu^k} \log \int p(y|f) \mathcal{N}(f|\mu, \sigma^2) df, \quad k = 0, 1, 2$$

and the i th likelihood hyperparameter ρ_i

$$d = \frac{\partial}{\partial \rho_i} \log \int p(y|f) \mathcal{N}(f|\mu, \sigma^2) df$$

which can be obtained by the likelihood calls (see section 4)

- `[d0, d1, d2] = lik(hyp, y, mu, s2, 'infEP')`

and

- `d = lik(hyp, y, mu, s2, 'infEP', i).`

3.4 Kullback Leibler Divergence Minimisation

Another well known approach to approximate inference implemented `inf/infKL.m` in attempts to directly find the closest Gaussian $q(f|\mathcal{D}) = \mathcal{N}(f|\boldsymbol{\mu}, \mathbf{V})$ to the exact posterior $p(f|\mathcal{D})$ w.r.t. to some proximity measure or equivalently to maximise a lower bound $Z(\boldsymbol{\mu}, \mathbf{V})$ to the marginal likelihood Z as described in Nickisch & Rasmussen *Approximations for Binary Gaussian Process Classification*, JMLR, 2008. In particular, one minimises $\text{KL}(\mathcal{N}(f|\boldsymbol{\mu}, \mathbf{V}) \| p(f|\mathcal{D}))$ which amounts to minimising $-\ln Z(\boldsymbol{\mu}, \mathbf{V})$ as defined by:

$$\begin{aligned} -\ln Z &= -\ln \int p(f)p(y|f)df = -\ln \int q(f|\mathcal{D}) \frac{p(f)}{q(f|\mathcal{D})} p(y|f)df \\ &\stackrel{\text{Jensen}}{\leq} \int q(f|\mathcal{D}) \ln \frac{q(f|\mathcal{D})}{p(f)} df - \int q(f|\mathcal{D}) \ln p(y|f) df =: -\ln Z(\boldsymbol{\mu}, \mathbf{V}) \\ &= \text{KL}(\mathcal{N}(f|\boldsymbol{\mu}, \mathbf{V}) \| \mathcal{N}(f|\mathbf{m}, \mathbf{K})) - \sum_{i=1}^n \int \mathcal{N}(f_i|\mu_i, \nu_{ii}) \ln p(y_i|f_i) df_i, \quad \nu_{ii} = [\mathbf{V}]_{ii} \\ &= \frac{1}{2} \left(\text{tr}(\mathbf{V}\mathbf{K}^{-1}) - \ln |\mathbf{V}\mathbf{K}^{-1}| \right) + \frac{1}{2} (\boldsymbol{\mu} - \mathbf{m})^\top \mathbf{K}^{-1} (\boldsymbol{\mu} - \mathbf{m}) - \sum_{i=1}^n \ell^{\text{KL}}(\mu_i, \nu_{ii}) \end{aligned}$$

where $\ell_v^{\text{KL}}(\mu_i) = \int \mathcal{N}(f_i|\mu_i, \nu_{ii}) \ell_i(f_i) df_i$ is the convolution of the log likelihood ℓ_i with the Gaussian \mathcal{N} and $\mathbf{v} = \text{dg}(\mathbf{V})$. Equivalently, one can view ℓ^{KL} as a smoothed version of ℓ with univariate smoothing kernel \mathcal{N} .

From Challis & Barber *Concave Gaussian Variational Approximations for Inference in Large Scale Bayesian Linear Models*, AISTATS, 2011 we know that the mapping $(\boldsymbol{\mu}, \mathbf{L}) \mapsto -\ln Z(\boldsymbol{\mu}, \mathbf{L}^\top \mathbf{L})$ is

jointly convex whenever the likelihoods $f_i \mapsto \mathbb{P}(y_i|f_i)$ are log concave. In particular, this implies that every $(\mu_i, \sqrt{v_{ii}}) \mapsto \ell^{\text{KL}}(\mu_i, v_{ii})$ is jointly convex.

We use an optimisation algorithm similar to EP (section 3.3) where we minimise the local KL-divergence the other way round $\mu_i, \sqrt{v_{ii}} = \arg \min_{\mu, \sigma} \text{KL}[\mathcal{N}(f|\mu_i, v_{ii}) || q_{-i}(f)p(y_i|f_i)/Z_{p,i}]$. This view was brought forward by Tom Minka *Convex Divergence measures and message passing*, MSR-TR, 2005. The KL minimisation constitutes a jointly convex 2d optimisation problem solved by `klmin` using a scaled Newton approach which is included as a sub function in `inf/infKL.m`. The smoothed likelihood $\ell^{\text{KL}}(\mu_i, v_{ii})$ is implemented as a meta likelihood in `likKL`; it uses Gaussian-Hermite quadrature to compute the required integrals. Note that – as opposed to EP – Gaussian-Hermite quadrature is appropriate since we integrate against the $\ln \mathbb{P}(y_i|f_i)$ (which can be well approximated by a polynomial) instead of $\mathbb{P}(y_i|f_i)$ itself. The algorithm is – again unlike EP – provably convergent for log-concave likelihoods (e.g. `likGauss`, `likLaplace`, `likSech2`, `likLogistic`, `likPoisson`) since it can be regarded as coordinate descent with guaranteed decrease in the objective in every step. Due to the complex update computations, `infKL` can be quite slow although it has the same $\mathcal{O}(n^3)$ asymptotic complexity as EP and Laplace.

3.5 Variational Bayes

One can drive the bounding even further by means of local quadratic lower bounds to the log likelihood $\ell(f) = \ln p(y|f)$. Suppose that we use a super-Gaussian likelihood $p(y|f)$ i.e. likelihoods that can be lower bounded by Gaussians of any width w (e.g. `likLaplace`, `likT`, `likLogistic`, `likSech2`). Formally, that means that there are $b, z \in \mathbb{R}$ such that

$$\rho(f) = \ln p(y|f - z) - bf$$

is symmetric and $\sqrt{f} \mapsto \rho(f)$ is a convex function for all $f \geq 0$. As a result, we obtain the following exact representation of the likelihood

$$\ell(f) = \ln p(y|f) = \max_{w>0} \left((b + wz)f - \frac{wf^2}{2} - \frac{1}{2}h(\gamma) \right),$$

which can be derived by convex duality and assuming the likelihoods to be super-Gaussian. Details can be found in papers by Palmer et al. *Variational EM Algorithms for Non-Gaussian Latent Variable Models*, NIPS, 2006 and Nickisch & Seeger *Convex Variational Bayesian Inference for Large Scale Generalized Linear Models*, ICML, 2009.

The bottom line is that we can treat the variational bounding as a sequence of Laplace approximations with the “variational Bayes” log likelihood

$$\ell^{\text{VB}}(f_i) = \ell(g_i) + b_i(f_i - g_i), \mathbf{g} = \text{sgn}(\mathbf{f} - \mathbf{z}) \odot \sqrt{(\mathbf{f} - \mathbf{z})^2 + \mathbf{v}} + \mathbf{z}$$

instead of the usual likelihood $\ell(f_i) = \ln p(y_i|f_i)$ i.e. we solve $\boldsymbol{\mu} \leftarrow \mathcal{L}(\ell_v^{\text{VB}})$ instead of $\boldsymbol{\mu} \leftarrow \mathcal{L}(\ell)$. See section 3.2. In the code of `inf/infVB.m`, the likelihood is implemented in the function `likVB`.

At the end, the optimal value of \mathbf{W} can be obtained analytically via $w_i = |b_i - \ell'(g_i)|/|g_i - z_i|$.

For the minimisation in `inf/infVB.m`, we use a provably convergent double loop algorithm, where in the inner loop a nonlinear least squares problem (convex for log-concave likelihoods) is solved using `inf/infLaplace.m` such that $\boldsymbol{\mu} \leftarrow \mathcal{L}(\ell_v^{\text{VB}})$ and in the outer loop, we compute $\mathbf{v} \leftarrow \text{dg}((\mathbf{K}^{-1} + \mathbf{W})^{-1})$. The only requirement to the likelihood function is that it returns the values z and b required by the bound which are delivered by the call (see section 4)

- `[b,z] = lik(hyp, y, [], ga, 'infVB')`

The negative marginal likelihood upper bound $-\ln Z_{VB}$ is obtained by integrating the prior times the exact representation of the likelihood

$$p(y|f) = \max_{\gamma > 0} q(y|f, \gamma), \quad q(y|f, \gamma) = \mathcal{N}(f|\mathbf{v}, \gamma) \exp\left(-\frac{h(\gamma)}{2} - \frac{\mathbf{v}^2}{2\gamma}\right) \sqrt{2\pi\gamma}, \quad \gamma = \frac{1}{w}, \quad \mathbf{v} = b\gamma + z$$

w.r.t. the latent variables \mathbf{f} yielding

$$\begin{aligned} -\ln Z_{VB} &= -\ln \int \mathcal{N}(\mathbf{f}|\mathbf{m}, \mathbf{K}) \prod_{i=1}^n q_i(y_i|\mathbf{f}_i, \gamma_i) d\mathbf{f} \\ &= -\ln \mathcal{N}(\mathbf{m}|\mathbf{v}, \mathbf{K} + \mathbf{\Gamma}) + \frac{1}{2} \left(h(\gamma) - \mathbf{w}^\top \mathbf{v}^2 - \mathbf{1}^\top \ln 2\pi\gamma \right). \end{aligned}$$

3.6 FITC Approximations

One of the main problems with GP models is the high computational load for inference computations. In a setting with n training points \mathbf{x} , exact inference with Gaussian likelihood requires $O(n^3)$ effort; approximations like Laplace or EP consist of a sequence of $O(n^3)$ operations.

There is a line of research with the goal to alleviate this burden by using approximate covariance functions $\tilde{\mathbf{K}}$ instead of \mathbf{K} . A review is given by Candela and Rasmussen *A Unifying View of Sparse Approximate Gaussian Process Regression*, JMLR, 2005. One basic idea in those approximations is to work with a set of m inducing inputs \mathbf{u} with a reduced computational load of $O(nm^2)$. In the following, we will provide a rough idea of the FITC approximation used in the toolbox. Let \mathbf{K} denote the $n \times n$ covariance matrix between the training points \mathbf{x} , \mathbf{K}_u the $m \times n$ covariance matrix between the n training points and the m inducing points, and \mathbf{K}_{uu} the $m \times m$ covariance matrix between the m inducing points. The FITC approximation to the covariance is given by

$$\mathbf{K} \approx \tilde{\mathbf{K}} = \mathbf{Q} + \mathbf{G}, \quad \mathbf{G} = \text{diag}(\mathbf{g}), \quad \mathbf{g} = \text{diag}(\mathbf{K} - \mathbf{Q}), \quad \mathbf{Q} = \mathbf{K}_u^\top \mathbf{Q}_{uu}^{-1} \mathbf{K}_u, \quad \mathbf{Q}_{uu} = \mathbf{K}_{uu} + \sigma_{n_u}^2 \mathbf{I},$$

where σ_{n_u} is the noise from the inducing inputs. Note that $\tilde{\mathbf{K}}$ and \mathbf{K} have the same diagonal elements $\text{diag}(\tilde{\mathbf{K}}) = \text{diag}(\mathbf{K})$; all off-diagonal elements are the same as for \mathbf{Q} . Internally, the necessary covariance evaluations are performed by a meta covariance function `cov/covFITC.m`. The toolbox offers FITC versions for regression with Gaussian likelihood `inf/infFITC.m`, as well as for Laplace's approximation `inf/infFITCLaplace.m` and expectation propagation `inf/infFITCEP.m`.

The user can decide whether to treat the inducing inputs \mathbf{u} as fixed or as hyperparameters. The latter is possible for a number of common stationary covariance functions (and also all three FITC inference methods `inf/infFITC*.m`) and allows to adjust the inducing inputs \mathbf{u} w.r.t. the marginal likelihood. As detailed in the documentation of `inf/infFITC*.m`, \mathbf{u} is treated as fixed if it is passed as the 2nd parameter of `covFITC(cov, xu, ...)`. If the hyperparameter structure `hyp` contains a field `hyp.xu` in inference method calls like `infFITC*(hyp, ...)` or inference/prediction calls like `gp(hyp, @infFITC*, ...)` the inducing inputs \mathbf{u} are treated as hyperparameters and can be optimised.

3.7 Grid Approximations

Another way to bring down computational costs is to take advantage of (partial) grid structure present in the training points \mathbf{x} . For example, in geostatistics or image processing, the training data $\mathbf{x} \in \mathbb{R}^{n \times D}$ could be a complete 2d lattice of size $n_1 \times n_2$ as given by the axes $\mathbf{x}_1 \in \mathbb{R}^{n_1}$, $\mathbf{x}_2 \in \mathbb{R}^{n_2}$ so that $n = n_1 \cdot n_2$, $D = 2$ and $\mathbf{x} = [\text{vec}(\mathbf{x}_1 \mathbf{1}^\top), \text{vec}(\mathbf{1} \mathbf{x}_2^\top)]$. In general, a p -dimensional grid $\mathbf{x}_g \in \mathbb{R}^{N \times D}$ is specified by a set of axis matrices $\{\mathbf{x}_i \in \mathbb{R}^{n_i \times D_i}\}_{i=1..p}$ so that $N = \prod_{i=1}^p n_i$ and $D = \sum_{i=1}^p D_i$ where the axes do not need to be 1d nor do their components need to be sorted. As a consequence,

\mathbf{x}_g represents a Cartesian product of its axes $\mathbf{x}_g = \mathbf{x}_1 \times \mathbf{x}_2 \times \dots \times \mathbf{x}_p$. The `cov/covGrid.m` covariance function represents a Kronecker product covariance matrix

$$\mathbf{K} = \mathbf{K}_p \otimes \dots \otimes \mathbf{K}_2 \otimes \mathbf{K}_1$$

whose factorisation structure is given by the grid \mathbf{x}_g . The gain in computational efficiency is due to the fact that matrix-vector product, determinant, inverse and eigenvalue computations decompose so that the overall cost of $\mathcal{O}(N^3)$ turns into $\mathcal{O}(\sum_{i=1}^p n_i^3)$. Internally, we use a meta covariance function `cov/covGrid.m` to represent the Kronecker covariance matrix and a Gaussian regression inference method `inf/infGrid.m`. We also support incomplete grids where $n < N$. A good starting point is Yunus Saatçi's PhD thesis *Scalable Inference for Structured Gaussian Process Models*, University of Cambridge, 2011. For incomplete grids, we use the extensions by Wilson et. al, *Fast Kernel Learning for Multidimensional Pattern Extrapolation*, NIPS, 2014 where conjugate gradients and a determinant approximations are used. See `doc/demoGrid.m` for an illustration.

4 Likelihood Functions

A likelihood function $p_\rho(y|f)$ (with hyperparameters ρ) is a conditional density $\int p_\rho(y|f)dy = 1$ defined for scalar latent function values f and outputs y . In the GPML toolbox, we use iid. likelihoods $p_\rho(y|f) = \prod_{i=1}^n p_\rho(y_i|f_i)$. The approximate inference engine does not explicitly distinguish between classification and regression likelihoods: it is fully generic in the likelihood allowing to use a single code in the inference step.

Likelihood functionality is needed both during inference and while predicting.

4.1 Prediction

A prediction at \mathbf{x}_* conditioned on the data $\mathcal{D} = (X, y)$ (as implemented in `gp.m`) consists of the predictive mean μ_{y_*} and variance $\sigma_{y_*}^2$ which are computed from the the latent marginal moments $\mu_{f_*}, \sigma_{f_*}^2$ i.e. the Gaussian marginal approximation $\mathcal{N}(f_*|\mu_{f_*}, \sigma_{f_*}^2)$ via

$$p(y_*|\mathcal{D}, \mathbf{x}_*) = \int p(y_*|f_*)p(f_*|\mathcal{D}, \mathbf{x}_*)df_* \approx \int p(y_*|f_*)\mathcal{N}(f_*|\mu_{f_*}, \sigma_{f_*}^2)df_*. \quad (3)$$

The moments are given by $\mu_{y_*} = \int y_*p(y_*|\mathcal{D}, \mathbf{x}_*)dy_*$ and $\sigma_{y_*}^2 = \int (y_* - \mu_{y_*})^2p(y_*|\mathcal{D}, \mathbf{x}_*)dy_*$. The likelihood call

$$\bullet \text{ [lp, ymu, ys2] = lik(hyp, [], fmu, fs2)}$$

does exactly this. Evaluation of the logarithm of $p_{y_*} = p(y_*|\mathcal{D}, \mathbf{x}_*)$ for values y_* can be done via

$$\bullet \text{ [lp, ymu, ys2] = lik(hyp, y, fmu, fs2)}$$

where `lp` contains the number $\ln p_{y_*}$.

Using the moments of the likelihood $\mu(f_*) = \int y_*p(y_*|f_*)dy_*$ and $\sigma^2(f_*) = \int (y_* - \mu(f_*))^2p(y_*|f_*)dy_*$ we obtain for the predictive moments the following (exact) expressions

$$\begin{aligned} \mu_{y_*} &= \int \mu(f_*)p(f_*|\mathcal{D}, \mathbf{x}_*)df_*, \text{ and} \\ \sigma_{y_*}^2 &= \int \left[\sigma^2(f_*) + (\mu(f_*) - \mu_{y_*})^2 \right] p(f_*|\mathcal{D}, \mathbf{x}_*)df_*. \end{aligned}$$

1. The binary case is simple since $y_* \in \{-1, +1\}$ and $1 = p_{y_*} + p_{-y_*}$. Using $\pi_* = p_{+1}$, we find

$$\begin{aligned} p_{y_*} &= \begin{cases} \pi_* & y_* = +1 \\ 1 - \pi_* & y_* = -1 \end{cases} \\ \mu_{y_*} &= \sum_{y_*=\pm 1} y_*p(y_*|\mathcal{D}, \mathbf{x}_*) = 2 \cdot \pi_* - 1 \in [-1, 1], \text{ and} \\ \sigma_{y_*}^2 &= \sum_{y_*=\pm 1} (y_* - \mu_{y_*})^2p(y_*|\mathcal{D}, \mathbf{x}_*) = 4 \cdot \pi_*(1 - \pi_*) \in [0, 1]. \end{aligned}$$

2. The continuous case for homoscedastic likelihoods depending on $r_* = y_* - f_*$ only and having noise variance $\sigma^2(f_*) = \sigma_n^2$ is also simple since the identity $p(y_*|f_*) = p(y_* - f_*|0)$ allows to substitute $y_* \leftarrow y_* + f_*$ yielding $\mu(f_*) = f_* + \int y_*p(y_*|0)dy_*$ and assuming $\int y_*p(y_*|0)dy_* = 0$ we arrive at

$$\begin{aligned} \mu_{y_*} &= \mu_{f_*}, \text{ and} \\ \sigma_{y_*}^2 &= \sigma_{f_*}^2 + \sigma_n^2. \end{aligned}$$

3. The generalised linear model (GLM) case is also feasible. Evaluation of the predictive distribution is done by quadrature

$$p_{y_*} = \int p(y_*|f_*)p(f_*|\mathcal{D}, \mathbf{x}_*)df_* \approx \int p(y_*|f_*)\mathcal{N}(f_*|\mu_{f_*}, \sigma_{f_*}^2)df_*.$$

For GLMs the mean is given by $\mu(f_*) = g(f_*)$ and the variance is usually given by a simple function of the mean $\sigma^2(f_*) = v(g(f_*))$, hence we use Gaussian-Hermite quadrature with $\mathcal{N}(f_*|\mu_{f_*}, \sigma_{f_*}^2) \approx p(f_*|\mathcal{D}, \mathbf{x}_*)$ to compute

$$\begin{aligned}\mu_{y_*} &= \int g(f_*)p(f_*|\mathcal{D}, \mathbf{x}_*)df_*, \text{ and} \\ \sigma_{y_*}^2 &= \int \left[v(g(f_*)) + (g(f_*) - \mu_{y_*})^2 \right] p(f_*|\mathcal{D}, \mathbf{x}_*)df_* \neq v(\mu_{y_*}).\end{aligned}$$

4. Finally the warped Gaussian likelihood predictive distribution with strictly monotonically increasing warping function g is given by the expression

$$p(y_*|\mathcal{D}, \mathbf{x}_*) = g'(y_*)\mathcal{N}\left(g(y_*)|\mu_{f_*}, \sigma_n^2 + \sigma_{f_*}^2\right)$$

so that the predictive moments can be computed by Gaussian-Hermite quadrature.

In the following, we will detail how and which likelihood functions are implemented in the GPML toolbox. Further, we will mention dependencies between likelihoods and inference methods and provide some analytical expressions in addition to some likelihood implementations.

4.2 Interface

The likelihoods are in fact the most challenging object in our implementation. Different inference algorithms require different aspects of the likelihood to be computed, therefore the interface is rather involved as detailed below.

```

4.3 Implemented Likelihood Functions

The following table enumerates all (currently) implemented likelihood functions that can be found at `lik/lik<NAME>.m` and their respective set of hyperparameters ρ .

lik<NAME>	regression $y_i \in \mathbb{R}$	$p_\rho(y_i f_i) =$	$\rho =$
Gauss	Gaussian	$\mathcal{N}(y_i f_i, \sigma^2) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{(y_i-f_i)^2}{2\sigma^2}\right)$	$\{\ln \sigma\}$
GaussWarp	Warped Gaussian	$\mathcal{N}(g_\theta(y_i) f_i, \sigma^2) g'_\theta(y_i)$	$\{\theta_1, \dots, \theta_{n_g}, \ln \sigma\}$
Gumbel	Gumbel	$\frac{\pi}{\sigma\sqrt{6}} \exp(-z_i - e^{-z_i}), z_i = \gamma + \frac{s \cdot \pi(y_i - f_i)}{\sigma\sqrt{6}}, s = 1$	$\{\ln \sigma\}$
Sech2	Sech-squared	$\frac{\tau}{2 \cosh^2(\tau(y_i - f_i))}, \tau = \frac{\pi}{2\sigma\sqrt{3}}$	$\{\ln \sigma\}$
Laplace	Laplacian	$\frac{1}{2b} \exp\left(-\frac{ y_i - f_i }{b}\right), b = \frac{\sigma}{\sqrt{2}}$	$\{\ln \sigma\}$
T	Student's t	$\frac{\Gamma(\frac{\nu+1}{2})}{\Gamma(\frac{\nu}{2})} \frac{1}{\sqrt{\nu\pi}\sigma} \left(1 + \frac{(y_i - f_i)^2}{\nu\sigma^2}\right)^{-\frac{\nu+1}{2}}$	$\{\ln(\nu - 1), \ln \sigma\}$
lik<NAME>	classification $y_i \in \{\pm 1\}$	$p_\rho(y_i f_i) =$	$\rho =$
Erf	Error function	$\int_{-\infty}^{y_i f_i} \mathcal{N}(t) dt$	\emptyset
Logistic	Logistic function	$\frac{1}{1 + \exp(-y_i f_i)}$	\emptyset
Uni	Label noise	$\frac{1}{2}$	\emptyset
lik<NAME>	count data $y_i \in \mathbb{N}$	$p_\rho(y_i f_i) =$	$\rho =$
Poisson	Poisson	$\mu^{y_i} \cdot \frac{e^{-\mu}}{y_i!}, \mu = e^f \text{ or } \mu = \log(1 + e^f)$	\emptyset
lik<NAME>	nonnegative data $y_i \in \mathbb{R}_+ \setminus \{0\}$	$p_\rho(y_i f_i) =$	$\rho =$
Weibull	Weibull, $\gamma_1 = \Gamma(1 + 1/\kappa)$	$\kappa \gamma_1 / \mu (y \gamma_1 / \mu)^{\kappa-1} \exp(-(y \gamma_1 / \mu)^\kappa)$	$\{\ln \kappa\}$
Gamma	Gamma	$\frac{\alpha^\alpha \gamma^{\alpha-1}}{\Gamma(\alpha)} \mu^{-\alpha} \exp\left(-\frac{y \alpha}{\mu}\right)$	$\{\ln \alpha\}$
Exp	Exponential	$\mu^{-1} \exp\left(-\frac{y}{\mu}\right)$	\emptyset
InvGauss	Inverse Gaussian	$\sqrt{\frac{\lambda}{2\pi y^3}} \exp\left(-\frac{\lambda(y-\mu)^2}{2\mu^2 y}\right)$	$\{\ln \lambda\}$
lik<NAME>	interval data $y_i \in [0, 1]$	$p_\rho(y_i f_i) =$	$\rho =$
Beta	Beta	$\frac{\Gamma(\Phi)}{\Gamma(\mu\Phi)\Gamma((1-\mu)\Phi)} y^{\mu\Phi-1} (1-y)^{(1-\mu)\Phi-1}$	$\{\ln \Phi\}$
Composite likelihood functions $[p_1(y_i f_i), p_1(y_i f_i), \dots] \mapsto p_\rho(y_i f_i)$			
Mix	Mixture	$\sum_j \alpha_j p_j(y_i f_i)$	$\{\ln \alpha_1, \ln \alpha_2, \dots\}$

4.4 Usage of Implemented Likelihood Functions

Some code examples taken from `doc/usageLik.m` illustrate how to use simple and composite likelihood functions to specify a GP model.

Syntactically, a likelihood function `lf` is defined by

```
lk := 'func' | @func // simple
```

```
lf := {lk} | {param, lk} | {lk, {lk, ..., lk}} // composite
```

i.e., it is either a string containing the name of a likelihood function, a pointer to a likelihood function or one of the former in combination with a cell array of likelihood functions and an additional list of parameters.

```

Beta			✓			✓	✓	interval data, $[0, 1]$	beta regression

(✓)* EP might not converge in some cases since quadrature is used.

Exact inference is only tractable for Gaussian likelihoods. Expectation propagation together with Student's t likelihood is inherently unstable due to non-log-concavity. Laplace's approximation for Laplace likelihoods is not sensible because at the mode the curvature and the gradient is undefined due to the non-differentiable peak of the Laplace distribution. Special care has been taken for the non-convex optimisation problem imposed by the combination Student's t likelihood and Laplace's approximation.

4.6 Gaussian Likelihood

The Gaussian likelihood is the simplest likelihood because the posterior distribution is not only Gaussian but can be computed analytically. In principle, the Gaussian likelihood would only be operated in conjunction with the exact inference method but we chose to provide compatibility with all other inference algorithms as well because it enables code testing and allows to switch between

different regression likelihoods very easily.

```

4 n = numel(s2); b = zeros(n,1); y = y.*ones(n,1); z = y;
5 varargout = {b,z};

```

4.7 Warped Gaussian Likelihood

Starting from the likelihood $p(y|f)$ we are sometimes facing the situation where the data $y \in \mathcal{Y} \subseteq \mathbb{R}$ is not distributed according to $p(y|f)$ but some nonlinear transformation of the data $g(y) = z$ so that $z \sim p(z|f)$. Here, the warping function $g : \mathcal{Y} \rightarrow \mathbb{R}$ needs to be strictly monotonically increasing i.e. $g'(y) > 0$. Formally, we start from the fact that $p(z|f)$ integrates to one and use the derivative $dz = g'(y)dy$ to substitute

$$\int p(z|f)dz = 1 = \int p_g(y|f)dy, \quad p_g(y|f) = p(g(y)|f)g'(y)$$

where we have defined the log warped likelihood $\ln p_g(y|f) = \ln p(g(y)|f) + \ln g'(y)$. The interesting bit is that approximate inference methods such as `infExact`, `infLaplace`, `infEP`, `infVB`, `infKL` remain fully feasible; only prediction and derivatives become more involved. The usual GP inference is recovered by using the identity warping function $g : y \mapsto y$. The construction works in principle for any likelihood but our implementation in `likGaussWarp` is limited to the Gaussian likelihood.

Hyperparameter derivatives

Hyperparameter derivatives for `infLaplace` are obtained as follows

$$\begin{aligned} \frac{\partial}{\partial \theta} \ln \frac{\partial^k}{\partial f^k} p_g(y|f) &= \frac{\partial}{\partial \theta} \ln \frac{\partial^k}{\partial f^k} p(g(y)|f) + \frac{\partial}{\partial \theta} \frac{\partial^k}{\partial f^k} \ln g'(y), \quad k = 0, 1, 2 \\ &= -\frac{\partial^{k+1}}{\partial f^{k+1}} \ln p(g(y)|f) \frac{\partial}{\partial \theta} g(y) + \frac{\partial}{\partial \theta} \frac{\partial^k}{\partial f^k} \ln g'(y). \end{aligned}$$

Similarly for `infEP` the derivatives are given by

$$\begin{aligned} \frac{\partial}{\partial \theta} \ln \int p_g(y|f) \mathcal{N}(f|\mu, \sigma^2) df &= \frac{\partial}{\partial \theta} \ln \int p(g(y)|f) \mathcal{N}(f|\mu, \sigma^2) df + \frac{\partial}{\partial \theta} \ln g'(y) \\ &= -\frac{\partial}{\partial \mu} \ln \int p(g(y)|f) \mathcal{N}(f|\mu, \sigma^2) df \frac{\partial}{\partial \theta} g(y) + \frac{\partial}{\partial \theta} \ln g'(y). \end{aligned}$$

This trick above works for any homoscedastic likelihood where $p(y|f) = p(y + \beta|f + \beta)$ such as `likGauss`, `likLaplace`, `likSech2` and `likT`.

Predictive moments

As detailed in 4, the predictive distribution is – for Gaussian likelihood – given by

$$\begin{aligned} p(z_*|\mathcal{D}, \mathbf{x}_*) &= \int p(z_*|f_*)p(f_*|\mathcal{D}, \mathbf{x}_*)df_* = \int \mathcal{N}(z_*|f_*, \sigma_n^2) \mathcal{N}(f_*|\mu_{f_*}, \sigma_{f_*}^2)df_* \\ &= \mathcal{N}(z_*|\mu_{f_*}, \sigma_n^2 + \sigma_{f_*}^2), \quad \text{where } z_* = g(y_*) \\ p(y_*|\mathcal{D}, \mathbf{x}_*) &= g'(y_*) \mathcal{N}(g(y_*)|\mu_{f_*}, \sigma_n^2 + \sigma_{f_*}^2). \end{aligned}$$

Hence, the predictive moments are obtained by the 1d integrals

$$\begin{aligned} \mu_{y_*} &= \int y_* g'(y_*) \mathcal{N}(g(y_*)|\mu_{f_*}, \sigma_n^2 + \sigma_{f_*}^2) dy_* \\ &= \int g^{-1}(z_*) \mathcal{N}(z_*|\mu_{f_*}, \sigma_n^2 + \sigma_{f_*}^2) dz_*, \quad \text{and} \\ \sigma_{y_*}^2 &= \int (y_* - \mu_{y_*})^2 g'(y_*) \mathcal{N}(g(y_*)|\mu_{f_*}, \sigma_n^2 + \sigma_{f_*}^2) dy_* \\ &= \int (g^{-1}(z_*) - \mu_{y_*})^2 \mathcal{N}(z_*|\mu_{f_*}, \sigma_n^2 + \sigma_{f_*}^2) dz_*. \end{aligned}$$

4.8 Gumbel Likelihood

Distributions of extrema are well captured by the Gumbel distribution

$$p(y) = \frac{1}{\beta} \exp(-z - e^{-z}), \quad z = s \frac{y - \eta}{\beta}, \quad s \in \{\pm 1\}$$

with mean $\mu = \eta + \beta\gamma$ and variance $\sigma^2 = \pi^2\beta^2/6$ where $\gamma = 0.57721566490153$ denotes Euler–Mascheroni’s constant. Skewness is approximately given by $1.1395s$ where s is a sign switching between left and right skewness and kurtosis is $12/5$. The final expression for the Gumbel likelihood is

$$p(y|f) = \frac{\pi}{\sigma\sqrt{6}} \exp(-z - e^{-z}), \quad z = \gamma + s \frac{\pi}{\sigma\sqrt{6}}(y - f), \quad s \in \{\pm 1\}.$$

4.9 Laplace Likelihood

Laplace’s Approximation

The following derivatives are needed:

$$\begin{aligned} \ln p(y|f) &= -\ln(2b) - \frac{|f - y|}{b} \\ \frac{\partial \ln p}{\partial f} &= \frac{\text{sign}(f - y)}{b} \\ \frac{\partial^2 \ln p}{(\partial f)^2} &= \frac{\partial^3 \ln p}{(\partial f)^3} = \frac{\partial^3 \ln p}{(\partial \ln \sigma_n)(\partial f)^2} = 0 \\ \frac{\partial \ln p}{\partial \ln \sigma_n} &= \frac{|f - y|}{b} - 1 \end{aligned}$$

Expectation Propagation

Expectation propagation requires integration against a Gaussian measure for moment matching.

We need to evaluate $\ln Z = \ln \int \mathcal{L}(y|f, \sigma_n^2) \mathcal{N}(f|\mu, \sigma^2) df$ as well as the derivatives $\frac{\partial \ln Z}{\partial \mu}$ and $\frac{\partial^2 \ln Z}{\partial \mu^2}$ where $\mathcal{N}(f|\mu, \sigma^2) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left(-\frac{(f-\mu)^2}{2\sigma^2}\right)$, $\mathcal{L}(y|f, \sigma_n^2) = \frac{1}{2b} \exp\left(-\frac{|y-f|}{b}\right)$, and $b = \frac{\sigma_n}{\sqrt{2}}$. As a first step, we reduce the number of parameters by means of the substitution $\tilde{f} = \frac{f-y}{\sigma_n}$ yielding

$$\begin{aligned} Z &= \int \mathcal{L}(y|f, \sigma_n^2) \mathcal{N}(f|\mu, \sigma^2) df \\ &= \frac{1}{\sqrt{2\pi\sigma}} \frac{\sqrt{2}}{2\sigma_n} \int \exp\left(-\frac{(f-\mu)^2}{2\sigma^2}\right) \exp\left(-\sqrt{2} \frac{|f-y|}{\sigma_n}\right) df \\ &= \frac{\sqrt{2}}{2\sigma\sqrt{2\pi}} \int \exp\left(-\frac{(\sigma_n \tilde{f} + y - \mu)^2}{2\sigma^2}\right) \exp\left(-\sqrt{2} |\tilde{f}| \right) d\tilde{f} \\ &= \frac{\sigma_n}{\sigma\sigma_n\sqrt{2\pi}} \int \exp\left(-\frac{\sigma_n^2 \left(\tilde{f} - \frac{\mu-y}{\sigma_n}\right)^2}{2\sigma^2}\right) \mathcal{L}(\tilde{f}|0, 1) d\tilde{f} \\ &= \frac{1}{\sigma_n} \int \mathcal{L}(f|0, 1) \mathcal{N}(f|\tilde{\mu}, \tilde{\sigma}^2) df \\ \ln Z &= \ln \tilde{Z} - \ln \sigma_n = \ln \int \mathcal{L}(f|0, 1) \mathcal{N}(f|\tilde{\mu}, \tilde{\sigma}^2) df - \ln \sigma_n \end{aligned}$$

with $\tilde{\mu} = \frac{\mu - \eta}{\sigma_n}$ and $\tilde{\sigma} = \frac{\sigma}{\sigma_n}$. Thus, we concentrate on the simpler quantity $\ln \tilde{Z}$.

$$\begin{aligned}
\ln Z &= \ln \int \exp \left(-\frac{(f - \tilde{\mu})^2}{2\tilde{\sigma}^2} - \sqrt{2}|f| \right) df - \overbrace{\ln \tilde{\sigma} \sqrt{2\pi} - \ln \sqrt{2}\sigma_n}^C \\
&= \ln \left[\int_{-\infty}^0 \exp \left(-\frac{(f - \tilde{\mu})^2}{2\tilde{\sigma}^2} + \sqrt{2}f \right) df + \int_0^{\infty} \exp \left(-\frac{(f - \tilde{\mu})^2}{2\tilde{\sigma}^2} - \sqrt{2}f \right) df \right] + C \\
&= \ln \left[\int_{-\infty}^0 \exp \left(-\frac{f^2 - 2(\overbrace{\tilde{\mu} + \tilde{\sigma}^2 \sqrt{2}}^{m_-})f + \tilde{\mu}^2}{2\tilde{\sigma}^2} \right) df + \int_0^{\infty} \exp \left(-\frac{f^2 - 2(\overbrace{\tilde{\mu} - \tilde{\sigma}^2 \sqrt{2}}^{m_+})f + \tilde{\mu}^2}{2\tilde{\sigma}^2} \right) df \right] + C \\
&= \ln \left[\exp \left(\frac{m_-^2}{2\tilde{\sigma}^2} \right) \int_{-\infty}^0 \exp \left(-\frac{(f - m_-)^2}{2\tilde{\sigma}^2} \right) df + \exp \left(\frac{m_+^2}{2\tilde{\sigma}^2} \right) \int_0^{\infty} \exp \left(-\frac{(f - m_+)^2}{2\tilde{\sigma}^2} \right) df \right] - \frac{\tilde{\mu}^2}{2\tilde{\sigma}^2} + C \\
&= \ln \left[\exp \left(\frac{m_-^2}{2\tilde{\sigma}^2} \right) \int_{-\infty}^0 \mathcal{N}(f|m_-, \tilde{\sigma}^2) df + \exp \left(\frac{m_+^2}{2\tilde{\sigma}^2} \right) \left(1 - \int_{-\infty}^0 \mathcal{N}(f|m_+, \tilde{\sigma}^2) df \right) \right] - \frac{\tilde{\mu}^2}{2\tilde{\sigma}^2} - \ln \sqrt{2}\sigma_n \\
&= \ln \left[\exp \left(\frac{m_-^2}{2\tilde{\sigma}^2} \right) \Phi \left(\frac{m_-}{\tilde{\sigma}} \right) - \exp \left(\frac{m_+^2}{2\tilde{\sigma}^2} \right) \Phi \left(\frac{m_+}{\tilde{\sigma}} \right) + \exp \left(\frac{m_+^2}{2\tilde{\sigma}^2} \right) \right] - \frac{\tilde{\mu}^2}{2\tilde{\sigma}^2} - \ln \sqrt{2}\sigma_n
\end{aligned}$$

Here, $\Phi(z) = \int_{-\infty}^z \mathcal{N}(f|0, 1)df$ denotes the cumulative Gaussian distribution. Finally, we have

$$\begin{aligned}
\ln Z &= \ln \left[\exp \left(-\sqrt{2}\tilde{\mu} \right) \Phi \left(\frac{m_-}{\tilde{\sigma}} \right) + \exp \left(\sqrt{2}\tilde{\mu} \right) \Phi \left(-\frac{m_+}{\tilde{\sigma}} \right) \right] + \tilde{\sigma}^2 - \ln \sqrt{2}\sigma_n \\
&= \ln \left[\exp \left(\underbrace{\ln \Phi(-z_+) + \sqrt{2}\tilde{\mu}}_{a_+} \right) + \exp \left(\underbrace{\ln \Phi(z_-) - \sqrt{2}\tilde{\mu}}_{a_-} \right) \right] + \tilde{\sigma}^2 - \ln \sqrt{2}\sigma_n \\
&= \ln(e^{a_+} + e^{a_-}) + \tilde{\sigma}^2 - \ln \sqrt{2}\sigma_n
\end{aligned}$$

where $z_+ = \frac{\tilde{\mu}}{\tilde{\sigma}} + \tilde{\sigma}\sqrt{2} = \frac{\mu - \eta}{\sigma} + \frac{\sigma}{\sigma_n}\sqrt{2}$, $z_- = \frac{\tilde{\mu}}{\tilde{\sigma}} - \tilde{\sigma}\sqrt{2} = \frac{\mu - \eta}{\sigma} - \frac{\sigma}{\sigma_n}\sqrt{2}$ and $\tilde{\mu} = \frac{\mu - \eta}{\sigma_n}$, $\tilde{\sigma} = \frac{\sigma}{\sigma_n}$.

Now, using $\frac{d}{d\theta} \ln \Phi(z) = \frac{1}{\Phi(z)} \frac{d}{d\theta} \Phi(z) = \frac{\mathcal{N}(z)}{\Phi(z)} \frac{dz}{d\theta}$ we tackle first derivative

$$\begin{aligned}
\frac{\partial \ln Z}{\partial \mu} &= \frac{e^{a_+} \frac{\partial a_+}{\partial \mu} + e^{a_-} \frac{\partial a_-}{\partial \mu}}{e^{a_+} + e^{a_-}} \\
\frac{\partial a_+}{\partial \mu} &= \frac{\partial}{\partial \mu} \ln \Phi(-z_+) + \frac{\sqrt{2}}{\sigma_n} \\
&= -\frac{\mathcal{N}(-z_+)}{\sigma \Phi(-z_+)} + \frac{\sqrt{2}}{\sigma_n} = -\frac{q_+}{\sigma} + \frac{\sqrt{2}}{\sigma_n} \\
\frac{\partial a_-}{\partial \mu} &= \frac{\partial}{\partial \mu} \ln \Phi(z_-) - \frac{\sqrt{2}}{\sigma_n} \\
&= \frac{\mathcal{N}(z_-)}{\sigma \Phi(z_-)} - \frac{\sqrt{2}}{\sigma_n} = \frac{q_-}{\sigma} - \frac{\sqrt{2}}{\sigma_n} \\
\frac{\partial a_{\pm}}{\partial \mu} &= \mp \frac{q_{\pm}}{\sigma} \pm \frac{\sqrt{2}}{\sigma_n}.
\end{aligned}$$

as well as the second derivative

$$\begin{aligned}
\frac{\partial^2 \ln Z}{\partial \mu^2} &= \frac{\frac{\partial}{\partial \mu} \left(e^{a_+} \frac{\partial a_+}{\partial \mu} \right) + \frac{\partial}{\partial \mu} \left(e^{a_-} \frac{\partial a_-}{\partial \mu} \right)}{e^{a_+} + e^{a_-}} - \left(\frac{\partial \ln Z}{\partial \mu} \right)^2 \\
\frac{\partial}{\partial \mu} \left(e^{a_{\pm}} \frac{\partial a_{\pm}}{\partial \mu} \right) &= e^{a_{\pm}} \left[\left(\frac{\partial a_{\pm}}{\partial \mu} \right)^2 + \frac{\partial^2 a_{\pm}}{\partial \mu^2} \right] \\
\frac{\partial^2 a_+}{\partial \mu^2} &= -\frac{1}{\sigma} \frac{\frac{\partial}{\partial \mu} \mathcal{N}(-z_+) \Phi(-z_+) - \frac{\partial}{\partial \mu} \Phi(-z_+) \mathcal{N}(-z_+)}{\Phi^2(-z_+)} \\
&= -\frac{1}{\sigma} \frac{\mathcal{N}(-z_+) \Phi(-z_+) \frac{\partial -z_+^2/2}{\partial \mu} - \mathcal{N}^2(-z_+) \frac{\partial -z_+}{\partial \mu}}{\Phi^2(-z_+)} \\
&= \frac{\mathcal{N}(-z_+)}{\sigma^2} \cdot \frac{\Phi(-z_+) z_+ - \mathcal{N}(-z_+)}{\Phi^2(-z_+)} = -\frac{q_+^2 - q_+ z_+}{\sigma^2} \\
\frac{\partial^2 a_-}{\partial \mu^2} &= \frac{1}{\sigma} \frac{\frac{\partial}{\partial \mu} \mathcal{N}(z_-) \Phi(z_-) - \frac{\partial}{\partial \mu} \Phi(z_-) \mathcal{N}(z_-)}{\Phi^2(z_-)} \\
&= \frac{1}{\sigma} \frac{\mathcal{N}(z_-) \Phi(z_-) \frac{\partial -z_-^2/2}{\partial \mu} - \mathcal{N}^2(z_-) \frac{\partial z_-}{\partial \mu}}{\Phi^2(z_-)} \\
&= \frac{\mathcal{N}(z_-)}{\sigma^2} \cdot \frac{-\Phi(z_-) z_- - \mathcal{N}(z_-)}{\Phi^2(z_-)} = -\frac{q_-^2 + q_- z_-}{\sigma^2} \\
\frac{\partial^2 a_{\pm}}{\partial \mu^2} &= -\frac{q_{\pm}^2 \mp q_{\pm} z_{\pm}}{\sigma^2}
\end{aligned}$$

which can be simplified to

$$\frac{\partial^2 \ln Z}{\partial \mu^2} = \frac{e^{a_+} b_+ + e^{a_-} b_-}{e^{a_+} + e^{a_-}} - \left(\frac{\partial \ln Z}{\partial \mu} \right)^2$$

using

$$\begin{aligned}
b_{\pm} = \left(\frac{\partial a_{\pm}}{\partial \mu} \right)^2 + \frac{\partial^2 a_{\pm}}{\partial \mu^2} &= \left(\mp \frac{q_{\pm}}{\sigma} \pm \frac{\sqrt{2}}{\sigma_n} \right)^2 - \frac{q_{\pm}^2 \mp q_{\pm} z_{\pm}}{\sigma^2} \\
&= \left(\frac{q_{\pm}}{\sigma} - \frac{\sqrt{2}}{\sigma_n} \right)^2 - \frac{q_{\pm}^2}{\sigma^2} \pm \frac{q_{\pm} z_{\pm}}{\sigma^2} \\
&= \frac{2}{\sigma_n^2} - \left(\frac{\sqrt{8}}{\sigma \sigma_n} \mp \frac{z_{\pm}}{\sigma^2} \right) q_{\pm}.
\end{aligned}$$

We also need

$$\frac{\partial \ln Z}{\partial \ln \sigma_n} = \frac{e^{a_+} \frac{\partial a_+}{\partial \ln \sigma_n} + e^{a_-} \frac{\partial a_-}{\partial \ln \sigma_n}}{e^{a_+} + e^{a_-}} - \frac{2\sigma^2}{\sigma_n^2} - 1.$$

Variational Bayes

We need $h(\gamma)$ and its derivatives as well as $\beta(\gamma)$:

$$\begin{aligned}
h(\gamma) &= \frac{2}{\sigma_n^2} \gamma + \ln(2\sigma_n^2) + y^2 \gamma^{-1} \\
h'(\gamma) &= \frac{2}{\sigma_n^2} - y^2 \gamma^{-2} \\
h''(\gamma) &= 2y^2 \gamma^{-3} \\
\beta(\gamma) &= y \gamma^{-1}
\end{aligned}$$

4.10 Student's t Likelihood

The likelihood has two hyperparameters (both represented in the log domain to ensure positivity): the degrees of freedom ν and the scale σ_n with mean y (for $\nu > 1$) and variance $\frac{\nu}{\nu-2} \sigma_n^2$ (for $\nu > 2$).

$$p(y|f) = Z \cdot \left(1 + \frac{(f-y)^2}{\nu \sigma_n^2}\right)^{-\frac{\nu+1}{2}}, \quad Z = \frac{\Gamma(\frac{\nu+1}{2})}{\Gamma(\frac{\nu}{2}) \sqrt{\nu \pi \sigma_n^2}}$$

Laplace's Approximation

For the mode fitting procedure, we need derivatives up to third order; the hyperparameter derivatives at the mode require some mixed derivatives. All in all, using $r = y - f$, we have

$$\begin{aligned}
\ln p(y|f) &= \ln \Gamma\left(\frac{\nu+1}{2}\right) - \ln \Gamma\left(\frac{\nu}{2}\right) - \frac{1}{2} \ln \nu \pi \sigma_n^2 - \frac{\nu+1}{2} \ln \left(1 + \frac{r^2}{\nu \sigma_n^2}\right) \\
\frac{\partial \ln p}{\partial f} &= (\nu+1) \frac{r}{r^2 + \nu \sigma_n^2} \\
\frac{\partial^2 \ln p}{(\partial f)^2} &= (\nu+1) \frac{r^2 - \nu \sigma_n^2}{(r^2 + \nu \sigma_n^2)^2} \\
\frac{\partial^3 \ln p}{(\partial f)^3} &= 2(\nu+1) \frac{r^3 - 3r\nu \sigma_n^2}{(r^2 + \nu \sigma_n^2)^3} \\
\frac{\partial \ln p}{\partial \ln \nu} &= \frac{\partial Z}{\partial \ln \nu} - \frac{\nu}{2} \ln \left(1 + \frac{r^2}{\nu \sigma_n^2}\right) + \frac{\nu+1}{2} \cdot \frac{r^2}{r^2 + \nu \sigma_n^2} \\
\frac{\partial Z}{\partial \ln \nu} &= \frac{\nu}{2} \frac{d \ln \Gamma(\frac{\nu+1}{2})}{d \ln \nu} - \frac{\nu}{2} \frac{d \ln \Gamma(\frac{\nu}{2})}{d \ln \nu} - \frac{1}{2} \\
\frac{\partial^3 \ln p}{(\partial \ln \nu)(\partial f)^2} &= \nu \frac{r^2(r^2 - 3(\nu+1)\sigma_n^2) + \nu \sigma_n^2}{(r^2 + \nu \sigma_n^2)^3} \\
\frac{\partial \ln p}{\partial \ln \sigma_n} &= (\nu+1) \frac{r^2}{r^2 + \nu \sigma_n^2} - 1 \\
\frac{\partial^3 \ln p}{(\partial \ln \sigma_n)(\partial f)^2} &= 2\nu \sigma_n^2 (\nu+1) \frac{\nu \sigma_n^2 - 3r^2}{(r^2 + \nu \sigma_n^2)^3}
\end{aligned}$$

4.11 Cumulative Logistic Likelihood

The likelihood has one hyperparameter (represented in the log domain), namely the standard deviation σ_n

$$p(y|f) = Z \cdot \cosh^{-2}(\tau(f-y)), \quad \tau = \frac{\pi}{2\sigma_n\sqrt{3}}, \quad Z = \frac{\pi}{4\sigma_n\sqrt{3}}$$

Laplace's Approximation

The following derivatives are needed where $\phi(x) \equiv \ln(\cosh(x))$

$$\begin{aligned}
\ln p(y|f) &= \ln(\pi) - \ln(4\sigma_n\sqrt{3}) - 2\phi(\tau(f-y)) \\
\frac{\partial \ln p}{\partial f} &= 2\tau\phi'(\tau(f-y)) \\
\frac{\partial^2 \ln p}{(\partial f)^2} &= -2\tau^2\phi''(\tau(f-y)) \\
\frac{\partial^3 \ln p}{(\partial f)^3} &= 2\tau^3\phi'''(\tau(f-y)) \\
\frac{\partial^3 \ln p}{(\partial \ln \sigma_n)(\partial f)^2} &= 2\tau^2(2\phi''(\tau(f-y)) + \tau(f-y)\phi'''(\tau(f-y))) \\
\frac{\partial \ln p}{\partial \ln \sigma_n} &= 2\tau(f-y)\phi'(\tau(f-y)) - 1
\end{aligned}$$

4.12 GLM Likelihoods: Poisson, Weibull, Gamma, Exponential, Inverse Gaussian and Beta

Data y from a space other than \mathbb{R} e.g. \mathbb{N} , \mathbb{R}_+ or $[0, 1]$ can be modeled using generalised linear model likelihoods $p(y|f)$ where the expected value $\mathbb{E}[y] = \mu$ is related to the underlying Gaussian process f by means of an inverse link function $\mu = g(f)$. Typically, the likelihoods are from an exponential family, hence the variance $\mathbb{V}[y] = v(\mu)$, is a simple function of the mean μ as well as higher order moments such as skewness $\mathbb{S}[y] = s(\mu)$ and kurtosis $\mathbb{K}[y] = k(\mu)$.

Here, we directly specify the inverse link function $\mu = g(f)$ defining the mapping from the GP f to the mean intensity μ . For numerical reasons, we work with the log of the inverse link function $h(f) = \ln g(f)$ and use its derivatives h' , h'' and h''' for subsequent computations. In the table below, we have summarised the GLM likelihood expressions, the moments, the range of their variables and the applicable inverse link functions.

Likelihood	$\rho =$	$v(\mu) =$	$s(\mu) =$	$k(\mu) =$	$p(y f) =$	$y \in$	$\mu \in$	Inverse Links
Poisson	\emptyset	μ	$1/\sqrt{\mu}$	$1/\mu$	$\mu^y \exp(-\mu)/y!$	\mathbb{N}	\mathbb{R}_+	exp, logistic
Weibull	$\{\ln \kappa\}$	$\mu^2(\gamma_2/\gamma_1^2 - 1)$	$\frac{\gamma_3 - 3\gamma_1\gamma_2 + 2\gamma_1^3}{(\gamma_2 - \gamma_1^2)^{3/2}}$	$\frac{\gamma_4 - 4\gamma_1\gamma_3 + 12\gamma_1^2\gamma_2 - 3\gamma_2^2 - 6\gamma_1^4}{(\gamma_2 - \gamma_1^2)^2}$	$\kappa\gamma_1/\mu (y\gamma_1/\mu)^{\kappa-1} \exp(-(y\gamma_1/\mu)^\kappa)$	$\mathbb{R}_+ \setminus \{0\}$	$\mathbb{R}_+ \setminus \{0\}$	exp, logistic
Gamma	$\{\ln \alpha\}$	μ^2/α	$2/\sqrt{\alpha}$	$6/\alpha$	$\frac{\alpha^\alpha y^{\alpha-1}}{\Gamma(\alpha)} \mu^{-\alpha} \exp\left(-\frac{y\alpha}{\mu}\right)$	$\mathbb{R}_+ \setminus \{0\}$	$\mathbb{R}_+ \setminus \{0\}$	exp, logistic
Exponential	\emptyset	μ^2	2	6	$\mu^{-1} \exp\left(-\frac{y}{\mu}\right)$	$\mathbb{R}_+ \setminus \{0\}$	$\mathbb{R}_+ \setminus \{0\}$	exp, logistic
Inv. Gauss	$\{\ln \lambda\}$	μ^3/λ	$3\sqrt{\mu/\lambda}$	$15\mu/\lambda$	$\sqrt{\frac{\lambda}{2\pi y^3}} \exp\left(-\frac{\lambda(y-\mu)^2}{2\mu^2 y}\right)$	$\mathbb{R}_+ \setminus \{0\}$	$\mathbb{R}_+ \setminus \{0\}$	exp, logistic
Beta	$\{\ln \phi\}$	$\mu(1-\mu)/(1+\phi)$	$\frac{(2-4\mu)(1+\phi)}{\sqrt{v(\mu)(2+\phi)}}$	$6 \frac{(\phi+1)^2 - v(\mu)(5\phi+6)}{v(\mu)(\phi+2)(\phi+3)}$	$\frac{\Gamma(\phi)}{\Gamma(\mu\phi)\Gamma((1-\mu)\phi)} y^{\mu\phi-1} (1-y)^{(1-\mu)\phi-1}$	$[0, 1]$	$[0, 1]$	expexp, logit

4.12.1 Inverse Link Functions

Possible inverse link functions and their properties (\cup convex, \cap concave, \uparrow monotone) are summarised below:

util/glm_invlink_*	$g(f) = \mu =$	$g : \mathbb{R} \rightarrow$	g is	$h(f) = \ln \mu =$	h is
exp	e^f	\mathbb{R}_+	\cup, \uparrow	f	\cup, \cap, \uparrow
logistic	$\ln(1 + e^f)$	\mathbb{R}_+	\cup, \uparrow	$\ln(\ln(1 + e^f))$	\cap, \uparrow
expexp	$\exp(-e^{-f})$	$[0, 1]$	\uparrow	$-e^{-f}$	\cup, \uparrow
logit	$1/(1 + e^{-f})$	$[0, 1]$	\uparrow	$-\ln(1 + e^{-f})$	\cup, \uparrow

Exponential inverse link: `exp`

For $g(f) = e^f$ things are simple since $h(f) = f$, $h'(f) = 1$ and $h''(f) = h'''(f) = 0$.

Logistic inverse link: `logistic`

For $g(f) = \ln(1 + e^f)$ the derivatives of $h(f)$ are given by

$$\begin{aligned} h(f) &= \ln(\ln(1 + e^f)) \\ h'(f) &= \frac{1}{\ln(1 + e^f)} s(-f), \quad s(f) = \frac{1}{1 + e^f}, \quad s'(f) = \frac{-e^f}{(1 + e^f)^2} = -s(-f)s(f) \\ h''(f) &= \frac{1}{\ln(1 + e^f)} \frac{e^{-f}}{(1 + e^{-f})^2} - \frac{1}{\ln^2(1 + e^f)} \frac{e^f}{1 + e^f} \frac{1}{1 + e^{-f}} \\ &= h'(f) [s(f) - h'(f)] \\ h'''(f) &= h''(f) [s(f) - h'(f)] + h'(f) \left[\frac{-e^f}{(1 + e^f)^2} - h''(f) \right] \\ &= h''(f) [s(f) - 2h'(f)] - h'(f)s(f)s(-f). \end{aligned}$$

Note that $g(f) = e^{h(f)} = \ln(1 + e^f)$ is convex and $h(f) = \ln(\ln(1 + e^f))$ with

$$h''(f) = \frac{1}{\ln(1 + e^f)} \left(1 - \frac{e^f}{\ln(1 + e^f)} \right) \frac{1}{1 + e^f} \frac{1}{1 + e^{-f}} \leq 0$$

is concave since $e^f \geq \ln(1 + e^f)$ for all $f \in \mathbb{R}$.

Double negative exponential inverse link: `expexp`

For $g(f) = \exp(-e^{-f})$ the derivatives of $h(f)$ are given by

$$\begin{aligned} h(f) &= -e^{-f} \\ h'(f) &= -h(f) \\ h''(f) &= h(f) \\ h'''(f) &= -h(f) \end{aligned}$$

Logit regression inverse link: `logit`

For $g(f) = 1/(1 + e^{-f})$ the derivatives of $h(f)$ can be computed using the logistic inverse link function $h_\ell(f)$ since $h(f) = f - \exp(h_\ell(f))$

$$\begin{aligned} h(f) &= f - e^{h_\ell(f)} \\ h'(f) &= 1 - e^{h_\ell(f)} h'_\ell(f) \\ h''(f) &= -e^{h_\ell(f)} [h'_\ell(f)^2 + h''_\ell(f)] = e^{h_\ell(f)} s_\ell(-f) s_\ell^2(f) \\ h'''(f) &= -e^{h_\ell(f)} [h'_\ell(f)^3 + 3h''_\ell(f) h'_\ell(f) + h'''_\ell(f)] \end{aligned}$$

4.12.2 Poisson Likelihood

Count data $y \in \mathbb{N}^n$ can be modeled in the GP framework using the Poisson distribution $p(y) = \mu^y e^{-\mu} / y!$ with mean/variance $\mathbb{E}[y] = \mathbb{V}[y] = \mu$, skewness $\mathbb{S}[y] = 1/\sqrt{\mu}$ and kurtosis $\mathbb{K}[y] = 1/\mu$

leading to the likelihood

$$\begin{aligned} p(y|f) &= \mu^y \exp(-\mu)/y!, \mu = g(f) \\ \Leftrightarrow \ln p(y|f) &= y \cdot \ln g(f) - g(f) - \ln \Gamma(y+1). \end{aligned}$$

For Laplace's method to work, we need the first three derivatives of the log likelihood $\ln p(y|f)$, where $h(f) = \ln g(f)$

$$\begin{aligned} \ln p(y|f) &= y \cdot h(f) - \exp(h(f)) - \ln \Gamma(y+1) \\ \frac{\partial}{\partial f} \ln p(y|f) &= h'(f) [y - \exp(h(f))] \\ \frac{\partial^2}{\partial f^2} \ln p(y|f) &= h''(f) [y - \exp(h(f))] - [h'(f)]^2 \exp(h(f)) \\ \frac{\partial^3}{\partial f^3} \ln p(y|f) &= h'''(f) [y - \exp(h(f))] - 3h'(f) \cdot h''(f) \exp(h(f)) - [h'(f)]^3 \exp(h(f)) \\ &\quad h'''(f) [y - \exp(h(f))] - h'(f)[h'(f)^2 + 3h''(f)] \exp(h(f)). \end{aligned}$$

Note that if $\ln \mu = h(f)$ is concave and $\mu = g(f)$ is convex then the Poisson likelihood $p(y|f)$ is log-concave in f which is the case for both `exp` and `logistic`.

4.12.3 Weibull Likelihood

Nonnegative data $y \in \mathbb{R}_+$ such as time-to-failure can be modeled in the GP framework using the Weibull distribution $p(y) = \kappa/\lambda(y/\lambda)^{\kappa-1}e^{-(y/\lambda)^\kappa}$ with shape parameter $\kappa > 0$, scale parameter $\lambda > 0$, mean $\mathbb{E}[y] = \lambda\gamma_1 = \mu$ where $\gamma_j = \Gamma(1 + j/\kappa)$, variance $\mathbb{V}[y] = \lambda^2\gamma_2 - \mu^2 = \mu^2(\gamma_2/\gamma_1^2 - 1)$, skewness $\mathbb{S}[y] = (\gamma_3 - 3\gamma_1\gamma_2 + 2\gamma_1^3)/(\gamma_2 - \gamma_1^2)^{3/2}$ and kurtosis $\mathbb{K}[y] = (\gamma_4 - 4\gamma_1\gamma_3 + 12\gamma_1^2\gamma_2 - 3\gamma_2^2 - 6\gamma_1^4)/(\gamma_2 - \gamma_1^2)^2$. Using the substitution $\mu = \lambda\gamma_1 \Leftrightarrow 1/\lambda = \gamma_1/\mu$, we obtain

$$\begin{aligned} p(y|f) &= \gamma_1 \frac{\kappa}{\mu} \left(\gamma_1 \frac{y}{\mu} \right)^{\kappa-1} \exp \left(- \left(\gamma_1 \frac{y}{\mu} \right)^\kappa \right), \mu = g(f) > 0 \\ \Leftrightarrow \ln p(y|f) &= \ln \left(\gamma_1 \frac{\kappa}{\mu} \right) + (\kappa-1) \ln \left(\gamma_1 \frac{y}{\mu} \right) - \left(\gamma_1 \frac{y}{\mu} \right)^\kappa. \end{aligned}$$

Note that the Weibull likelihood $p(y|f)$ is log-concave in f neither for the `exp` nor for the `logistic` inverse link.

4.12.4 Gamma Likelihood

Nonnegative data $y \in \mathbb{R}_+$ can be modeled in the GP framework using the Gamma distribution $p(y) = \theta^{-\alpha}/\Gamma(\alpha)y^{\alpha-1}e^{-y/\theta}$ with shape parameter $\alpha > 0$, scale parameter $\theta > 0$, mean $\mathbb{E}[y] = \alpha\theta = \mu$, variance $\mathbb{V}[y] = \alpha\theta^2 = \mu^2/\alpha$, skewness $\mathbb{S}[y] = 2/\sqrt{\alpha}$ and kurtosis $\mathbb{K}[y] = 6/\alpha$. Using the substitution $\mu = \alpha\theta \Leftrightarrow \alpha/\mu = 1/\theta$, we obtain

$$\begin{aligned} p(y|f) &= \frac{\alpha^\alpha y^{\alpha-1}}{\Gamma(\alpha)} \mu^{-\alpha} \exp \left(- \frac{y\alpha}{\mu} \right), \mu = g(f) > 0 \\ \Leftrightarrow \ln p(y|f) &= -\alpha \left(\ln \mu + \frac{y}{\mu} \right) - \ln Z_\alpha(y), \ln Z_\alpha(y) = \ln \Gamma(\alpha) - \alpha \ln \alpha + (1-\alpha) \ln y. \end{aligned}$$

Note that if $\ln \mu = h(f)$ was convex and $\mu = g(f)$ was concave then the Gamma likelihood $p(y|f)$ would be log-concave in f which is not the case for both `exp` and `logistic`.

4.12.5 Exponential Likelihood

Nonnegative data $y \in \mathbb{R}_+$ can be modeled in the GP framework using the Exponential distribution $p(y) = \theta^{-1} e^{-y/\theta}$ with scale parameter $\theta > 0$, mean $\mathbb{E}[y] = \theta = \mu$, variance $\mathbb{V}[y] = \mu^2$, skewness $\mathbb{S}[y] = 2$ and kurtosis $\mathbb{K}[y] = 6$. We obtain

$$\begin{aligned} p(y|f) &= \mu^{-1} \exp\left(-\frac{y}{\mu}\right), \mu = g(f) > 0 \\ \Leftrightarrow \ln p(y|f) &= -\ln \mu - \frac{y}{\mu}. \end{aligned}$$

Note that for `exp` (but not for `logistic`) the likelihood is log-concave. The exponential distribution corresponds to the Gamma distribution with $\alpha = 1$ and the Weibull distribution with $\kappa = 1$.

4.12.6 Inverse Gaussian Likelihood

Nonnegative data $y \in \mathbb{R}_+^n$ can be modeled in the GP framework using the Inverse Gaussian distribution $p(y) = \sqrt{\lambda/(2\pi y^3)} \exp(-\lambda(y - \mu)^2/(2\mu^2 y))$ with shape parameter $\lambda > 0$, mean parameter $\mu > 0$, mean $\mathbb{E}[y] = \mu$, variance $\mathbb{V}[y] = \mu^3/\lambda$, skewness $\mathbb{S}[y] = 3\sqrt{\mu/\lambda}$ and kurtosis $\mathbb{K}[y] = 15\mu/\lambda$. We obtain

$$\begin{aligned} p(y|f) &= \sqrt{\frac{\lambda}{2\pi y^3}} \exp\left(-\frac{\lambda(y - \mu)^2}{2\mu^2 y}\right), \mu = g(f) > 0 \\ \Leftrightarrow \ln p(y|f) &= -\frac{\lambda(y - \mu)^2}{2\mu^2 y} - \ln Z_\alpha(y), \ln Z_\alpha(y) = -\frac{1}{2}(\ln \lambda - \ln 2\pi y^3). \end{aligned}$$

The inverse Gaussian likelihood is in general not log-concave in f for both `exp` and `logistic`.

4.12.7 Beta Likelihood

Interval data $y \in [0, 1]^n$ can be modeled in the GP framework using the Beta distribution $p(y) = y^{\alpha-1}(1-y)^{\beta-1}/B(\alpha, \beta)$ with shape parameters $\alpha, \beta > 0$, mean $\mathbb{E}[y] = \alpha/(\alpha + \beta)$ and variance $\mathbb{V}[y] = \alpha\beta/[(\alpha + \beta)^2(\alpha + \beta + 1)]$ and $1/B(\alpha, \beta) = \Gamma(\alpha + \beta)/[\Gamma(\alpha)\Gamma(\beta)]$. Reparametrising using the mean parameter $\mu = \mathbb{E}[y] = \alpha/(\alpha + \beta)$, the shape parameter $\phi = \alpha + \beta$, the variance $\mathbb{V}[y] = \mu(1 - \mu)/(1 + \phi)$ and hence

$$\begin{aligned} p(y|f) &= \frac{\Gamma(\phi)}{\Gamma(\mu\phi)\Gamma((1-\mu)\phi)} y^{\mu\phi-1} (1-y)^{(1-\mu)\phi-1}, \mu = g(f) > 0 \\ \Leftrightarrow \ln p(y|f) &= \ln \Gamma(\phi) - \ln \Gamma(\mu\phi) - \ln \Gamma((1-\mu)\phi) + (\mu\phi - 1) \ln y + ((1-\mu)\phi - 1) \ln(1-y). \end{aligned}$$

The Beta likelihood is in general not log-concave in f for both `exp` and `logistic`.

5 Mean Functions

A mean function $m_\phi : \mathcal{X} \rightarrow \mathbb{R}$ (with hyperparameters ϕ) of a GP f is a scalar function defined over the whole domain \mathcal{X} that computes the expected value $m(\mathbf{x}) = \mathbb{E}[f(\mathbf{x})]$ of f for the input \mathbf{x} .

5.1 Interface

In the GPML toolbox, a mean function $m : \mathcal{X} \rightarrow \mathbb{R}$ needs to implement evaluation $\mathbf{m} = m_\phi(\mathbf{X})$ and first derivatives $\mathbf{m}_i = \frac{\partial}{\partial \phi_i} \mathbf{m}$ with respect to the components i of the parameter $\phi \in \Phi$ as detailed below.

```

```

5.2 Implemented Mean Functions

We offer simple and composite mean functions producing new mean functions $m(\mathbf{x})$ from existing mean functions $\mu_j(\mathbf{x})$. All code files are named according to the pattern `mean/mean<NAME>.m` for simple identification. This modular specification allows to define affine mean functions $m(\mathbf{x}) = \mathbf{c} + \mathbf{a}^\top \mathbf{x}$ or polynomial mean functions $m(\mathbf{x}) = (\mathbf{c} + \mathbf{a}^\top \mathbf{x})^2$. All currently available mean functions are summarised in the following table.

Simple mean functions $m(\mathbf{x})$			
<NAME>	Meaning	$m(\mathbf{x}) =$	Φ
Zero	mean vanishes always	0	\emptyset
One	mean equals 1	1	\emptyset
Const	mean equals a constant	\mathbf{c}	$\mathbf{c} \in \mathbb{R}$
Linear	mean linearly depends on $\mathbf{x} \in \mathcal{X} \subseteq \mathbb{R}^D$	$\mathbf{a}^\top \mathbf{x}$	$\mathbf{a} \in \mathbb{R}^D$
Poly	mean polynomially depends on $\mathbf{x} \in \mathcal{X} \subseteq \mathbb{R}^D$	$\sum_d \mathbf{a}_d^\top \mathbf{x}^d$	$\mathbf{a} \in \mathbb{R}^{D \times d}$
Discrete	precomputed mean for discrete data $\mathbf{x} \in \mathcal{X} \subseteq \mathbb{N}$	$\mu_{\mathbf{x}}$	$\mu \in \mathbb{R}^s$
GP	predictive mean of another GP	$\int \mathbf{y} \cdot p(\mathbf{y} \mathcal{D}, \mathbf{x}) d\mathbf{y}$	\emptyset
GPexact	predictive mean of a regression GP	$\int \mathbf{y} \cdot p(\mathbf{y} \mathcal{D}, \mathbf{x}) d\mathbf{y}$	ρ, ψ, σ_n
NN	nearest neighbor for a set $(\mathbf{z}_j, m_j) \in \mathcal{X} \times \mathbb{R}$	$m_i, i = \arg \min_j d(\mathbf{x}, \mathbf{z}_j)$	\emptyset
Composite mean functions $[\mu_1(\mathbf{x}), \mu_2(\mathbf{x}), \dots] \mapsto m(\mathbf{x})$			
<NAME>	Meaning	$m(\mathbf{x}) =$	Φ
Scale	scale a mean	$\alpha \mu(\mathbf{x})$	$\alpha \in \mathbb{R}$
Sum	add up mean functions	$\sum_j \mu_j(\mathbf{x})$	\emptyset
Prod	multiply mean functions	$\prod_j \mu_j(\mathbf{x})$	\emptyset
Pow	raise a mean to a power	$\mu(\mathbf{x})^d$	\emptyset
Mask	act on components $I \subseteq [1, 2, \dots, D]$ of $\mathbf{x} \in \mathcal{X} \subseteq \mathbb{R}^D$ only	$\mu(\mathbf{x}_I)$	\emptyset
Pref	preference learning mean $\mathbf{x} = [\mathbf{x}_1; \mathbf{x}_2], \mathbf{x}_i \subseteq \mathbb{R}^{D/2}$	$\mu(\mathbf{x}_1) - \mu(\mathbf{x}_2)$	\emptyset

5.3 Usage of Implemented Mean Functions

Some code examples taken from `doc/usageMean.m` illustrate how to use simple and composite mean functions to specify a GP model.

Syntactically, a mean function `mf` is defined by

```
mn := 'func' | @func // simple
```

```
mf := {mn} | {mn, {param, mf}} | {mn, {mf, ..., mf}} // composite
```

i.e., it is either a string containing the name of a mean function, a pointer to a mean function or one of the former in combination with a cell array of mean functions and an additional list of parameters.

35 <doc/usageMean.m 35>≡

```

```

6 Covariance Functions

A covariance function $k_{\psi} : \mathcal{X} \times \mathcal{X} \rightarrow \mathbb{R}$ (with hyperparameters ψ) of a GP f is a scalar function defined over the whole domain \mathcal{X}^2 that computes the covariance $k(\mathbf{x}, \mathbf{x}') = \mathbb{V}[f(\mathbf{x}), f(\mathbf{x}')] = \mathbb{E}[(f(\mathbf{x}) - m(\mathbf{x}))(f(\mathbf{x}') - m(\mathbf{x}'))]$ of f between the inputs \mathbf{x} and \mathbf{x}' .

6.1 Interface

Again, the interface is simple since only evaluation of the full covariance matrix $\mathbf{K} = k_{\psi}(\mathbf{X})$ and its derivatives $\mathbf{K}_i = \frac{\partial}{\partial \psi_i} \mathbf{K}$ as well as cross terms $\mathbf{k}_* = k_{\psi}(\mathbf{X}, \mathbf{x}_*)$ and $\mathbf{k}_{**} = k_{\psi}(\mathbf{x}_*, \mathbf{x}_*)$ for prediction are required.

```
37 <covFunctions.m 37>≡
1 % covariance functions to be use by Gaussian process functions. There are two
2 % different kinds of covariance functions: simple and composite:
3 %
4 % simple covariance functions:
5 %   covConst      - covariance for constant functions
6 %   covCos        - sine periodic covariance function (1d) with unit period
7 %   covLIN        - linear covariance function without parameters
8 %   covLINard     - linear covariance function with ARD
9 %   covLINiso     - linear covariance function
10 %  covLINone     - linear covariance function with bias
11 %  covMaternard  - Matern covariance function with nu=1/2, 3/2 or 5/2 with ARD
12 %  covMaterniso  - Matern covariance function with nu=1/2, 3/2 or 5/2
13 %  covNNone     - neural network covariance function
14 %  covNoise     - independent covariance function (i.e. white noise)
15 %  covPeriodic  - smooth periodic covariance function (1d)
16 %  covPeriodicNoDC - as above but with zero DC component and properly scaled
17 %  covPoly      - polynomial covariance function
18 %  covPPard     - piecewise polynomial covariance function (compact support)
19 %  covPPiso     - piecewise polynomial covariance function (compact support)
20 %  covRQard     - rational quadratic covariance function with ARD
21 %  covRQiso     - isotropic rational quadratic covariance function
22 %  covSEard     - squared exponential covariance function with ARD
23 %  covSEiso     - isotropic squared exponential covariance function
24 %  covSEisoU    - same as above but without latent scale
25 %  covSEvlen    - spatially varying lengthscale squared exponential
26 %  covSEfact    - factor analysis squared exponential covariance function
27 %  covSM        - spectral mixture covariance function
28 %  covGaborard  - Gabor covariance function with ARD
29 %  covGaborsio  - isotropic Gabor covariance function
30 %  covDiscrete  - precomputed covariance for discrete data
31 %
32 % composite (meta) covariance functions (see explanation at the bottom):
33 %   covScale     - scaled version of a covariance function
34 %   covProd      - products of covariance functions
35 %   covSum       - sums of covariance functions
36 %   covADD       - additive covariance function
37 %   covMask      - mask some dimensions of the data
38 %   covPERard    - make ARD stationary covariance periodic
39 %   covPERiso    - make isotropic stationary covariance periodic
40 %   covPref      - difference covariance for preference learning
41 %
42 % special purpose (wrapper) covariance functions
43 %   covFITC      - to be used in conjunction with infFITC* for large scale
```

```

44 %             inference problems; any covariance can be wrapped by
45 %             covFITC such that the FITC approximation is applicable
46 %   covGrid      - to be used in conjunction with infGrid* for large scale
47 %                 inference problems on grids resulting Kronecker structure
48 %
49 % Naming convention: all covariance functions are named "cov/cov*.m". A trailing
50 % "iso" means isotropic, "ard" means Automatic Relevance Determination, and
51 % "one" means that the distance measure is parameterized by a single parameter.
52 %
53 % The covariance functions are written according to a special convention where
54 % the exact behaviour depends on the number of input and output arguments
55 % passed to the function. If you want to add new covariance functions, you
56 % should follow this convention if you want them to work with the function gp.
57 % There are four different ways of calling the covariance functions:
58 %
59 % 1) With no (or one) input argument(s):
60 %
61 %     s = cov
62 %
63 % The covariance function returns a string s telling how many hyperparameters it
64 % expects, using the convention that "D" is the dimension of the input space.
65 % For example, calling "covRQard" returns the string '(D+2)'.
66 %
67 % 2) With two input arguments:
68 %
69 %     K = cov(hyp, x) equivalent to K = cov(hyp, x, [])
70 %
71 % The function computes and returns the covariance matrix where hyp are
72 % the hyperparameters and x is an n by D matrix of cases, where
73 % D is the dimension of the input space. The returned covariance matrix is of
74 % size n by n.
75 %
76 % 3) With three input arguments:
77 %
78 %     Ks = cov(hyp, x, xs)
79 %     kss = cov(hyp, xs, 'diag')
80 %
81 % The function computes test set covariances; kss is a vector of self covariances
82 % for the test cases in xs (of length ns) and Ks is an (n by ns) matrix of cross
83 % covariances between training cases x and test cases xs.
84 %
85 % 4) With four input arguments:
86 %
87 %     dKi = cov(hyp, x, [], i)
88 %     dKsi = cov(hyp, x, xs, i)
89 %     dkssi = cov(hyp, xs, 'diag', i)
90 %
91 % The function computes and returns the partial derivatives of the
92 % covariance matrices with respect to hyp(i), i.e. with
93 % respect to the hyperparameter number i.
94 %
95 % Covariance functions can be specified in two ways: either as a string
96 % containing the name of the covariance function or using a cell array. For
97 % example:
98 %
99 %     cov = 'covRQard';
100 %     cov = {'covRQard'};
101 %     cov = {@covRQard};

```

```

102 %
103 % are supported. Only the second and third form using the cell array can be used
104 % for specifying composite covariance functions, made up of several
105 % contributions. For example:
106 %
107 %         cov = {'covScale', {'covRQiso'}};
108 %         cov = {'covSum', {'covRQiso','covSEard','covNoise'}};
109 %         cov = {'covProd',{'covRQiso','covSEard','covNoise'}};
110 %         cov = {'covMask',{mask,'covSEiso'}}
111 %     q=1; cov = {'covPPiso',q};
112 %     d=3; cov = {'covPoly',d};
113 %         cov = {'covADD',{[1,2],'covSEiso'}};
114 %         cov = {@covFITC, {@covSEiso}, u}; where u are the inducing inputs
115 %
116 % specifies a covariance function which is the sum of three contributions. To
117 % find out how many hyperparameters this covariance function requires, we do:
118 %
119 %     feval(cov{:})
120 %
121 % which returns the string '3+(D+1)+1' (i.e. the 'covRQiso' contribution uses
122 % 3 parameters, the 'covSEard' uses D+1 and 'covNoise' a single parameter).
123 %
124 % See also doc/usageCov.m.
125 %
126 (gpml copyright 6a)

```

6.2 Implemented Covariance Functions

Similarly to the mean functions, we provide a whole algebra of covariance functions $k : \mathcal{X} \times \mathcal{X} \rightarrow \mathbb{R}$ with the same generic name pattern `cov/cov<NAME>.m` as before.

Besides a long list of simple covariance functions, we also offer a variety of composite covariance functions as shown in the following table.

Simple covariance functions $k(\mathbf{x}, \mathbf{x}')$			
<NAME>	Meaning	$k(\mathbf{x}, \mathbf{x}') =$	Ψ
Zero	covariance vanishes always	0	\emptyset
Eye	unit additive measurement noise	$\delta(\mathbf{x} - \mathbf{x}')$	\emptyset
Noise	additive measurement noise	$\sigma_f^2 \delta(\mathbf{x} - \mathbf{x}')$	$\ln \sigma_f$
Const	covariance equals a constant	σ_f^2	$\ln \sigma_f$
LIN	linear, $\mathcal{X} \subseteq \mathbb{R}^D$	$\mathbf{x}^\top \mathbf{x}'$	\emptyset
LINard	linear with diagonal weighting, $\mathcal{X} \subseteq \mathbb{R}^D$	$\mathbf{x}^\top \Lambda^{-2} \mathbf{x}'$	$\{\ln \lambda_1, \dots, \ln \lambda_D\}$
LINiso	linear with isotropic weighting, $\mathcal{X} \subseteq \mathbb{R}^D$	$\mathbf{x}^\top \mathbf{x}' / \ell^2$	$\ln \ell$
LINone	linear with bias, $\mathcal{X} \subseteq \mathbb{R}^D$	$(\mathbf{x}^\top \mathbf{x}' + 1) / \ell^2$	$\ln \ell$
Poly	polynomial covariance, $\mathcal{X} \subseteq \mathbb{R}^D$	$\sigma_f^2 (\mathbf{x}^\top \mathbf{x}' + c)^d$	$\{\ln c, \ln \sigma_f\}$
SEard	automatic relevance determination squared exponential, $\mathcal{X} \subseteq \mathbb{R}^D$	$\sigma_f^2 \exp(-\frac{1}{2}(\mathbf{x} - \mathbf{x}')^\top \Lambda^{-2}(\mathbf{x} - \mathbf{x}'))$	$\{\ln \lambda_1, \dots, \ln \lambda_D, \ln \sigma_f\}$
SEiso	diagonal squared exponential, $\mathcal{X} \subseteq \mathbb{R}^D$	$\sigma_f^2 \exp(-\frac{1}{2\ell^2}(\mathbf{x} - \mathbf{x}')^\top (\mathbf{x} - \mathbf{x}'))$	$\{\ln \ell, \ln \sigma_f\}$
SEisoU	squared exponential, $\mathcal{X} \subseteq \mathbb{R}^D$	$\exp(-\frac{1}{2\ell^2} \mathbf{x}^\top \mathbf{x}')$	$\ln \ell$
SEvlen	spatially varying lengthscale squared exponential $\mathcal{X} \subseteq \mathbb{R}^D$	$\sigma_f^2 \left(\frac{b}{a}\right)^{\frac{D}{2}} \exp\left(-\frac{\ \mathbf{x} - \mathbf{x}'\ ^2}{b}\right)$, $a = 2\ell(\mathbf{x})\ell(\mathbf{x}')$, $b = \ell^2(\mathbf{x}) + \ell^2(\mathbf{x}')$	$\{\Phi_f, \ln \sigma_f\}$
SEfact	factor analysis squared exponential $\mathcal{X} \subseteq \mathbb{R}^D$	$\sigma_f^2 \exp(-\frac{1}{2}(\mathbf{x} - \mathbf{x}')^\top \mathbf{L}^\top \mathbf{L}(\mathbf{x} - \mathbf{x}'))$, $\mathbf{L} \in \mathbb{R}^{d \times D}$, $d \leq D$	$\{\mathbf{L}, \ln \sigma_f\}$
RQard	rational quadratic, $\mathcal{X} \subseteq \mathbb{R}^D$	$\sigma_f^2 \left(1 + \frac{1}{2\alpha}(\mathbf{x} - \mathbf{x}')^\top \Lambda^{-2}(\mathbf{x} - \mathbf{x}')\right)^{-\alpha}$	$\{\ln \lambda_1, \dots, \ln \lambda_D, \ln \sigma_f, \ln \alpha\}$

Gaborard	anisotropic Gabor function, $\mathcal{X} \subseteq \mathbb{R}^D$, $\lambda, \mathbf{p} \in \mathbb{R}_+^D$	$\exp\left(-\sum_{d=1}^D \frac{r_d^2}{2\lambda_d^2}\right) \cos\left(2\pi \sum_{d=1}^D r_d / p_d\right)$, $r_d = \mathbf{x}_d - \mathbf{x}'_d $	$\{\ln \lambda, \ln \mathbf{p}\}$
Gaboriso	isotropic Gabor function, $\mathcal{X} \subseteq \mathbb{R}^D$, $\ell, p \in \mathbb{R}_+$	$\exp(-\frac{r^2}{2\ell^2}) \cos(2\pi r / p)$, $r = \ \mathbf{x} - \mathbf{x}'\ $	$\{\ln \ell, \ln p\}$
Discrete	precomputed covariance for discrete data $\mathbf{x} \in \mathcal{X} \subseteq \mathbb{N}$	$\mathbf{K}_{\mathbf{x}\mathbf{x}'}$ where $\mathbf{K} = \mathbf{L}^\top \mathbf{L}$ is Cholesky decomposition, $\mathbf{L} \in \mathbb{R}^{s \times s}$	$\{\mathbf{L}\}$
Composite covariance functions $\kappa_1(\mathbf{x}, \mathbf{x}'), \kappa_2(\mathbf{x}, \mathbf{x}'), \dots \mapsto k(\mathbf{x}, \mathbf{x}')$			
<NAME>	Meaning	$k(\mathbf{x}, \mathbf{x}') =$	Ψ
Scale	scale a covariance	$\sigma_f^2 \kappa(\mathbf{x}, \mathbf{x}')$ and $\sigma_f(\mathbf{x}) \kappa(\mathbf{x}, \mathbf{x}') \sigma_f(\mathbf{x}')$	$\{\ln \sigma_f\}$
Sum	add up covariance functions	$\sum_j \kappa_j(\mathbf{x}, \mathbf{x}')$	\emptyset
Prod	multiply covariance functions	$\prod_j \kappa_j(\mathbf{x}, \mathbf{x}')$	\emptyset
PERard	turn ARD stationary into a periodic, $\mathcal{X} \subseteq \mathbb{R}^D$	$\kappa(\mathbf{u}(\mathbf{x}), \mathbf{u}(\mathbf{x}'))$, $\mathbf{u}(\mathbf{x}) = [\sin \mathbf{x}_p, \cos \mathbf{x}_p]$, $\mathbf{x}_p = 2\pi \text{diag}(\mathbf{p}^{-1}) \mathbf{x}$	$\{\ln p_1, \dots, \ln p_D\}$
PERiso	turn isotropic stationary into a periodic, $\mathcal{X} \subseteq \mathbb{R}^D$	$\kappa(\mathbf{u}(\mathbf{x}), \mathbf{u}(\mathbf{x}'))$, $\mathbf{u}(\mathbf{x}) = [\sin \mathbf{x}_p, \cos \mathbf{x}_p]$, $\mathbf{x}_p = 2\pi \mathbf{x} / p$	$\ln p$
Mask	act on components $\mathbf{I} \subseteq \{1, 2, \dots, D\}$ of $\mathbf{x} \in \mathcal{X} \subseteq \mathbb{R}^D$ only	$\kappa(\mathbf{x}_\mathbf{I}, \mathbf{x}'_\mathbf{I})$	\emptyset
ADD	additive, $\mathcal{X} \subseteq \mathbb{R}^D$, index degree set $\mathcal{D} = \{1, \dots, D\}$	$\sum_{d \in \mathcal{D}} \sigma_{f_d}^2 \sum_{ \mathbf{I} =d} \prod_{i \in \mathbf{I}} \kappa(\mathbf{x}_i, \mathbf{x}'_i; \psi_i)$	$\{\psi_1, \dots, \psi_D, \ln \sigma_{f_1}, \dots, \ln \sigma_{f_{ \mathcal{D} }}\}$
Pref	preference learning covariance $\mathbf{x} = [\mathbf{x}_1; \mathbf{x}_2]$, $\mathbf{x}_i \in \mathbb{R}^{D/2}$	$\kappa(\mathbf{x}_1, \mathbf{x}'_1) + \kappa(\mathbf{x}_2, \mathbf{x}'_2) - \kappa(\mathbf{x}_1, \mathbf{x}'_2) - \kappa(\mathbf{x}_2, \mathbf{x}'_1)$	\emptyset

The spectral mixture covariance `covSM` was introduced by Wilson & Adams *Gaussian Process Kernels for Pattern Discovery and Extrapolation*, ICML, 2013.

The periodic covariance functions `covPERiso` and `covPERard` start from a stationary isotropic or ARD covariance function that depends on the data only through a distance $r^2 = (\mathbf{x} - \mathbf{x}')^\top \Lambda^{-2}(\mathbf{x} - \mathbf{x}')$ such as `covMatern*`, `covPP*`, `covRQ*`, `covSE*` where `*=ard|iso` and turn them into a periodic covariance function by embedding the data $\mathbf{x} \in \mathbb{R}^D$ into a periodic high-dimensional space $\mathbf{x}_p = \mathbf{u}(\mathbf{x}) \in \mathbb{R}^{2D}$ by a function $\mathbf{u}(\mathbf{x}) = 2\pi \text{diag}(\mathbf{p}^{-1}) \mathbf{x}$.

The additive covariance function `covADD` starts from a one-dimensional covariance function $\kappa(\mathbf{x}_i, \mathbf{x}'_i; \psi_i)$ acting on a single component $i \in \{1, \dots, D\}$ of \mathbf{x} . From that, we define covariance functions $\kappa_\mathbf{I}(\mathbf{x}_\mathbf{I}, \mathbf{x}'_\mathbf{I}) = \prod_{i \in \mathbf{I}} \kappa(\mathbf{x}_i, \mathbf{x}'_i; \psi_i)$ acting on vector-valued inputs $\mathbf{x}_\mathbf{I}$. The sums of exponential size can efficiently be computed using the Newton-Girard formulae. Samples functions drawn from a GP with additive covariance are additive functions. The number of interacting variables $|\mathbf{I}|$ is a measure of how complex the additive functions are.

6.3 Usage of Implemented Covariance Functions

Some code examples taken from `doc/usageCov.m` illustrate how to use simple and composite covariance functions to specify a GP model.

Syntactically, a covariance function `cf` is defined by

```
cv := 'func' | @func // simple
```

```
cf := {cv} | {cv, {param, cf}} | {cv, {cf, ..., cf}} // composite
```

i.e., it is either a string containing the name of a covariance function, a pointer to a covariance function or one of the former in combination with a cell array of covariance functions and an additional list of parameters.

```

7 Hyperpriors

A hyperprior $p(\theta)$ with $\theta = [\rho, \phi, \psi]$ is a joint probability distribution over the likelihood hyperparameters ρ , the mean hyperparameters ϕ and the covariance hyperparameters ψ . We concentrate on factorial priors $p(\theta) = \prod_j p_j(\theta_j)$. Hyperpriors can be used to regularise the optimisation of the hyperparameters via the marginal likelihood $Z(\theta)$ so that $p(\theta)Z(\theta)$ is maximised instead. As we wish to perform unconstrained optimisation, we require (mainly) smooth hyperpriors with infinite support.

7.1 Interface

In the GPML toolbox, a prior distribution $p(\theta)$ needs to implement the evaluation of the log density $\ln p(\theta)$ and its first derivative $\frac{\partial}{\partial \theta} \ln p(\theta)$. In addition, we require sampling capabilities i.e. the generation of $\theta \sim p(\theta)$.

```

7.2 Implemented Hyperpriors

All code files are named according to the pattern `prior/prior<NAME>.m` for simple identification. All currently available hyperpriors are summarised in the following table.

Simple hyperpriors $p(\theta)$			
Univariate hyperpriors defined over the whole reals with mean μ and variance σ^2			
<NAME>	Meaning	$p(\theta) =$	τ
Gauss	normally distributed hyperparameter $\theta \in \mathbb{R}$	$\frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(\theta-\mu)^2}{2\sigma^2}\right)$	$\mu \in \mathbb{R}, \sigma^2 \in \mathbb{R}_+$
Laplace	double exponentially hyperparameter $\theta \in \mathbb{R}$	$\frac{1}{2b} \exp\left(-\frac{ \theta-\mu }{b}\right), b = \sigma/\sqrt{2}$	$\mu \in \mathbb{R}, \sigma^2 \in \mathbb{R}_+$
T	Student's t distributed hyperparameter $\theta \in \mathbb{R}$	$\frac{\Gamma(\frac{\nu+1}{2})}{\Gamma(\frac{\nu}{2})} \frac{1}{\sqrt{(\nu-2)\pi\sigma^2}} \left(1 + \frac{(\theta-\mu)^2}{(\nu-2)\sigma^2}\right)^{-\frac{\nu+1}{2}}$	$\mu \in \mathbb{R}, \sigma^2, \nu \in \mathbb{R}_+$
Univariate hyperpriors with effective bounded support but defined over the whole real line			
SmoothBox1	localised hyperparameter $\theta \in \mathbb{R}$	$\frac{1-\exp(\eta(a-b))}{b-a} \cdot \frac{1}{1+\exp(-\eta(\theta-a))} \cdot \frac{1}{1+\exp(\eta(\theta-b))}$	$a \leq b \in \mathbb{R}, \eta \in \mathbb{R}_+$
SmoothBox2	localised hyperparameter $\theta \in \mathbb{R}$	$\frac{1}{(1/\eta+1)(b-a)} \begin{cases} \mathcal{N}(\theta a, \sigma_{ab}^2) & t < a \\ 1 & t \in [a, b], \sigma_{ab} = \frac{b-a}{\eta\sqrt{2\pi}} \\ \mathcal{N}(\theta a, \sigma_{ab}^2) & b < t \end{cases}$	$a \leq b \in \mathbb{R}, \eta \in \mathbb{R}_+$
Univariate hyperpriors supported only over the positive reals			
Gamma	Gamma hyperparameter $\theta \in \mathbb{R}_+$	$\frac{1}{\Gamma(k)t^k} \exp(\frac{\theta}{t}) \theta^{k-1}$	$k \in \mathbb{R}_+, t \in \mathbb{R}_+$
Weibull	Weibull hyperparameter $\theta \in \mathbb{R}_+$	$\frac{k}{\lambda} \left(\frac{\theta}{\lambda}\right)^{k-1} \exp\left(-\left(\frac{\theta}{\lambda}\right)^k\right)$	$k \in \mathbb{R}_+, \lambda \in \mathbb{R}_+$
InverseGauss	inverse Gaussian hyperparameter $\theta \in \mathbb{R}_+$	$\frac{1}{\sqrt{2\pi\theta^3/\lambda}} \exp\left(-\frac{\lambda(\theta-\mu)^2}{2\mu^2\theta}\right)$	$k \in \mathbb{R}_+, \lambda \in \mathbb{R}_+$
LogNormal	log-normal hyperparameter $\theta \in \mathbb{R}_+$	$\mathcal{N}(\theta \mu, \sigma^2) = \frac{1}{\theta\sigma\sqrt{2\pi}} \exp\left(-\frac{(\ln\theta-\mu)^2}{2\sigma^2}\right)$	$\mu \in \mathbb{R}, \sigma^2 \in \mathbb{R}_+$
Multivariate hyperpriors supported all over \mathbb{R}^D with mean μ and covariance Σ			
GaussMulti	multivariate normal distribution $\theta \in \mathbb{R}^D$	$ 2\pi\Sigma ^{-\frac{1}{2}} \exp\left(-\frac{1}{2}(\theta-\mu)^\top \Sigma^{-1}(\theta-\mu)\right)$	$\mu \in \mathbb{R}^D, \Sigma \in \mathbb{R}^{D \times D}$
LaplaceMulti	multivariate Laplace distribution $\theta \in \mathbb{R}^D$	$ \sqrt{2}\Sigma ^{-\frac{1}{2}} \exp\left(-\sqrt{2}\ \mathbf{L}^{-1}(\theta-\mu)\ _1\right), \mathbf{L}^\top \mathbf{L} = \Sigma$	$\mu \in \mathbb{R}^D, \Sigma \in \mathbb{R}^{D \times D}$
TMulti	multivariate Student's t distribution $\theta \in \mathbb{R}^D$	$ (\nu-2)\pi\Sigma ^{-\frac{1}{2}} \frac{\Gamma(\frac{\nu+D}{2})}{\Gamma(\frac{\nu}{2})} \left(1 + \frac{(\theta-\mu)^\top \Sigma^{-1}(\theta-\mu)}{(\nu-2)}\right)^{-\frac{\nu+D}{2}}$	$\mu \in \mathbb{R}^D, \Sigma \in \mathbb{R}^{D \times D}, \nu \in \mathbb{R}$
Improper hyperpriors used to fix the value of a particular hyperparameter			
Delta	clamped hyperparameter $\theta = \theta_0 \in \mathbb{R}$	$\delta(\theta - \theta_0)$	\emptyset
Clamped			
DeltaMulti			
ClampedMulti			
Composite hyperpriors $[\pi_1(\theta), \pi_2(\theta), ..] \mapsto p(\theta)$			
Transform	prior distribution on $g(\theta)$ instead of θ	$\pi(g(\theta))$	$\{g\}$
Mix	mixture distribution	$\sum_i w_i \pi_i(\theta)$	$\{w\}$

The `priorSmoothBox2` is a Gauss-uniform sandwich obtained by complementing a uniform distribution on $[a, b]$ with two Gaussian halves at each side. The parameter η balances the probability mass between the constituents so that $\eta/(\eta+1)$ is used for the box and $1/(\eta+1)$ for the Gaussian sides. Its brother `priorSmoothBox1` is the product of two sigmoidal functions.

The `priorDelta` or equivalently `priorClamped` can be used to exclude some hyperparameters from the optimisation. Their values are clamped to θ_0 and the derivative vanishes. There are also multivariate counterparts `priorDeltaMulti` and `priorClampedMulti`.

7.3 Usage of Implemented Hyperpriors

Some code examples taken from `doc/usagePrior.m` illustrate how to use univariate, multivariate and composite priors on hyperparameters. Syntactically, a hyperprior `hp` is defined by

```

func := Dist                                // prior distributions in prior/
      | Clamped | Delta // predefined for fixing the hyperparameter

pr  := 'func'          | @func              // univariate hyperprior
      | 'funcMulti'    | @funcMulti         // multivariate hyperprior

hp  := {pr} | {pr, {param, hp}} | {pr, {hp, .., hp}} // composite

```

i.e., it is either a string containing the name of a hyperprior function, a pointer to a hyperprior function or one of the former in combination with a cell array of hyperprior functions and an additional list of parameters. Furthermore, we have multivariate hyperprior variants and 2 (equivalent) predefined hyperpriors allowing to exclude variables from optimisation.

```
