# Vascular filling

- Vascular filling = intravenous administration of fluid to a patient in order to increase the stroke volume
- Clinical treatment proposed because of the Frank-Starling mechanism

- An increase in **preload** (= stretching of the heart muscle fibers before contraction) leads to an increase in **stroke volume** (= volume of blood ejected by the ventricle)

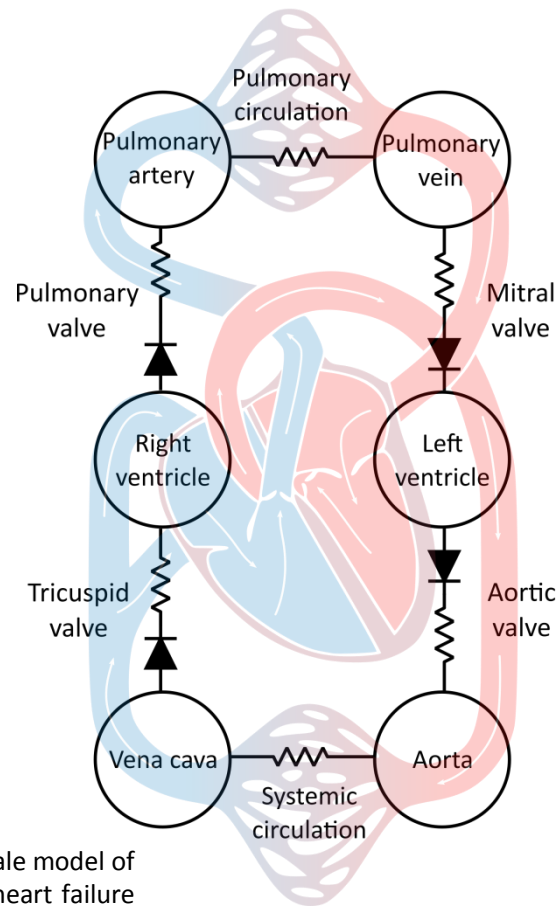

- Vascular filling = intravenous administration of fluid to a patient in order to increase the stroke volume
- Clinical treatment proposed because of the Frank-Starling mechanism

- An increase in **preload** (= stretching of the heart muscle fibers before contraction) leads to an increase in **stroke volume** (= volume of blood ejected by the ventricle)
- A patient will be « fluid-responsive » if the increase in circulating blood volume substantially increases stroke volume.

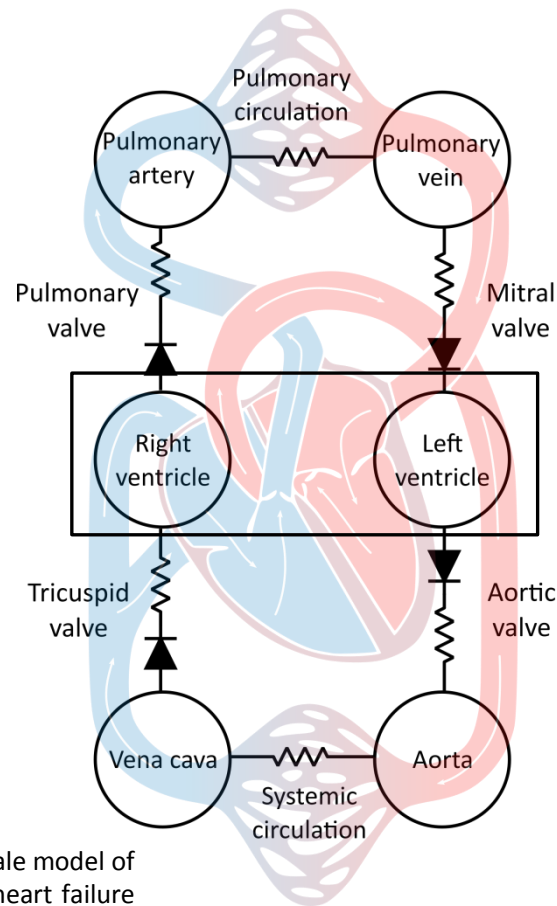

# Human cardiovascular system model

Human CVS is assimilated to a six-chamber model

# Human cardiovascular system model

Ventricular contraction is described at the cellular scale

## Cardiac cell model

Electrophysiological model

+

Mechanical model

Intracellular calcium

Normalized force

Half-sarcomere length

## Spherical ventricle model

Ventricular pressure

Ventricular blood volume

# Stressed blood volume

- The total stressed blood volume (SBV) is defined as the total blood volume responsible for a non-zero pressure inside the cardiovascular system
- In our 6-chamber model:

$$SBV = V_{lv} + V_{rv} + V_{ao} + V_{vc} + V_{pv} + V_{pa}$$

- Vascular filling experiments (fluid injections) are modeled with an increase in SBV

- Stroke volume is calculated for different values of SBV once the system has reached its steady state

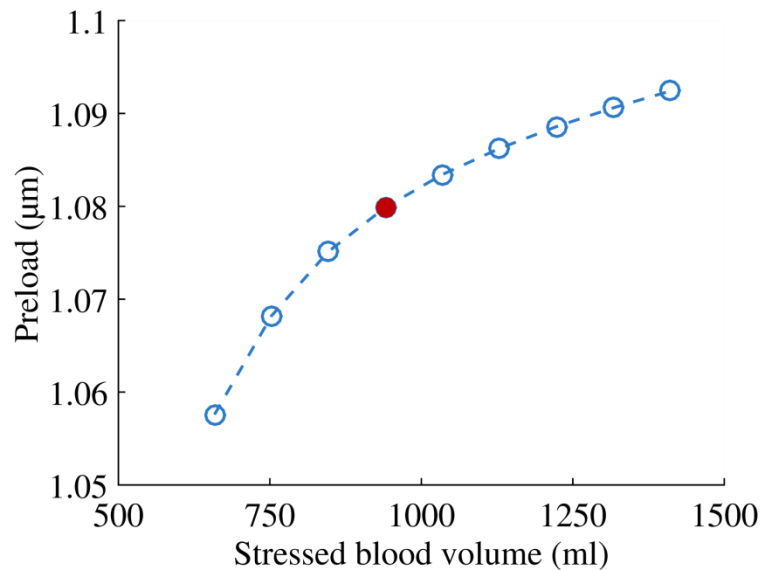

# Link with the Frank-Starling mechanism

- The increase in SBV lead to an increase in preload

# Link with the Frank-Starling mechanism

- The vascular filling curves can not be directly compared to the Frank-Starling curves

Transitory effect of an increase in preload  
 $\Rightarrow$  All other variables remain unchanged

$\neq$

Stabilized behavior following an increase in SBV  
 $\Rightarrow$  Other variables are altered

# Instantaneous preload increase

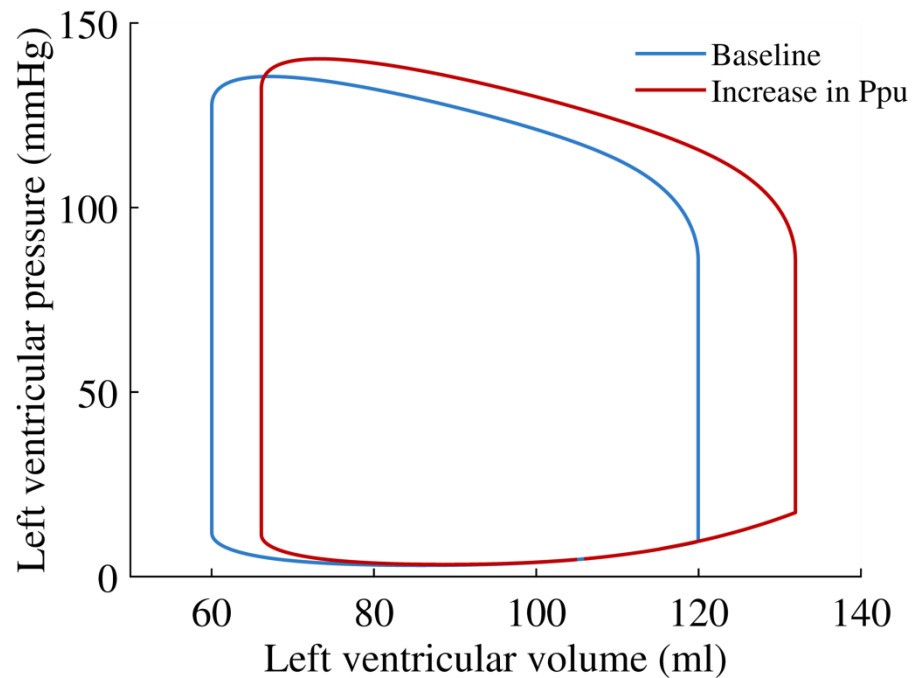

Simulation of an instantaneous increase of the pulmonary pressure during left ventricular filling

- ⇒ increase in the blood flow entering the ventricle
- ⇒ increase in preload

# Instantaneous preload increase

The resulting pressure-volume loop shows that the stroke volume and the maximal developed pressure increase

# Length effect

- Increase in half-sarcomere length  $\Rightarrow$  increase in the developed cardiac cellular force (length-dependent activation)
- Increase in force  $\Rightarrow$  increase in ventricular pressure  $\Rightarrow$  **increase in stroke volume**

But the timescale of the cardiac beat is also affected !

# Timing effect

- Ventricular filling (stops at the mitral valve closing)
- - - Isovolumic contraction (stops at the aortic valve opening)
- Blood ejection (stops at the aortic valve closing)
- - - Isovolumic relaxation (stops at the mitral valve opening)

# Timing effect

	Baseline	Preload increase
$t_1$ (mitral valve closing)	142,4 ms	110,4 ms
$t_2$ (aortic valve opening)	226,4 ms	222,4 ms
$t_3$ (aortic valve closing)	471,2 ms	483,2 ms
Isovolumic contraction ( $t_2 - t_1$ )	84 ms	112 ms
Blood ejection ( $t_3 - t_2$ )	244,8 ms	260,8 ms

- ⇒ The isovolumic contraction starts earlier
- ⇒ The isovolumic contraction and the blood ejection phases last longer
- ⇒ The timing of valves opening and closing also **affects the stroke volume**

# Length & timing effect

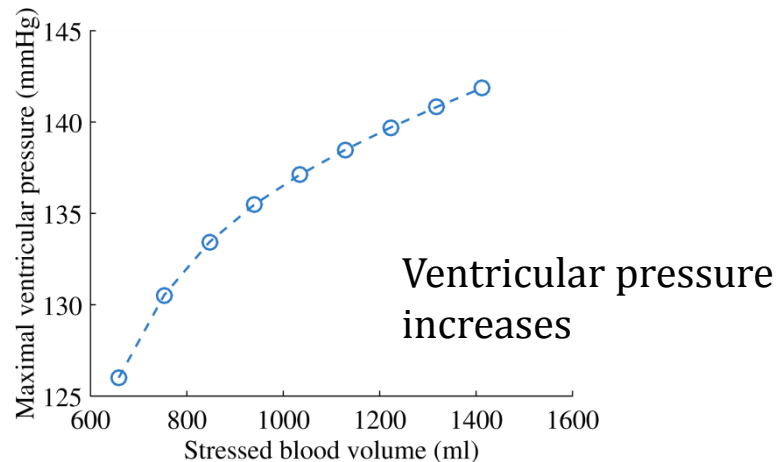

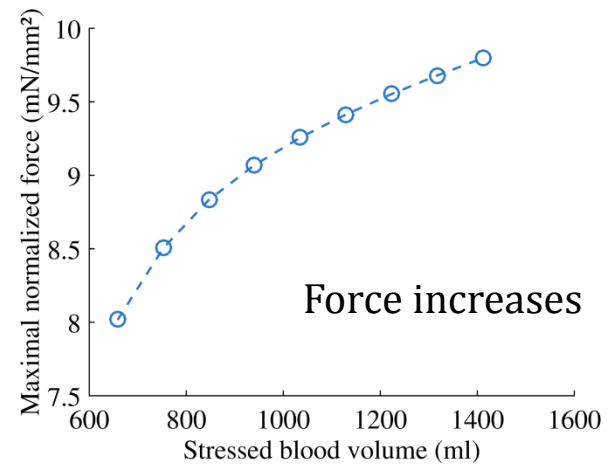

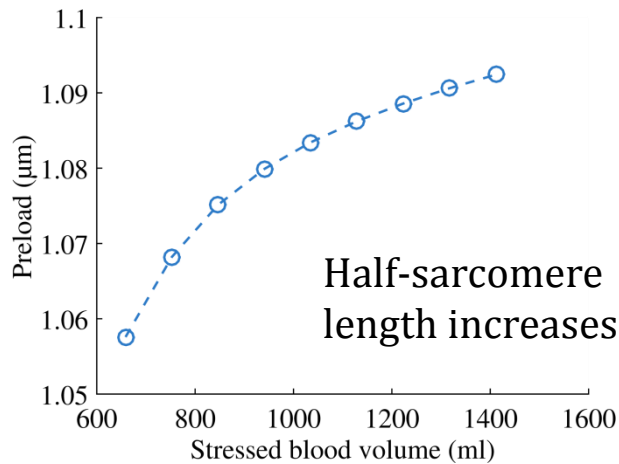

- Instantaneous increase in preload
  - ⇒ increase in the developed cardiac cellular force (length-dependent activation) and in ventricular pressure
  - ⇒ longer isovolumic contraction and blood ejection phases
  - ⇒ increase in stroke volume
- Do the length and timing effect play a role in the vascular filling results ?

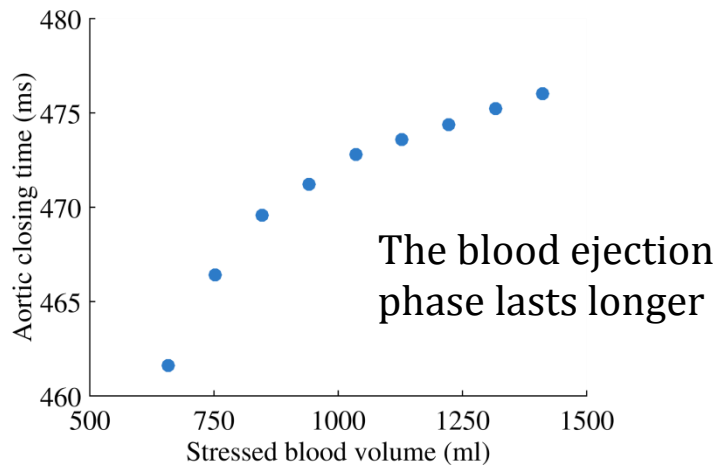

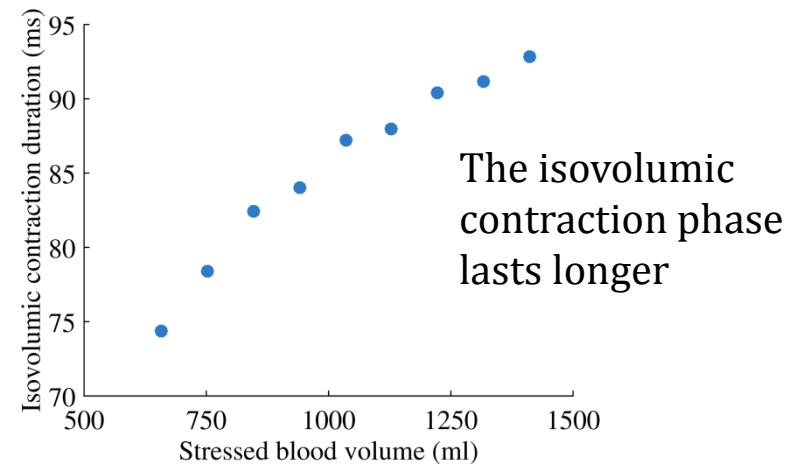

As SBV increases,

As SBV increases,

⇒ There is a link between the Frank-Starling mechanism and the vascular filling effect on stroke volume

# Afterload effect

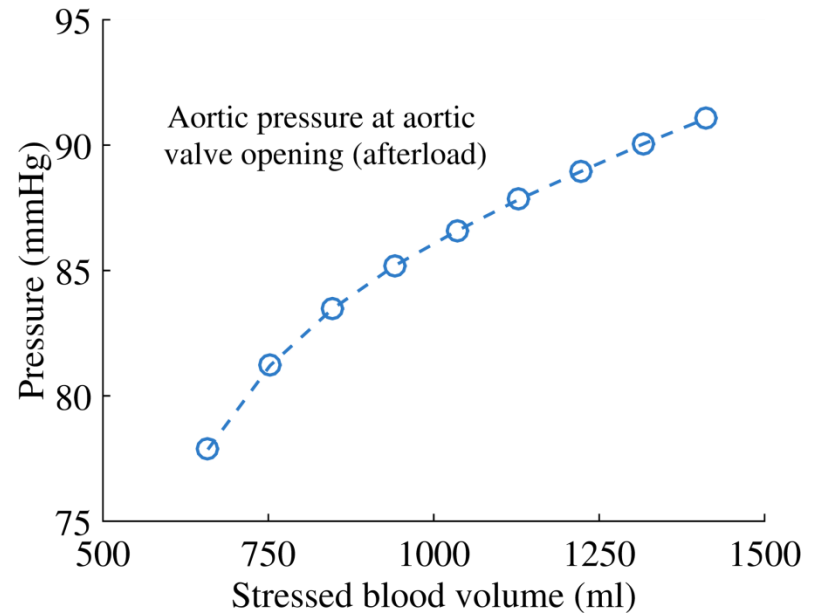

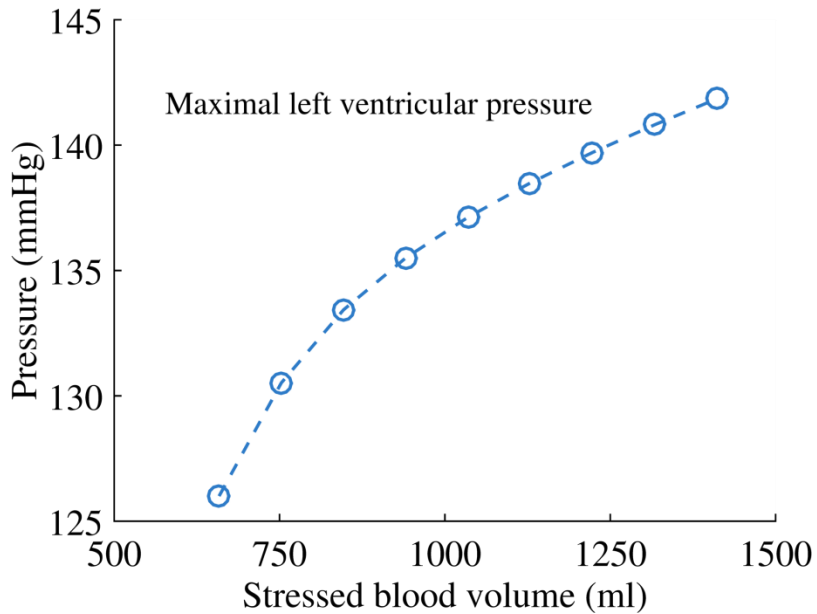

- Variables other than preload are affected by the SBV increase
- The afterload (= aortic pressure at the opening of the aortic valve) also increases with SBV

# Afterload effect

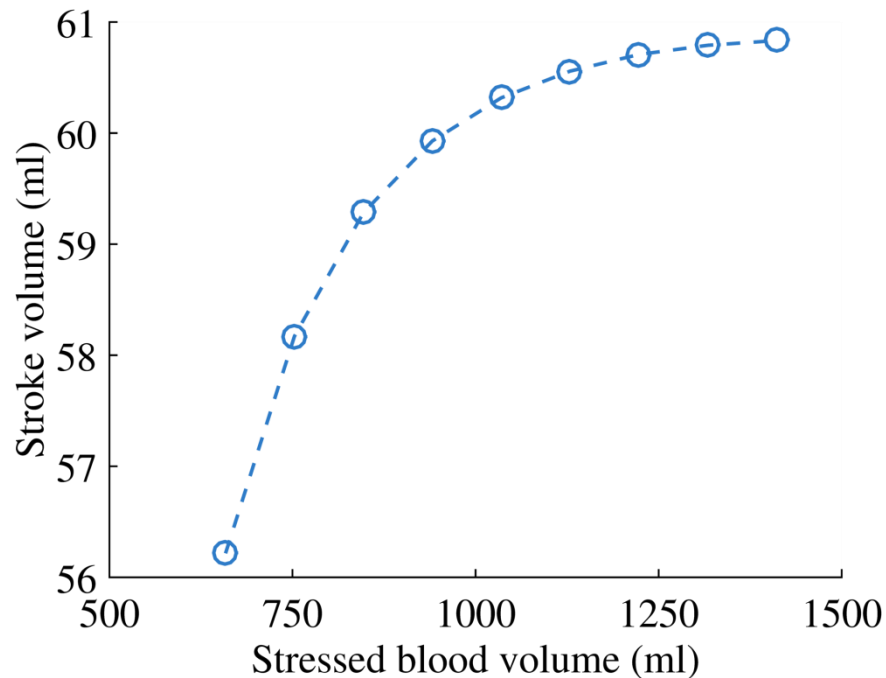

- The stroke volume depends on the blood flow through the aortic valve, which is dictated by the difference between ventricular and aortic pressure

# Afterload effect

- The saturating portion of the vascular filling curve occurs because the preload increase is not large enough to counterbalance the afterload increase

# Conclusion

- Is the Frank-Starling mechanism the founding principle of vascular filling therapy ?

# Conclusion

- Is the Frank-Starling mechanism the founding principle of vascular filling therapy ?
- Vascular filling simulations : SBV  $\nearrow$   $\Rightarrow$  preload  $\nearrow$   $\Rightarrow$  stroke volume  $\nearrow$

# Conclusion

- Is the Frank-Starling mechanism the founding principle of vascular filling therapy ?
- Vascular filling simulations : SBV  $\nearrow$   $\Rightarrow$  preload  $\nearrow$   $\Rightarrow$  stroke volume  $\nearrow$
- A length and a timing effect are involved in the instantaneous Frank-Starling mechanism

# Conclusion

- Is the Frank-Starling mechanism the founding principle of vascular filling therapy ?
- Vascular filling simulations : SBV  $\nearrow$   $\Rightarrow$  preload  $\nearrow$   $\Rightarrow$  stroke volume  $\nearrow$
- A length and a timing effect are involved in the instantaneous Frank-Starling mechanism
- Those two effects are also found in the vascular filling experiments  
 $\Rightarrow$  The Frank-Starling mechanism plays a role in the stroke volume increase following an increase in SBV

- Is the Frank-Starling mechanism the founding principle of vascular filling therapy ?
- Vascular filling simulations : SBV  $\nearrow$   $\Rightarrow$  preload  $\nearrow$   $\Rightarrow$  stroke volume  $\nearrow$
- A length and a timing effect are involved in the instantaneous Frank-Starling mechanism
- Those two effects are also found in the vascular filling experiments  
 $\Rightarrow$  The Frank-Starling mechanism plays a role in the stroke volume increase following an increase in SBV
- Vascular filling also increases afterload and as a consequence fluid responsiveness may be compromised for high preloads (or high SBV values)  
 $\Rightarrow$  The Frank-Starling effect is not the only determinant of fluid responsiveness
